Influenza is generated by influenza viruses A and B that are members of *Orthomyxiviridae* family. These viruses are enveloped, single-stranded RNA. The envelope is derived from host cell membrane, and hemagglutinin (HA) and neuraminidase (NA) form rod-like spikes and spikes with globular heads. The matrix-1 (M1) protein is present between nucleocapsid and the envelope, and the matrix 2(M2) protein forms an ion channel across the envelope in influenza A virus.

Epidemiology and Transmission

Influenza viruses are known for their ability to cause epidemics and pandemics during which acute respiratory diseases occur in all age groups. Immigrants may be more vulnerable than other groups to influenza because of preexisting diseases, inadequate access to medical care, inadequate living conditions (many people living in a small area favor the spread of influenza), and poor hygiene. Although there are no reliable estimates of influenza prevalence among immigrants, the prevalence among immigrants is likely higher than among host high-income country populations for two reasons. First, most migrants are from low-income countries characterized by poor vaccination programs. Second, many of the countries from which migrants originate are known to have a high prevalence of influenza (e.g., Thailand, Philippines).

Influenza viruses are usually transmitted via air droplets generated by sneezing, coughing, and speaking, from person to person. Direct contact with contaminated secretion may be another route of transmission. There are several recorded pandemics of influenza starting with Spanish flu (1918–1919), then Asian flu (1956–1958), Hong Kong flu (1968–1968), and most recently the H1N1 strain epidemic (2009–2010).

Viral Aggression and Host's Response

The pathogenicity of the influenza viruses depends on host factors such as presence of target receptors on host cells, immunocompetence of the individual, ability of the immune system to control the viral replication effectively without causing serious collateral damage for the host by its inflammatory response along with viral factors, such as ability to bind to host cells escape from immunosurveillance by evolution of antigenic variation driven by selective pressure of the immune response or by recombination with different virus strains from zoonotic disease.

The Humoral Immune Response

Influenza is associated with systemic production of antibody to both influenza glycoproteins HA and NA, as well as M and NP proteins. HA-specific immunoglobulins appear within 2 weeks inoculation. The peak in antibody titers is seen between 4 and 7 weeks after infection, and are followed by a decline. Antibodies remain detectable for years after infection even without re-exposure. The anti-HA antibody protects against both disease and infection with homologous virus. Serum HA-inhibiting titers of 1:40 or greater, or serum neutralizing titers of 1:8 or greater, protect against infection. Higher levels of antibody are required for complete protection in older individuals.

Anti-NA antibody does not neutralize virus infectivity, but instead reduces the efficient release of virus from infected cells because neuraminidase cleaves the cellular-receptor sialic acid residues to which the newly formed particles are attached.

Anti-NA antibody can protect against the disease and results in decreased virus shedding and severity of symptoms. Similar effects have antibodies against M2 protein of influenza A, although in general, antibodies against internal antigens are non-neutralizing, disappear more rapidly, and do not appear to play a role in protective immunity.

The Cellular Immune Response

Dendritic cells play a central role in initiating and driving T lymphocyte responses. Lung-resident dendritic cells acquire antigen from the invading pathogen, become activated, and subsequently travel to the local draining lymph nodes. The antigenic sample is processed and fixed on the dendritic cell surface as peptides that are presented to CD8 T and CD4 T lymphocytes that are activated. Their activation correlates with a reduction in the duration and level of virus replication. Moreover, CD4 T lymphocytes help B lymphocytes to generate anti-HA and anti-NA antibodies.

Clinical Aspects

Influenza is characterized by fever, dry cough, sore throat, rhinorrhea, nasal congestion, and nasal discharge. Elderly people may present with lassitude and confusion instead, as well as myalgia, headache, malaise. Illness typically begins suddenly after 1–5 days of incubation. Fever lasts for 3–5 days but symptoms such as malaise and dry cough may persist for several weeks. Adults are infectious from as early as 24 h before the onset of symptoms until about 7 days thereafter. Children are even more contagious: young children can shed virus for several days before the onset of their illness and can be infectious for >10 days. Severely immunocompromised persons can shed influenza virus for weeks or months.

Complications

There are several potential complications of influenza including otitis media in children, secondary bacterial pneumonia (*Staphylococcus aureus*, *Hemophilus influenzae* and *Streptococcus pneumoniae*), seizures, acute encephalopathy, Reye's syndrome (associated with aspirin use), and myopericarditis.

Diagnosis

This can be done in two different ways: direct using techniques such as immunofluorescence, Enzyme immunoassay or Polymerase chain reaction or serologic diagnosis based on detection of antibodies.

Treatment

There are four licensed antiviral drugs available for the treatment of influenza A infection (two neuraminidase inhibitors-Zanamavir, Osetamavir and two M2 ion channel inhibitors Amantadine and Rimantadine), and the neuraminidase inhibitors oseltamivir and zanamivir are also active against influenza B. All are administered within a few hours of the onset of symptoms. These drugs can modify the severity of illness, as well as reduce the intensity of influenza symptoms and decrease the duration of illness by about 1–3 days.

Prophylaxis

Prophylaxis is possible using a trivalent vaccine that includes circulating stains of influenza viruses The strains to be included in the vaccine are selected in January and February to make a vaccine for use in September. There are two types of vaccines: one uses an inactivated virus and the other one includes a live attenuated virus.

Informed Consent

ROBINDRA PAUL
Private Practice, San Diego, CA, USA

History has shaped how patients discuss various treatment options with their medical providers.

Traditionally, there has been an asymmetry of knowledge between provider and patient about various forms of treatment. This had led to patients placing faith in their doctors to act in the patient's best interest and to do no harm. However, as patients have become more educated about their treatment options and their rights, the asymmetry of knowledge has decreased. Patients have become more active participants and have taken increasing responsibility for their care. The concept of informed consent has evolved to protect the rights of patients and to ensure that the minimum adequate information is communicated and understood by the patients both before and during treatment.

Informed consent is a process that occurs between patients and providers. The process may involve family members or other significant persons in the patient's life and may be influenced by culture and religion. The process leads to the patient accepting a form of medical treatment such as a medication or a surgical procedure. The process can occur after one meeting between the patient and provider or after a series of meetings. The process can also occur over the course of treatment. As more information about a treatment or alternative treatments becomes available, patients will continue to work with their providers on understanding their current and available treatment choices. This is especially true of modern-day medicine where the asymmetry of knowledge between providers and patients has decreased because of the Internet.

A patient must have the capacity to provide informed consent. This means patients must have the ability to make health care decisions, and the decisions made must be both rational and reasonable. For example, a psychotic patient with no intracranial pathology who only chooses to have surgery to remove most of their brain as a treatment of their psychosis does not have the capacity to consent to treatment as their choice of treatment is neither rational nor reasonable. Having the capacity to make a health care decision is relative to both the decision being made and the individual making the decision. For example, patients, with intellectual disabilities may have less capacity to make treatment decisions when treatment decisions are complicated and potentially life-threatening but may have the capacity to choose among simple and relatively harmless forms of treatment. Children who are not at the age of majority may require a parent or guardian to make treatment decisions for them. One example of a patient not having any present capacity to make a choice regarding treatment is an unconscious person who presents to an emergency room. Absent other information, providers will act in the best interest of the patient, make treatment choices, and work toward saving that individual's life.

If a patient does not have the capacity to provide informed consent, there are other options in which consent can be obtained. In certain areas, family members or other substitute decision makers may be able to consent to treatment on behalf of the patient. In other areas, a judge may be legally authorized to make medical decisions on behalf of a patient. It is therefore important to understand the patient's social and family background as well as legal and other factors influencing or determining who can make treatment decisions on behalf of patients with less or no ability to choose between or among treatment options. Sometimes patients will have specified their wishes for treatment in the event that they lose the capacity to participate in the informed consent process. A living will is an example of a document in which patients can express these wishes.

Informed consent requires that the patients have information or knowledge about the proposed treatment. This includes adequately understanding the benefits, risks, and alternatives to treatment. The patient must first understand their diagnosis so they have a basis upon which to accept or refuse treatment. Understanding the benefits includes understanding the extent to which a particular treatment will cure or relieve a given ailment. Discussing risks with a patient raises the question as to how much information should be disclose to a patient. A provider may opt to provide volumes of information including listing every known potential side effect and complication of a particular treatment. However, the patient may not read and/or understand information presented in this manner. One concept regarding the disclosure of information is that providers disclose to patients' material information about a proposed treatment. Material information is information that is relevant to the patient in that patient's particular circumstance. For example, although there may be a small chance that a particular treatment can cause a heart attack, this information may be material to someone who has a history or coronary artery disease. Choosing among alternative treatments may include choosing among different medications or choosing among alternative modalities of treatment. For example, a patient with back problems may be offered the choices of physical therapy and/or medications.

Patients should also understand the option of not having treatment at all. This includes understanding their prognosis with and without treatment. One reason it is important to understand the option of not accepting a proposed treatment is that although a treatment may have benefits, there may be risks or other factors associated with the treatment that are not acceptable to a patient. For example, a patient with a terminal illness may opt to not accept potentially life-lengthening interventions if the intervention will lead to prolonged suffering. A Jehovah's Witness may not accept a blood transfusion because of his or her religious beliefs.

A patient's decision to choose a treatment must be voluntary. This means that a patient must be able to exercise his or her free power of choice when providing informed consent. This does not mean that others such as providers and family cannot have a due influence on a patient's decision for treatment, such as providing a good faith recommendation and reasons to accept a particular treatment modality. A patient's decision to accept treatment is not voluntary if he or she was forced or tortured into accepting treatment. There exist situations in which the voluntary exercise of power of choice may not be possible. For example, in a psychiatric hospital, a patient may be violent to the extent that there is no option but to provide involuntary medications to the patient in order to help protect the lives and safety of the patient and others.

In conclusion, informed consent is a process. It can be obtained after one or multiple visits between patient and provider but can continue during the course of treatment. The process empowers patients to make an informed decision regarding their treatment options. Potential positive outcomes of engaging in an adequate informed consent process include but are not limited to increased dialog between the provider and patient, an increased likelihood that a patient will be compliant and an active participant in treatment, and a strengthening of the provider–patient relationship.

Inheritance

Lalit Kalra
KCL-BHF Centre of Research Excellence, King's College London, London, UK

Immigration is a complex issue in healthcare as it places people of different ethnicities in alien environments, with differing susceptibility to diseases, different healthcare needs, and different health-seeking behaviors. These differences present a challenge to adopted healthcare systems in meeting population needs, especially with the disproportionate increase in the prevalence of vascular risk factors and diseases in immigrant populations, which far exceed the prevalence rates in native people. Recent years have seen considerable effort being devoted to understanding inherited and non-inherited factors that may underlie predisposition to excess vascular disease.

A dramatic increase in the risk of vascular diseases such as myocardial infarction, stroke, and sudden death with migration was first identified in Japanese immigrants to Hawaii, in whom the status from a low-risk group to a high-risk group changed in one generation. A similar increase in risk with migration has been identified in African origin populations in the West Indies, Americas, and European and Asian origin populations in the United States and the United Kingdom. Initially this was attributed to acquisition of behavioral risk factors prevalent in local cultures, but it does not fully explain why the vascular risk in migrants should exceed that of the local population. The increased predisposition of immigrant populations to vascular diseases is probably attributable to a clustering of genetic and environmental factors within these populations, represented as:

$$\text{Phenotype} = \text{genotype} + \text{environment} + \text{gene} \times \text{environment}$$

This assumes that differences in disease prevalence may not be due to genetic differences alone but may also reflect differences in environmental influences (some of which may also be inherited as food habits, cultural beliefs, and traditions) or interactions between genetic heterogeneity and environmental pressures.

The determination of the role that inheritance may play in disease patterns amongst immigrant populations is complex. Migration is not a homogenous phenomenon that occurs at one point in time; it has occurred at different periods, quite often separated by decades or even centuries. Despite a common ethnicity, immigrants come from a range of different source populations, especially if they are of African or Asian origin. Most of the migrations from West Africa to the Americas or later from the Indian subcontinent in the eighteenth and nineteenth centuries were forced migrations because of slavery, bonded labor, or wars. The source population for these migrations is very different from that of the economic migration seen in the latter half of the twentieth century and may represent different frequencies of variations in the genes within populations, food habits, and cultural practices despite a common ethnicity or geographical region of origin. Hence, heterogeneity is the rule rather than the exception, which is further complicated by different environments to which people have migrated over time and the evolution of societies to which they have migrated.

Do differences in genetics between migrant ethnic groups and native populations explain increased susceptibility to disease in immigrant people? Various studies have shown that the frequencies of different forms of the same gene differ between ethnic groups and there is a higher prevalence of disease-associated gene variations (such as those regulating control of blood pressure, health of blood vessels, salt handling by the kidneys, and control of atherosclerosis) in African and Asian origin populations. In addition, there are minor differences in the structure of blood vessels and how they react under stress between different ethnic groups, which predispose some groups to earlier or faster degenerative changes associated with high blood pressure and furring of arteries. However, only a low percentage of differences between ethnic groups are explained by differences in gene composition; many studies have shown that differences within individuals of the same ethnic group and much greater than those seen between different ethnic groups. Furthermore, there are variations in disease susceptibility within the same ethnic group (and hence, sharing the same genetic inheritance) with geography, with risk increasing proportionally to the degree of urbanization or westernization. Clearly, inherited genetic traits alone are not enough to explain the higher incidence of disease in immigrant ethnic groups.

If inherited factors do not explain increased disease incidence, can this be attributed to a change from the native "low-risk" environment to an alien "high-risk" setting? There is considerable literature to support this view. A move to more urbanized settings has been associated with changes in diet (e.g., increased calorie, fat salt intake, and decreased fruit, vegetable, and fiber consumption), reduced physical activity, relatively lower socioeconomic status in adopted settings, increased psychosocial stress, and inequities in health care access. However, it would be expected that this increase of risk in immigrants due to change of environment will eventually match that of the native populations. However, studies show that risk factor acquisition and its impact in immigrant populations exceed that of the native population, suggesting that there is an interaction between the changed environment and inherited traits (whether genetic or nongenetic) that may be responsible for the higher risk. Researchers have identified various physiological mechanisms to support this concept, such as exaggerated insulin responsiveness to energy/metabolic challenges in Africans or Asians living in highly urbanized settings, increased salt sensitivity in Africans leading to increased sodium reabsorption, hypertension, and vascular disease in Western societies and dysregulation of the hypothalamic-pituitary-adrenal axis leading to changes in diurnal variations of stress hormones.

Several models have been developed to explain the interactions between genetic inheritance and the environment. The "thrifty genotype" hypothesis is based on an assumption that evolution has selected genes that promote insulin resistance (the main hormone involved in energy handling) and confer a survival advantage in nutritionally deplete environments. However, the same genes polymorphisms (potentially more frequent in less urbanized immigrant populations) lead to a greater disease risk in nutritionally rich environment, affecting handling of energy or metabolic challenges and leading to early atherosclerosis. The "thrifty phenotype" model focuses on preprograming of metabolic responses and vascular modelling during the fetal phases, which has consequences for health in later life. It has been suggested that the fetus, regardless of genetic inheritance, makes adaptive changes to intrauterine nutrient limitation by inducing insulin resistance. Although this would continue to remain beneficial in nutritionally deplete environments, the phenotype would confer predisposition to developing the metabolic syndrome and early atherosclerosis in nutritionally enriched environments. Gluckman and Hanson have proposed a model that combines elements of both the "thrifty genotype" and the "thrifty phenotype" models. They suggest that the fetus constantly interprets the environment created by the maternal milieu and placental function and responds to this by a process of silencing or expression of genes in the cells of specific tissues, organs, and systems.

Changes in how genes are expressed in a particular individual or ethnic group are largely regulated by genes themselves. However, recent evidence suggests that early environmental exposures can modify these processes during growth and development, thus having a durable effect on adult biology and disease risk. Some fetal responses to environment act to help the fetus cope better with the existing milieu, some reflect developmental disruption and have echoes in later life, and some confer advantage by establishing metabolic physiology appropriate for the predicted postnatal environment. Such responses are appropriate if the predicted and actual postnatal environments match, but inappropriate if they do not, as would happen with migration to a different ecological niche.

The relationship between inherited traits, environmental pressure, and cardiovascular disease is complex, and noninherited influences within the environment may play a significant, but potentially modifiable, role in ethnic predisposition to vascular disease. Literature supports a focus on the investigation of multiple environmental factors and gene–environment interactions, specific to ethnic groups in different environments, as an approach to eliminating the excess of vascular disease in immigrant populations.

Injection Drug Use

Laura Janine Mintz
Department of Epidemiology and Biostatistics, Case
Western Reserve University School of Medicine,
Cleveland, OH, USA

Injection drug use (IDU) in immigrant populations has been a substantial concern primarily due to HIV transmission. Many different small studies have examined the prevalence of injection drug use relative to the immigrant community's country of origin or country of residence.

One of the greatest concerns is the ability of immigrant IDUs to access medical care, and/or the paraphernalia they need to protect themselves against HIV and other blood-borne illnesses (like hepatitis C), as well as illnesses that tend to be prevalent in injection drug using communities (like TB). Additionally, IDUs are at risk of overdose from their drug(s) of choice, and so may need to access medical care or drug treatment as a result of overdose.

Immigrant IDUs are at additional risks from adulterants in street drugs, or from fillers in prescription pills that are crushed and then injected, leading to a wide variety of heart, lung, kidney, and blood problems like endocarditis (inflammation of the lining of the heart), interstitial lung disease (causing fibrosis and difficulty breathing), and kidney failure (the inability of the kidney to rid the body of waste). Immigrant IDUs, like other IDUs, are often in need of both urgent medical care and medical care for chronic conditions that may result directly from injection drug use, or from the stress and difficulty of acquiring sufficient income to maintain a chronic drug habit.

Injection drug use tends to be a part of progressive increasing addictive drug use, as injection is the least expensive manner of ingesting drugs. Individuals often begin injecting after a period of snorting, swallowing, or smoking the drug of choice. Of course, some injection drug users also begin with injection. Immigrant populations are no different in this regard.

Harm reduction is a drug treatment modality that aims to address the needs of drug users who may or may not want to stop using drugs. A harm reduction approach offers them services and skills to take care of their health and prevent disease, such as syringe exchange, hepatitis B vaccination, overdose prevention, and information about how to use drugs more safely.

Immigrant IDUs face several barriers to care in accessing these services. First, they face the access to care issues that confront immigrants in general: language, ability to navigate the health system in the new country, lack of income, and lack of culturally competent health care providers and services. Beyond these already significant issues, immigrant IDUs also must face the discriminatory attitudes many communities (and traditional service providers) have against drug use in general, and injection drug use in particular. This means that immigrant IDUs may not be able to use traditional community channels (like talking to immigrants with longer experience in the country of residence about navigating medical systems) and may face barriers accessing competent drug treatment services that respond to their particular social needs. If immigrant IDUs face the additional barrier of undocumented status, these problems are only increased, as they may feel that any and all services aren't available to them (even if the services in question do not require documentation of immigration status from their patients/participants).

In all, the experience of injection drug use among immigrant populations varies widely by culture and country of origin, country of residence, access to services (particularly drug treatment and harm reduction services), and values, attitudes, and beliefs in immigrants and their country of residence about injection drug use.

Injuries

SUSAN SCAVO GALLAGHER, EMILY TAYLOR
Department of Public Health and Community Medicine, Tufts University School of Medicine, Boston, MA, USA

Injuries are a significant public health challenge that can be studied just like disease. Using a public health approach, they are often predictable, preventable, and responsive to intervention. Injury results from unintentional and intentional damage to the body due to acute exposure to thermal, mechanical, electrical, or chemical energy or from the absence of essentials like oxygen or heat. Injuries encompass both intentional violence that is purposely inflicted (e.g., homicide and assaults, suicide and attempts, child abuse, domestic violence) and unintentional injuries or so-called "accidents." The unintentional category includes injuries from drowning, fires and burns, motor vehicles, poisonings, falls, choking, and suffocation among others.

Injuries and their adverse health outcomes are a major public health concern for countries across the world. As public health improvements in the twentieth century reduced the prevalence of infectious diseases, the negative toll of injury on the public's health has become more significant. For example, in the United States, injury and violence kill 170,000 people annually. Injuries are the leading cause of death for those 39 years of age and younger, a leading cause of disability, and a major contributor to health costs. And injury ranks fourth as the leading cause of death overall. Injuries disproportionately affect a younger population – children, teens, and young adults. Half of all deaths to 5–14 year olds and nearly three quarters of all deaths to 15–24 year olds are due to injuries.

Despite the magnitude of the problem, injury is not near the top of society's list of preventable health problems and has been called a neglected epidemic:

- People seem resigned and accepting of injury as an "accident" and inevitable part of life – a mistaken belief.
- The media sensationalizes the reporting of separate and unique injury events rather than focusing on patterns of injury and long-term trends as is done with the study of disease.
- There is a tendency to blame the victim and portray injury largely as a matter of individual fault (carelessness, aberrant behavior), much more so than with cancer, heart disease, and infectious disease.
- The medical community and advocacy coalitions concerned with injury issues tend to focus on post-injury treatment rather than prevention.
- Because the contributors to injury are largely man-made (consumer products, motor vehicles, firearms), business considerations often overshadow the adoption of technology for safety of the public.

Immigrant populations experiencing rates of injuries are of specific concern for countries hosting these populations. Immigrant populations often face health disparities, including health disparities resulting from injuries.

Injury Data and Immigrants

Injury and violence-related data specific to immigrants are limited, both in the United States and other countries. Immigrants may be less likely to report injuries and violence if they are in a country illegally or if there is cultural stigma associated with the injury (e.g., suicide, intimate partner violence). In the USA, data are largely collected by race and ethnicity, not by nativity. And death data available through the National Center for Health Statistics have not recently been analyzed to separate out injury for the foreign-born population. Although many US studies focus on Hispanic and Asian populations, it is rarely clear what percentage of the populations is foreign- versus native-born.

While a systematic analysis of the overall picture of injuries in immigrants has not been done, we do know that injuries disproportionately affect the young and the poor and that the causes of injury vary by age and by sex. There are some studies in specific immigrant populations that examine a specific type of injury in a specific locale. Some of these findings illustrate higher risks for immigrant than native populations. These include:

- Drowning in California irrigation canals, mostly in the process of illegal entry into the USA
- Motor vehicle fatalities among Mexican-Americans in Imperial County, California
- Severe scald burns from hot water and oil among children of mostly Middle Eastern and Balkan immigrant families in Sweden
- Burns from hot water, tea, or oil among children of foreign-born mothers in Denmark
- Severe scald burns from hot food in young Hispanic children whose parents were immigrant farmworkers in Washington state
- Pedestrian hospitalizations and deaths among Latino children in California
- Escalation of partner violence in Latinas since emigration to the USA
- Intimate partner violence among young, foreign born, and minority women in NYC
- Homicide among Nicaraguan born immigrants versus Costa Rican natives
- Gunshot injury among immigrants in Sweden
- Homicide among White, Hispanic, and Asian immigrants' ages 15–34 years in California

In general, it seems that border communities in the USA have higher risks of injury. It has been suggested that enforcement has pushed illegal immigrants into more physically challenging areas with mountains, deserts, and irrigation canals. Heat stroke and heat fatalities are one outcome. Overcrowded motor vehicles, high speeds and poor vehicle maintenance have led to deaths and injuries of illegal immigrants being smuggled into AZ.

Immigrants may also be at higher risk of occupationally related injuries. They often are hired in lower paying jobs that may be dangerous and safety issues may not be explained or understood.

In the USA, studies indicate that immigrants seem to have a lower risk of *unintentional* injuries with the exception of transportation-related injuries. This difference in injury risk between foreign-born and native-born has **not** been attributed to socio-demographic characteristics, such as age, sex, education, poverty status, region of residence, family size, and health insurance coverage status. Foreign-born persons are less likely to be injured outside the home or at school and more likely to be injured at an industrial/construction area. They receive significantly more injuries working at a paid job and significantly fewer injuries during sports or leisure activities.

Foreign-born individuals 25 years and older in the USA also have a reduced risk for suicide when compared to those native-born. Although there is research indicating a relationship between acculturative stress and physical health problems such as cancer, hypertension, and coronary artery disease, such research has not been done for injury and violence. One hypothesis is that less acculturated children in the USA may be protected from injury. Sociocultural factors in immigrants that may be protective of unintentional injury include stronger behavioral, familial, and social support than US born persons as well as other lifestyle factors and cultural practices.

In the USA, studies indicate that male immigrants have a 66% higher risk of *homicide* than US-born men. However, the excess risk is entirely accounted for by nativity differences in socioeconomic characteristics, including urban/rural residence.

Immigrants are less likely to be involved in risk taking behaviors related to injury, but equally likely to receive an injury if they are involved in risk-taking behaviors. Little is known about the association between behavioral risk factors and injuries among immigrants in the USA. However, risk factor data from the National Epidemiological Survey on Alcohol and Related Conditions indicate that immigrant adults are less likely to be involved in ten selected risk behaviors for unintentional nonfatal injuries than US-born counterparts including: driving a motor vehicle while drinking, driving after three alcoholic drinks, riding in a vehicle while a driver is drinking, receiving more than three tickets for reckless driving, receiving a license suspension for a moving violation, and doing things that could have easily hurt someone. A protective effect of being an immigrant disappears for immigrants engaged in more than four of the ten risk behaviors;

the latter have similar injury prevalence as their US born counterparts. There does not appear to be an association between years of US residence and injuries.

These latter findings for unintentional injuries seem somewhat contradictive of studies that show an increased risk of transportation-related injuries among immigrants.

Given the lack of solid data and discrepancies in reported injuries and risk factors among immigrants, where should the focus be for prevention efforts?

Injury Prevention Interventions

The general approach to successfully reducing injuries is to implement comprehensive interventions that include a combination of:

- Education that changes knowledge, attitudes, and beliefs and fosters safer, and less risky behaviors; often directed at an individual, policy-makers or the Sociocultural environment (e.g., media campaigns to persuade people or change norms regarding seat belt use or counseling by physicians on the same topic)
- Engineering design of products to make them safer (e.g., removing lead paint from toys, self-extinguishing cigarettes to reduce fires, airbags that absorb energy in a car crash)
- Environmental changes that modify the environment and surroundings to make behavior change easier or, better yet, make behavior change unnecessary (creating pedestrian walkways and bicycle paths, safe playground alternatives to playing in the street)
- Enactment and enforcement of regulations and laws to promote behavior change and reduce injury risk (specify speed limits, institute graduated driver licensing law for teens, school enforcement of rules to reduce bullying).

The framework that is most often used to understand injuries and how they can be prevented is the Haddon Matrix. It analyzes events that can cause injuries with an epidemiological model to create a matrix that identifies aspects of the host, the agent or vector, the physical environment and the social environment with three time phases – pre-event, event, and post-event (Table 1).

There are many interventions that have been successful in reducing injuries and deaths including: use of motorcycle helmets, seat belts and child booster seats; tai chi to prevent falls and their sequelae; installation of smoke detectors as a warning to escape from fires; four-sided fencing around swimming pools; personal flotation devices when boating, etc. The trick is to be able to adapt the implementation of proven methods to the culture, health beliefs, and practices of the foreign born.

Most injury prevention programs fail to target immigrants as a unique population. Large-scale interventions relating to immigrants have addressed other adverse health outcomes with little or no emphasis on injury and violence prevention. And the majority of interventions relating to immigrant health and injury risk have occurred at the local level without grant money or formal program evaluation.

Notable exceptions have occurred, including a program to increase child restraint usage among

Injuries. Table 1 Example of a Haddon Matrix for motor vehicle crashes

Phases	Host factors	Agent or vector factors	Physical environmental factors	Social environmental factors
Pre-event	Driver training/ driver vision/ fatigue	Maintenance of brakes, tires	Roadway markings and lighting/rain	Public attitudes on text messaging/drinking and driving
Event	Use of a seat belt or child restraint	Crashworthiness/no dashboard protusions/ airbag/vehicle size	Presence of a fixed object like a tree too close to road/ guard rail	Enforcement of mandatory seat belt–use laws
Post-event	Crash victim's general health/ sobriety/age	Gas tank design to minimize likelihood of a fire	Availability of effective EMS/ distance to trauma care	Public support for trauma care and rehabilitation

Hispanic pre-school children in Dallas, Texas; a program to decrease carbon monoxide poisonings in immigrant populations in the Pacific Northwest; and the Home Safety Council's Home Safety Literacy Project to understand and apply fire protection and disaster preparedness measures in the home. A low budget, small organization example is that of a local refugee injury prevention group in Concord, New Hampshire that created some materials and a home safety kit that were used by volunteers to work with the refugees they were assigned to through Lutheran Social Services. The group also assisted with providing car seats to refugees; spoke at English as a Second Language (ESL) classes on topics such as poisoning and pedestrian/bike safety; collaborated with a fire department on fire prevention, worked with refugees about whom to call in an emergency; collaborated with the Northern New England Poison Center and 911 to actually pose scenarios and then practice calling into the centers; and presented to nurses at a local community college to help raise their awareness around injury prevention issues for refugees.

Future Directions

There are many health and service programs for immigrants, but it is unknown whether preventing risks from injury are included. State health agencies often have a department of immigrant or refugee health. In Hawaii, the health department has bilingual health aides, who do home visits and provide health education to immigrants on immunization, nutrition, and chronic disease prevention. It seems logical that such programs should include injury and violence prevention as part of the visit. What is required for integration within existing service provision is training on injury prevention for staff, culturally relevant information, local data on the most frequent causes of injury in this population, and the political will to get what we know works for injury prevention put into practice for immigrants.

Insomnia

Renee Sorrentino
Massachusetts General Hospital, Quincy, MA, USA

Insomnia is the most common of the sleep disorders affecting 10–30% of the population depending on the criteria used to define insomnia. The term “insomnia” may refer to a symptom of a larger sleep, medical or psychiatric disorder, or as a primary disorder. The definitions of insomnia vary but most often, insomnia is defined as an inability to remain asleep throughout the night and reflects an assessment of sleep quality. Insomnia, as a primary disorder, has been further defined by subtypes based on frequency, duration, and etiology. Acute insomnia refers to insomnia lasting from several days to a few weeks. Episodic or infrequent insomnia is referred to as transient insomnia. Chronic insomnia refers to insomnia lasting 1 month or longer.

Diagnosis

The diagnosis of insomnia is based on an individual’s description of his or her sleep schedule. The majority of individuals with insomnia are diagnosed based on self-report. Individuals who do not respond to initial treatments or report an inconsistent history may be referred for objective testing. Objective tests include actigraphy and polysomnography. Actigraphy is a technique that uses an actigraph, an instrument worn on the body, to measure body movement. Actigraphy characterizes rest-activity patterns, which is useful in evaluating sleep–wake cycles. Polysomnography is a sleep study that monitors stages of sleep, blood oxygen levels, brain waves, breathing rate, eye movement, heart rate, and the electrical activity of muscles. Actigraphy and polysomnography are reserved for cases of treatment failure, unclear diagnosis, and sleep-related breathing disorders.

Pathophysiology

Insomnia is thought to arise from a hyperarousal state. This hyperarousal state is defined by increased brain glucose metabolism and increased adrenocorticotropic hormone (a hormone produced by the pituitary gland) activity. Sleep studies demonstrate that individuals with insomnia have increased brain arousal measured by increased beta activity and lower delta activity on electroencephalography. Individuals with insomnia also have an increased whole body metabolic rate compared to individuals without insomnia.

Risk Factors

Several risk factors or precipitants of insomnia in individuals predisposed to the disorder have been identified. Age and sex are the most well-studied risk factors with an increased prevalence of insomnia in older adults and women. Sleep studies in the elderly suggest that the primary change in the sleep of older adults is an inability to sustain sleep throughout the night. Insomnia in women is associated with the onset of menses and menopause. Comorbid medical disorders, psychiatric disorders, and working night or rotating shifts are additional risk factors. Psychiatric disorders, specifically depression and anxiety, are the most common comorbid disorders associated with insomnia. The relationship between cultural influences and sleep is not fully understood. Immigration studies suggest that the prevalence of insomnia in women immigrants is higher than that reported in most epidemiologic studies of women in Western societies. More specifically, immigrant women who make efforts to assimilate into their new culture were found to have the highest rates of insomnia.

Impact of Insomnia

Individuals suffering from insomnia may develop medical conditions, psychiatric disorders, impairment in the ability to function during the daytime (work time productivity), and are at increased risk for motor vehicle accidents. Individuals with chronic insomnia commonly report a decreased quality of life. Chronic insomniacs are more likely to experience bodily pain and psychiatric symptoms. The high rate of psychiatric symptoms experienced by chronic insomniacs raises the question as to whether insomnia leads to psychiatric disorders. It is unclear whether insomnia causes psychiatric symptoms or vice versa. However, it is clear that the treatment of insomnia results in the improvement of psychiatric symptoms. In community-based studies chronic insomniacs reported more heart disease, hypertension, chronic pain, and gastrointestinal, neurologic, urinary and breathing difficulties. Studies have also identified a relationship between cardiovascular disease and insomnia. Men with chronic insomnia were shown to have an increased risk of death secondary to coronary heart disease.

The socioeconomic cost of insomnia is related to health care utilization as well as work absenteeism in insomniacs. Health care utilization, namely, office visits and hospitalizations, is higher in individuals with insomnia compared to individuals without sleep disruption. Individuals with insomnia have high rates of work absenteeism and lower work productivity compared to individuals without insomnia.

Treatment

The treatment of insomnia is based on the etiology or cause of the insomnia. For example, if the insomnia is a symptom of depression or pain, the treatment should be aimed at the underlying diagnosis. In most cases of insomnia, however, the etiology is multifactorial. As such the treatment should be multimodal combining nonpharmacological and pharmacologic intervention. Nonpharmacologic interventions included education about sleep hygiene, light therapy, exercise, and behavioral modifications including cognitive behavioral therapy, and relaxation training. Cognitive and behavioral methods have been shown to be the most effective for the short-term treatment of patients with insomnia. Pharmacologic treatments include FDA-approved medications for insomnia, off-label use of medications, and alternative (herbal) medications. The use of off-label medications refers to the use of psychiatric medications, which have a hypnotic side effect. Alternative medications included herbal remedies such as valerian and melatonin. Pharmacologic treatments are recommended for immediate symptoms reduction, when insomnia causes serious impairment in functioning and when nonpharmacologic interventions do not produce an amelioration of symptoms.

Intelligence Testing

Kristi Ninnemann
Department of Anthropology, Case Western Reserve University, Cleveland, OH, USA

Historically, the use of intelligence tests with immigrant populations, and the ways in which those tests have been interpreted and used, have been controversial. In the early nineteenth century, a hereditarian theory of intelligence dominated academic and popular thought in the United States. This hereditarian position viewed intelligence as an inherited, biologically determined trait. As such, an individual's level of intelligence was directly reflective of his or her genetic, and therefore ethnic, lineage. Although not unchallenged, popular fears maintained that the acceptance of immigrants believed to be of genetically lower levels of intelligence into the United States would, through partnering and procreation across generations, lead to a general degradation of intelligence throughout the country. While the influence of intelligence testing on actual passage of immigration laws has been debated, a wide perception remains that eugenics-based arguments against admittance of the "feeble-minded" were used by many to justify early nineteenth century US policy that favored immigrants from northern European countries to the exclusion of those from other parts of the world. Although no country currently administers intelligence tests to potential immigrants, nor does any country impose a minimum IQ to filter immigration, the history of misinterpretation and misappropriation of IQ testing with immigrant populations may well influence the opinions and experiences of modern-day immigrants with whom intelligence testing is suggested and/or performed.

Broader theories of intelligence were formulated in the second half of the nineteenth century, and with them came recognition of the limitations of intelligence testing. Dominant hereditarian ideas were largely replaced by theories that understood intelligence to be influenced by a dynamic interaction of biological, cultural, historical, sociopolitical, and environmental factors. Through these theories, intelligence came to be considered contextually, and the variety of skills and knowledge that constitute intelligence between and within cultures became apparent. Research into the relationship of culture and intelligence has shown that societies value differing abilities, types of knowledge, and cognitive processing traits. What is deemed valuable in one culture is then instructed, supported, and fostered in members of that society. As a result, an individual's mastery of these culturally-approved skills and abilities becomes viewed as reflective of intelligence. As an example, whereas dominant US culture values speed in mental processing and considers such ability as reflective of intelligence, other cultures have been shown to view speed in decision-making as reckless and unwise. Using this example, if speed of processing is built into a measure of intelligence, and greater speed equals a greater score, administration and scoring of the measure with an individual from a culture that does not value or support speed would be problematic, raising issues of construct validity and cultural equivalence.

Intelligence tests are culturally dependent measures, created largely by and for majority populations, and are normed and standardized to a particular culture. In addition to issues of validity and equivalence, the performance of a culturally-different individual on a test of intelligence may reflect problems related to method bias, or the degree of familiarity a person has with the test-taking process. Language bias is also a significant issue in the administration of intelligence tests to migrants. Most measures of intelligence are heavily language-based, thus individuals who are not proficient in the language in which the test has been developed, normed/standardized, and administered are likely to have impacted comprehension and thus artificially lowered scores. Attempts have been made to make nonverbal measures of intelligence; however, many of these instruments contain passages of verbal instruction that can still influence and hamper individual performance.

Many measures of intelligence, such as the Wechsler Adult Intelligence Scale, have been normed and standardized for use with a variety of cultural groups. These groupings, however, are limited to larger minority groups, and these norms assume a level of homogeneity that in today's pluralistic and multicultural society often does not exist. Despite its limitations, there are occurrences wherein a measure of intelligence is needed for an immigrant individual. For such situations, Rivera Mindt et al. provide recommendations to ensure the greatest level of success. First, it is important to choose the most appropriate test available for administration, with clear recognition of the limitations of the instrument when scoring or making conclusions. Second, it is important to evaluate and include in interpretation a number of sociocultural variables unique to the migrant individual with whom the instrument is being used. Such variables for consideration should include: language, with concern for language preference, degree of test-language fluency, and bilingualism; quality of education, including years of formal education, place of education, and years of education within the culture in which the test is being administered; the processes and motivation for migration, such as forced versus voluntary migration; health status pre- and post-migration, both physical and mental; personal experiences of prejudice, racism, and transition to minority status that can often accompany the migration process; and degree of acculturation, loosely defined here as the assimilation of cultural traits and values dominant in the area to which one has immigrated. Lastly, if able, Rivera Mindt et al. recommend referring the migrant to a professional, familiar and competent in test administration with that population, and if unable to refer, consultation should be sought with such an individual.

Intergenerational Differences

Marjorie Nigar Edguer
Mandel School of Applied Social Sciences, Case Western Reserve University, Cleveland, OH, USA

Intergenerational differences are divergences between family members of different age groups in immigrant families, and they are due usually to variations in acculturation. As immigrant families meld the culture and values of their sending and receiving countries, family members experience this melding process individually and collectively. The results often are a function of varying interactions with the receiving country's culture and individual developmental differences. Intergenerational differences may occur between parent and child, grandparent and parent, and grandparent and child; it is inherent in the process that there are different generations from the nuclear and extended family structure involved. It is important to note that intergenerational differences occur in all families, but may be perceived differently or may have greater significance in immigrant families.

The more disparate the acculturation between family members, the more likely it is that they will perceive greater intergenerational differences. There are a variety of aspects to acculturation: language skills and preferences, values and beliefs, behaviors, and customs. To varying degrees, one may incorporate in each aspect characteristics of both sending and receiving countries, and even employ them differently according to the setting. For instance, immigrant youths may use exclusively at home the language of their sending country; conversely, they may use exclusively at school the language of their receiving country. However, when immigrant youth are among their peers, their verbal communication may be specific to that particular peer group. Regardless of their language choices, they may express consistently the same values in all settings; or, expecting the same freedoms as their peers in the receiving country, they may argue with parents about values, while not being comfortable acting just as their peers. Acculturation is not a uniform process, even for one individual, which is why intergenerational differences can vary widely.

An important influence on intergenerational differences is gender. Depending on how rigid the gender expectations are in the sending and receiving countries, and the degree to which they differ, conflicts between immigrant generations may be significant. Because many families become more conservative following immigration, this will impact children's experiences. Girls often are seen as the bearers of culture, because they are responsible for childrearing and the transmission of culture to the next generation. This likely will translate into a discrepancy in the rigidity of the limits for boys and girls: with boys being allowed a variety of peers, traveling and exploring freely; and with girls being monitored more closely, while their actions and behavior outside the home are curtailed. This dynamic may increase intergenerational conflict, or the girls may acquiesce to limits in some area, but find ways to do the things that are important to them. Some children, especially those who are supported by a larger immigrant group, may see these limits as an important way to maintain their connection to the sending country.

The dynamics related to having extended family or a larger immigrant community will effect interactions with the receiving country: they provide support for the continuity of culture. They provide resources also; so the family is less reliant on outside supports to meet their needs. This may minimize the interactions with outside systems and decrease potential influences that may lead to intergenerational conflicts. For families without a larger network, either there may be more interactions with and exposure to the culture of the receiving country or there may be increased isolation. If parents feel that they need to protect their child from the receiving country's culture, and they restrict opportunities for interactions, the child may live a life of isolation even as a young adult (going to work and coming home to spend non-work hours with their parents). Conflicts may arise if children resent the limits. Extended family may mean that there are elderly to be cared for, some of whom may have a difficult time adjusting to immigration. The elder members of the family may have the least acculturation. They may struggle with the loss of their advice-giving role and the accompanying respect that is traditionally associated with this role. They may become dependent on other family members, all of which contributes to intergenerational differences and possible conflicts.

Intergenerational differences also can develop owing to changes in parents' status and opportunities following immigration. If the parents' ability to provide for their family is compromised, family members will have to distribute responsibilities differently. Adults may lose social status if they do not have a peer group that knows them and respects them. Children may have more relevant information about the receiving country's culture than adults in the family, further diminishing parental authority. Additionally, children may become the family's translators for dealing with outside systems in the receiving country, shifting the distribution of power within the family. These dynamics may all contribute to intergenerational differences and conflicts.

Internally Displaced Persons

Robindra Paul
Private Practice, San Diego, CA, USA

The United Nations Office for the Coordination of Humanitarian Affairs Guiding Principles of Internal Displacement defines internally displaced persons (IDPs) as, "…persons or groups of persons who have been forced or obliged to flee or to leave their homes or place of habitual residence, in particular as a result of or in order to avoid the effects of armed conflict, situations of generalized violence, violations of human rights or natural or human-made disasters, and who have not crossed an internationally recognized State border (Office for the Coordination of Humanitarian Affairs [OCHA])."

The United Nations *Guiding Principles* recognizes that IDPs have a right to physical and mental integrity and that if authorities undertake displacements, IDPs should be accommodated in conditions that would afford satisfactory health (OCHA). Furthermore, Principle 19 of the *Guiding Principles* states, "All wounded and sick internally displaced persons as well as those with disabilities shall receive to the fullest extent practicable and with the least possible delay, the medical care and attention they require, without distinction on any grounds other than medical ones. When necessary, internally displaced persons shall have access to psychological and social services (OCHA)."

Doctors without Borders displayed estimates that there are 26 million IDPs. More than half of the IDPs are from six countries including Sudan, Colombia, Iraq, the Democratic Republic of Congo, Uganda, and Somalia. The group characterized the situation of IDPs as "bleak" because although there may be local and international aid organizations, IDPs are under the jurisdiction of their national authority which may be the source of the violence from which they are fleeing.

Many agencies around the world have had significant experience dealing with IDPs and it is important to understand what they have learned in order to identify IDPs and provide an adequate healthcare response both during and after any displacement. The following are examples of what has been learned about IDPs by the International Committee of the Red Cross (ICRC). IDPs are likely to stay with friends and family in nearby communities in order to minimize the disruption to their lives. However, these persons may go unnoticed by international or government aid agencies and this places an enormous strain on communities. Camps have their benefits and risks. Camps may be able to provide food, water, and shelter when there are no other choices. However, it is possible that camps can promote violence and exploitation or foster resentment with persons in nearby communities when the services in camps are not available in the communities.

Internally displaced persons suffer from unique sets of healthcare challenges depending upon the reason that they are displaced, the resources that are available, and the resiliency of the country. The health needs of IDPs can be assessed and addressed on a population and on an individual level. On a population level, the most important and basic need is access to food and water. Sanitary and uncrowded conditions can lessen the risk of the spread of infectious diseases. Other needs include access to adequate shelter, medical facilities, and health care personnel.

Vulnerable populations of IDPs must be identified so that their needs can be adequately assessed and addressed. The UN has recognized a need to pay attention to the following populations of internally displaced populations: children, mothers, pregnant women, the elderly, and the disabled.

On an individual basis, IDPs can be triaged based upon the acuity of their medical illnesses. Acute care requires identifying and stabilizing those who are critically ill. Those persons with medical ailments who would typically be stable under normal circumstances may acutely decompensate in the face of a lack of adequate medical care or equipment. Even a simple infection can lead to a life-threatening illness without access to proper treatment. Emergent mental health problems include mental illnesses that lead individuals to want to harm themselves or others or will lead them to be gravely disabled (i.e., not eating food or drinking water).

Internal displacement can last for years, and untreated chronic or other health conditions can lead to significant morbidity or mortality without adequate assessment and treatment. For example, chronic malnutrition can lead to inadequate growth and development. Inadequate treatment for diabetes can lead to the loss of eyesight and the need for amputations. Inadequate treatment for mental illness can lead to a significant decline in functioning. Any needs assessment and treatment provision has to take into account the sustainability of resources over the course of displacement.

Although vulnerable groups may be identified, decision makers may not see these groups as a priority and this may lead to increased morbidity and mortality that could have been reduced or averted. For example, according to the World Health Organization (WHO), despite evidence demonstrating that conflicts have a devastating impact on mental health, many decisionmakers do not see mental health as a priority. However, the WHO has urged that community-based psychosocial interventions become integrated as part of both the emergency response and the public healthcare system including camps and national services. Therefore, it is important to identify and address any biases or lack of understanding on the part of decisionmakers in order to adequately address the needs of those who may otherwise be ignored or not able to advocate for themselves.

In summary, there are many reasons why persons become internally displaced, but once displacement occurs, it can last for years. The response to those who are internally displaced is limited by available resources. The provision of adequate treatment first requires that an including the identification of vulnerable populations be conducted. Efforts should be made to make resources to address identified needs are sustainable. Interventions should be consistent with the evidence-based. Furthermore, human rights must be respected in order to help ensure the best possible outcome given the circumstances on the ground.

International, or inter-country, adoption is a type of adoption that occurs following the transfer of all parental rights and responsibilities from a child's birth parent (s) to biologically unrelated, adoptive parent(s) who live in a country different from the child's country of origin. Once a family is formed through inter-country adoption, the child moves to a new home with his or her adoptive parents and becomes a citizen of the adoptive family's country. Inter-country adoptees may have lived some of their childhood with birth families, but become orphaned for a myriad of reasons (i.e., parental death, abuse, neglect, abandonment, or poverty). Children often end up in institutional settings like orphanages, foster homes, child-headed households, or are homeless. Typically, children's pre-adoptive lives are filled with a multitude of challenges that expose them to risk and trauma, a factor noted in the literature as having an instrumental effect on child development. Considerations must be made by parents and pediatric professionals when evaluating children's further development following placement. To promote the defining of such considerations, there must first be an understanding of the current framework that is used for child developmental evaluation.

International Growth and Development Criteria (IGDC) is a developmental screening tool endorsed by the International Pediatric Association (IPA). A standard for child growth and development like the IGDC serves parents and pediatric professionals when evaluating how healthy children should sequentially develop in their physical, emotional, and cognitive domains for their chronological age. This approach bases its standards on families' having ideal access to resources, a nurturing primary caregiver, and an environment where children are most likely to reach their developmental potential.

Applying tools like the IGDC to the internationally adopted, post-institutionalized child is valuable, as it gives firm standards to evaluate developmental delays and guide interventions. However, parents and care providers unfamiliar with the unique needs of inter-country adoptees may be too literal when utilizing the IGDC, encouraging myopic focus on the child's delay "catch-up." Understanding and incorporating the etiology of the children's delays into care is essential in formulating effective interventions. Exclusively using a standardized approach like the IGDC may also prompt unrealistic expectations in terms of the chronological timing and pace of the adoptee's milestone accomplishments, priming an environment for anxiety and frustration during critical periods that could impede child–family attachment.

With post-institutionalized children, it may be beneficial to utilize the sequential nature of the IGDC in combination with a more tailored approach, or an individualized child development trajectory (ICDT). The ICDT is an approach that would incorporate known experiences with pre-adoptive risk factors when formulating interventions and goals related to the child's expected timing/pacing of milestone accomplishment. This developmental evaluation method would also encourage the child and family in the adoptee's development without adding frustration and anxiety linked to "catching-up" pressures during critical stages of relationship and attachment formation.

The interrelatedness of impacts from pre-adoptive risk factors must be understood when formulating a child's ICDT. Genetics, prenatal toxin exposures (alcohol/drugs), and the institutions' environmental impacts (i.e., sensory deprivation; malnutrition; abuse) create what is known as pre-adoptive risk factors. Another common, damaging risk factor for institutionalized children is the lack of primary caregiver consistency/emotional warmth needed by infants and children for survival, safety, trust building, social cue learning, and relationship building. Introduction of such risk factors during the child's critical periods of sensitive brain development can promote long-term effects, impacting how the child thinks, feels, and behaves when coping with stressors throughout life. This can also affect health in other developmental systems for the child. For example, links have been made to increased risk for contraction of infectious diseases (i.e., parasites; tuberculosis; hepatitis B), growth retardation, early onset menarche/precocious puberty, sensory problems, quasi-autistic behaviors, attachment difficulties, and long-term relationship challenges.

Consequences of child neglect are delays in major growth domains such as gross/fine motor skills, cognition and learning, language, and social-emotional development. For every 3 months the child spends institutionalized, his or her growth will reportedly lag approximately 1 month. The longer a child remains institutionalized, the greater the negative impacts on cognition, brain growth/head circumference, psychiatric impairments, economic dependency, cognitive/executive functioning, attention, language, learning, memory, visual-spatial functions, and struggles with attachment and social relationships.

Physiologically, children's brains experience neglect similarly to traumatic events. The brain's amygdala is activated in the presence of neglect, triggering the biological stress response system (BSRS), or the "fight or flight response." Anxiety and distress can impede the child/parents in attachment formation and lowers immunity. The chronic nature of this activation contributes to adverse brain development, increasing levels of cortisol (stress hormone) that trigger survival behaviors associated with hyper-arousal/hyper-vigilance, as well as difficulty with normal age-related behavior/emotion regulation. This often manifests like typical acting out, prompting most parents to respond with traditional child-rearing practices in an attempt to remediate negative behaviors. These practices (i.e., rewards/punishments) are often ineffective, as the child's acting out is symptomatic of behavioral responses to the bodies' physiological cues conditioned during earlier traumatic experiences. Post-institutionalized children who experience such effects need parenting and pediatric professional support that aids them in building adaptive skills to their stress/trauma coping responses. To provide optimal support, parents and pediatric professionals must be informed and have appropriate expectations when it comes to the child's developmental needs.

Although children reportedly thrive in many ways after adoption and follow a sequential growth pattern much like the standards stated in the IGDC, differences also exist that require consideration when evaluating their development. For example, attempts to define children's ages may result in inconsistencies. Adoptees may have a chronologic age, a second developmental age due to delays, and/or a third reproductive age when there is an early onset of menarche/puberty. Also, the pace of milestone accomplishment can differ as crossover may exist with one delay impacting another. Attempts to ameliorate one area of delay may impede progress in another domain or trigger the simultaneous accomplishment of a delay in another, prompting an erratic pattern in milestones completion.

Assessment and monitoring growth/development in post-institutionalized children is essential due to their often fragile states upon leaving the institution. Incorporating a tool like the IGDC paired with an individualized child development trajectory would provide a "standard" as well as a "reference" for supportive goal-setting/measurement while taking into consideration the effects of pre-adoptive risk factor exposures on the ideal course of growth and development.

International Health Regulations

Kristin Bright
Department of Sociology & Anthropology, Carleton University, Ottawa, ON, Canada

The International Health Regulations (IHR) are a legally binding agreement adopted by all 194 World Health Organization (WHO) member States on May 23, 2005, and officially in force since June 15, 2007. The primary goal of the regulations is to reduce and contain the risk of disease spread in international travel, trade, and transportation. The IHR replace the 1969 set of regulations that initially covered six "quarantinable diseases" but were amended in 1973 and 1981 to reduce the number of covered diseases to three (yellow fever, plague, and cholera) and to acknowledge the global eradication of smallpox. The newly revised IHR contain a number of changes with implications for immigrants and immigrant health. Motivated by concerns about novel and potential epidemics such as severe acute respiratory syndrome (SARS), H5N1 ("avian flu"), H1N1 ("swine flu"), and drug-resistant tuberculosis (TB), the IHR expand the range of events about which member states must notify the WHO. In this respect, the regulations increase the mandate (and legal reach) of states to conduct disease surveillance at airports, hospitals, immigration services, ports, postal services, and other settings.

The regulations contain new provisions for inspection at ports of entry of people, individuals, cargo, containers, luggage, parcels, and human remains that are contaminated or that might be contaminated and that, as a result, place the public health at risk. If sources of infection or contamination are found, the regulations advise for the containment, decontamination, and if necessary quarantine or refusal of entry of "suspect persons" or goods.

At the same time, the IHR provide greater authority to the WHO to recommend changes in existing state systems for public health monitoring and response. Member States are required to notify the WHO of any event "that may constitute a public health emergency of international concern," including new and evolving public health risks. The IHR 2005 also contain a number of changes with regard to the duties of States in terms of "global preparedness" including the creation of new surveillance systems to detect and respond to events by June 2012. Specifically, member States are required to set up National IHR Focal Points, or communication systems for the relay of information between States and the WHO and within member States. For example, in the USA, this would be between public health departments in each of the 50 states and federal agencies like the Centers for Disease Control and Prevention (CDC). In addition, the IHR 2005 introduce a new category of "event" called a Public Health Emergency of International Concern (PHEIC) whereby member States are required to use new "decision instruments" to assess risk and if necessary to coordinate with the WHO to declare a PHEIC. In 2009, the outbreak of influenza A (H1N1) led to the first declaration of a PHEIC.

While many in the public health community agree that the new IHR regime has led to a strengthening of global health security, others, particularly in developing countries, have expressed doubts both as to the use of surveillance data for their best interests and the extent to which the new IHR will synchronize with local or regional interests of human rights, diplomacy, trade, and development. Perhaps the best-known case of a refusal to participate in the new IHR regime occurred in 2007, when Indonesian scientists refused to send H5H1 ("avian flu") samples to the WHO's reference labs. The scientists explained in a 2008 medical journal article (see Sedyaningsih et al.) that they were concerned that samples provided freely by developing countries were being used by companies in wealthy countries to develop vaccines and other products that the developing countries could not afford. From a financial standpoint, public health advocates have voiced concerns about the cost of IHR implementation and enforcement. While the WHO provides grants for the development of National Public Health Institutes (NPHIs), the burden of cost for setting up and maintaining disease surveillance is primarily on member States. This has led to a concern among public health advocates in the USA that funds previously designated for community health services are being re-routed into national disease and bioterrorism surveillance systems. Concerns about cost are coupled with concerns about the adequacy of human rights provisions; and critics have pointed out that legal and ethical protections are only superficially mentioned in the IHR 2005. Supporters of the new IHR have argued that increased data gathering and sharing will enable member States to better detect and respond to health threats of global significance. Whether increased opportunities for data sharing translate into more robust systems of public health is not clear and is difficult to assess outside of the context of actual epidemic situations. As was the case in recent debates about changes in US Transportation Security Administration (TSA) airport screening procedures (e.g., the introduction of new full body scanners and more extensive pat-downs), groups like the American Civil Liberties Union (ACLU) have questioned whether more invasive screening procedures can be justified given increased risks for violation of travelers' civil liberties.

From a sociocultural standpoint, the IHR 2005 raise important questions about language, norms, and differences in how risk is defined. What may be perceived as practical or meaningful "risk assessment" in one cultural setting may not be in another; the actual social and institutional norms through which IHR 2005 are practiced (e.g., how health workers count cases of disease and according to what diagnostic criteria) can vary considerably across borders. In regard to language and meaning, terms such as "global health emergency" are controversial and not easily agreed upon, as was revealed in the context of debates about how many H1N1 cases were required before an "epidemic" could be upgraded to a "pandemic." In January 2010, Dr. Wolfgang Wodarg, who now chairs the health committee at the Council of Europe, came forward to argue that pharmaceutical firms had organized a "campaign of panic" to put pressure on the WHO to declare a "false pandemic" in order to sell vaccines, resulting in a medical scandal. It later emerged that one third of the experts advising the WHO about the pandemic had ties to drug firms.

By November 2009 there had been 622,482 lab-confirmed cases of H1N1 reported from 207 countries and territories, with a total of 7,820 lab-confirmed deaths. The H1N1 epidemic was a litmus test for the new IHR 2005; it provided a staging ground for the collection and reporting of surveillance data within and between countries. Despite demonstrably "high" compliance of US epidemiologists reporting to the CDC and WHO, reporting capacity was lower among community and primary care providers. And, although there has been growing international acceptance of a general idea of "health security," multiple and incompatible definitions of the term remain. Divergent understandings among policymakers of what or how much surveillance constitutes "security," combined with insufficient reconciliation of the concept with community based primary health care, have stymied efforts to implement the IHR 2005.

In the USA, where "health security" is increasingly aligned with hegemonic ideals of "prophylaxis" against immigrant or foreign-borne diseases – coupled with an increased emphasis on shielding the nation from risks of bioterrorism – the latest regulations (2005) present significant social and legal consequences for immigrants and immigrant health. In 2009 the response of authorities in Beijing to the appearance of influenza A (H1N1) virus illustrated a level of discrimination reminiscent of the 1980s–1990s when hundreds of Haitian asylum-seekers were tested for HIV and then imprisoned by the US Immigration and Naturalization Services (INS) in the Guantánamo HIV Camp, one the world's first and only detention centers for people diagnosed with HIV or AIDS. In 2009, travelers to China from Mexico, as well as Mexican residents living in China, were targeted for quarantine both in airports and at their homes in Beijing, including individuals in whom no flu symptoms had been detected. In the USA and Mexico, limitations to the effectiveness of the IHR were revealed somewhat differently: namely, in inadequacies in surveillance, in mixed response capacities, and in the potential for narrowing the scope of IHR application only to influenza pandemic events. Analysts have argued that such limitations could undermine the IHR's potential to contribute to national and global efforts to detect or mitigate future public health crises.

Yet this assumes another sort of agreement or gloss of the term "crisis." According to whom (which decision makers) and what interests (diplomatic, economic, humanitarian) is a crisis determined? Better understanding of the heteroglossia of crisis and its analogs (concern, risk, threat, event, emergency, epidemic, pandemic) and the uses of these concepts in different locations and contexts would likely lead to better chances for cooperation. Likewise a clearer articulation of "common good" (rather than simply obligations and rights) especially in the area of data and sample sharing is greatly needed. Collaborating laboratories and scientists will need to see evidence (e.g., contractual plans) rather than "good faith" that the data they hand over will be used for a global common good rather than the increased share value of Western pharmaceutical firms. Also, there have been few quantitative assessments of whether global outbreak detection and communication processes have actually changed over time, that is, before and after the implementation of the IHR in 2007. There are also no clearly established guidelines for how countries should conduct IHR surveillance, which emerging disease syndromes should be reported, or what means for enforcement should be used. A cost benefit analysis would likely help to reveal whether changes prescribed by the IHR justify the expense of new high-tech systems for data capture and surveillance for example.

The WHO will remain stymied in its efforts to enforce the IHR as long as health workers in developing contexts are focused on more immediate quotidian needs, such as access to essential drugs, sterile medical supplies, and clean water; training and retention of qualified health care workers; economic security for immigrants and refugees; and the promotion of legal protections for persecuted groups. These concerns are likely to remain higher priorities than "specialized disease surveillance," particularly if such tracking systems suggest the reassignment of funds or staff within resource-poor settings including the majority of immigrant communities in the USA.

International Labour Organization

Moon Choi
Department of Epidemiology and Community Health,
Virginia Commonwealth University, School of
Medicine, Richmond, VA, USA

The International Labour Organization (ILO) is a specialized agency of the United Nations and responsible for drawing up and overseeing international labor standards. The missions of the ILO are to promote rights at work, support decent employment opportunities, enhance social protection, and strengthen dialogue on work-related issues. Due to the nature of its missions, the ILO has a tripartite governing structure, representing governments, employers, and worker representatives. This tripartite structure enables the ILO to develop a forum, wherein the governments and their socioeconomic partners can openly debate and develop labor standards and policies. Today the ILO has 183 member states.

The focal point for the ILO's main activities is the International Labour Office. The Office has approximately 2,700 officials from over 150 nations at its headquarters in Geneva, Switzerland and in around 40 field offices around the world. These field offices collaborate to promote the "Decent Work Agenda" as an integral part of regional and national development policies. The executive body of the International Labour Office is the governing body, which decides the agenda of the International Labour Conference, adopts the draft programme and budget of the organization for submission to the conference, and elects the director-general. The governing body, consisting of 56 titular members (28 governments, 14 employers, and 14 workers) and 66 deputy members (28 governments, 19 employers, and 19 workers), meets three times a year.

The ILO defines "Decent Work" as adequate income, safeguarding of rights, and assured social protection and identifies the "Decent Work Agenda" as its major priority. The goal of Decent Work is not simply the creation of jobs, but the creation of jobs of acceptable quality. This "Decent Work Agenda" is related to the human rights of immigrants considering that many of them are primarily employed in unskilled manual labor and are generally assigned to arduous or dangerous work, which national workers are reluctant to do. Moreover, immigrant workers often experience discrimination at both the recruitment and post-hire stages, resulting in their underemployment. Decent Work is the key element to achieve a fair globalization, reduce poverty, and achieve equitable, inclusive, and sustainable development. In this context, the ILO provides support for member states to put the Decent Work Agenda into practice through integrated Decent Work Country Programmes.

International Organization for Migration

Cristina Cazacu Chinole
Center for Ethics and Public Policies, Bucharest and Iasi, Romania

The International Organization for Migration (IOM) is an intergovernmental organization that has been established in 1951 to promote humane and orderly migration for the benefit of all. Having 100 offices all over the world, 127 Member States, and another 17 holding an observer status, this agency works closely with governmental, intergovernmental, and nongovernmental partners being the leading intergovernmental organization in the field of migration.

As a core value, IOM is committed to the principle that humane and orderly migration benefits both migrants and society, as well. Therefore, the scope of the organization is to safeguard the management of migration flows, promote international cooperation on migration issues, and assist in finding the appropriate solutions to various problems raised by migration.

Having offices and operations on every continent, the Organization offers support for governments and civil society to find solutions to migration issues, such as: rapid humanitarian responses to sudden migration flows, post-emergency return, and reintegration programs; support to immigrants in building a new life; aid to immigrants in distress; identification of mechanisms to combat trafficking of children, women, and other groups at risk; measures to respond to medical and public health issues in relation to migration; and research, education, and information on immigration issues.

The Organization cooperates with governmental, intergovernmental, and nongovernmental partners in the four broad areas of migration management: migration and development, facilitating migration, regulating migration, and forced migration. Cross-cutting activities of IOM specialization are linked to the elaboration of international migration law, policy debate and guidance, protection of immigrants' rights, migration health, and the gender dimension of migration. Furthermore, IOM provides humanitarian assistance to immigrants that are in need of help, including refugees and internally displaced people.

In terms of regulating migration, IOM offers tailored technical assistance to governments in the development and implementation of migration policy and the proper legislation and necessary administrative mechanism that regulates migrant labor and other migratory movements, as well as training courses for public servants in terms of border management, visa systems, regulating entry and stay, and collecting and using biometric information.

Since the IOM Constitution gives explicit recognition to the link between migration and economic, social and cultural development, as well as to the right of freedom of movement of persons, the work of the Organization is centered on the promotion of an international policy dialogue and toward policy-oriented research and programs and activities to build capacity of governments, improve remittance management, build human capital through labor migration programs, facilitate return and reintegration, and promote empowerment of immigrant women.

In terms of forced migration, IOM offers assistance for refugees and internally displaced persons (IDPs) who are a different category of immigrants. These people are "on the move" but they need a different type of assistance. The Organization offers help for refugees after emergencies and facilitates their resettlement in a new country, if this is a durable solution. The Organization seeks also to find solutions for internally displaced persons (IDPs), former combatants, and populations in transition or recovery environments.

IOM also offers support and technical advice to governments with the aim of facilitating migration, so to have the capacity to properly regulate the migrant labor and other migratory movements. The Organization is active in offering assistance for governments and immigrants, as well, with issues such as: selection/recruitment, language and cultural orientation, consular services, training, reception, integration, and return.

As health issues affect all immigrants and potentially cut across all areas of IOM's work, the Migration Health Department within the Organization responds to the health needs of migrants throughout all phases of the migration process, and to the public health needs of host and home communities. The Department coordinates health operations, offers health policy advices, and contributes to public health research.

Some of the issues that the Department is in charge of include: control of infectious, emerging, and reemerging diseases; health activities in response to population movements caused by natural or man-made disasters, ecosystem change, chronic diseases, mental health, and psycho-social health concerns, including culturally appropriate health services; the human rights of immigrants and mobile populations; immigration health management; and many other issues that affect the immigrants' health and the communities they live in or transit through.

Internment

Delaney Smith
Timothy B Moritz Forensic Unit, Twin Valley
Behavioral Healthcare, Columbus, OH, USA

The term internment is used to refer to the confinement or imprisonment of large groups of people within the context of warfare. Typically, nonnaturalized immigrants are the subject of internment; however, at times this practice has been extended to those who hold different political convictions, belong to a group considered undesirable, or who the government perceives as a threat to wartime security. Such individuals are typically held without the benefit of a trial and with no specific charges, thus distinguishing internees from prisoners who are held for punishment after being found guilty of a crime and typically have access to a trial within the civil or military courts of the country.

In North America the best-known case of internment was that of Japanese-Americans during World War II. President Franklin D. Roosevelt signed Order 9066 into law on February 19, 1942 leading to the evacuation and relocation of an estimated 112,000 ethnic Japanese, most of whom were first and second generation citizens, from the West Coast of the USA. Numerous other examples of internment during World War II exist, including noncombat Allied citizens interned by the Japanese in the Philippines and China. The Nazi internment of Jews, those with mental illness and physical disabilities, homosexuals, and others in what became known as concentration camps will be dealt with in a separate entry (see ► Holocaust). Internment was also widespread in World War I. Examples include the USA in its internment of over 6,000 individuals, France's internment of German civilians, and Canada's internment of Ukrainians residing in Canada. This practice can also be traced back to the confinement and resettlement of native people by colonizing nations.

The experiences of those confined in internment camps vary both by the war and the country in which they were detained. The emotional consequences of internment are frequently long lasting. While living in internment camps, individuals are forced to leave their homes and jobs, are sometimes separated from family and support networks, and frequently housed in prison-like settings with armed guards. Unrest is common in internment camps and violence can occur both between those interned and their guards and amongst those confined. Posttraumatic stress disorder can occur as a consequence of experiencing and witnessing traumatic events within this setting. Individuals with posttraumatic stress disorder can experience problems relating to family and peers. They can avoid things and people that remind them of their trauma and experience flashbacks to their time in the camps. Other possible consequences of posttraumatic stress disorder include irritability, an inability to concentrate, and difficulty envisioning one's future.

Those who have lived through internment may also have problems with depression or anxiety disorders. If they escaped an internment situation while others did not they may have feelings of guilt or survivor's syndrome. They may have a difficult time trusting those in authority, have low self-esteem, feelings of pressure to assimilate, and either a loss of connection with their own culture or an over-identification with it. Earning potential and productivity may be affected both by anxiety and depressive disorders as well as the lack of formal education during time spent in internment camps.

The internment camp experience also has a significant impact on an individuals' physical health. Lack of proper sanitation and close quarters in camps can lead to rampant spread of infectious diseases which both sicken the immigrant and those who come in contact with him or her after release. Harsh climates and lack of access to medical practitioners, medications, and equipment can lead to lack of diagnosis and proper treatment of chronic medical conditions and poor prenatal care that can have long-term negative health consequences. A 2006 study by Hahn et al. showed an increase risk of cardiovascular diseases including hypertension and chronic ischemic heart disease in such populations.

One of the main physical consequences of internment is malnutrition. During wartime, resources are frequently scarce and those who have already been identified as a potential threat to the State are typically of low priority for dwindling food supplies. Immediate consequences of long term, severe malnutrition can include refeeding syndrome in which the body is unable to properly metabolize nutrients during the first several days of food availability resulting in fluid and electrolyte disturbances. If not properly treated, this can lead to seizures, coma, or death. Malnutrition can also increase ones susceptibility to infectious disease including active tuberculosis. Longer-term sequelae of malnutrition can include osteopenia and osteoporosis with its associated increase in risk of bone fractures as well as overall increased mortality rates. Malnutrition in childhood has also been associated with lower educational achievement. Even in internment camps where food is adequate, if the diet is lacking in specific essential nutrients individuals may have mental impairment, heart disease, or bleeding disorders, and pregnant women may give birth to children with birth defects.

In summary, the consequences of internment both on physical and emotional health are significant and should not be overlooked. The 1949, the Geneva Convention outlined appropriate treatment of internees, giving special attention to issues of hygiene, access to food and medical attention. Public criticism of internment has grown since World War II. In the USA, attempts were made to address the "significant human suffering" caused by the internment of ethnic Japanese during World War II. On August 10, 1988, President Ronald Reagan signed a law issuing reparations payments of $20,000 to those Japanese-American citizens and permanent residents who had been subject to the internment process. Additional monies were set aside to fund education programs related to these experiences.

When compared to patients who share the same language with their providers, language-discordant patients experience lower quality of care, including but not limited to worse interpersonal care, less communication, and lower patient satisfaction even in areas unrelated to language. Translators (i.e., individuals who work with written documents) and interpreters (i.e., individuals who provide oral communication) often are considered the standard solutions to provide culturally appropriate and sensitive care. Interpreter Services, which may be a contracted independent agency or a division housed within a health care organization, often provide services for both medical translation and interpretation.

Medical interpreting is not only well organized but is also extensively studied in various multiethnic societies (e.g., Australia and Canada) and in countries that represent a destination of intensive immigration (e.g., Denmark, Germany, the Netherlands, Spain, Switzerland, the United States, and the United Kingdom). In the United States, starting from the late 1970s, there have been federal and state legislative efforts to require physicians to provide interpreters for patients with limited English proficiency (LEP). At the federal level, the White House issued an Executive Order on *Improving Access to Services for Persons with Limited English Proficiency* on August 11, 2000, which resulted in written guidelines being provided, by the Department of Health and Human Services in 2003, to health care providers to ensure language assistance for persons with LEP. The guidelines were rooted in the Title VI of 1964 Civil Rights Act, which prohibits discriminations on the basis of race, color, or national origin by any recipient of federal financial assistance. In short, health care providers who do not provide interpreter services will be cut off from federal reimbursements, including Medicare, Medicaid, and the State Children's Health Insurance Program. Because by law the cost for interpreters cannot be transferred directly to the patients, health care facilities often struggle to find sufficient funding through federal/state-level sources, insurance companies, and private funds. In early 2009, California became the first state in the United States to pass a law requiring health insurance organizations to pay for interpreting and translating services. Although the American Medical Association (AMA) and health maintenance organizations often raise concerns about the high costs of interpreter services, recent studies have demonstrated that providing interpreter services as a part of standard care often increases the overall number of immigrant patients, resulting greater revenue for the hospitals.

As of 2010, many national and regional interpreter associations in the United States have advocated for a national certification although a standardized process is still a work-in-progress. A national survey in 2010 showed that nationally certified American Sign Language interpreters are better compensated than spoken language interpreters in health care settings. The efforts to push for national certification reflect the interests in recognizing medical interpreters not only as bilingual go-betweens but also as health care professionals. The local certification requirement for medical interpreters often differs from state to state. In states where the certification tests are required, they often are limited to a few languages (e.g., Spanish). As a result, there are no federal or state regulations in place that prohibit the use of noncertified/professional interpreters in health care settings.

The cultural and linguistic diversity of patients make it unrealistic for health care organizations to provide professional interpreters in all languages at all times and/or all points of contact. The AMA, in fact, has provided guidelines to providers for the effective and appropriate utilization of different types of interpreters, including on-site professional interpreters, telephone interpreters, ad hoc interpreters, family interpreters, bilingual staff, and bilingual health care providers. Professional interpreters are typically defined as individuals who have received a minimum of 40 hours of training in medical interpreting. Different health care organizations may have additional requirements, including intern hours or (internal) certification. Several recent reviews have found that on-site professional interpreters appear to raise LEP patients' satisfaction and quality of care to approach or equal that for patients without language barriers. However, researchers have also found that even in states that institute interpreter legislation, health care providers often underuse on-site professional interpreters, citing time constraints and lack of availability of interpreters as primary reasons. On-site professional interpreters can also be unrealistic if the patient population cannot support such services.

Most health care facilities also use other types of interpreters, which are not without flaws. For example, telephone interpreters do not have access to other speakers' nonverbal cues and tend to have concise talk that centers on medical information (as opposed to rapport-building). Ad hoc and family interpreters, including bilingual children, may not understand complex medical procedures, pose additional risks to malpractice lawsuits and patient privacy, and/or experience unanticipated stress. Bilingual staff and providers need to manage other institutional roles and responsibilities that may conflict with that of interpreters.

It is important to note that providers and patients do not share the same preference for interpreters. Generally speaking, both providers and patients prefer on-site professional interpreters; however, they do not share the same attitude for other types of interpreters. Other issues (e.g., trust, interpreter availability, and specific tasks) may influence their preferences. For example, patients may prefer family interpreters because they can assist them after medical encounters and have their best interests in mind. In addition, in small immigrant communities where privacy can be a concern, minority patients may feel reluctant to disclose information to individuals outside of their social network, including a professional interpreter. In contrast, health care providers often are concerned that family interpreters may side with patients and become a liability in malpractice lawsuits. Many providers argued that in situations that require emotional support (e.g., disclosing poor prognosis), they prefer nonprofessional on-site interpreters over professional telephone interpreters. Some providers cited the convenience, medical knowledge, and institutional role of bilingual staff and colleagues as reasons why they are preferred choices in the absence of on-site professional interpreters. Several researchers recently have noted that family interpreters can be very valuable for specific tasks (e.g., obtaining medical history and patient advocacy). Finally, although providers generally are satisfied with medical encounters conducted through their (limited) second language skills, patients often find the interaction biased toward the providers' informational needs and does not allow them to communicate freely.

In addition to different types of interpreters, health care facilities also have introduced various modes of medical interpreting, including video medical interpreting, computer-based preprogrammed screening, and remote simultaneous medical interpreting. These interventions primarily aim to improve interpreting services to rural areas and emergency rooms, which traditionally have difficulties in providing on-site professional interpreters at all hours. Although the different types of interpreters and modes of interpreting are not interchangeable as they each have their own distinctive strengths and weaknesses, they serve as valuable resources in complementing and/or supplementing on-site professional interpreters' services.

By recognizing the variety of interpreters and modes of interpreting available in health care settings, researchers have explored their corresponding impacts on patient satisfaction, provider expectations, patient–interpreter relationships, institutional costs, and clinical consequences. It is important to note that researchers and providers have shifted away from the argument that only professional interpreters should be used in health care settings. Rather, they have proposed that the ability of providers to work with different types of medical interpreters is critical to the efficiency, quality, and informal economy of bilingual health care. For example, for routine care, providers may feel comfortable to communicate through nonverbal communication, limited second language skills and/or family members; however, they should use on-site professional interpreters for interactions that may be complex or have high stakes. Recent studies on medical interpreters have centered on identifying the contextual factors and guidelines that allow providers to develop effective and appropriate strategies when working with different types of interpreters.

Currently, there is no standardized code of ethics for medical interpreters although many interpreter associations and health care organizations have proposed various forms of code of ethics for interpreters. Reviews of the codes of ethics for medical interpreters have concluded that many of the codes emphasize a mode of interpretation that calls for an objective and neutral role for interpreters. Professional medical interpreters are trained with a default role, which is often called the conduit model. In the conduit model, interpreters assume a passive and neutral role, faithfully transferring information from one language to another without any agency or distortion. The prevalence of the conduit model also is reflected in the public's and providers' attitude and expectations for interpreters, envisioning interpreters as neutral translating machines. Interpreters often viewed the conduit role as a mechanical, robotic performance in which interpreters are prohibited to intervene in the interactions or to have personal opinions. Although professional interpreters often identify strongly with the conduit model, they also report significant dissonance and/or distress if they believe a strict adherence to the conduit model may lead to, if not worsen, miscommunication, prejudice, bias, and/or problematic care.

The research and health care communities, as a result, increasingly have recognized the complexity of interpreters' functions, which is reflected in the emerging trends in reexamining and expanding interpreters' roles and code of ethics. Researchers have demonstrated that interpreters do not assume a passive or neutral role as prescribed by the conduit model. Rather, they are active participants who systematically adopt purposeful strategies to improve a patient's health literacy, to protect institutional resources, to reduce the cultural gap between the provider and the patient, to reconcile provider–patient conflicts, to reinforce provider–patient relationship, and to ensure the quality of provider–patient interactions. Many researchers have concluded that the complexity of bilingual health care makes the conduit model impractical, if not unrealistic. As researchers noticed interpreters' active involvement in the communicative process, however, they also have questioned interpreters' ethics and raised concerns about how some of their communicative strategies may infringe on providers' authority or patients' autonomy. It is important not to romanticize interpreters' active role in interpreter-mediated medical encounters and examine their performance and communicative strategies critically.

There is a growing attention on viewing medical interpreting as a goal-oriented activity (i.e., achieving optimal care for patients). Interpreters are not necessarily expected to remain passive or neutral. Rather, they should actively shift between various roles (e.g., from the least intrusive role of conduit, to clarifier, to culture broker and finally, to the most intrusive role of advocate) in response to the tasks, issues, and contexts emerged during medical encounters. Interpreters are encouraged to actively evaluate other speakers' communicative goals and to modify their strategies and role performances accordingly. Interpreters, thus, are a part of a health care team and share the responsibilities in ensuring the quality of care.

A successful interpreter-mediated encounter is a coordinated accomplishment of all individuals involved. All participants (e.g., the provider, the interpreter, the patient, and even the family members) in the interpreter-mediated medical encounters can influence the process and quality of bilingual health communication. Interpreters can play a significant role in this process by overtly and covertly enhancing the patient and/or provider communicative competence. For example, to ensure effective and appropriate provider–interpreter interactions, interpreters may conceal the providers' problematic behaviors or ask questions on behalf of the patient. One study found that, when interpreters are friendly and emotionally supportive, Latino patients are more receptive to providers' suggestions of amniocentesis. A neutral/slightly cheerful interpreter can act as a buffer to the patient in reducing the negative moods caused by a despondent therapist. In fact, interpreters actively provide emotional support by noting the needs to bridge cultural differences and to ensure quality care. Conversely, interpreters' behaviors may compromise other speakers' communicative competence. For example, when interpreters focus on medical information and ignore providers' rapport-building talk, providers may appear emotionally detached. These studies highlight the fact that medical interpreters play a critical role in patients' health care experiences and in shaping provider–patient communication and relationship.

Providers' communicative behaviors may create dilemma for interpreters in managing medical encounters. For example, providers often feel comfortable in saying things that they would not have said during a monolingual medical encounter (e.g., showing confusion about the actual diagnosis or making disrespectful comments about the patients) believing that the patient would not understand them anyway. An interpreter may feel obligated to relay such information but fear that doing so may worsen the provider–patient relationship. In addition, interpreters may be motivated to bias toward providers (as opposed to patients) and to accomplish providers' communicative goals (e.g., pressuring patients to accept the providers' treatment suggestions) due to the lack of job security. Both interpreters and providers have reported instances in which an interpreter was sanctioned or even fired because they fail to meet the providers' expectations. The hierarchy of health care teams privileges physicians' status and perspective. As a result, researchers have argued that successful bilingual health care requires providers to create an environment in which others (e.g., interpreters and patients) are comfortable to voice their opinions without fear of retribution (e.g., getting fired or reprimanded). In other words, both providers and interpreters should feel empowered to challenge each other's perspectives and derive mutually acceptable solutions based on open discussion of the optimal utilization of their medical, cultural, and/or linguistic expertise.

This is a perspective that has been neglected in the conceptualization of bilingual health care until very recently. Traditionally, interpreters are believed to be the persons who are solely responsible for the success of an interpreter-mediated medical encounter, which is accomplished through their neutral, faithful, and accurate relay of information from one language to another. The emerging perspective, however, highlights the importance of providers' and patients' roles in contributing to a successful medical encounter. Many health care organizations now offer workshops on cultural competence and interpreter-mediated interactions to providers and/or patients, aiming to improve their communicative competence in cross-cultural health care.

A national survey in 2006 found that roughly 50% resident physicians reported no training on adapting their communicative strategies when working with interpreters and 67% reported no training to manage situations in which they suspect the interpreter has misinterpreted. The lack of training can lead to provider–interpreter miscommunication and problematic collaboration. When providers are familiar with interpreters' practices (e.g., first-person, emotionally detached, and/or simultaneous interpreting style), they can understand the purposes of interpreters' specific behaviors and, if necessary, negotiate with interpreters about other alternatives to achieve optimal care. In 2004, New Jersey became the first state in the United States to adopt a law requiring medical schools to include cultural competency into curriculum, which include working with medical interpreters. Cultural competency education also was required for physician relicensure. Since then, many other states have also adopted laws or introduced bills on similar topics. These legislative efforts provide strong support to recognize successful bilingual care as a coordinated accomplishment between the provider, the interpreter, and the patient.

Intestinal Parasites

RUTH MAGTANONG
Department of Anthropology, Case Western Reserve University, Cleveland, OH, USA

Infections with intestinal parasites are one of the most common medical conditions observed among immigrant populations coming from endemic areas. Although many individuals report to have little or no symptoms, intestinal parasitic infections may lead to severe health problems if left untreated. Commonly detected pathogenic intestinal parasites through routine stool examinations are: *Entamoeba histolytica (Amoebiasis)*, *Giardia intestinalis*, *Ascaris lumbricoides, Trichuris trichiura, hookworm, Strongyloides stercoralis, Schistosoma mansoni*, *Schistosoma haematobium*, and *tapeworm (Taenia* species*)*. Some parasites may be less frequently observed in stool samples, but instead, detected through an elevated number of eosinophils in response to the infection. Prior to departure, presumptive therapy is recommended for immigrants originating from endemic areas, for example, Middle East, South/Southeast Asia, and Africa. Respective oral drug regimens of albendazole, ivermectin, and praziquantal are provided. Pre-departure treatments have reduced parasitic infections among newly arrived immigrants. Special considerations are recommended in administering presumptive treatment to the following populations: infants, under five children, pregnant women, women who are breastfeeding, and immunocompromised individuals. Despite treatment during medical screenings, some intestinal parasites can persist years after resettlement. Comprehensive health exams are recommended post-resettlement to detect persistent infections and prevent more serious complications from developing.

Commonly Detected Intestinal Parasites

Commonly detected intestinal parasites fall under two general categories: protozoa or helminth. Frequently observed pathogenic protozoan infections are *Giardia Lamblia* and *Entamoeba histolytica*. Helminth infections are further classified into three main groups: nematodes, flukes, and tapeworms. Nematodes are intestinal parasites transmitted through oral-fecal route or skin penetration with infective larvae. These parasites include hookworm *(Necator americanis, Ancylostoma duodenale)*, *Trichuris trichiura*, *Ascaris lumbricoidis* and *S. stercoralis*. Flukes are parasites that require an intermediate host and are associated with chronic infections contributing to severe mortality and morbidity. Infections with the *Schistosoma* species are frequently diagnosed in immigrants originating from sub-Saharan African countries. Transmission occurs via skin penetration by infective larvae resulting from exposure to water sources proliferating with infected intermediate hosts, that is, snails. Infection with tapeworms (*Taenia* species) occurs through the human consumption of eating undercooked beef, pork, or fish with the parasite larvae.

Risk Factors

While infections with intestinal parasites are common medical diagnoses among newly arrived immigrants, these infections are preventable and easily treated with access to medical services particularly the availability of oral medications. A significant risk factor for the presence of intestinal parasites is residence in areas with high disease burden for parasitic infections. Contributing to the disease burden, these areas are located in resource-poor countries in which access to clean, protected water sources, sanitation facilities, and medical services is limited or nonexistent. These infections correlate to impoverished living conditions, social and economic upheavals, and gaps in the health systems of the originating countries. Specific regions place individuals at greater risk for particular parasitic infections. For example, immigrants arriving to Canada from East African countries were more frequently observed to be infected with schistosomiasis and strongloidiasis, while clonorchiasis infection was often seen in immigrants coming from Southeast Asia.

Epidemiology

The pattern of intestinal parasitic infections observed in different countries varies according to length of residence in the host country and the country of origin. Besides these two factors, prevalence rates observed ranging from 20% to 80% are also dependent on age and parasite type. Helminth and protozoan infections present different epidemiological patterns. Helminth infections are more commonly detected in newly arrived immigrants. Newly arrived immigrants from specific regions and originating from resource-poor communities are at greater risk. Surveillance data from Toronto, Canada between 1997 and 2003 recorded 29% of returned travelers and new immigrants with parasitic infection. Diagnoses with parasitic infections were more likely to be observed in newly arrived immigrants as well as having multiple parasite infections. In 2000 and 2002, surveillance data in Australia from East African and Cambodian immigrants assessed disease burden of intestinal parasites and found the following results: 77 of 117 fecal samples from East Africa were positive for intestinal parasites compared to 25 of 204 fecal samples from Cambodian immigrants who were positive. In addition, 15% of East African immigrants and 42% of the Cambodian immigrants tested positive for *S. stercoralis.* Eighteen percent of children from East Africa were infected with pathogenic parasites; 11% of these children were positive for *S. stercoralis* and 2% for schistosomiais. In 2003, 50% of stool samples from East Africa were pathogenic. Twenty-five percent had multiple species detected. However, of the 133 children providing stool samples, all were asymptomatic. Also in this sample, intestinal parasites were more likely to be observed in older children. *S. stercoralis* and schistosomiasis were also documented in immigrants coming from East African countries to USA, Europe, and Israel. In the USA, specifically Santa Clara County in California between 2001 and 2004, 1,174 referrals for medical screenings were recommended to recent refugee arrivals. Sixty-six percent were selected to receive these health assessments. Of these individuals, 14% of the stool samples assessed were found to be positive for a parasite. Nine percent of these infections were classified to be protozoan, while 6% were helminthic. Twelve percent of these individuals had multiple species infection. The most common infections observed were *Giardia lamblia*, *Entamoeba histolytica* hookworm, *A. lumbricoides, and S. sterocoralis.* In this sample, different species were concentrated in refugees from specific regions. Individuals from South Central Asia were more likely to be diagnosed with hookworm and *A. lumbricoides*, while *S. stercoralis* was frequently found among refugees originating from African countries. In addition, immigrants from Africa were observed to be infected with a wider range of helminth species. Protozoan infections were more likely to be found among children. The prevalence for Santa Clara County was found to be lower compared to 22% in Minnesota and 56% in Massachusetts. A probable explanation for the observed lower prevalence is the health impact of providing drug treatments prior to departure. In San Francisco, 96 children were screened for intestinal parasites at a local health center serving immigrants from Central America. Sixty-five percent of the foreign-born children had parasitic infection. Forty-six percent of these infections were from pathogenic parasites, while 14% of the children were infected with multiple parasite species. The most common parasites were *Trichuris trichiura, A. lumbricoides, and Giardia lamblia.* In contrast, of the 32 children born in the USA who were tested along with the foreign-born children, only four tested positive for parasites; none of the parasites were pathogenic.

Among immigrant populations in Europe, 80% originated from sub-Saharan Africa. During medical screenings, 25% tested positive for filariasis and 22% for intestinal parasites. Of the individuals who tested positive, 33% were children and 70% were adults. Furthermore, 30% of the individuals who tested positive for intestinal parasites were co-infected with multiple parasite species. Twenty-seven percent of the individuals infected reported symptoms of diarrhea and abdominal pain, while 53% of infected individuals were observed to have increased eosinophils. Among the individuals observed to have elevated levels of eosinophils, 43% was attributed to filariasis, 17% with coinfections with filariasis and intestinal helminthiasis, 3% intestinal helminth infections, and 2% with schistosomiasis. Eleven percent of immigrants were asymptomatic during the medical screening and of these asymptomatic individuals 40% of the stool samples were observed to be positive for a parasite. African immigrants showed a higher prevalence of parasites compared to other regions. Although the symptoms of fever, stomach pain, weight loss, and diarrhea were often reported, the presence of symptoms did not necessarily indicate a positive diagnosis for parasitic infections. However, the presence of increased eosinophils correlated to a positive diagnosis for *S. stercoralis.* This marker is currently under investigation as a possible screening tool to detect *S. stercoralis* infections.

Immigration and Health Screenings

In many countries, medical screenings for recently arrived immigrant populations are prioritized due to the high prevalence rates of intestinal parasitic infections documented from refugees entering the USA in the 1980s and 1990s. Based on the findings, 38% of individuals living in refugee camps were found to be infected with pathogenic intestinal parasites, the Centers for Disease Control and Prevention (CDC) regulated the administration of pre-departure drug treatments prior to entering the USA in 1999. Predeparture drug therapy in the form of single oral doses of 600 mg of albendazole has been estimated to reduce infection rates and health care expenses. Overseas, these treatments are coordinated by the International Organization for Migration (IOM). During 1991 and 2001, 81% of refugees from Africa were given albendazole treatment prior to entering the USA which corresponds to reduced prevalence rates observed in later years. Implementation of universal intestinal parasitic therapy prior to immigration has drastically lowered prevalence rates of intestinal parasitic infections among newly arrived immigrants. However, previous presumptive therapy programs have been criticized for inadequate treatment of strongyloides and schistosomiasis, intestinal parasites that were associated with severe mortality and morbidity among immigrant populations. Furthermore, parasite detection through stool examinations, although widely available, may not serve as sensitive tests to detect these two parasitic infections. An alternative test, for example, ELISA, is needed, but is not widely available or cost effective. The CDC guidelines for presumptive therapy have been revised accordingly. In addition to albendazole, immigrants from specific regions at high risk for strongyloides or schistosomiasis are also provided with either ivermectin and/or praziquantal.

Upon arrival to the USA, the Department of Health and Human Services Office of Refugee Resettlement under the Immigration and Nationality Act is responsible for providing refugees with medical care while undergoing the immigration process in the USA. With the cooperation of state health agencies, health assessments are provided including screenings for parasitic infections. Immigrants with refugee status are offered comprehensive health exams through participating state and county health clinics. These health assessments are recommended due to findings of persistent infections observed in immigrant populations and to prevent serious complications from developing attributed to untreated parasitic infections. For example, persistent infections were reported in Cambodian immigrants despite receiving treatment 2–6 years after resettlement in Canada. Furthermore, untreated parasitic infections may result in anemia (hookworm), intestinal obstruction (roundworm), pulmonary hypersensitivity (*Ascaris*), bladder cancer (*S. haematobium*), and severe tissue inflammation (*Stronglyoidiasis*). Low education levels, language barriers, and cultural factors contribute to reasons for nonparticipation among immigrant populations in these health assessments.

Intimate Partner Violence

Susan Hatters Friedman
Departments of Psychiatry and Pediatrics,
Case Western Reserve University School of Medicine,
Cleveland, OH, USA

Intimate partner violence (IPV) includes not only physical violence but also emotional and sexual abuse. The "partner" can include a spouse, but also a live-in partner, or even a date – and may be part of a heterosexual or a homosexual relationship. Beating, raping, or murder may occur and weapons may be used. Some studies suggest that the rate of IPV committed by women may be equal to that committed by men. However, male batterers often commit the more serious violent acts.

A "cycle of violence" has been put forward to describe a frequent pattern. In the tension-building phase, verbal and emotional abuse occur. The victim tries to placate the batterer. But, it inexorably leads to the acute battering phase. This often unpredictably timed violence is usually triggered by a stressor for the batterer – such as problems at work. During the final "honeymoon" phase, the batterer apologizes and may give gifts and make promises. In the cycle, the victim stays because the victim wants to believe in the partner's commitment to change.

There are many theories for why violence occurs in relationships. A culture of violence theory suggests that subcultures develop their own norms which allow the use of physical violence in relationships. Another theory, of marital power, indicates that if one partner lacks power, he or she may use physical abuse toward his or her partner to gain some power. Control over the resources outside of the family unit may be protective, according to the resource theory. Alternately, the exchange theory posits that partners use violence to reach their goals if the benefits outweigh the costs. Finally, the evolutionary theory holds that violence is a way of securing obedience, and that partner violence evolved to ensure sexual dominance and sexual proprietariness related to the female's reproductive value. Women's violence toward their partners occurs for various reasons as well, such as self-defense, but also control, anger, and revenge.

Emigrating from a more patriarchal society (such as China) to the USA may change some relationship dynamics, such as the decrease in decisionmaking power by the man. The subjective loss of power may relate to the batterer's attitude about IPV perpetration. In the study of IPV, it is critical to consider not only the individual relationship, but also the broader culture and subculture. Even across Latino immigrant subgroups, for example, rates of IPV are quite variable. "Role strain" related to immigration and acculturation, as well as male dominance, requires futher consideration vis-á-vis various immigrant groups.

Studies indicate that the lifetime prevalence of physical abuse by an intimate partner against US women ranges from 9% to 30% depending on the study and methods used. The prevalence of rape by an intimate partner is 8%. Older persons are not exempt from IPV. A recent study of older Chinese immigrants on the US west coast found the 7% of the women and 6% of the men experienced minor physical violence by their spouse in the previous year. It was recommended that interventions explore hostile attributional bias.

Factors increasing risk of IPV victimization borne out by research include: younger age, lower education, lower income, urban residence, personal history of abuse (including as a child), alcohol or drug use, and current pregnancy. Further, mental illness may increase risk of being battered, by various mechanisms.

Risk factors for the perpetration of IPV include: past violence, physical victimization as a child, parental rejection, fears of abandonment, alcohol or drug use, anger, mood swings, blaming others, need for excessive control, insecurity, jealousy, and low self-esteem. A recent Boston study of Caribbean and Cape Verde immigrants found that those men who reported exposure to political violence were more likely to report that they themselves perpetrated IPV.

Screening is important, particularly in the emergency room, community health centers, and community mental health centers. Dental offices and pediatrician's offices also are opportune locations for screening; mothers may bring their children in for care whilst neglecting their own healthcare. IPV victims may be reticent to discuss their abuse because they are ashamed (male victims in particular), have low self-worth, think it is normal or private behavior, or have not disclosed even their relationship to others. Therefore, routine inquiry into victimization experiences can be helpful in screening and diagnosis. Asking about violence can occur in several contexts: asking about fears, discussing decision making, and direct inquiry. The risk of violence by same-sex partners should not be forgotten by the practitioner. In addition to the obvious physical sequelae, IPV may also lead to psychological symptoms including anxiety, posttraumatic stress disorder, depression, and an increased risk for substance misuse. Children's exposure to relationship violence will also increase their own risk.

Emotional isolation, mistrust of others, and self-esteem are often topics for the clinician to address with the patient. Information about shelters, domestic violence services, and crisis management services should be made available. Complex issues including the development of a safety plan and legal options such as protection orders are important to consider and educate victims about. Immigrants' knowledge about local services and restraining orders may be limited. The decision to leave a violent relationship should not be made lightly. Separation and pursuing restraining orders could potentially increase the risk of harm to the victim. Arrest rates vary even when IPV incidents are reported to the police. Restraining orders can decrease risk but do not guarantee safety; up to two-fifths are violated.

In the USA, some states require health care providers to report injuries from IPV and other crimes. However, many providers are unaware of these laws. Others argue that the mandatory reporting could increase risk of retaliation, deter victims from seeking health care, and change the expectation of confidentiality.

A recent California survey investigated immigrant versus US-born participants' perceptions of a scenario of IPV. Immigrants from various groups were more likely to describe behavior as illegal and to believe in the removal of guns.

A recent study of battered Latinas found that they conceptualized their role as a mother as central in their decision making – including their decisions about how to manage the abuse and avoiding disclosure. They may be concerned about losing custody of their children, their immigration status, protecting their partner, and not want to worry their family. Latinas who experienced IPV more often lacked social support and had children. Another recent study, by the Centers for Disease Control and Prevention, found that Latino immigrants were less likely than those born in the USA to seek help from IPV agencies. Overall, a lower prevalence lifetime for IPV was found among Latino immigrants, but they had a higher victimization rate over the past year.

Social support is critical in responding to IPV; yet, this may be difficult for immigrants. A recent Canadian study noted that other barriers to care for abused immigrants included: poor service coordination, lack of awareness of services, and discriminatory/racist practices. They recommended that to improve care, health care professionals must work together with settlement workers and social workers.

In sum, partner violence could be perpetrated by either sex against their heterosexual or homosexual partner, spouse, or date. Abuse may not be readily disclosed because of shame, fear, and embarrassment. It is important that health professionals ask about violence and are aware of referral resources that could help the victim.

Iraq

Nadia El-Shaarawi
Department of Anthropology, Case Western
Reserve University, Cleveland, OH, USA

In 2010, the population of Iraq was estimated to be 31.5 million. Iraq is a country of great ethnic and religious diversity. A number of ethnicities are represented in Iraq including Arab, Kurdish, Turkoman, Chaldean and Assyrian. In addition, Iraqis practice a range of religions such as Islam, Christianity and others. Recent conflict and instability in the country have altered demographic composition and rendered some population parameters difficult to estimate because, for example, there has been no national census in Iraq since 1997. However, some estimates of migration are available. From the perspective of migration, Iraq has undergone a shift in the last three decades from being a country of immigration to becoming primarily a sending country. Iraq has most recently become a refugee-producing state, with Iraqi refugees among the largest number of forced migrants in the Middle East and North Africa (MENA) region and with Iraqis making up a high proportion of asylum-seekers and refugees in North America, Australia, and Europe. Estimates of Iraqis abroad vary, but recent estimates suggest that from the most recent wave of forced migration alone, there are nearly two million Iraqis who have been forced to leave their country.

Migration to Iraq

Before the 1991 Gulf War, Iraq was mostly a country of immigration in the Middle East, hosting migrant workers and some refugees. For example, between the establishment of the state of Israel in 1948 and the first Gulf War in 1991, some 35,000 Palestinian refugees migrated to Iraq of whom only 15,000 now remain in the country as a result of more recent persecution and unrest. Before its invasion of Kuwait on August 2, 1990, it is estimated that Iraq was host to at least 1.3 million migrants, more than 70% of whom were Egyptians. These migrants were primarily men who had traveled to Iraq for work, especially agricultural work or for the purpose of fighting in the Iraqi army in the Iraq–Iran War.

Currently, the United Nations High Commissioner for Refugees (UNHCR) estimates that there are some 42,350 registered refugees and 2,500 asylum-seekers in Iraq. Among these are Palestinians, a small number of Sudanese and ethnic and ideological dissidents from Syria, Iran, and Turkey. Some of these migrants live in urban areas, mostly in Baghdad or the Kurdish-administered regions, while others have sought refuge in camps. In these camps, especially those on Iraq's borders, security, health and basic infrastructure are lacking. Refugees have often been unable to access needed health services, although there have been instances where Jordan or Syria have allowed particularly grave cases to enter for treatment. Under the 1971 Refugee Act, refugees have access to the same health care as nationals, but in practice this has only occurred in some areas of the country, and food and medicine shortages have been reported in the desert camps. In addition to refugees, there are more than 1.5 million internally displaced persons in Iraq, bringing the total population of concern in the country for UNHCR to more than two million people.

Migration from Iraq

Since the 1940s, Iraqis have emigrated from their country in a number of waves and for a variety of reasons including economic betterment, the pursuit of higher education, political repression, and fear of persecution. Political repression, persecution, and war have been major determinants of Iraqi migration throughout history. However, in the Iraqi case, the distinction between forced and voluntary migration is often blurred as Iraqis may have left for complex and varied reasons. The most recent reasons for emigration from Iraq include the 1980–1988 Iraq–Iran war, the Gulf War in 1991, the invasion of Iraq in 2003, and the sectarian violence and unrest that followed and which continue to this day. Throughout this period, political repression and humanitarian problems as a result of the economic sanctions imposed on Iraq further impelled people to leave the country. The result is that there are currently at least 1.5 million internally displaced persons in Iraq as well as more than two million refugees displaced throughout the region, with the largest number in Syria and Jordan.

Historically, Iraqis have migrated from their country for a range of reasons, including political, ethnic, or religious repression, as occurred with the majority of Iraqi Jews in the late 1940s and early 1950s, and among political dissidents when the Ba'ath party later came to power. The first Gulf War led to widespread population movement in Iraq and in the region as a whole, and marked a turning point for Iraq in terms of migration. Just 4 months after the Iraqi occupation of Kuwait in 1990, many foreigners in Iraq left the country in a mass exodus, including European, North American, and Japanese citizens who had been kept as hostages or "human shields" in Iraq following the invasion of Kuwait. By the end of 1990, of the three million foreigners who had been residents in Iraq and Kuwait, only one million remained. Some, such as Kuwaitis, were forcibly repatriated. In 1991, between the outbreak of open hostilities and the ceasefire, another 65, 000 people emigrated from the region. Following the liberation of Kuwait, Shi'i uprisings in the south of Iraq and Kurdish uprisings in the North of Iraq led to one of the fastest moving forced migrations in the history of the United Nations High Commissioner for Refugees (UNHCR) in which up to two million Kurdish and Shi'i people fled Iraq for Turkey and Iran. Many of these forced migrants subsequently returned to Iraq about a month later as a result of a coordinated international response to the forced migration.

More recently, emigration has included the mass exodus of Iraqis fleeing persecution, war, and instability, which has led to massive, prolonged forced migration particularly in the countries surrounding Iraq. In 2010, the United Nations High Commissioner for Refugees estimate their "population of concern" (comprising refugees, asylum-seekers, internally displaced persons (IDPs), stateless persons, and other forced migrants) originating from Iraq as 3,565, 375 persons. Estimates from nongovernmental organizations (NGOs) suggest that these numbers may be low. The majority of Iraqi refugees reside in Syria and Jordan with smaller numbers in other countries in the region, including Egypt and Lebanon. Many of these refugees, most of whom have been living in exile for several years, face difficulties related to socioeconomic status, access to services, recovery from violence, and uncertainty. While some Iraqi refugees are returning to their country of origin, those who do go back face threats to their security, economic hardship, a lack of opportunities, and difficulties accessing services. In 2010, a survey conducted by UNHCR found that the majority of Iraqi refugees who had repatriated regretted their decision to return to Iraq, primarily because of concerns related to safety.

The Iraqi Diaspora

There are large Iraqi communities in many countries throughout the world, most notably in neighboring countries in the region, the United States, and a number of European countries, including Sweden and the UK. The Iraqi diaspora was estimated to account for three million dollars in remittances in 2008. Since 1965, Iraqis have made up the fourth largest group of immigrants from the Arab Middle East in the United States. At first, these immigrants primarily included Assyrians and Chaldeans who immigrated for reasons of family reunification. In the 1980s, some Iraqis came to the United States to avoid being forced to serve in the Iraq–Iran War. From the 1990s until the end of the regime of Saddam Hussein, Iraqis who immigrated to the United States were fleeing political repression or the hardships associated with economic sanctions in Iraq. Among these, many were politically active Shi'i Iraqis who fled the repressive and Sunni-dominated government of Saddam Hussein. Because of the variation in ethnicity, religion, political opinion, and length of stay of the Iraqis in the United States, the extent of acculturation varies.

Given the recent history of conflict in Iraq, research on the health of Iraqis has largely focused on mental health and recovery from traumatic experience. Among Iraqi refugees in the United States, studies have found a high prevalence of posttraumatic stress disorder (PTSD) and other mental disorders, which is perhaps not surprising given the legacy of war in Iraq. The psychological response to war violence and trauma is complex and may be affected by conditions in exile, such as social support, economic opportunity, discrimination, and other factors. Among the Iraqi diaspora, religion and social support have been particularly identified as important factors in health status and well-being.

Ireland

Amy N. Sharpton
Department of Veterans Affairs, Louis Stokes DVA Medical Center Cleveland, Brecksville, OH, USA

Introduction

The island of Ireland is the 3rd largest island in Europe and the 20th largest island in the world. In 1921, the island was divided into two jurisdictions between the Republic of Ireland, which comprises approximately 80% of the land, and Northern Ireland, a part of the United Kingdom, located in the island's northeast region. The population of Ireland is approximately 6.2 million people, with nearly 4.5 million residing in the Republic of Ireland, and slightly fewer than 1.8 million residing in Northern Ireland. The content of this article is limited to information on the Republic of Ireland.

History

The Irish Free State, a self-governing province within the British Commonwealth, was formed on December 6, 1922, and gained increasing autonomy through the Statute of Westminster 1931. With a few exceptions, the Statute established legislative equality for the self-governing dominions of the British Empire and the United Kingdom. A new constitution introduced in 1937 declared the Irish Free State an entirely sovereign nation named *Ireland*. The remaining link with the United Kingdom was severed in 1949 as Ireland's national parliament passed the Republic of Ireland Act. The Act declared Ireland as a republic and established for the President of Ireland executive authority of any executive function of the state and in external relations of the state.

Geography

The Republic of Ireland shares its only land border with the UK's Northern Ireland; otherwise, it is bounded by the Atlantic Ocean, the Irish Sea to the east, St. George's Channel to the southeast, and the Celtic Sea to the south. The nation is northwest of continental Europe and is surrounded by hundreds of islands and islets. The Irish Sea separates the Republic of Ireland from its neighbor to the east, Great Britain.

The Republic of Ireland covers an area approximately 70,280 km^2. Key urban centers include Dublin in the east, Cork in the south, Limerick in the midwest, Galway in the west, and Waterford in the southeast. With a varied terrain, the western landscape consists mostly of cliffs, hills, and mountains. The country's highest point is located in the western region in County Kerry; standing at 1,038 m, it is the central peak of the Macgillycuddy's Reeks range. The nation's interior is relatively flat, traversed by rivers, numerous lakes, or *loughs* – a long inlet of the sea. The large central lowlands feature limestone enclosed in glacial deposits of clay and sand. The River Shannon watershed contains large bogs from which peat is extracted and produced. Also, Ireland possesses some small off-shore deposits of oil and gas.

Climate

Ireland's climate is classified as a temperate oceanic climate. Generally, oceanic climates are characterized by cool summers and warm winters, a narrow annual temperature range, little to no dry season, and precipitation that is more evenly dispersed through the year. Ireland's weather follows that climate pattern temperately, with temperatures rarely lower than $-3°C$ in winter or higher than 22°C in summer. The Atlantic Ocean and the warming influence of the Gulf Stream serve to shape the country's weather patterns, with central and eastern areas tending to be more extreme. The extreme north and west are two of Europe's windiest regions, providing great potential for wind energy generation. The highest temperature recorded in Ireland was 33.3°C in June 1887 at Kilkenny, while the lowest was $-19.1°C$ in January 1881 at Sligo.

Culture

There are cultural distinctions noted between geographical regions in the Republic of Ireland, for example, between urban and rural areas, between the capital city of Dublin and the rest of the country, and between regional cultures that are discussed frequently in terms of the West, the South, the Midlands, and the North. While the vast majority of Irish people identify with being ethnically Irish, some Irish nationals see themselves as Irish of British descent; some refer to this group as the *Anglo-Irish* or *West Britons*.

The *Travellers*, an important cultural minority, live predominantly in Ireland, although they can also be found in Great Britain and the United States. The itinerant ethnic group has been known historically for their roles in the informal economy as artisans, traders, and entertainers.

Economy

Since the 1980s, Ireland's economy has transformed from being a predominantly agricultural one to one focused on high-tech industries and services. It is characterized more as a knowledge economy that seeks to leverage knowledge technologies to produce economic benefits and job creation. A 2005 study by *The Economist* found Ireland to have the best quality of life in the world.

The country relies heavily on foreign direct investment (FDI), and with its highly educated workforce, low corporation tax rate, and as the sole English-speaking country within the Euro zone, Ireland has attracted several multinational corporations. Companies such as Intel invested in Ireland in the late 1980s; Microsoft and Google followed. According to *Tax Notes*, a US tax journal, Ireland is the world's most profitable country for US corporations. The country is one of the largest exporters of pharmaceuticals and software-related goods and services in the world, the 7th largest producer of zinc concentrates, and the 12th largest producer of lead concentrates. The country contains significant deposits of gypsum, limestone, and smaller quantities of copper, silver, gold, barite, and dolomite.

Ireland is ranked as the world's 7th most "economically free" economy according to the Index of Economic Freedom, a series of ten economic measures designed to measure the degree to which an economy protects the liberty of individuals to pursue their own economic interests, resulting in greater prosperity for the larger society. In terms of GDP per capita, Ireland is one of the wealthiest countries in EU and in the 34-member Organization for Economic Cooperation and Development (OECD). However, Ireland ranks below the OECD average in terms of GNP per capita, which differs from GDP in that it allocates production based on ownership rather than on geographic location. Naturally, Ireland's GDP is significantly greater than its GNP owing to the large amount of multinational firms based in the country.

A dramatic rise in consumer spending, construction, and business investment led to rapid economic growth between 1995 and 2007, an interlude that became known as the Celtic Tiger period. However, Ireland's economy has been significantly affected by the global financial crisis that began in 2007, including a major property bubble burst in 2008, dramatic reductions in domestic and commercial property values, and an ongoing Irish banking crisis. The country officially exited recession in 2010; however, its economy remains fragile.

Government

Ireland is a constitutional republic with a parliamentary system of government. The Oireachtas, the national parliament, is a bicameral parliament comprised of the President of Ireland, Seanad Éireann as the upper house, and Dáil Éireann as the lower house. The President serves as the head of state, is elected for a 7-year term, and may be reelected once. The President is primarily a figurehead, although the office is entrusted with certain constitutional powers with the advice of the Council of State. In some matters, the President has absolute discretion, for example, referring a bill to the Supreme Court for a judgment. The President appoints the Prime Minister, and most have served as the leader of the political party that gains the most seats in national elections. It has become customary for coalitions to form a government, as there has not been a single-party government since 1989.

Education

Ireland's education system features three distinct levels: primary, secondary, and higher or *third level*. Recently, further education – known in the United States as continuing education – has grown immensely. Much of the change in Ireland's education system has been driven by growth in the economy since the 1960s. Notably, for students applying from the EU, education is free at all levels, including university studies.

Health Care

The average life expectancy in Ireland is 79.2 years – 76.8 years for men and 81.6 years for women. It has the highest birth rate in the EU at 16.8 births per 1,000 inhabitants, compared to an EU average of 10.7. Additionally, Ireland has achieved a very low infant mortality rate at 3.5 per 1,000 live births.

Every resident in Ireland is entitled to receive health care through the public health care system, which came into operation at the start of 2005 and is funded by general taxation. A subsidized fee may be required for certain health care services; the fee depends on income, age, illness, or disability. Provided free of charge are maternity services, care for children up to 6 months of age, and emergency care to any person admitted through the emergency department.

A European Health Insurance Card entitles the holder to free maintenance and treatment in public beds in government-supported and voluntary hospitals, while outpatient services are provided also for free. The majority of patients on median incomes or above, however, are required to pay subsidized hospital charges. Private health insurance is available for purchase.

Migration

Until the recent past, Ireland was characterized as a country of emigration; from the Great Famine of 1845–1847 to the 1950s, the natural increase in the population was offset by out-migration. This continual emigration was relatively higher than any other European country and led to an almost continuous population decline for more than a century.

At the close of the 1950s, Ireland adopted new economic policies in an effort to encourage FDI from the multinational corporate sector. Over the following decade, the country realized increased job creation, a dramatic drop in emigration, and a consequent rise in marriage and birth rates.

Ireland's entrance into the European Community in 1973 led to net in-migration, which was largely explained by the return of Irish migrants to meet specific skill shortages in the Irish economy. With the increase in the marriage rate in the 1960s and the net immigration in the 1970s, the population grew by almost 22% between 1961 and 1981.

Today, Ireland has evolved from a nation of emigration to a nation that frequently receives migrants. The country is experiencing an upward trend in numbers of immigrants, both short- and long-term, from non-EU countries. The recent in-migration flows have been primarily from the following groups: Irish migrants returning home; migration from other EU and EEA (European Economic Area) countries: asylum-seekers; programme refugees; high-skill migrants from non-EEA countries; and other migrants from non-EEA countries.

From 1820 to 1920, five million Irish immigrants settled in the United States. They were not received well by some in the larger culture. Nativists criticized the Irish for their social behavior, their impact on the economy, and their Catholic religion. Even still, the Irish assimilated successfully by the early twentieth century, so much so, that they comprised almost half of all immigrants in the United States in the 1840s and one-third in the 1850s. Between 1846 and 1855, due to repeated massive failures of the potato crop, 1.5 million Irish immigrants fled to the United States alone.

The Irish who emigrated because of the famine were the most disadvantaged the United States had ever seen. Some of the poorest lived in the Five Points district of lower Manhattan in New York City. The English novelist Charles Dickens' sentiment regarding the city was that *all that is loathsome, drooping, and decayed is here*. The Irish poor accounted for a grossly disproportionate number of admissions to poorhouses, public hospitals, and prison. In New York City in 1859, for example, 55% of all people arrested were of Irish origin.

Frequently, the Irish immigrants were unskilled, and, when they could secure work, were paid low pages. At times, they were used even as substitute labor to break strikes. Many Americans feared that the Irish would never advance socially and would threaten the central principle of nineteenth-century American life: upward social mobility through hard work. The nativists of the larger culture were also disturbed by the Irish immigrants' religion; they questioned whether Irish Catholic immigrants would be loyal ultimately to the United States or to the church in Rome. Further, did a church headed by a pope, cardinals, archbishops, and bishops have a legitimate place in a democratic republic? However, Irish immigrants insisted that they could become successful Americans, and that they would do so on their own terms.

Until 1960, when John F. Kennedy was elected President of the United States, anti-Catholicism remained part of the American culture. His election underscored that, indeed, Irish immigrants could become good Americans without sacrificing their religious and cultural heritage. Their incorporation into the American culture established that assimilation is not a one-way process in which immigrants must conform to a dominant culture while forsaking their own traditions.

Irregular Immigration

René Manenti
Center for Migration Studies of New York (CMS),
New York, NY, USA

Migration and health are major concerns of human society. Historically, health and people on the move have a long and intertwined association. For example, diseases were carried with armies, explorations, conquests, trade, and new settlements. According to most scholars, epidemic diseases represented the overwhelming reason for the population decline of the American natives. Also by the mid-seventeenth century, a common strategy to prevent the spreading of the plague and other communicable infections, especially in trading ports such as Genoa and Venice, was quarantine. Throughout the nineteenth century and during the first half of the twentieth century, newcomers to the Americas were regularly screened for diseases. In this line of prevention, the International Health Regulations came to formalize the rights of the nation-states to manage and restrict the movement of people. By examining immigrants and excluding, detaining, or treating individuals who were considered to pose a health threat, nations took measures to safeguard the public health of their citizens.

The terms of irregular, undocumented, unlawful, and illegal migrants are often used interchangeably to refer to persons without a residence permit authorizing them to legally reside in the country of destination. The discussion regarding their health deals with arguments and considers problems that are similar to the health issues in regular migration.

The process of migration can be thought of as occurring in three phases: origin, journey, and destination. When people move from their country of origin they bring with them, among other things, their health conditions and profile. Irregular migrants from less-developed regions may have higher probabilities of contracting the typical illnesses that are common in less-developed environments but are less prevalent in more developed nations, such as tuberculosis. Yet broad indicators of underdevelopment are to be used with caution in defining the medical problems of immigrants because individual characteristics, such as social status and economic privileges, may operate as intervening factors.

The second element of the paradigm, that is, the journey, constitutes a relevant component in the consideration of the health of irregular migrants. This journey requires a series of painful breaks with the world left behind. Family members, friends, habits, familiar places, and food are abandoned for an uncertain future in nations that are becoming increasingly intolerant of illegal migrants. The illegal crossing, either with the help of a *coyote* (smuggler) or with fraudulent documents, leads to additional tension and anxiety. Increasing border security, especially in the most common places of unlawful trespassing, often pushes people toward the most dangerous and in some cases deadly areas. These and related transit challenges seriously impact and deteriorate the immigrants' physical and psychological conditions.

With respect to the third geographic element of migration, that is, destination, illegal migrants tend to move to wealthier countries, settling in low-status neighborhoods with poor living conditions. Frequently, they live in overcrowded houses and take on difficult and dangerous jobs in construction, mining, and agriculture. All of these factors may contribute to the development of impairments in their physical and psychological health. When injured or ill, for example, irregular migrants often do not seek medical care due to lack of health insurance, language barriers, and fear of being reported to authorities. Even in countries that provide universal health care, language and cultural barriers, along with administrative regulations, might discourage irregular aliens from accessing medical services. Adapting to a social environment with different habits, a new language and an unfamiliar bureaucracy creates additional challenges for irregular migrants. They are likely to feel lonely, homesick, and excluded from mainstream society. These circumstances may sometimes lead to tobacco, alcohol, or drug use. Some studies have found that irregular migrants are more susceptible to chronic stress; in conjunction with poor dietary habits and rapidly changing lifestyles, they may become increasingly vulnerable to certain diseases, such as type 2 diabetes, hypertension, and stroke.

Also, it is important to keep in mind what scholars have identified as "healthy immigration effect" and "Americanization." Immigration seems to operate according to a selection process whereby healthier individuals are more likely than others to leave their country and migrate elsewhere. Once these newcomers have settled, however, the previous health advantages may diminish because immigrants tend to adopt the less healthy behaviors of the destination society. The health status of women and children may be particularly impacted. In particular, a gender perspective offers novel elements that the neutral approach often neglects.

In conclusion, irregular migration and health are critical concerns of governments and the general public. The transit and destination countries may be concerned not only about the health status of the irregular migrants within their borders, but also about the health consequences of illegal migration to their own citizens. This suggests the need for improved health screening and basic medical care regardless of individuals' legal status.

Islam

Lucia Volk
Department of Anthropology and Middle East and Islamic Studies, San Francisco State University, San Francisco, CA, USA

Introduction

The word Islam derives from the Arabic 3-consonant root s-l-m, which it shares with the word *salaam* (= peace). The standard Muslim greeting "*As-salaam* *alaykum*" means "Peace be with you," to which one responds "*Wa alaykum as-salaam*," "And peace be also with you." Literally, Islam translates to the English words "surrender" or "submission" that refer to a believer's predisposition toward God's kindness and mercy. A person who submits to God's will and follows his teaching is a Muslim (male) or a Muslima (female) – again based on the Arabic root s-l-m. Arabic shares with all other Semitic languages the system of deriving word clusters from three-consonant stems, where vowels are not always put in writing. This linguistic feature leads to inconsistent renderings of Arabic names and concepts in English (i.e., Muhammad vs Mohammed; Muslim vs Moslem; Qur'an vs Koran), which can be confusing.

Foundational Texts: Qur'an, Hadith, and Shari'a

Arabic is central to Islam because its main text, the Qur'an, was revealed in Arabic. Muslims regard the Qur'an as God's final revelation, surpassing and completing previous revelations that came to the world in the form of God's laws to Moses and Jesus' ministry recorded in the Old and New Testaments, respectively. Islamic rulers throughout history – of course there have been exceptions – have considered Jews and Christians to be "People of the Book," and have granted them special rights, such as autonomy over family affairs and religious practice. Those who have pointed out that Islam practices tolerance often cite a verse at the beginning of the Qur'an that states "there is no compulsion in the matter of religion" (2: 256).

The Qur'an was revealed to Prophet Muhammad (570–632 C.E.) over a span of 20 years via the archangel Gabriel, who appeared to him and spoke the verses of the Qur'an, which Muhammad memorized and then recited to his followers who wrote them down. Muhammad himself is said to have been illiterate, an orphan who was raised by an uncle, and who became a respected merchant through hard work and his marriage to the successful business woman Khadija, the first convert to Islam. The Qur'an is organized into 114 chapters (or *suras*), which are subdivided further into verses (or *ayat*, literally signs [of God]). Suras are arranged from the longest to the shortest, and each sura is known by a name or title, such as "Abraham," "Mary," "The Feast," or "The Cow." The very first sura in the Qur'an, however, has only seven verses, and it is called "The Opening" (or *al-fatiha*). It is recited each time a Muslim or Muslima conduct his or her daily prayers, and therefore it has been compared in significance to the Lord's Prayer in Christianity.

The verses in the Qur'an instruct believers how to lead an ethical life that is pleasing to God. They do not tell the life story of the Prophet that follows a narrative structure with a beginning, middle, and end. Westerners, accustomed to the stories of prophets and kings in the Old Testament, or the life story of Jesus in the New Testament, can find the Qur'an difficult to grasp. What is often not understood is that the Qur'an is not to be read quietly, but it is to be recited out loud. The sound itself is believed to carry a divine message. Islam scholar Michael Sells published his study of the early revelations of the Qur'an with a companion CD, since he believes that mere textual study of Islam cannot transmit the meaning of the religion. (There are a variety of Internet sites today that make Qur'an recitations easily accessible to a non-Muslim audience.)

The second most important book in Islam is the Hadith, a collection of sayings and deeds of the Prophet Muhammad, compiled in the eighth and ninth centuries by several Islamic scholars. Since these collections were written down more than a century after Muhammad's death, there were some disagreements over the accuracy and reliability of certain hadith accounts. Scholars investigated not only the content of the account, but also the reputation of the persons who had transmitted it. Different branches of Islam today rely on slightly different Hadiths. Together with the Qur'an, the Hadith serves in administering Islamic justice. When a contemporary dispute arises, scholars or jurists turn to the Qur'an and to the Hadith to deduce a just verdict. Certain laws are clearly spelled out in the Qur'an, such as the right to divorce (2: 228–242). But if the issue under question is not addressed directly, sayings and deeds of the prophet are consulted. For instance, is a woman allowed to initiate a divorce? The Qur'an does not clearly answer that question. But according to one hadith, Habiba, the wife of Thabit bin Qais, once approached the Prophet to tell him that she and her husband could not get along, so the prophet told the husband to leave her. This hadith played an important role in the rewriting of the Moroccan Family Code in 2004, which gave women more rights in making their own marriage and divorce choices. (Not all Islamic jurists interpret this particular hadith in the same way.) Over the course of many years of adjudicating based on the Qur'an and the Hadith, Islamic scholar and jurists accumulated a third important body of Islamic texts: the Shariʿa, or Islamic Law.

The Arabic word Shariʿa translates to "path" or "pathway to be followed." There is no centrally codified and agreed upon body of Islamic Law; rather, within Islam, there are multiple schools of law, which differ on the question of process of legal interpretation. Some Islamic jurists believe that they must solely rely on the Qur'an and Hadith in formulating judgments, while others allow for independent reasoning by analogy and inference. There are four main schools of Sunni legal thinking, named after the medieval scholars that founded them: Hanafi, Shafi'i, Maliki, and Hanbali, and two main schools of Shiite legal thinking: Jafari and Zaidi. The Hanbali legal school is primarily practiced in Saudi Arabia and is considered the most conservative, while Hanafi legal scholars in South, South West, and Central Asia are considered more open to independent reasoning. In other words, there is considerable variation in Shariʿa Law as it is practiced across the Muslim world.

Branches of Islam

Islam can be divided into two distinct confessional groups – the Sunnis and the Shiites – each of which is further subdivided into smaller denominations, similar to the division between Protestants and Catholics in Christianity, or the division between Reform and Orthodox Judaisms. The reasons for the internal splits within each of the monotheistic religions need to be found in their specific historical and political contexts, yet it might be fair to say that the question of legitimacy and authority of the leader at the time played an important role in most of them.

In the case of Islam, the divide between Sunnis and Shiites happened very shortly after the death of Prophet Muhammad. Since he died without a male heir who might have been his unquestioned successor following existing conventions in patriarchal societies, his closest companions ended up in a dispute: should they elect a respectable elder from the community (in this case, Abu Bakr, the prophet's father-in-law and one of the earliest converts), or should the mantle of the prophet pass on to a blood relative (in this case, his cousin as well as son-in-law, Ali)? Both Abu Bakr and Ali had leadership qualities that their supporters valued. The group that supported Abu Bakr and his successors Umar and Uthman became known as the Sunnis. The group that was on the side of Ali as well as his direct descendants came to be known as the Shiites. Both groups came into armed conflict in a battle in 680 C. E. in Karbala (present-day Iraq), where the forces of Sunni Caliph Yazid routed the outnumbered Shiite forces of Ali's son Husayn. As a result, in contemporary practice, Sunnis begin each Islamic New Year (they follow a lunar calendar) with joyful celebrations, whereas Shiites commemorate Husayn's death with passion plays and tearful remembrance of his defeat. Shiites consider the sayings and deeds of Ali and his descendents as worthy of emulations, while Sunnis maintain that only the Hadith of the Prophet Muhammad should guide a Muslim believer. Shiites cite a saying of the Prophet Muhammad on his deathbed that designated Ali as his successor, while Sunnis dispute the reliability of this hadith account. Sunni and Shiite prayer practices vary slightly, as does their call to prayer.

Both groups, however, adhere to the so-called five Pillars of Islam, or five distinct ritual practices, that mark believers publicly as Muslims: (1) the declaration (or witnessing) of the oneness of God and Muhammad's status as prophet (*shahada*); (2) the performance of daily prayers (*salat*); (3) the annual payment of a fixed percentage of one's income to charity (*zakat*); (4) the commitment to fast during the month of Ramadan (*sawm* or *siyam*); and (5) the pilgrimage to Mecca (*hajj*) at least once in a believer's lifetime. Each of the rituals described above can be carried out with sincere intention or by rote, with enthusiasm or with reluctance, or not at all, and the actual disposition of the believer matters to many Muslims more than the difference between Sunni or Shiite traditions.

Approximately 85–90% of the world's Muslims are Sunnis and 10–15% are Shiites. Currently, the Islamic Republic of Iran is the only country with a clear Shiite majority and a Shiite religious government, while countries like Iraq, Bahrain, and Lebanon have sizable or majority Shiite communities that have significant influence in multi-sectarian or Sunni governments. In most other Muslim countries, Shiites constitute a small minority. At different points in history, Sunni majority governments persecuted members of the Shiite faith, and Sunni and Shiite conflicts persist in many countries until today.

In both Sunni and Shiite Islam, there are members of the communities that practice Sufism, which is not a separate branch of Islam, but a different philosophy about Islamic practice. Sufism emphasizes spiritual principles over religious dogma and Islamic Law. Sufism also has a monastic tradition with a strong emphasis on simplicity and asceticism. Historically, Sufis often criticized established Islamic rulers for their pursuit of riches and power rather than salvation. Probably the best-known Sufi figure in the West is Jalal ad-Din Muhammad Rumi, or simply Rumi, who lived in the thirteenth century in what is now Turkey. From his order came the so-called whirling dervishes (they call themselves *semazen*) who meditate while rotating on the same spot, an exercise that takes significant bodily and spiritual practice. A lesser known figure is Rabia al-Adawiyya, a woman who lived in eighth-century Iraq and who became an important Sufi saint. Men and women both play important roles in Sufism. Music, poetry, and decorative arts are part of Sufi practice, which is frowned upon by strictly orthodox practitioners of Islam. However, it is possible to incorporate both traditional and Sufi practices in one's life, and many Muslims do, which is why it is impossible to draw a clear line between them. It is difficult to ascertain how many followers Sufism has at this time, but scholars posit that Sufism is what currently attracts most converts to Islam in the West, as well as Africa and Asia.

Islam and/in the West

Islam came to Europe in 711 C.E. with the arrival of the Umayyad forces in what is today southern Spain and Portugal. The Umayyad Empire was the first Islamic dynasty established in Damascus in 611 C.E. and it rapidly spread westward. The Umayyads remained in Spain even after the end of their reign in Damascus, and were expelled from European soil in 1492 C.E. Prominent reminders of Spain's Islamic heritage are the Great Mosque in Cordoba and the Alhambra palace in Granada.

The second significant encounter between Islam and the Christian West occurred at the time of the crusades between the eleventh and thirteenth centuries. The European crusaders were defeated by the forces of Saladin (*Salah ad-Din*) in 1187 C.E., and the encounter between Saladin and the English king Richard the Lionheart became the stuff of legends and movies. Several more crusades were undertaken after that defeat, but they did not manage to reconquer Jerusalem. Instead, in 1204 C.E., crusaders sacked the then still Christian metropolis of Constantinople (present-day Istanbul), rather than attacking their Muslim enemies in the "holy land." French-Lebanese author Amin Maalouf wrote a fascinating account of the crusades as Europe's "holy war" against Muslims.

The third most important historical encounter between Islam and the West occurred in the sixteenth century, when Suleiman the Magnificent, the ruler of the Ottoman Empire from 1520–1566 C.E., laid siege to Vienna with a heavy death toll on both sides. While the Ottoman conquest of Europe was ultimately halted, it had a profound impact on the way Europeans viewed Islam as a powerful and threatening force.

From the turn of the eighteenth century onward – and more systematically after the end of the Ottoman Empire in 1918 – much of the Muslim world came under European colonial rule. Islam was seen as an obstacle to modernization and (industrial) development, and European rulers expected Muslims to follow Europe's lead in embracing secularism. Quite a few did. The most prominent example is Mustafa Kemal Ataturk, who embarked on a path of Westernization of the newly created nation of Turkey. In order to break from what he regarded a backward and reactionary Ottoman past, he ordered Turkish citizens to wear Western clothing (and asked women to abandon the veil), to write in Western script instead of Arabic, and to follow secular laws. Arab intellectuals and politicians who opposed European colonial rule similarly embraced secular, left-leaning, nationalist ideologies. The most prominent proponent of Arab Nationalism was Egyptian President Gamal Abdel Nasser. In South Asia, tragically, religious identities became conflated with nationalist aspirations, which led to the bloody 1947 partition of India and Pakistan after the British had given up their control over that part of their commonwealth.

In the immediate postcolonial era, Islamic political organizations had little mass appeal. It was only when the secular nationalists failed to deliver on their promises of better jobs and improved standards of living that Islamists became popular as possible political alternatives. Over the last two decades, Islamist parties grew and have been voted into governments across the Arab and Islamic world. Their appeal rests to a large extent on Islamic charitable organizations that provide much-needed services in education and health for growing populations. Some Islamist parties, such as Hizbollah in Lebanon or Hamas in the Palestinian Territories, have also organized sophisticated militias in addition to their political and charitable institutions. The most prominent face of militant Islam in the West is the organization of Al-Qaida under Osama Bin Laden, responsible for the attacks on the World Trade Center and the Pentagon on September 11, 2001. Their stated goal is to defend Islam, by all means necessary, against Western encroachment. The geopolitics of groups of armed Islamist extremists battling Western armies, as well as fellow-Muslims, in various parts of the world has created a climate of fear and suspicion that significantly affects Muslim immigrants who have come to live in the West.

The Nation of Islam

Islam's history in the USA dates back to the time of slavery and the arrival of West African Muslims on North American soil. Islam in the West grew primarily through the arrival of immigrants; however, in the twentieth century distinct American forms of Islam emerged, the most prominent of which was the Nation of Islam. The Nation emerged in 1930 in Detroit, Michigan, under the leadership of Wallace Fard Muhammad. After his mysterious disappearance in 1934, his successor Elijah Muhammad declared him to be God's manifestation on earth.

The Nation of Islam mixed Islamic teachings with Black empowerment politics, equating Christianity with White supremacy, and declaring that African Americans had no truly equal place in the religion of their former slaveholders. The notion of separating African Americans from the White mainstream resonated with some members in the US Civil Rights Movement. For instance, Malcolm X became a member of the Nation of Islam while serving a prison sentence. He worked with Elijah Muhammad for over 10 years before going on a pilgrimage to Mecca, where his experience of a multi-racial religious community tempered his Black separatist views. After his return from Mecca, he changed his name from Malcolm X to Hajj Malik al-Shabbaz.

After the death of Elijah Muhammad in 1975, the Nation of Islam split into two organizations, one led by Elijah Muhammad's son Warith Deen Muhammad, and Louis Farrakhan, who had been a member of the Nation of Islam since 1955. Warith Deen moved his group closer to Sunni Islamic practice, refuted the claim of Wallace Fard Muhammad's divinity, and gave up the name Nation of Islam in favor of American Society of Muslims. Louis Farrakhan continued to lead the Nation of Islam with a more explicit and radical Black empowerment politics. The majority of Muslims do not consider the Nation of Islam to be truly Islamic.

Islam After 9/11

Since the attacks of September 11, 2001, were carried out by men who carried copies of the Qur'an in their luggage and who promoted a violent form of jihad, Islam has come under increasing scrutiny in the West. To many, Islam has come to be synonymous with terrorism. Members of the Muslim faith have been profiled, interrogated, and jailed without recourse to the customary due process. In January 2010, the USA issued a terror watch list of 14 countries, which mandated automatic, additional airport screening of passengers from countries including Saudi Arabia, Afghanistan, Pakistan, Iran, Iraq, Syria, Lebanon, Nigeria, Sudan, Somalia, and Yemen. With each new act of violence perpetrated on US soil by a member of the Muslim faith, as in the shooting of American servicemen on a base in Fort Hood, Texas, in 2009 or the failed bombing of Times Square, New York, in 2010, Islam's reputation of promoting terror solidifies. It merits pointing out that the media did not draw a similar link between Timothy McVeigh and Christianity after he bombed the federal building in Oklahoma City in 1995.

How much in an act of terror is driven by religious rather than political, psychological, or other motives is difficult to ascertain, yet it appears that Islam is considered by many an immediate and satisfactory explanation of such an act. In other words, in the West, "Muslim terror" has much more currency than "Christian terror" or "Jewish terror," for instance. This widespread perception of "Islam equals terror" matters in everyday interactions between Muslims and non-Muslims, and leads to stereotyping and scapegoating. Even if Muslim holidays are now part of the American holiday calendar, Muslim prayers are used to open sessions of Congress, and Americans can buy postage stamps that commemorate Muslim holidays, Islam is not granted equal status and respect next to Christianity and Judaism. It will take significant political will and educational work to make it so.

Islam and Health

Different verses in the Qur'an instruct believers to lead a balanced life (55: 7–9), to eat a wholesome and balanced diet (2: 173; 20: 81), and to abstain from intoxicating substances (5: 90). The Qur'an also focuses on cleanliness and general hygiene, and Muslims wash their hands, face, and feet as part of their daily prayer rituals. Spiritual and bodily cleanliness are closely linked, as the prophet told his followers, "Cleanse your bodies and God will cleanse your hearts." Additionally, the hadith literature contains sayings and deeds of the prophet that directly refer to health. For instance, in one saying concerning the Day of Judgment the prophet explains that God will ask what kind of life each person lived, how they earned and spent their money, how they used their knowledge, and what they did with their bodies and their health. The prophet told his followers to seek health care in times of sickness, and enjoined them to ask God not only for forgiveness of sins but also for good health. Some Muslims believe that their daily prayer rituals – which involve several sets (*rakats*) of bowing, kneeling, and prostrations on the floor – have cardiovascular health benefits in addition to their spiritual meaning. Moreover, some scholars find health benefits in the annual practice of fasting during the month of Ramadan. Some also believe that the active recitation of the Qur'an by a sick person or for a sick person can have healing effects.

There are, however, also verses in the Qur'an that have been interpreted as preventing the active pursuit of medical treatment, for instance, "If God sends you harm, only he can remove it" (6:17) and it is God "who heals me when I am sick" (6:80). Some Muslim patients may consider their illness predestined by God and therefore may not make healthful life choices that might help prevent the onset of an illness, or, once they fall ill, they may not seek help or, if they do seek help, they may not follow treatment instructions. A health practitioner in the West may want to discuss a Muslim patient's belief system as part of the treatment, and may want to acknowledge that the efficacy of biomedicine does not preclude God's healing power – or in other words, God's work may manifest through the doctor's work. A practicing Muslim may respond to a doctor's encouraging words of, "with this treatment, you should feel better," with the words "*insha'allah*" (God willing), to which the health provider may want to respond "*insha'allah*," as a way of acknowledging the patient's belief system.

As explained earlier, Islam comes in many different forms. Therefore it is acceptable to ask a patient to explain their particular views and practices, rather than to assume that they have one standard set of beliefs. Without turning the doctor's office into a theological seminary, health professionals can show their cross-cultural sensibilities by asking how important Islam is in a patient's life. A practicing Muslim woman may not want a male gynecologist to treat her, or she may want her husband or male relative to stay with her in the treatment room. A Muslim man may prefer a male doctor to treat him. To ask a Muslim patient if she has a strong gender preference for her health care provider may be a good way to establish cross-cultural rapport. To ask a patient about the health of (extended) family members, or to share some details about one's own family, may help establish a more familiar and less intimidating rapport between doctor and patient.

Depending on the class and educational background of Muslim patients, as well as their length of residency in the USA or Europe, their attitudes toward biomedicine will vary. For some Muslim immigrants, a doctor may hold a position of absolute and unquestioned authority – in which case the patient may be reluctant to ask questions or demand clarification during a consultation. In other cases, a doctor may be considered a mere gatekeeper on the way to obtain needed prescriptions to get to the pills that will cure (or so the patient hopes). In the latter case, patients may be nonresponsive, or even resistant to suggestions that they can improve their situation by making lifestyle choices. In this way, Muslim immigrants may not differ much from non-Muslim immigrants or members of other minority groups. Some immigrants may continue to rely on traditional healing practices, while consulting with a Western doctor, and while holding on to a belief of the efficacy of prayer. In other words, the degree to which Islam matters during medical treatment – similar to Christianity or Judaism – will vary from patient to patient.

Isolation

Holly C. Sienkiewicz
Department of Public Health Education, The University of North Carolina at Greensboro, Greensboro, NC, USA

Isolation is common among recently arrived immigrants and refugee populations. The isolation that these populations experience is typically in the form of social exclusion. Social isolation occurs when persons, groups, or cultures do not have open communication with one another. Social isolation is exacerbated in immigrant populations due to language barriers, transportation difficulties, lack of social support, and familial interdependence. These same reasons can hinder access to medical care and mental health services as well.

Language barriers are especially apparent in the USA, and the inability to speak English is a barrier for many immigrants. Because they do not speak English, it is difficult to form social bonds with other individuals around them. Language barriers are also more difficult for non-Spanish speaking immigrants due to the pervasiveness of the Spanish language spoken in the USA. Language barriers are present in most areas of life outside of the home until a basic level of English comprehension (or native language of the country in which the individual has immigrated) is achieved.

Transportation difficulties and community design also contribute to the social isolation of immigrant populations. Public transportation is often more efficient elsewhere in the world than in the USA. For immigrants living in smaller cities and suburban areas, transportation is a significant barrier to social engagement. Those who are used to walking everywhere may feel secluded to their residence in the USA. Community design may also contribute to the isolation of immigrants. Through zoning, the USA largely separates residential from commercial properties to the effect that few conveniences are within walking distance of each other further contributing to the isolation felt by many immigrants.

After migration many immigrants may feel a lack of social support in their new country. Shortly after immigration many lack the support of the extended family left behind and may feel socially isolated. Many feel they cannot discuss difficulties in their new country with those back home. They feel that they should be grateful for the opportunity given to them to start a new life and cannot burden those back home with their troubles. Immigrants have not yet formed social networks in their new country and do not have anyone in which to confide. Therefore, many do not have an outlet to discuss problems that they may be experiencing.

Immigrants display familial interdependence and are more likely to reside in extended family households than nonimmigrant populations; however, immigrants can become isolated within the family unit. They are less likely to have outside friends and often lack the knowledge or ability to navigate their new environment. Because of this, immigrants sequester themselves within their living quarters. While interdependence is capable of keeping the family in physical proximity of one another, it has the potential to ostracize certain members and the elderly in particular.

Few seniors would leave their native communities to start a new life in a foreign country if not for close family ties. The children of the elderly encourage their parents to migrate to share the benefits of life in a new country or so that they can receive the care that they may need. The elderly do not adapt to their new life as quickly as younger family members and can feel high levels of alienation. They are often quick to define themselves as subordinates in their children's households. In the many societies from which immigrants relocate the elderly are well respected and their knowledge sought by younger generations. The skills that youth once desired, however, may no longer be useful in post-migration settings, and the elderly may feel that they have little useful wisdom to impart on their children and grandchildren creating a disconnect between generations.

Elderly immigrants often experience isolation more so than younger generations. Younger generations acculturate to life in a new society more rapidly than the elderly, because they are more likely to be engaged in their new society due to immersion in school or work. The elderly can find their new environment intimidating and may stay at their place of residence as a result. Disabilities and infirmities may also prevent seniors from exploring their new environment. Social isolation among elderly immigrants can be mitigated by involvement in ethnic enclaves and traditional practices. Without social support, the elderly are prone to adverse cultural stresses.

Italy

Bettina Rausa
Salk Institute for Biological Studies, La Jolla, CA, USA

Italy's history of immigration is fairly recent. It became a destination country for immigrants beginning in the 1970s. Prior to that, Italians migrated from Italy in the millions. Beginning in 1860 and up to 1975, an average of one out of every four Italians migrated from Italy. Most of those immigrants were from agricultural areas, with the first waves of immigration from Northern Italy, followed by waves of immigration from Southern Italy. Northern Italians immigrated primarily to other parts of Europe, while Southern Italians tended to migrate to places such as the United States, Latin America, and Australia. The peak of immigration from Italy was in 1880. The Italian government began implementing laws restricting emigration in 1868 due to concern that too many citizens were leaving; however, the poor economy of Italy during that period was the major driving force for emigration. Northern Italian emigration tapered when industrial development and growth was concentrated in that area, yet agricultural underdevelopment in the South continued to drive more Southern Italians out of Italy in search of work.

Italy became an immigration destination beginning in the 1970s. As of 2002, there were more than 1.5 million immigrants living in Italy, 20% of whom are believed to be undocumented. Eighty-six percent of immigrants in Italy originate from outside of the European Union. Although the number of African and Asian immigrants has increased steadily since 1970, many more come from Eastern European countries such as the former Yugoslavia, Albania, and Romania. In fact, they accounted for more than 46% of all immigrants between 1980 and 2000. During the period of 1970 to 1985, Eastern European immigrants consistently constituted 50–60% of all immigrants moving to Italy. African and Asian immigrants increased noticeably beginning in 1980. During the period from 1980 to 2000, Africans accounted for approximately 24% of all immigrants and Asians made up roughly 17%. This was a drastic change in profile from that of the immigrants prior to the 1980s, who came primarily from other European countries. Beginning in 1990, Latin Americans began migrating to Italy at slightly more than 8% of the total number of immigrants.

Immigrants moving to Italy settle in areas that have the highest demand for their labor. The Northeast, which includes Venice and Trieste, Central Italy (Rome), and the Northwest area made up of Lombardy, Piedmont, and Liguria have absorbed the majority of immigrants. Southern Italy's immigrants number about 11%, and about 5% of immigrants settle in Italy's island territories, including Sicily and Sardinia. The cities of Rome and Milan, Italy's largest urban areas, contain 15% of resident aliens, but the fastest growing areas are Brescia, Vicenza, and Verona in the Northeast.

Immigrant males make up almost 55% of all immigrants to Italy, yet more Asian and Latin American women migrate to Italy than their male counterparts. Among Moroccans, Tunisians, and Senegalese immigrants, over 80% are male. Eastern Europeans are also predominantly male, especially among former Yugoslavians and Albanians; however, immigrants from Romania and Poland are mostly female, as are immigrants from Somalia and Ethiopia. The age range making up over 65% of immigrants is 18–39; 75% of immigrants do not have children. However, beginning in 1999, the number of immigrants going to Italy to reunite with family reached 40%.

Most immigrants work in manual labor jobs and most of those jobs are in the informal or "underground" employment networks. Rates of illiteracy are approximately 80%.

Health care is considered a fundamental right in Italy, and the country's constitution itself guarantees access to health care to all regardless of citizenship. One of the challenges, however, is that with so many immigrants from starkly different cultural backgrounds, practical issues such as language and cultural barriers hinder health care education, access, and delivery. Several steps have been taken by Italy's National Health System (NHS) to ensure that immigrants are informed about the health services available to them and that they are accessing them. The NHS has invested in many areas in an effort to meet immigrants' health care needs including conducting needs assessments, providing training to health care providers on cultural issues, and developing and training health mediators to help bridge the communication gap between health providers and patients.

Immigrants in Italy are often transient due to a desire for better work opportunities; consequently, it is difficult to follow their health status over time. A few health studies reveal some of the health issues immigrants in Italy face. A comparative study of the health status of immigrants and native Italians in early adolescence demonstrated that immigrant adolescents have poorer psychological health compared to their native Italian counterparts. Immigrant adolescents report feeling less satisfied about their health and lives in general, are less happy, feel more isolated, report more victimization and bullying, and have fewer friends and less support from friends than do native Italian adolescents.

A study of hospital utilization in the Lazio region indicates that hospital utilization rates are lower among immigrants than nonimmigrants, especially for acute care. When examining those hospitalized for injuries, infectious diseases, and abortions, however, the rates go up for immigrants. Immigrants are more prone to injuries which are usually related to poor living and working conditions – they often perform hazardous work with insufficient safety training. Infectious disease rates for HIV and tuberculosis are higher for immigrants as well. Reproductive health is a particular problem among immigrants in Italy as the number of abortions are high, typically three times that of nonimmigrant women. One explanation for this could be the challenges that immigrant women face in controlling their own reproductive health, living in poverty/lack of income stability, and lack of social support. Youth aged 18 years and younger have the same rates of hospitalization as nonimmigrants for respiratory diseases, injuries, and poisoning, but higher rates for infectious and parasitic diseases. In 2004, a study comparing the health of immigrants in 11 different European countries showed that in Italy, of the 2,508 people surveyed (all of whom had obtained citizenship), 52.3% reported functioning difficulties; 45.4% reported suffering from a chronic disease(s); 51.8% had low self-perceived health; 18.2% used tobacco; and 61.7% reported being overweight.

Although immigrants, even noncitizens, have the same rights to health care as Italian natives, they are facing more challenges recently with respect to acceptance and assimilation. Immigrants in Italy have become the target of frustration among Italians over a lagging economy and high unemployment. They have also been blamed for an increase in crime. They are facing more overt acts of discrimination and racism, sometimes resulting in violence. New legislation passed in 2008/2009 makes it mandatory for medical professionals to report illegal immigrants to Italian law enforcement authorities. The law also makes illegal immigration a criminal offense, punishable by fines up to 10,000 Euro, detainment, and/or immediate deportation. Jail terms are also imposed upon those who are found to offer housing to immigrants who cannot prove they are in the country legally. Furthermore, new legislation allows for the creation of citizen patrols to help police and the military identify illegal immigrants. Elected officials state that Italy is facing a crisis, having allowed too many immigrants into a country that does not have the infrastructure or the economic capacity to support so many additional people. This is in very stark contrast to the liberal immigration policies that Italy has held for many years. The new legislation was spearheaded by the Northern League, a political party known for its anti-immigration philosophy and its strong alliance with the ruling party of Prime Minister, Silvio Berlusconi. The European Commission and the United Nations High Commissioner for Refugees are currently investigating Italy's new anti-immigrant legislation. Since Italy is a member of the European Union (EU), the law may be in direct violation of EU policies.

Jamaica

Sarah Parsons
Norton Cancer Institute, Louisville, KY, USA

Jamaica, measuring 4,441 square miles, is one of four islands of the Caribbean archipelago. Initially claimed by Columbus in 1494, Jamaica served as a sugar plantation based on slave labor for hundreds of years. Limited self-governance was granted in 1944, and Jamaica became an independent nation in 1962. The country's motto, "Out of many, one people" illustrates its diverse history and population. Ninety percent of Jamaica's 2.8 million inhabitants endorse African ancestry. The population is considered a Christian nation, representing 80% of Jamaicans. Eight percent of the population practice Rastafari, a religion founded in 1930 and based on a messianic interpretation of Christian scripture. Immigrants to Jamaica represent a small portion of the population, approximately 18,000 currently residing in the country. The rate of immigration is − 5.88/1,000 people. Economic hardship and a lack of economic diversity are postulated to impact immigration to Jamaica.

Emigration from Jamaica was largely tied to slavery and post-emancipation migration in the nineteenth century. Large numbers of Jamaicans were recruited by the USA to work in Panama and Costa Rica in the 1850s; after slavery was abolished in the USA in 1865, temporary workers were recruited to harvest crops annually. From 1881 to the start of World War I, ninety thousand Jamaican immigrants worked on the Panama Canal. The largest wave of Jamaican immigrants to the USA occurred from 1965 to 1984 after immigration laws were changed in the USA. Three hundred thousand Jamaican immigrants entered the country during that time. Prior to 1965, many Jamaicans immigrated to Britain. During the 1970s and 1980s, 15% of Jamaica's population immigrated to other countries, creating an acute lack of professionals, including skilled workers, doctors, lawyers, managers, and technicians. A failing economy based on plantation agriculture, lack of economic diversity, and a scarcity of professional positions are blamed for this mass emigration. In the 1990s, Jamaica offered incentives for these professionals to return to their home country. There remains a Jamaican cultural mentality of emigrating to gain success and riches and then returning to show evidence of their wealth; most emigrants do not return to permanently reside in Jamaica.

Assimilation of Jamaican immigrants in other countries is complicated by adaptation to different cultures and weather, as well as adjusting to social roles of racial and ethnic groups in predominantly White countries. Jamaican immigrants tend to become more conscious of their race, transitioning from being a majority to a minority in other countries. In the USA, Jamaican immigrants have settled in all states across the country with a greater concentration in the northeast. The 1990 census reported 435,025 Jamaican immigrants; however, the actual number was estimated at close to one million; the difference is based on the high number of illegal aliens and Jamaican attitude toward the census. Jamaican immigrants tend to form smaller communities to provide support to each other and aid in assimilation. Many large Jamaican populations are present in large US inner cities; Jamaican youth have become involved in the gang and drug cultures of these areas. Overall, Jamaican immigrants tend to have good relations with other groups, despite some report of intraracial conflict between US-born African Americans and Jamaican immigrants.

The overall health of Jamaican immigrants in the USA tends to be better than US-born African

Sana Loue & Martha Sajatovic (eds.), *Encyclopedia of Immigrant Health*, DOI 10.1007/978-1-4419-5659-0,

Americans. Data indicate that Jamaican immigrants are less likely to report adverse health behaviors and are more likely to be uninsured. They tend to avoid health care visits for fear of hearing bad news and a desire for privacy. Jamaican men have the highest rate of prostate cancer in the world. Emigration from Jamaica is associated with increased survival rate, though Jamaican immigrants continue to have an increased rate of prostate cancer. Data indicate that the perception of cancer among Jamaican immigrants is that cancer is associated with death. Improved health education and screening can impact early detection of prostate cancer in this population. There are no other reported health problems specific to the Jamaican population.

The mental health of Jamaican immigrants reveals an increased prevalence of psychotic and affective disorders over native populations. Second and third generation Jamaican immigrants are more susceptible, presumably due to the increased age of first generation immigrants. Another contributing factor is postulated to be the increased exposure to minority status and the downward social mobility in the USA and Britain. Mental health literacy and early intervention can be helpful in the Jamaican immigrant population.

Japan

Amy N. Sharpton
Department of Veterans Affairs, Louis Stokes DVA Medical Center Cleveland, Brecksville, OH, USA

Introduction

Japan is an island nation in the eastern region of the continent of Asia. The island is located in the Pacific Ocean; is situated to the east of the Sea of Japan, China, North Korea, South Korea, and Russia; and extends from the Sea of Okhotsk in the north to the East China Sea and Taiwan in the south. Japan is an archipelago, a chain or cluster of islands, comprised of 6,852 islands. The four largest islands are Honshu, Hokkaido, Kyushu, and Shikoku; together they account for 97% of Japan's land area. With over 127 million people, Japan has the world's tenth largest population. The Greater Tokyo Area is the largest metropolitan area in the world, with greater than 30 million residents.

History

The first known habitation of Japan is the Paleolithic culture of around 30,000 BC.

The Jōmon period followed beginning around 14,000 BC, characterized as a semi-sedentary, hunter-gatherer culture, with pit-dwelling and rudimentary agriculture. Included in this period are ancestors of the contemporary Ainu and Yamato people. Around 300 BC, the Yayoi people began to enter the Japanese islands, intermingling with the Jōmon. The Yayoi period began around 500 BC, and employed new practices such as wet-rice farming, a new style of pottery, and metallurgy introduced from China and Korea.

The Nara period of the eighth century marked the emergence of a strong Japanese state, with an imperial court, the continuing adoption of Chinese administrative practices, and emerging literary works. A smallpox epidemic took place between 735 and 737; it is believed to have killed as much as one-third of Japan's population. The Heian period followed, marked by Emperor Kammu's decision in 784 to move the capital from Nara to Heian-kyō, modern-day Kyoto. During the Heian period, a distinctly indigenous Japanese culture emerged, noted for its art, poetry, and literature. The lyrics of Japan's national anthem *Kimigayo* were written during this time.

Japan's feudal era was typified by the emergence and subsequent dominance of a ruling class of warriors, the samurai, who were considered military nobility. In 1185, samurai Minamoto no Yoritomo was appointed *shogun* – a military rank, in most cases, a hereditary military dictator. Following Yoritomo's death, the Hōjō clan came to power as regents for the shoguns. The Zen school of Buddhism was introduced from China in the Kamakura period, 1185–1333, and became popular among the samurai class.

During the sixteenth century, traders and Jesuit missionaries from Portugal reached Japan for the first time ever, thus initiating commercial and cultural exchange between Japan and the West. This is known in Japanese history as the *Nanban trade period*, or the *Southern barbarian trade period*; it extends from the arrival of the first Europeans to Japan in 1543–1641 and their near-total exclusion from the archipelago.

Marking the beginning of the Edo period, a *closed country* policy was implemented in 1639; it spanned two and a half centuries and was characterized by weak political unity. *Rangaku,* the study of Western sciences, continued through contact with the Dutch enclave in Nagasaki. The Edo period gave rise also to *kokugaku*, national studies, the study of Japan by the Japanese.

On March 31, 1854, the US Navy, led by Commodore Matthew Perry, compelled the opening of Japan to the West with the Convention of Kanagawa. Ensuing treaties with Western countries during the period brought economic and political crises, eventually leading to the Boshin War, the resignation of the shogun, and the establishment of a centralized state that was unified somewhat under the Emperor. Adopting Western political, judicial, and military institutions, the Cabinet organized the Privy Council, an advisory council to the Emperor of Japan that operated from 1888 to 1947; introduced the Meiji Constitution, the organic law of the Empire of Japan, in force from November 29, 1890, until May 2, 1947; and assembled the Imperial Diet, Japan's bicameral legislature. This period saw the Empire of Japan transformed into an industrialized world power, which pursued military conflict to expand its sphere of influence. Japan's population grew from 35 million in 1873 to 70 million in 1935.

July 30, 1912, to December 25, 1926, the Taishō era, is a period in the history of Japan that corresponds with the reign of the Taishō Emperor. The new emperor's weak health drove the transition in political power from the former oligarchic group of elder statesmen to the Diet of Japan and the democratic parties. This era in Japan's history is considered a period of liberal movement known as the *Taishō democracy*. This period was brief, however, as it was overshadowed quickly by growing expansionism and militarization.

A member of the Allied forces during World War I, Japan increased its influence and expanded its territorial holdings; it continued its expansionist policy and occupied Manchuria in 1931. In response to international condemnation over the occupation, Japan resigned from the League of Nations 2 years later. Furthermore, the country signed three decisive pacts: in 1936 Japan signed the Anti-Comintern Pact with Nazi Germany, a pact directed against the Soviet Union's Communist International; in 1940 they signed the Tripartite Pact, which made it one of the Axis Powers; and in 1941 Japan negotiated the Soviet–Japanese Neutrality Pact.

Expansionism continued as the Empire of Japan invaded other parts of China in 1937; French Indochina in 1940; and on December 7, 1941, Japan attacked the US naval base at Pearl Harbor and declared war on the USA, the UK, and the Netherlands. Japan's attack on Pearl Harbor was the catalyst for the USA's entry into World War II; on December 8, those three countries (the USA, the UK, and the Netherlands) declared war on Japan. Following the Soviet invasion of Manchuria and the atomic bombings of Hiroshima and Nagasaki in 1945, Japan agreed to an unconditional surrender on August 15.

In 1947, Japan adopted a new constitution with an emphasis on liberal democratic practices. The Allied occupation ended with the Treaty of San Francisco in 1952, and Japan was granted membership in the United Nations in 1956. Eventually, the country achieved rapid growth; at one point, it was the second-largest economy in the world. However, in the mid-1990s, Japan suffered a major recession. While positive growth at the beginning of the twenty-first century signaled a gradual economic recovery, on March 11, 2011, Japan suffered the strongest earthquake in its recorded history. The devastation was made worse by a tsunami that affected the northeast area of Honshu, including Tokyo. While yet unfolding, doubtless, the impact of the disaster will be far reaching.

Geography

Japan has a total of 6,852 islands extending along the Pacific coast of Asia. The main islands, from north to south, are Hokkaido, Honshū, Shikoku, and Kyūshū. Approximately 73% of Japan is forested, mountainous, and unsuitable for agricultural, industrial, or residential use; hence, the coastal habitable zones have extremely high population densities. Japan is one of the most densely populated countries in the world.

The islands of Japan are located in a volcanic zone on the Pacific Ring of Fire, an area where large numbers of earthquakes and volcanic eruptions occur in the basin of the Pacific Ocean. Japan has 108 active volcanoes, while destructive earthquakes, often resulting in tsunamis, occur several times each century. The 1923 Tokyo earthquake killed over 140,000 people. The most recent major quakes are the 2004 Chūetsu earthquake and the 2011 Tōhoku earthquake, a 9.0-magnitude quake, which triggered a tsunami. The devastation for the most recent event is still being calculated.

Government

Japan is a constitutional monarchy where the Emperor acts as head of state, and his or her power is confined within the parameters of a constitution. This form of government differs from absolute monarchy in that an absolute monarch is the sole source of political power – not bound legally by a constitution of any form. As a ceremonial figurehead, the constitution defines the Emperor as "the symbol of the state and of the unity of the people." In the Japanese government, sovereignty is vested in the Japanese people, and the political power is held chiefly by the Prime Minister of Japan and other elected members of the Diet – Japan's bicameral legislature. Akihito is the current Emperor of Japan; Naruhito, Crown Prince of Japan, stands as next in line to the throne.

Japan's legislative body is the National Diet; it is a bicameral parliament consisting of a 480-member House of Representatives who are elected by popular vote every 4 years or when dissolved, and a 242-member House of Councilors who are popularly elected for 6 year terms. For all elected offices, there is universal suffrage via secret ballot for adults over 20 years of age. In 2009, the social liberal Democratic Party of Japan took power after 54 years of the liberal conservative Liberal Democratic Party's rule.

Culture

From the country's original Jōmon arts to its contemporary culture, Japanese culture has evolved significantly. Today's Japanese culture combines influences from Asia, Europe, and North America. Traditional Japanese arts include: crafts, folklore, performances, and traditions. Examples of Japanese crafts are ikebana, the Japanese art of flower arrangement; origami, the traditional Japanese art of paper folding; dolls; lacquer ware; pottery; and ceramics.

The folklore of Japan is influenced greatly by the country's two primary religions, Shinto and Buddhism. Frequently, the folklore involves humorous or bizarre characters and situations and includes also a variety of supernatural beings.

Japanese culture includes a variety of performances such as Bunraku, dance, Kabuki, Noh, and rakugo. Bunraku is a form of traditional Japanese puppet theater founded in Osaka in 1684. There are two types of Japanese traditional dance: Odori, which originated in the Edo period, and Mai, which originated in the western part of Japan. Odori grew out of Kabuki drama and is more oriented toward male sentiments, while Mai was influenced by Noh Drama and is performed traditionally in Japanese rooms rather than on stage. Kabuki is classical Japanese dance-drama known for the stylization of its drama and for the elaborate makeup worn by some of its performers. Performed since the fourteenth century, Noh or Nogaku is a style of classical Japanese musical drama in which many characters are masked; men play male and female roles; and a *performance* lasts all day – consisting of five Noh plays interspersed with shorter, humorous Kyōgen pieces. Rakugo means *fallen words*; it constitutes Japanese verbal entertainment, wherein the lone storyteller sits on the stage, uses as props only a paper fan and a small cloth, and depicts a long and complicated comical story involving always the dialogue of two or more characters. The story teller never rises from a seated position, and only through change in pitch, tone, or a slight turn of the head, are the different characters represented.

Japanese cultural traditions include games, tea ceremony, Budō, architecture, gardens, and katana. Traditional Japanese games fall within the following categories: children's, board, card, tile, dice, and word; within each category there can be dozens of particular games. The Japanese tea ceremony is known also as the *Way of Tea*. It is a Japanese cultural activity involving the ceremonial preparation and presentation of *matcha*, a powdered green tea. Zen Buddhism was a primary influence in the development of the ceremony. Budō refers to the idea of formulating propositions, subjecting them to philosophical critique, and then to following a "path" to realize them. Although Japanese architecture was influenced greatly by Chinese architecture from the Tang Dynasty, it has developed many unique differences and aspects indigenous to Japan. Gardens in traditional Japanese style are centered on the use of stones, water, and plantings. The Katana is Japanese for *backsword*. The katana, historically associated with the samurai, is characterized by its distinctive curved, slender, single-edged blade, circular or squared guard, and long grip.

Economy

Due to its overall economic growth, the period from the 1960s to the 1980s in Japan has been called a *Japanese miracle*, averaging 7.5% in the 1960s and 1970s, and 3.2% in the 1980s and early 1990s. Conversely, growth slowed considerably throughout the 1990s; the Japanese refer to this time as the *Lost Decade*. Government efforts to revive economic growth did little to reverse the economic turndown, and endeavors were hampered further by the global slowdown in 2000. The economy showed strong signs of recovery after 2005; GDP growth for that year was 2.8%, surpassing the growth rates of the USA and the EU during the same period.

As of 2010, Japan's national economy was third only to the USA and China in terms of nominal GDP and purchasing power parity. During that same year, it was also the world's fourth largest exporter and fourth largest importer. As of January 2011, Japan's public debt was more than 200% of its annual GDP, the largest of any nation in the world. The service sector accounts for three-quarters of its GDP. The nation has a large industrial capacity, and is home to some of the largest and most technologically advanced companies. Japanese agricultural businesses often utilize a system of terrace farming, and crop yields are high; 13% of Japan's land is cultivated. Japan accounts for approximately 15% of the global fish catch.

As of 2010, Japan had a low unemployment rate of approximately 4% and a labor force of greater than 65.9 million workers. However, nearly one in six Japanese, or 20 million people, lived in poverty in 2007. Housing is characterized by limited land supply in urban areas; more than half of all Japanese live in suburbs or more rural areas.

Education

During the course of the Meiji Restoration, primary schools, secondary schools, and universities were introduced in 1872. Since 1947, compulsory education in Japan comprises elementary and middle school; students attend from ages 6 to 15, although nearly all children continue their education at a 3-year senior high school. According to Japan's Ministry of Education, Culture, Sports, Science and Technology (MEXT), as of 2005 approximately 75.9% of high-school graduates attend a university, junior college, trade school, or other institution of higher learning.

Japan's education system is intensely competitive, particularly for entrance to institutions of higher learning. The two top-ranking universities in Japan are the University of Tokyo and Kyoto University. Currently, the Organization for Economic Cooperation and Development (OECD) ranks the overall knowledge and skills of Japanese 15-year-olds as sixth best in the world.

Health Care

Health care in Japan is provided by the national and local governments; patients are responsible for 30% of the cost of services rendered, while the government pays for the remaining 70%. Fees for services are set by a government committee, and remittance for personal medical services is offered through a universal health insurance system that provides relative equality of access. Those without employer-sponsored insurance may participate in a national health insurance program administered by local governments. Patients cannot be denied coverage and are free to select physicians or facilities of their choice. By law, hospitals are managed by physicians and must be run as nonprofit; for-profit corporations are not permitted to own or operate hospitals.

Since 1973, all elderly persons have been covered by government-sponsored insurance.

Enrollment in one of Japan's health insurance programs is compulsory; however, enforcement is somewhat lax. Of late, a growing number of individuals are not covered by insurance. This trend has come to the forefront as economic conditions have deteriorated and some Japanese companies have ceased paying for employees' insurance premiums.

Migration

Globalization, labor shortages, and an aging population are a few of the issues forcing Japan to consider how widely it should open its domestic labor market to foreign workers.

Some social and economic factors are pushing Japan toward a more open immigration policy, while other factors, such as mounting concerns about public security and growing apprehensions about international terrorism, are prompting Japan to enact stricter immigration controls.

Between six million and seven million Japanese migrated each year during the 1980s. About 50% of these moves were within the same jurisdiction, or prefecture, (Japan has 47); the others were relocations from one prefecture to another. During Japan's economic development in the twentieth century, and especially during the 1950s and 1960s, migration was characterized by urbanization as people moved in search of better jobs and education. Out-migration from rural prefectures continued in the late 1980s, but more slowly than in previous decades.

In the 1980s, government policy provided for new urban development away from the large cities, particularly Tokyo. Regional cities sought to attract young people to live and work there. While in comparison to larger urban areas, regional cities offered lower costs of living, shorter commutes, and, in general, a more relaxed life style, young people continued to move to large cities to attend universities and to find work. However, some returned to regional cities (a pattern known as U-turn) or to their prefecture of origin (a pattern known as J-turn).

Government statistics indicate that in the 1980s, significant numbers of people left the largest cities (Tokyo and Osaka). In 1988 more than 500,000 people left Tokyo, which experienced for the year a net loss through migration of nearly 73,000. Osaka had a net loss of nearly 36,000 in the same year. However, the prefectures showing the highest net growth are located near the major urban centers. This pattern suggests a process of suburbanization – residents moving away from the cities for affordable housing but still commuting there for work and recreation, rather than a true decentralization.

Japanese economic success has led to an increase in certain types of external migration. In 1990 about 11 million Japanese went abroad. More than 80% of these people traveled as tourists, visiting most often other parts of Asia and North America. However, about 663,000 Japanese were living abroad, approximately 75,000 of whom had permanent foreign residency, more than six times the number who had that status in 1975.

More than 200,000 Japanese went abroad in 1990 for extended periods of study, research, or business assignments. As the government and private corporations have stressed internationalization, Japan's historically claimed insularity has decreased. Frequently, individuals who have lived outside of Japan for extended periods have faced discrimination upon repatriation as fellow nationals have considered them no longer fully Japanese. By the late 1980s, these problems, particularly the bullying of returnee children in the schools, had become a major public issue both in Japan and in Japanese communities abroad.

The number of foreign nationals entering Japan has grown substantially in recent years. Including new and returning visitors and residents, the total number of entrants was 3.5 million in 1990 and 5.27 million in 2000. By 2005, the number had grown to 7.45 million, including 2 million Koreans, 1.32 million Chinese from Taiwan, 780,000 Chinese from the People's Republic of China, 250,000 Chinese from Hong Kong, and 221,000 Filipinos. Among Koreans, many were students; the Chinese were generally trainees and students; and nearly 40% of the Filipinos arrived with *entertainer* visas, given to actors, singers, dancers, and professional athletes. Japan continues to be relatively closed to asylum seekers, and the number of applicants has also been very small. Between 1982 and 2004, there were 3,544 applications; only 330 of them were approved. Of the 3,544 applications, 408 (11.5%) were filed by Indochinese, mostly before 1985.

Currently, Japan's population is estimated at around 127.3 million, with a linguistically and culturally homogeneous society, and only small populations of foreign workers. Zainichi Koreans, Zainichi Chinese, Filipinos, Japanese Brazilians, and Japanese Peruvians are among the small minority groups in Japan. In 2003, there were about 136,000 Western expatriates.

By 2050, almost 40% of Japan's population will be aged 65 and over, as projected in December 2006. Immigration and birth incentives are sometimes suggested as a solution to provide support for the nation's aging population. While Japan has a steady flow of about 15,000 immigrants per year, many do not stay on a permanent basis. Furthermore, according to the UNHCR, in 2007 Japan accepted just 41 refugees for resettlement, while the USA took in 50,000.

Jewish Migration

Amir Poreh[1], Jennifer Levin[2]
[1]Clinical Psychology Program, Department of Psychology, Cleveland State University, Cleveland, OH, USA
[2]Department of Psychiatry, Case Western Reserve University School of Medicine, Cleveland, OH, USA

Jews trace their roots to the Middle East and particularly to the area known as Judea. The initial immigration of members of this tribe occurred during biblical times. However, in the annals of Jewish history, the most influential immigration occurred after the Judea region was occupied by Nebuchadnezzar, the king of Babylon. In 588 BC, following the destruction of the Jewish temple and the destruction of the Judean Kingdom, the inhabitants were exiled to what is now Iraq. Unlike other exiles, they did not assimilate and developed a more abstract religion that emphasized abstract and holy texts rather than physical worship. In 539 BC, when the Kingdom of Babylon was conquered by the Persians, the Jews returned to Judea, rebuilt the second temple, and reestablished their place of worship, the second temple. Not all of the Jews returned and some remained in Babylon, establishing what was the first Jewish Diaspora. This was the result of Jewish exile or forced immigration out of their original homeland.

By the second century BC, the Jews were immigrating to countries around the Mediterranean basin. Following the Jewish revolt against the Romans and the subsequent destruction of Jerusalem, the center of Jewish life shifted, although according to historical accounts, a large population remained in this Judea until the sixth century, particularly in the Galilee region. The migration of Jews continued during the post-Roman period. During the Middle Ages, Spain and North Africa became the center of Jewish studies. However, in 1492 the Jews were forced to convert to Christianity or leave Spain within 3 months.

The Expulsion Chronicles describe the wholesale killing of women and children. Following this expulsion, Jews from Spain migrated to Western Europe where they established several large communities. Persecuted and abused, the Jews in Germany were eventually expelled and moved to Eastern Europe. This move led to the development of a new language called Yiddish, a combination of medieval German and Hebrew.

In the mid-1600s, Jews were massacred in Poland, and some moved back to Germany and other Western European countries. During the 1800s, as nationalistic movements in Europe started to flourish, the European Jews started to assimilate into the mainstream of society. Jews viewed the period of "Enlightment" and started to pursue professions that emphasized intellectual rather than manual skills. Their Eastern European counterparts, who continued to be subjected to severe persecution and routine massacres, started to immigrate on mass to the USA, South America, and the Turkish- and later British-controlled Palestine.

Prior to World War II, the Nazi regime reinstated many of the anti-Semitic discriminatory laws in Europe. Jews who had foresight or were well known in their area of expertise, such as scientists, immigrated to the USA, British Palestine, and some even to China. These forced immigrations ended during World War II when the Germans perpetrated the Holocaust. After the destruction of the European Jewry during World War II when approximately six million Jews were systematically murdered, the majority of Eastern and Western European Jews immigrated to other countries including what later became the State of Israel.

Following the establishment of the State of Israel, Jews in Arab countries were subjected to massacres and persecution. Anti-Jewish riots involving the loss of life also took place in Libya in 1945, in Yemen in 1947, and in Egypt, Morocco, and Iraq in 1948. Jewish places of worship (synagogues) and property were confiscated. Those Jews who were forced to emigrate were not allowed to take their property. From 1948 to 1949, the Israeli government secretly airlifted 50,000 Jews from Yemen and from 1950 to 1952, 130,000 Jews were airlifted from Iraq. From 1949 to 1951, 30,000 Jews fled Libya to Israel. In these cases, over 90% of the Jewish population opted to leave, despite the necessity of leaving their property behind. Overall, approximately 900,000 Jews were forced to immigrate. The majority settled in Israel, while some settled in France, the USA, and South America.

In the late 1970s, with the rise of extreme Islam and anti-Semitism in Iran, people of the Christian, Zoroastrian, Bahai, and Jewish faiths were persecuted. These persecutions resulted in a new wave of Jewish immigration to the USA. After the Holocaust, a large center of Jewish population remained in Russia and other Eastern European countries. During the communist era, the Jews in these countries were subjected to subtle discrimination such as university quotas and random imprisonment. With the fall of the Soviet Union and the rise of ultra nationalism in these countries, anti-Semitism again flourished. As a result, between 1988 and 1999, a wave of Jews emigrated out of the former Soviet Union. During this decade, 700,000 Jews arrived in Israel becoming 15% of that country's population. These new wave immigrants, like their predecessors, reshaped their new host countries with their know-how and intellectual curiosity, leading to the formation of numerous high-tech companies both in the USA and Israel, including companies such as Google.

Job Stress

Jeannette Dagam[1], Delaney Smith[2]
[1]Ohio State University Medical Center, Columbus, OH, USA
[2]Timothy B Moritz Forensic Unit, Twin Valley Behavioral Healthcare, Columbus, OH, USA

Stress can be defined as a state in which one's equilibrium has been disrupted by physical or psychosocial factors. This imbalance, as well as an individual's efforts to behaviorally, psychologically, and physiologically compensate, can exacerbate or contribute to various disease states. Stress can be further characterized by duration, sphere of life in which it occurs, severity, and its perception by the individual.

While all populations are prone to stress, immigrants face unique challenges that can make them particularly vulnerable. Researchers have cited three major variables within the immigrant experience that can provide a framework for stress: the migration process, employment, and general acculturation. One longitudinal study examined employment, duration of residence, and mental health of skilled immigrants from China, India, and South Africa to New Zealand. The authors found that unemployed and underemployed immigrants had poorer mental health when compared with those employed full time as well as the general population. Substantial research supports the notion that unemployment, particularly long term, adversely affects psychological and physical well-being. Immigrants face exceptional challenges to employment over their native counterparts, due in part to discrimination, lack of fluency in the dominant society's language/cultural nuances, and general selection bias by recruitment agencies and employers. Even those immigrants with full-time employment are susceptible given their need to adapt to the unfamiliar work environment of another country as well as the stress that accompanies learning to communicate effectively in a foreign tongue.

Acculturative stress refers to various aspects inherent to the immigrant experience: discrimination, language inadequacy, the lack of social and financial resources, employment barriers, feeling out of place in a new environment, and the conflict of trying to adapt to a new culture while still retaining the traditions, values, and customs of the old. High levels of acculturative stress have been correlated with depression and suicidal thoughts in Mexican and Central American immigrants. In addition to work stress, contributing factors such as family dysfunction, inadequate social support, low levels of religiosity, bleaker expectations for the future, lack of choice in the decision to immigrate, and low levels of education and income were predictors of psychological duress.

When looking specifically at migrant farmworkers in the Midwestern United States, of which there are over one million, one can see how the nature of the work plays a significant role in an individual's level of acculturative stress. By the nature of the work they do, migrant farmworkers are socially marginalized peoples. Many earn less than US$6,000 a year, endure strenuous labor conditions, find themselves subject to hazardous working conditions (e.g., pesticide exposure), and are forced to live in substandard conditions often without running water or adequate toilet facilities. In part due to the nature of their work and limited access to healthcare, the average life expectancy of a migrant farmworker is 49 years. Through health opinion surveys among migrant workers it was discovered that the immigrant experience, compounded with the rigors of their lifestyle, placed these individuals at particularly elevated psychological risk. Migrant farmworkers generally reported high levels of anxiety and depression in large part related to the discrimination and exploitation that they experience as a result of the service they provide.

One criticism of studies looking at job stress is that they generally fail to account for the potential effects of one's ethnicity and cultural background. In the late 1990s, the term *ethnocultural occupational stress* was introduced to reference stressors within the work environment that directly pertained to an individual's minority ethnic status with a strong emphasis on cultural self-identification. It was observed that among ethnic minorities job stress was particularly influenced by cultural conflicts, lack of social support, and perceived discrimination. One study that examined job stress ratings among Hispanic professionals compared to a normative group revealed higher levels of stress which were most closely correlated with the perception of poor support from peers, supervisors, and their organization rather than pressure such as meeting deadlines, damage control, etc. To the extent that these outcomes stemmed from cultural conflicts and/or discrimination is speculative.

Research indicates that stress has a significant impact on physical functioning and well-being. No organ system is spared from its impact. Initially, when confronted by a stressor, our bodies respond with an adaptive fight or flight reaction. Chemical mediators are released that facilitate energy, alertness, and an increased capacity to respond. Once the stressor has ceased, our bodies return to their baseline. Persistent stress, on the other hand, results in chronic activation of these chemical mediators and can result in suppression of growth and tissue renewal/healing, increased fat stores, and sugar dysregulation. When elevated, the stress hormone cortisol can also interfere with working memory and information processing in some individuals.

Those under a lot of stress often report difficulties related to the gastrointestinal tract. In affected individuals, stress can mediate a hyperreactivity to chemicals produced by the brain and result in increased transit time through the large bowel and delayed emptying of the stomach. Those suffering from irritable bowel syndrome often find symptoms of bloating, abdominal discomfort, and alternating constipation and diarrhea, worsened when under psychological duress. Peptic ulcers can also be mediated by stress. The presence of ulcers in those who test negative for infection with the *Heliobacter pylori* bacteria as well as the rate of persons infected who do not go on to develop ulcers emphasized the role of "negative health behaviors" fueled by stress – that is, smoking, increased alcohol intake, irregular sleep, and poor eating habits just to name a few. It is believed that stress and these behaviors physically alter the landscape of the gut increasing acid secretion, dampening motility, and making the inner lining more susceptible to colonization by bacteria, inflammation, and ulceration.

Acute and chronic stress responses and its effects on the cardiovascular system have been well established. Chronic elevations of stress hormones can contribute to hypertension with resultant heart enlargement and plaque formation within arteries. The INTERHEART study indicated that psychosocial stress (i.e., work, martial, low social support, financial, etc.) was a variable comparable to smoking and high blood pressure in its association with coronary artery disease and heart attack.

Psychosocial stress has also long been known to impact mental well-being. Chronic stress can contribute to the onset of psychiatric illnesses such as depression and anxiety as well as exacerbate preexisting conditions. Persistently elevated levels of stress-induced inflammatory markers play a role in dysregulation of sleep, appetite, energy, and concentration. Numerous studies have demonstrated a correlation between depressive symptoms and markers of inflammation with some implication that chronic stress can adversely impact the central nervous system's serotonergic system with resultant alterations in mood and behavior.

Although the impact of work-related concerns on well-being has not been systematically investigated in relation to immigrants, a few studies have attempted to look at this. In addition to examining Hispanics, which comprise the largest foreign-born population in the USA, other authors have examined stress in relation to Asian Americans. As of 2000, Filipinos comprised the second largest foreign-born population in the USA. A few studies have looked at the types of job stressors encountered by Filipino workers, which include management insensitivity, racism, and lack of mentorship. One study examining the association between work stress and health showed the strongest correlation for new immigrants. It has been suggested that over time immigrants may be better able to cope and adapt to their new environments and subsequently ameliorate the effects of acculturative stress. More studies are beginning to demonstrate that length of time spent in the USA lends itself to more job opportunities and occupational mobility and can perhaps mediate some of the stressors unique to the immigrant experience.

One final consideration is the impact of subtle discrimination of marginalized groups and its impact on general health once factors such as age, gender, region, income, employment, marital status, and social desirability bias are controlled for. One such study examined the association between self-reported everyday discrimination and chronic health conditions – particularly among the Asian subgroups of Chinese, Filipino, and Vietnamese. An increase in the number of chronic health conditions, particularly those affecting the cardiovascular, endocrine, and immune systems, correlated with the frequency of reports of discrimination. This data is supported by several other longitudinal studies that have found an association between discrimination and health issues.

While stress in the immigrant population can be multifactorial, work stress is a predominant component. The specific work-related stressors in the immigrant population and their affect on health should not be overlooked.

The Fertile Crescent is a region in Western Asia. It includes the regions of Mesopotamia and the Levant. Due to its unique climate, it gave rise to many edible plants that could be cultivated and animal species such as cows, sheep, and goats that could be domesticated. This unique ecosystem led to the emergence of complex societies and cultures, earning this region the nickname “The Cradle of Civilization.” Most of the societies and cultures that were formed in this region emphasized a system of beliefs or religions that associated the good fortunes of its members with supernatural protectors or gods. Those were represented in the form of statues and temples. When one tribe or kingdom was conquered by another, they would typically force the other tribe to adopt their gods, culture, and system of beliefs. One tribe, the Kingdom of Judea, which occupied the region known as modern day Israel, took a unique approach toward religion. They developed a system of beliefs that emphasized a single supernatural being that did not have a physical representation, and emphasized the importance of sacred writings (the Old Testament) to guide their day to day activities. In 587 BC, the ancient Kingdom of Judea was conquered by the Babylonians, a regional empire of that time. The Babylonians destroyed the Kingdom of Judea’s temple and exiled its inhabitants to what is now the northern region of Iraq. Unlike other tribes, members of the Kingdom of Judea did not abandon their religion or culture. In fact, the elimination of their political independence led to further affirmation of their abstract belief system and the development of religious worship that can be carried out wherever ten members of the tribe (Jews) were present. Additionally, the exiled members of the tribe developed a text recording discussions pertaining to Jewish law, ethics, customs, and history and made sweeping changes in their religion. These writings are known as the Talmud. The forced migration of the Jews to Babylon again strengthened their abstract belief system and written scriptures over physical representations of God. Fifty years after the Jews were forced to migrate from the land, the Babylonian Empire was destroyed by the Persians, and most but not all of the members of the tribe returned to Judea. Upon the return of the Jews to the Land of Judea, they rebuilt a new (second) temple for their God. However, unlike their previous temple, they deemphasized its religious centrality. Four hundred years later, when the Romans destroyed the second Jewish temple and forcefully exiled most of the Judea inhabitants, the Jews were already living across most areas of the Mediterranean region, and had developed a culture and religion that emphasized migration, allowing them to move from one location to another with great ease.

The ability of the Jewish tribe to employ inductive and deductive reasoning toward the interpretation of their scriptures also allowed them to adapt their laws to technological and climate changes wherever they resided. Often these adaptations addressed issues in public health such as strict dietary laws and hygiene practices. One such practice, for example, is the ritual of washing hands prior to touching food. This ritual involves pouring water out from a cup first twice over the right hand and then twice over the left hand. The unwashed hands are supposed to not touch the water used for the washing. The hands are then dried with a towel before partaking of the meal. Another ritual is the Jewish law of bathing regularly which requires complete immersion in a ritual bath as part of the end of the week preparation. Jewish rituals regarding grief and mourning have been conducive for mental health.

Another prime example of adaptations was introduced by Moshe Maimonides, a preeminent medieval Jewish philosopher, spiritual leader (Rabbi), and physician. Maimonides (1137–1204) was born in Northern Africa. When the Berber Muslims conquered the region, his family fled to Southern Spain and eventually settled in Morocco. Later, the family briefly immigrated to the Judea and eventually settled in Egypt. Maimonides's immigration experiences exposed him to Greek and Persian philosophy as well as medicine. In time, he became a renowned court physician to the Egyptian royal family. Maimonides's writings, which continued to be studied by Orthodox Jews, describe various medical conditions including asthma, diabetes, hepatitis, and pneumonia. He emphasized moderation and a healthy life style and living on a balanced diet. Moshe Maimonides also wrote one of the earliest toxicology textbooks. Maimonides's forced immigration experience also affected his sense of justice. One of his often cited legal maxims states that "It is better and more satisfactory to acquit a thousand guilty persons than to put a single innocent one to death." This principle was also applied to his medical practice. In a letter to one of his patients, a nephew of Saladin the Great in Cairo, Maimonides discussed the possible use of alcohol to treat bipolar disorder. In his letter to his Moslem patient, Maimonides quotes from the Koran and addresses the conflict between religious beliefs and the Muslim prohibition of alcohol consumption. Maimonides forged a link between religion and medicine and intercultural sensitivity and emphasized the common Jewish belief that saving life itself is a religious duty that supersedes virtually all other religious obligations.

The above example is particularly important in illustrating how immigrants' familiarity with various cultures and ideas provides them with the opportunity of fusing diverse ideas and approaching problems in unique and creative ways. A century after Maimonides's death, Jews of Spain were repeatedly discriminated against, persecuted, and forced to convert throughout Europe. In 1290, King Edward expelled the Jews from England, and in 1492 Queen Isabella expelled them from Spain. Many of the Jews from these countries immigrated to Western and later to Eastern Europe where they sought refuge. However, the tolerance in these countries to immigrants (Jews and Gypsies) did not last very long, and the local population often engaged in pogroms and persecution of the Jews. During the bubonic plague (*Circa* 1348), the Jews in Western and Eastern Europe were blamed for the outbreak and were massacred. In 1543, Martin Luther wrote *On Jews and Their Lies* and advocated their persecution. In the 1700s, during the uprising of the Ukrainians against the Poles, the Jews were persecuted and massacred. Finally, in the 1800s, anti-Jewish riots were common in Eastern Europe during various political upheavals. Similar massacres occurred in other parts of the world.

In the late 1800s, as Jews in Europe were being persecuted, Jews started immigrating to the USA. The Jewish American Immigration experience was also characterized by discrimination in the "New World." Jews were not allowed into certain professions including medicine. The first Jewish hospital, Mount Sinai, was founded in 1852. Other hospitals did not serve Kosher food or have Rabbis. In the 1920s, the children of Jewish immigrants pursued medical careers. However, most hospitals were closed to Jewish residents. As a result, most Jewish doctors completed their residency training in the various Jewish hospitals that were formed across the country such as Mount Sinai, Beth Israel, and Montefiore. In the 1930s, most colleges had a quota on the admission of Jewish students. At Yale, the dean of Yale Medical School, a Jew himself, formally limited Jewish faculty.

In 1933, German law restricted Jews from being reimbursed by the state health insurance funds. In 1939, Jews' licenses to practice medicine were revoked. As a result, Jewish doctors started immigrating to the USA. According to a Time Magazine article from that time, this led to Germany facing a shortage of doctors. Many of the remaining physicians committed suicide and others escaped to other countries. The American physicians were not hospitable to the new immigrants and many argued that they introduced “unfair competition” and “low standards of medical treatment.” Another argument was that many of these physicians were poorly trained in medical schools that “emphasize research and specialization rather than broad clinical experience.” Calls for restriction of practice were addressed by the Boston Committee on Medical Émigrés which stated that “There will be no placing of émigrés in competition with American doctors.” Hence, while famous immigrant researchers, such as the dermatologist, Wilhelm Frei, who developed the Frei test for the detection of syphilis, had no trouble in securing academic positions, other Jewish German immigrants had limited job prospects. Some were able to secure jobs at Jewish hospitals while others could not find work. Some doctors, such as the famous researcher Salome Gluecksohn-Waelsch, volunteered so as to get access to laboratories.

The effects of the European Jewish physicians and scientists’ immigration to the USA during and after World War II can be seen today in many areas. Many of these physicians blended their unique combination of training with that of American ideas to form new and exciting areas of science. Eugene Kennedy reflected on the contributions of Jewish immigrants to biochemistry by noting that “before the Second World War biochemistry in the United States had a strong flavor of clinical chemistry. It was much occupied with problems of analysis of blood and tissues and the determination of the structures of body constituents. This was important and indeed essential work, but American students had to go abroad to Germany or to England for training in what came to be called dynamic aspects of biochemistry. After the war, the flow of students was largely reversed. This transformation was in considerable part the result of new insights and new approaches brought to America by immigrant scientists.” In spite of these contributions, many prominent physicians, such as the biochemist Rudolf Schoenheimer, who pioneered the use of isotopes for the study of metabolism, committed suicide a few years after their arrival.

Throughout the centuries, Jewish immigration resulted from persecution and discrimination. Their attempts to acculturate to the host countries shaped their religion, philosophy, and their traditional professions. Because Jews were often persecuted and not allowed to own land, they often gravitated to professions that emphasized knowledge such as medicine, rather than more manual professions. In more recent times, as the world gravitated toward the licensing of various professions, minorities, including Jews, have found that traditional professions do not provide them with the mobility they expect. In Russia, for example, Jews could not pursue medical professions due to ethnic quotas. As a result, many of them gravitated toward other professions such as mathematics. With the advent of software and hardware engineering, these immigrants were able move from one society or country to another with ease. In Israel, the largest Jewish community outside the USA, as many as one million immigrants arrived between 1989 and 2000 as anti-Semitic activities became rampant in the former Soviet Union. Many of these immigrants arrived with exceptional mathematical training. Their training, combined with the knowhow of European immigrants who established most of the higher education institutes in that country, invigorated the scientific and medical community. It introduced new ideas, particularly in the field of software engineering which together with Israeli risk taking behavior led to various technological breakthroughs and the formation of hundreds of medical startups, many of which were later moved to the USA or Europe.

K

Karma

ELIZABETH CHACKO
Department of Geography, The George Washington University, Washington, DC, USA

Karma is popularly understood as the law of cause and effect, whereby an individual's actions or deeds shape their past, present, and future life and afterlife experiences. Karma is associated with Eastern religions such as Hinduism, Buddhism, Jainism, and Sikhism, each of which has its own way of viewing it. The effects of karma can be: (1) visible and invisible outcomes that are brought about by one's actions and (2) tendencies to act, think, experience, or interpret experiences in ways that are conducive to one's happiness or unhappiness that are brought about in the person by his or her actions. Associated with the doctrine of karma is the notion that the soul is reincarnated in a new physical body after death and that the particular body, family, as well as social and economic circumstances into which the soul transmigrates after a person dies is determined by that person's deeds during his or her lifetime.

The belief that former acts (even in a past life) have produced present realities has led to a differentiation between good karma and evil karma. Good karma in a past life is understood to result in superior current personal attributes, quality of life, and living environments. Evil karma in a past incarnation on the other hand condemns a human being to a life of suffering and sorrow. Merit can however be earned by virtuous actions and through good and moral conduct. An individual may therefore accumulate enough merit to be born in superior circumstances in the next life while righteous human beings who have reached an enlightened state of consciousness attain liberation from the cycle of birth, death, and rebirth.

Today, the bulk of immigrants to the major receiving countries, such as the USA, Canada, and Australia, are from the less developed world. All have large numbers of immigrants from Asia. These immigrants vary enormously in their cultural and educational backgrounds, their prior exposure to Western cultures and norms, and in their ability to integrate and adjust to a new and often, alien culture. Culturally embedded meanings of disease can shape immigrants' attitudes, interpretations, and responses to illness and to preventive and curative care in the Western biomedical tradition. Although the doctrine of karma posits that individuals can change their lives and their experiences through their actions, some may attribute chronic illnesses and disabilities to destiny or actions in a past life. Those who came from rural areas, with little or no education and are used to traditional methods of healing (such as immigrants from Cambodia and Laos, who fled genocide and sought political asylum in host countries) are less likely to wholeheartedly embrace biomedicine. Disconnections between physicians trained in the biomedical tradition and immigrants who may use multiple healing strategies or attribute ill health to causes beyond those that are scientifically based may result in mistrust on both sides and barriers to good health.

A belief in karma may affect preventive health care and referrals. For example, studies of Cambodian immigrant women in the USA showed that their experiences of domestic violence were attributed to negative karmic actions in a previous life and that those who believed in karma were less likely to have ever been screened for cancer that those who did not. However, other investigations have determined that it is possible for persons who believe in the existence of house and ancestral spirits and the doctrine of karma to avail of and use Western biomedicine and health, provided it is delivered in a culturally sensitive and culturally appropriate manner. Therefore, an understanding of the

Sana Loue & Martha Sajatovic (eds.), *Encyclopedia of Immigrant Health*, DOI 10.1007/978-1-4419-5659-0,

cultural background of immigrants and their beliefs regarding the cause of ill health (including karma) and adjustment of health care and service delivery to incorporate the beliefs of immigrants who maintain strong home-country cultural values would allow for better treatment and care and better health.

Kennedy, Edward

Jennifer Durand
School of Public Health, University of Texas Health Science Center, Houston, TX, USA

Born in Brookline, Massachusetts on February 22, 1932, Edward Moore "Ted" Kennedy was the youngest of nine children of Rose Fitzgerald and Joseph P. Kennedy, Sr. His father, a multimillionaire businessman, held many important governmental posts, including serving as US ambassador to Britain. These positions afforded the family many travel opportunities. By 11 years old, Ted had enrolled in ten schools at different locales.

Joseph and Rose Kennedy emphasized the importance of healthy competition and success in their children's development. Rose, especially, enforced high levels of academic performance in her children. During dinner, the Kennedy children often were quizzed on history, politics, and literature, with lively discussions highly encouraged by the parents. Ted, however, preferred sports to academics. He was noted to be the family prankster and an extrovert who planned family trips and entertained guests.

Ted was the youngest brother of Senator Robert F. Kennedy and President John F. Kennedy, who were assassinated while serving in office; Joseph P. Kennedy, Jr., who was killed during World War II; sister Rosemary who was institutionalized following lobotomy surgery; and sister Kathleen who died in a plane crash over the French Alps. These incidents became known as "The Kennedy Curse." His other sisters were Eunice, Jean, and Patricia.

For most of his life, Ted grew up in Bronxville, New York, and attended private boarding schools. In 1946, Ted attended a college prep boarding school, Milton Academy, near Boston. At Milton, Ted was heavily involved in sports, debate, drama, and the glee club. After graduating in 1950, he followed his brothers to Harvard University.

Kennedy left Harvard and enlisted for a two-year stint in the Army, where he served as a guard at the Supreme Headquarters Allied Command in Paris, France. He resumed his studies at Harvard and completed his degree. After graduation, he studied for a brief period at the Academy of International Law in the Netherlands and then entered Virginia Law School, where he received his law degree in 1959.

While studying at the University of Virginia, he met and married Virginia Joan Bennett in 1958. The couple had three children, Kara, Edward Jr., and Patrick.

Kennedy campaigned for his brother John in the 1960 presidential race. In 1962, at the age of 30, Ted was elected to John F. Kennedy's former US Senate seat in a special election. He was elected to a full six-year term in 1964, and was reelected seven more times throughout his career.

During his time in office, he advocated for voting rights, education, volunteerism, immigration reform, increasing minimum wage, the nation's first major legislation to combat AIDS, and equality for minorities, women, the disabled, and gay Americans. He also supported mental health benefits, cancer research, and children's health insurance. Kennedy and his staff wrote more than 300 bills that were enacted into law. Kennedy sponsored legislation on immigration reform, criminal code reform, fair housing, public education, health care, AIDS research, and a variety of programs to aid the poor. On the Senate Judiciary Committee, he upheld liberal positions on abortion and capital punishment.

As a Senator, Kennedy became known for his oration skills. Among his best-known speeches were his 1968 eulogy for his brother Robert and the 1980 rallying cry for modern American liberalism. Kennedy also was known for his bipartisan friendships with conservative Republicans, while maintaining his liberal roots. Ted supported governmental intervention that encouraged social justice, as well as finding compromises with Republicans where dissimilar views existed. For example, he partnered with Senators Nancy Kassebaum and John McCain to cosponsor legislation on worker's healthcare benefits, immigration, and funding for traumatic brain injuries.

Kennedy faced many troubles in his personal life. Accusations of philandering and alcohol abuse existed throughout his time in office. And, in 1982, after 24 years of marriage, he and wife Joan Bennett Kennedy divorced. Later, in 1992, he married Washington, D.C. lawyer, Victoria Reggie, a woman to whom he credits his alcohol abuse recovery. He had two stepchildren from that union, Grier and Caroline Raclin.

In May 2008, Kennedy was diagnosed with a malignant brain tumor and, on August 25, 2009, he passed away at his home in Hyannis Port, Massachusetts. When he died, he was the second most senior member of the Senate and the third longest-serving senator in US history, known as "The Lion of the Senate" as a result of his 47-year long tenure influence in Congress.

Kennedy, John Fitzgerald

Tambra K. Cain
Barrett, Twomey, Broom, Hughes & Hoke, LLP,
Carbondale, IL, USA

John Fitzgerald Kennedy, born in Brookline, Massachusetts, on May 29, 1917, was the 35th president of the United States. Early in his life, John F. Kennedy attended Harvard, graduating in 1940. He then served in U.S. Navy in the South Pacific during World War II, as a Patrol Torpedo "PT" boat commander. While serving in the Navy, John F. Kennedy was awarded the Navy and Marine Corps Medal, the Purple Heart, the American Defense Service Medal, the American Campaign Medal, the Asiatic-Pacific Campaign Medal with two bronze service stars, and the World War II Victory Medal. On September 12, 1953, Jacqueline Bouvier became Mrs. John F. Kennedy. President and Mrs. Kennedy had three children, namely, Caroline Bouvier Kennedy, born in 1957; John F. Kennedy, Jr., born in 1960; and Patrick Bouvier Kennedy, born in 1963 and died in his infancy.

John F. Kennedy served in the U.S. House of Representatives from 1947 to 1953 and served in the U.S. Senate from 1953 until 1960. Then, at the age of 43, he was the youngest person elected to U. S. Presidency. The quote, “ask not what your country can do for you – ask what you can do for your country,” is a widely known quote from his inaugural address.

As President, he had many “firsts.” He was the first Catholic president as well as the first Irish American president. John F. Kennedy also is the only president to have won a Pulitzer Prize; he was awarded the 1957 Pulitzer Prize in Biography for his book “Profiles in Courage,” a book about U.S. Senators who fought for what they believed, and in doing so had had risked their careers. Kennedy also wrote “Why England Slept” in 1940, and an essay for the Anti-Defamation League, entitled “A Nation of Immigrants,” which was published in book form after his death. Further, he published an article, “The Soft American,” in the December 26, 1960 edition of Sports Illustrated.

During his presidency, John F. Kennedy addressed many difficult issues, such as the nuclear weapons situation, war, racial segregation and discrimination, immigration, and the physical fitness of the nation’s population. For example, Kennedy developed the White House Committee on Health and Fitness, which was supervised by the Department of Health, Education, and Welfare. He also instituted an annual youth fitness conference. His appointment of African-Americans to key administrative posts, such as Administrator of the Housing and Home Finance Agency, Associate White House Press Secretary, and Deputy Assistant Secretary of State for Public Affairs was groundbreaking.

The relationship between the United States and Cuba was an ongoing issue for the Kennedy Administration. Even though it was planned by the Eisenhower Administration, Kennedy ordered an invasion of Cuba to overthrow Fidel Castro in what would later be called the Bay of Pigs invasion. On April 17, 1961, some 1,500 U.S. trained Cuban exiles entered Cuba. However, the invasion failed and resulted in the survivors being released in return for U.S. medical aid and food. The U.S.–Cuba relationship would forever be tainted.

In October 1962, U.S. military intelligence learned that nuclear missile sites were being built in Cuba by the Soviet Union. The political tension between the United States and the Soviet Union, as well as the threat of nuclear war, created a “Cold War,” where communications between these two nations were frozen. Cuba’s close proximity to the United States caused John F. Kennedy to be concerned about the growing nuclear armament in Cuba. To prevent the Soviet Union from continuing to supply the missile sites, Kennedy put a naval blockade around Cuba. For a week, the United States and the Soviets teetered on the brink of nuclear war. However, the situation was ultimately defused. The Soviets agreed to dismantle the weapon sites and the United States agreed not to invade Cuba. On August 5, 1963, the Nuclear Test Ban Treaty was signed in Moscow, and on October 7, 1963, John F. Kennedy signed the ratified Treaty.

Vietnam also was a focus of Kennedy’s administration. During his time as President, he increased the number of U.S. military in Vietnam from 800 to 16,300. Even though there was no conclusive proof, it was generally believed that Kennedy planned to decrease the number of U.S. military personnel in Vietnam by the end of 1963, and eventually withdraw totally. The systematized declassification of certain governmental documents in the 1990 does tend to support this view. Additionally, at a press conference on November 12, 1963, Kennedy stated that his plans were “to bring Americans out of there.”

After Kennedy’s death, his successor, Lyndon B. Johnson, soon issued orders to reverse John F. Kennedy’s previously announced reduction plans. On August 2, 1964, in what is now known as the Gulf of Tonkin Incident, the USSS Maddox was engaged by the North Vietnamese in a naval battle. This was the catalyst that led to the Gulf of Tonkin Resolution, which gave the President the exclusive right to use military force without consulting the Senate. Johnson used this authority to begin America’s direct involvement in the ground war in Vietnam.

Civil Rights and women’s equality were topics for discussion in America during the early 1960s, and President Kennedy’s involvement led to greater freedoms for all Americans. He proposed what would become the Civil Rights Act of 1964. John F. Kennedy was instrumental in orchestrating the release of Martin Luther King from jail. He also provided Federal support for the integration of the University of Mississippi in 1962 and the integration of the University of Alabama in 1963. Also, in 1961, Kennedy signed an executive order to create the Presidential Commission on the Status of Women, whose report detailing the discrimination of women was issued in October 1963.

Though not as well-known as some of his other achievements, John F. Kennedy began the reformation of the nation's immigration policy. His efforts would later be the foundation for the Immigration and Nationality Act of 1965, which was sponsored by Senator Edward Kennedy, Kennedy's brother. He told congress that "no naturalized citizen will suffer discrimination because of legal disabilities" and asserted that "there is no place for second-class citizenship in America."

He also addressed economic and social progress issues at home and globally. For example, Kennedy created the Peace Corps by executive order in 1961, a program in which Americans volunteer to help underdeveloped nations in such areas as education, farming, and health care. Kennedy also expanded the U.S. space program. During John F. Kennedy's administration, Alan Shepard and Gus Grissom became the first two Americans to travel into space and John Glenn Jr. became the first American to orbit Earth.

Unfortunately, Kennedy's vision for America was cut short in Dallas, Texas on Friday, November 22, 1963, when, at the age of 46, John F. Kennedy was assassinated by Lee Harvey Oswald while riding in a motorcade with his wife, Jacqueline. On November 25, 1963, John F. Kennedy was buried in Arlington National Cemetery, Arlington, Virginia.

Korea

Tambra K. Cain
Barrett, Twomey, Broom, Hughes & Hoke, LLP,
Carbondale, IL, USA

History

The Republic of Korea (ROK), otherwise known as South Korea, is located on the southern half of the Korean Peninsula. It is called the *Land of the Morning Calm*. To the north lies North Korea, officially named the Democratic People's Republic of Korea (DPRK). South Korea is bordered by China to the northwest, Russia to the northeast, and it is separated from Japan to the east by the Korea Strait.

Korea was annexed to Japan in 1910 and was operated as a Japanese Colony until 1945, when the end of World War II brought about the end of the Japanese rule of the Korean people. At that time, the United States agreed to assist Korea by setting up a provisional government, with the goal of free and independent government. The Soviet Union also wanted to assist Korea to set up a provisional government, leaning toward communism. Though each side had differing political goals, the intention was to establish one unified Korea. However, due to the tensions between the United States and the Soviet Union, as well as the escalation of the Cold War, neither country wanted to abandon their efforts. The United States and the Soviet Union agreed to use the 38th Parallel as a demarcation zone – the United States would continue to provide assistance to the portion of Korea south of that line, and the Soviet Union to the north. During the Korean War, the 38th Parallel became a demilitarized zone, and is now commonly referred to as the DMZ.

On June 25, 1950, North Korea invaded South Korea, which led to the Korean War. From 1950 to 1953, the Korean War further divided the Korean people. Eventually, the DMZ became the separation between what is now the Republic of Korea, that being South Korea, and the Democratic People's Republic of Korea, that being North Korea. South Korea is a democratic state, while North Korea is a communist state. On July 27, 1953, at Panmunjom, a village on the DMZ, an armistice was reached. Even though a cease fire was agreed to, no formal peace treaty was ever signed; and therefore, the two Koreas are still technically at war.

In 1953, the United States and South Korea entered into the Mutual Defense Treaty, which resulted in the United States agreeing to help South Korea defend itself against external aggression. Since then, the US Military has maintained a sizable force located throughout South Korea. Since 2004, the United States has been reducing its forces on the Korean Peninsula; and in 2008, the United States and South Korea agreed to place a cap of no more than 28,500 US soldiers stationed in Korea. The relationship between the United States and South Korea remains strong. The United States maintains an embassy in South Korea located in Seoul, and South Korea maintains an embassy in the United States in Washington, D.C.

Population and Culture

As of 2009, South Korea has a total population of approximately 50 million, with around 1,106,884 foreign residents. South Korea's capital is Seoul, which has approximately 9.8 million inhabitants. The Seoul metropolitan area is the world's second largest populated metropolitan area. Other South Korean cities include Busan, with a population of 3.5 million; Incheon, with a population of 2.5 million; Daegu, with a population of 2.5 million; Daejeon, with a population of 1.4 million; and Gwangju, with a population of 1.4 million.

Over half of South Koreans have no religious affiliation. Of those that claim a preference, Christianity is the most common, with Buddhism being a close second. Also represented, but to a much lesser degree, are Confucianism, Korean shamanism, Taoism, and Islam.

Both traditional sports and western sports are commonly played and viewed in South Korea. Some traditional Korean sports are Korean wrestling, much like Sumo wrestling, bull fighting, and Taekwondo. Some popular imported sports are soccer, called football, golf, and baseball. Seoul was host to the 1988 Summer Olympics. Korea cohosted the 2002 World Cup Soccer Tournament with Japan.

The Cuisine of South Korea is comprised mostly of rice, noodles, tofu, vegetables, fish, and meats. Perhaps one of Korea's most widely known dishes is *Kimchi*. *Kimchi* is a fermented, usually spicy, vegetable dish that is commonly served at every meal. Typically, a Korean meal is accented with several side dishes, called "banchan." Many varieties of street food can be purchased, usually from vender's carts. One such food is "kimbap," which is made from steamed white rice and a variety of other ingredients, rolled in dried seaweed. Kimbap is similar to Japanese sushi. Another popular street food is "Ho-tteok," a Korean pancake with a sweet filling. "Bulgogi" is a popular Korean dish that usually consists of marinated beef, or sometimes chicken. Typically, Korean cuisine is eaten with "sujeo," a set of eating utensils that includes a spoon and chopsticks.

Economy and Government

Some of the economic areas in which South Korea excels in are electronics, automobile manufacturing, and robotics.

In 1991, South Korea joined the United Nations. South Korea is also a member of the World Trade Organization and the Organization for Economic Cooperation and Development (OECD). In June 2007, the United States and South Korea entered into the US-Korea Free Trade Agreement, having an active economic trade relationship with the United States.

The South Korean governmental design is set forth in the Constitution of the Republic of Korea, which was enacted in 1948. South Korea's government has three branches – the Executive, the Legislative, and the Judicial. The Executive branch is lead by the president, which serves one 5-year term, no additional terms being permitted. The Legislative branch is made up of the National Assembly of South Korea, which is a single large assembly with 299 members. The National Judicial branch is composed of the Constitutional Court, which has nine justices. The Constitutional Court deals with constitutional matters and with impeachments. Other judicial matters are overseen by the Supreme Court, which has 14 justices.

Citizenship, Immigration, and Emigration

South Korea's immigration policy is administered by the Korean Immigration Service which is a part of the Korean Ministry of Justice. Those Koreans who are natural born citizens are: those who, at the time of their birth, had at least one Korean parent who was a citizen, provided that if the Korean parent died before the child's birth, then the person is eligible for citizenship only if the Korean parent had maintained her/his Korean nationality at the time of their birth; or those born in South Korea, whose parents' citizenship was nonexistent or unclear; or abandoned children found in South Korea.

In order to become a naturalized Korean citizen, a person must: be domiciled in South Korea for a period of more than five consecutive years; be an adult according to Korean law; have good conduct; have the ability to financially support himself or herself or be a dependant of such a person; and have the basic knowledge befitting a Korean citizen, including the Korean language, culture, and customs.

To apply for permanent residency, a person must meet one of the following qualifications: be an adult by Korea's civil law and have stayed in Korea with resident status for more than 5 years, and have the financial capacity to support themselves and their family, have qualities such as being well-behaved and understanding Korean traditions; be a person who has invested more than 500,000 US dollars in Korea and have stayed in Korea with corporate investor status for more than 3 years, while contributing to creating employment opportunities for Korean nationals; be a person who has invested more than 5,000,000 US dollars in Korea and whose acquisition of Permanent Residency is deemed proper by the Justice Minister; be a person who has made special contributions to Korea that are recognized by the Justice Minister.

South Korea has a sizable emigration rate. There are approximately 2.4 million Koreans residing in China, approximately 2.1 million in the United States, approximately 600,000 residing in Japan, and approximately 534,000 residing in the countries of the former Soviet Union.

Kwashiorkor

Stefani Parrisbalogun
Department of Psychiatry, University Hospitals Case Medical Center, Cleveland, OH, USA

The word kwashiorkor, originally introduced in 1935, comes from the Ga language of Ghana of West Africa. It can be translated as "disease or sickness of the displaced child." Kwashiorkor is a type of malnutrition that was commonly seen in older infants or young children after quickly weaning from breastfeeding, usually as a result of another child or pregnancy.

Severe protein and essential amino acid deprivation coupled with sufficient caloric intake can lead to kwashiorkor malnutrition at the time of weaning to a high-carbohydrate, low-protein diet. Superimposed bacterial, parasitic, or viral infection can exacerbate kwashiorkor malnutrition. This form of protein deficiency is more often seen in children in less developed countries with inadequate food supplies due to socioeconomic, political, religious, educational, sanitation, and environmental factors. In the USA, kwashiorkor malnutrition can also be seen in the chronically ill or elderly. Kwashiorkor malnutrition is also called protein malnutrition or protein-energy malnutrition and is considered a severe form of childhood undernutrition or macronutrient deficiency associated with increased morbidity as well as mortality.

Historically, the most severe forms of malnutrition are marasmus and kwashiorkor. Traditionally, kwashiorkor was distinguished from marasmus malnutrition by the presence of edema, lack of wasting, and sufficient caloric intake in an older infant or toddler. However, these disorders are now thought to exist on a spectrum of malnutrition with overlapping features, similar pathophysiological mechanisms, and underlying causes.

Kwashiorkor malnutrition can be primary or secondary. Primary kwashiorkor malnutrition is mainly due to poverty and is impacted heavily by season and climate conditions, cultural and religious food customs, breastfeeding habits and maternal nutrition, prevalence of infectious diseases and vaccination, the existence and effectiveness of nutrition educational programs and the availability and quality of healthcare services. When etiologies of secondary malnutrition are investigated, causes are usually due to chronic illness, for instance, cystic fibrosis, renal failure, congenital heart disease, neuromuscular disease, HIV/AIDS, failure to thrive, chronic diarrhea syndromes, malignancies, bone marrow transplantation, inborn errors of metabolism, and burns.

The pathogenesis of kwashiorkor is not completely understood, but it is likely a maladaptive response to the physiologic stress of an infection that induces a pro-inflammatory metabolic cascade in a chronically malnourished individual. In this way, kwashiorkor can be thought of as an acute illness or injury. This form of malnutrition affects most organ systems of the body, including the endocrine, immune, gastrointestinal, respiratory, neurologic, dermatologic, and hematologic systems. Specifically, endocrine manifestations of kwashiorkor malnutrition are decreased plasma insulin concentrations, decreased glucose intolerance, increased plasma cortisol concentration, increased growth hormone, decreased serum albumin, decreased levels of thyroxine, and decrease plasma leptin concentration. Cellular immunity is depressed and ventilatory response to hypoxia (low oxygen levels) is impaired. Intestinal malabsorption and pancreatic insufficiency are also commonly seen. There is an overall reduction in brain size and cerebral cortex atrophy, resulting in neurodevelopmental delays in global brain function, motor function, and memory which may not be reversible.

Distinct clinical features have been associated with kwashiorkor malnutrition such as: normal weight for age, marked generalized edema, dermatoses, hypopigmented hair, distended abdomen, decreased muscle mass, hypotonia, hyporeflexia, immune system depression, hypothermia, cardiac arrhythmias, hepatomegaly (liver enlargement), and cardiomegaly due to fatty infiltration. The abdomen is distended due to loss of abdominal muscle mass, intestinal distention from malabsorption, and hepatomegaly due to fatty infiltration. Hair is usually dry, brittle, sparse, and depigmented, appearing reddish yellow. Hair changes may demonstrate the “flag sign” with alternating bands of pale and normal color, indicating periods of poor and good nutrition. Cutaneous manifestations are characteristic and progressive. Depending on baseline skin pigmentation, children can have dry atrophic skin with hyperkeratosis and hyperpigmentation. Eventually, these skin lesions erode, resulting in hypopigmented erythematous skin. Sun-exposed skin is relatively spared, as are the feet and dorsal aspects of the hands. Nails are thin and soft.

Children with kwashiorkor malnutrition exhibit psychiatric symptoms such as lethargy and apathy when left alone, with increased irritability with physical contact. Other constellations of psychiatric symptoms may be more attributable to specific vitamin deficiencies rather than kwashiorkor malnutrition. Laboratory evaluation can reveal typical results such as anemia, hypoglycemia, intravascular volume depletion hyponatremia, hypokalemia, hypomagnesia, metabolic acidosis or alkalosis, low total protein, low album, or low pre-albumin, elevated creatinine, and elevated c-reactive protein. The serum zinc level is often low and, in some cases, skin lesions of kwashiorkor exhibit improved healing when zinc is applied topically.

Treatment of kwashiorkor malnutrition is based largely on the World Health Organization recommendations for managing severe malnutrition with important attention paid to treating underlying infections, treating dehydration, enhancing gastrointestinal tract recovery, and managing cardiac sequelae. Depending on the severity of the malnutrition, treatment can be initiated on an outpatient or inpatient basis with more symptomatic clinical presentations warranting higher level of care. A potential complication of treating malnutrition in general is the "refeeding syndrome" with decreased serum levels of potassium, phosphate, glucose, and magnesium. For this reason, small continuous meals or continuous nasogastric feeding should be done along with various vitamin supplementations such as thiamine to avoid encephalopathy. Nutritional rehabilitation, follow-up, and reoccurrence prevention are also important components of treating malnutrition after initial management strategies as described above have been undertaken.

Labor Migration

Domniţa Oana Bădărău
Department of Bioethics, Case Western Reserve
University School of Medicine, Cleveland, OH, USA

Economic development relies on many factors: social, political, access to resources, trade, and labor. A key element that produced a shift in the old economic models is globalization, a process that has particularly important consequences for migration and human capital circulation. Labor migration influences the origin countries as well as the receiving ones and raises many issues regarding the labor market and the economic structure of the sending and host countries. In analyzing the effects of labor migration, positive and negative effects have to be taken into consideration. The remittances that reach the country of origin influence the economic structures, creating a dependency and development model that is not sustainable.

Labor Migration a Result of Globalization

Changes brought by globalization in the international economy generate challenges in the employment market. As international labor migration has been growing constantly for the last decades, many issues emerged in relation to the integration of workers in the host labor market. This has repercussions for the social and economic development aspects of that country and on employment relations. Migrants seek to improve their economic situation and this leads them to immigrate to developed countries that offer a higher income perspective. The workforce void in the originating country is compensated by the inflow of remittances sent by migrants, which has a significant impact on the regional development of the economy.

From a neoclassical theory perspective, economics globalization stimulates free trade and productivity fosters mobility, especially capital, and this generates a decrease of migration as the labor force is integrated in a sound and prosperous labor market. Moreover, implementing trade agreements that set a framework for the liberalization of trade between countries and free capital movements, at an international, regional, or bilateral level, should have as a result a significant low migration phenomenon. Agreements such as NAFTA, Mercosur, and all the World Trade Organization's policies facilitate international economic relations and trade. However, it seems that all these measures affect the labor migration differently than expected. The workforce movements are more frequent and this reflects on the income between the origin countries and the hosts. Instead of improving wage differentials between the countries, the commercial liberalization maintains or even increases the difference. Even so, international labor migration is a complex phenomenon and income levels or investments in the origin country fail to explain all the effects that foreign workforce has on economies.

As a manifestation of the globalization process, labor migration produces economic, political, and cultural changes in the societies of the sending and receiving states. Globalization brings the integration of international markets for capital, services, goods, and workforce. Of these, workforce is significantly restricted by existing immigration laws and state policies that enforce nationalism and promote protectionism in order to secure jobs for their citizens. Nevertheless, globalization opens frontiers and facilitates the cross border movement, having the effect of a catalyst. Advances in communication technologies and access to information make it easier for labor markets to interact.

Irregular Migration

Migrants' status in the receiving country varies depending on the lawful basis of their settling in another

Sana Loue & Martha Sajatovic (eds.), *Encyclopedia of Immigrant Health*, DOI 10.1007/978-1-4419-5659-0,

state. Terms like clandestine, illegal or undocumented are used to describe the migratory behavior and the act of entering a country in violation of the immigration laws of that territory. Irregular migration is a more accepted term, as the use of *illegal migration* suggests only negative consequences and overrides the migrants' contribution to the development of the receiving state.

Labor migrants actively engage in the economy of the host country. Often, their entry into the underground labor market is made possible due to the employer's commission of illegal acts. Employers may exploit individuals' irregular status in the country. Labor migration victims could suffer wage discrimination and be denied the right to work in a safe environment. In addition, when an individual becomes an irregular labor migrant as a result of a recruiting process, he is not solely to blame for breaching immigration laws. Moreover, his status may be a result of deception and monetary inducement and the developing countries' labor force is more likely to become a victim of such techniques. In this case, recruiting agents and intermediaries also commit illegal acts and are not less culpable than the migrants are. They receive monetary compensation for facilitating access into a country or as a liaison between employers and the migrants.

The labor migration phenomenon should not be approached only from a negative perspective, as it offers advantages and creates disadvantages for all the parts involved: the country of origin, the receiving country, and the worker himself or herself. Labor migration should not be viewed only as a criminal phenomenon. Migrants are easily abused as long as they are the subjects of an illegal status, not entitled to that state's protection.

The Phenomenon of Labor Migration Reflected in International Documents

One of the most representative organizations that address the status of migrant workers is the International Labor Organization in Geneva. The ILO's 1949 Convention on Migration for Employment defined the labor migrant as a person who leaves a country to seek employment in another one. The Convention stated that the migrant for employment does not include frontier workers or persons who exercise their profession in another country for a short period of time.

In 1990, the United Nations Convention on the Protection of all Migrant Workers and their families extends the definition and clarifies some aspects of the labor migration phenomenon. According to the UN, the migrant worker is any person who will be, is, or was previously employed in an activity for which he received remuneration. The Convention text clearly specifies that such a worker cannot be a national of the state that offered the employment opportunity. A major distinction from the ILO's document is that it includes in this category individuals who are currently unemployed.

In the context of globalization and the advances made in transportation, mobility has increased significantly, thus creating complex situations regarding migrants. Individuals travel not only for employment, but also for pleasure, for education, or because they feel forced to do so by extraordinary situations in their country (civil conflicts, wars, persecution). Making the distinction between all these categories of migrants is important in establishing their legal status and for analyzing the socioeconomical implications.

International organizations, and the UN in particular, pay special attention to the migration process and promote human rights in dealing with migrants. In this context, it is important to make the distinction between labor migration and any other type of migration. Labor migration is part of the migration process and migrant workers are only responsible for a part of the movement flows that take place internationally. The term "migrant" is general and does not separate voluntary migrants from the forced ones. The latter can be easily identified as an individual that faces some kind of coercion, without which he or she will not have moved across the state's borders.

The complex situations that appear at an international level concerning migrants and their status underscore the need for a clearer definition and being precise when making the difference between voluntary and forced migration. Therefore, the 2000 United Nations *World Migration Report* states that a voluntary migrant travels across borders motivated by a personal need/factor: employment, studies, joining relatives. Forced migrants cannot control the cause that pushes them to make the decision to settle in another country, as it is extrinsic. In most cases, forced migrants flee from conflict areas, for political reasons (persecution) or any other situation that arises and represents a threat to their physical and mental well-being.

Labor migrants are also called economic migrants and are easily associated with voluntary migrants. Within the labor migrants there is a distinction based on the nature of the work performed or the worker's skills. A correct distinction is between highly skilled workers and unskilled workers. In developed countries, there are segments of the labor market that became unattractive for the local population and which migrant workers are more inclined to accept. Unskilled labor specifically reflects this kind of work and includes the migrants that take it. Highly skilled workers, on the other hand, are professionals who often seek better pay and working conditions than they are able to secure in their home countries.

The distinction between these two groups is relevant for the social and economic consequences that their presence brings in the receiving countries. They adapt differently and have a substantially distinct effect on the labor market. Unskilled migrant workers are more likely to face rejection and social discrimination than the highly skilled ones.

Labor Unions

C. Eduardo Siqueira
Department of Community Health and Sustainability, School of Health and Environment, University of Massachusetts Lowell, Lowell, MA, USA

Historical Aspects

Immigrant workers have contributed a great deal to the formation and development of labor unions in the United States for over 100 years. Important achievements of the labor movement, such as the 8-h workday, were the result of European immigrants' struggles for better working and living conditions. The famous Bread and Roses 10-week strike in Lawrence, Massachusetts, in 1912, exemplifies the participation and solidarity of immigrant families to fight mill owners' cut in pay to compensate for a state law that reduced the work week for women and children from 56 to 54 h. The Industrial Workers of the World, also known as IWW or Wobblies, organized the strike of 25,000 foreign-born, unskilled textile workers from dozens of different ethnicities.

The history of the relationship between unions and immigrants throughout the twentieth century is marked by racial and ethnic conflict and intense debates among union leaders about immigrant workers' right to preserve their own cultures while becoming Americans. While European immigrants were welcomed in unions, immigrants from Asia and South America were excluded from joining unions for decades. Jewish workers originally from Russia had a strong role in organizing universalistic industrial unions that overcame ethnic divisions fomented by employers to weaken solidarity between rank-and-file immigrant manufacturing workers. The creation of the Amalgamated Clothing Workers of America, led by Sidney Hillman, a founding father of the "Jewish labor movement," illustrates this legacy. The American Federation of Labor (AFL) had a long history of craft-based unionism, coupled with nativism and bigotry against non-European immigrants, while the Congress of Industrial Unions adopted in the 1930s an inclusive industrial union model that organized workers from all skills and trades into one single union. The merged AFL-CIO adopted a more pro-immigrant stance, especially after the Civil Rights movement of the 1960s. This position can be seen, for example, when the AFL-CIO joined Cesar Chavez in organizing immigrant Mexican farm worker strikes and grape boycotts in California, which resulted in the creation of the United Farm Workers (UFW).

Yet, in 1985, the AFL-CIO supported the Immigration Reform and Control Act (IRCA), which established sanctions for employers who knowingly hire undocumented workers and made it illegal for immigrants to work without legal documents. While this reform enabled millions of new immigrants to obtain documents and become American citizens, its enforcement created new problems because of discrimination against employees who appeared to be foreign-born and selective enforcement of immigration laws against workers who complained of labor standard violations. It became clear to union leaders in the mid - to late 1990s that employer sanctions regulations did not reduce unauthorized immigration to the United States. Thus, The AFL-CIO reversed its nativist position in the late 1990s by supporting immigrant amnesty, enforcement of labor laws, and immigrant family reunification. This new policy followed the universalistic tradition of the IWW and Jewish labor.

The 9/11 attacks in New York City brought about significant changes in immigration enforcement policy by government officials, who now operate in a political environment that accepts the criminalization of undocumented workers under the banner of considering them as potential threats to national security. Reform of immigration laws to provide a legal path to citizenship, labor protections, family reunification, and improved civil rights lost momentum and was downplayed in Congress in the last decade. Instead, unions that represent large numbers of immigrants, such as the United Food and Commercial Workers (UFCW) and UFW, have had to fight against raids, deportations, and persecution of their immigrant members throughout the country.

Despite the recent anti-immigrant climate, the demand for cheap immigrant labor in the meatpacking, poultry, agricultural, health care, construction, and hospitality industries, among others, remains strong though weaker given the economic recession of the last few years. This demand is actually structural to the U.S economy and can be explained by the restructuring that occurred after the 1970s, when decline of manufacturing and the rise of the service sector developed. Restructuring of manufacturing led to downsizing, contracting out, "lean and mean," and just-in-time production, coupled with deregulation of workplace rights and weak enforcement of labor laws. The expansion of service sector created low-wage, low-benefits, and contingent jobs in the informal economy, characterized by pay in cash and work under-the-table and off-the-books. This change in labor markets can be clearly seen in major U.S. metropolises, such as Los Angeles and New York, where manufacturing jobs were replaced by service sector jobs held by immigrant workers from Asia, Latin America, Eastern Europe, and Africa.

Immigrant Union Membership

There were 1.8 foreign-born members of unions in 2003, which represented about 10% of all foreign-born employed wage and salaried workers in the United States, i.e., one in ten foreign-born employed wage and salaried workers belonged to a union. In addition, another 202,000 were covered by a union or employee association contract. The number of immigrant workers with union representation increased from 1.6 million in 1996 to 2 million in 2003. The proportion of foreign-born wage and salaried employed workers who were union members decreased from 12% in 1996 to 10% in 2003. Therefore, there has been a trend of increase in absolute numbers but decrease in relative numbers for immigrant union membership, similar to what is happening with native workers. However, the percentage of all union members who are foreign-born increased from 9% in 1996 to over 11% in 2003, and the percentage of immigrants amongst all workers with

Source notes:

The data are from the Current Population Survey, 1996–2003 (annual averages). Note the data series from 1996 to 2002 were weighted with population controls based on the 1990 census. By comparison, the 2003 data were weighted with population controls based on the 2000 census. This means that the 2003 data are not consistent with earlier CPS data series, and any conclusions about trends through time must be made carefully

[a] Data refer to members of a labor union or an employee association similar to a union

[b] Data refer to members of a labor union or an employee association similar to a union as well as workers who report no union affiliation but whose jobs are covered by a union or an employee association contract

union representation increased from 9% in 1996 to 11% in 2003 (Table 1).

The contribution of immigrants to the growth of unions has been particularly recognized by the Change to Win Coalition (CTW), which is composed of a group of five unions – representing 5.5 million members – which left the AFL-CIO in 2005. These unions are the United Food and Commercial Workers International Union, the United Farm Workers of America, the Service Employees International Union (SEIU), the Laborers' International Union of North America (LIUNA), and the International Brotherhood of Teamsters (IBT). In 2005, the CTW adopted a resolution about principles to organize new members that stated: "our movement must empower and unite today's diverse workforce, including millions of people of color, immigrant workers, and working women."

Unions protect the workplace health and safety of unionized immigrant workers by negotiating collective bargaining agreements that usually provide better wages, working conditions, and benefits, including health care, eye and dental insurance coverage, paid vacations, maternity leave, legal advice and representation, pensions, among others. According to Mishel and Waters, unions raise wages of unionized workers by about 20% and compensation, including wages and benefits, by 28%. In addition, unions reduce wage inequality, set a pay standard for nonunion members, improve fringe benefits – including an 18–28% higher likelihood for unionized workers to have employer-based and a 23–54% higher likelihood to be in employer-provided pension plans. In a word, unions may be a fundamental resource for immigrant workers and their families to maintain and improve their health through workplace rules and practices that protect basic human rights values, such as equality, justice, and democracy.

Unions also play an important role in advocating for and voicing the concerns of immigrant workers regarding job health and safety protections. Most workplace health and safety regulations adopted by OSHA were either proposed or strongly supported by labor leaders. Examples are the workers' right to know about the properties of chemicals used in the workplace, the requirement that employers provide adequate training about any number of workplace hazards, the language of the Occupational Safety and Health Act mandating that employers provide every worker a healthy and safe workplace, as well as the duty of employers to allow OSHA inspectors to talk to workers without management interference.

On the other hand, immigrant workers have also had to organize themselves in different economic sectors with labor union help, without help, or sometimes with opposition from organized labor. They created community-based grassroots organizations known as worker centers to defend low-wage workers' rights and fight for justice in the workplace. There are dozens of such organizations across the country, which tend to be geographically concentrated in large urban centers. For example, the Mexican American Worker Association (AMAT) organized grocery store workers in New York City, the Coalition for Humane Immigrant Rights of Los Angeles (CHIRLA) organized Mexican and Central American day laborers in Los Angeles, and the Chicago Interfaith Workers Right Center organized Mexican, Central, and South American workers. The dozens of existing worker centers led successful campaigns similar to union campaigns and proved that undocumented immigrant workers are not less inclined to join unions than native workers. Their advocacy, service delivery, and organizing approaches contributed to address the needs of a diverse ethnic/racial population that did not belong to unions.

The worker centers have some common defining features: they combine service delivery, organizing, and advocacy; operate at the metropolitan, city or neighborhood level; provide services that range from English for Speakers of Other Language (ESOL) classes to legal clinics that educate and file cases against labor violations; develop leadership training programs to empower workers to take action. As a result of these activities, the centers gave voice to a substantial group of immigrant workers who would otherwise have no mechanisms to redress their grievances. In addition, worker centers established alliances with churches, community groups at the local, regional and international levels, foundations, governments, and progressive employers to produce reports and exposés about working conditions in particular industries, e.g., the construction, restaurant, and garment industries.

These organizations have become important instruments for the new working class to build class, racial, ethnic, and religious solidarity, which are essential prerequisites for immigrants to hope for social mobility and feel integrated into the in the U.S. society, as was the case with previous waves of immigrants in the late nineteenth–early twentieth centuries.

Language

Jaina Amin
Department of Psychiatry, University Hospitals Case Medical Center, Cleveland, OH, USA

Communication is vital to get by in this world. There are many forms of communication all with the goal of having one's needs addressed. Some forms include sign language, written communication, sounds, and words. This section will be focusing on spoken communication. Languages have been studied to assess if they are inherent in children or learned from the environment, and at what age learning another language becomes more difficult.

Most experts in language development acknowledge that children learn their first words near their first birthday, are at two word sentences by their second birthday, and by the age of 5 or so, have completed their linguistic development. Shore proposed that children develop languages differently accounting for the differing developmental schedules that children have. Two differing schools of thought described by Shore were empiricism and nativism. Empiricism emphasizes the role of the child's environment; the child will imitate the parents' speech and will respond to corrections by the parents, thus developing proper language. The other school of thought is nativism, which proposes that children are born with a "language acquisition device." Nativists state that children are born with the rules to speak any language but by hearing a specific language, then that specific set of rules get activated and utilized.

In looking at gender differences and the acquisition of language, small research samples showed girls having a more referential style, and boys having a more expressive style. Referential language acquisition is described as single words, often nouns, giving way to multiword combinations and eventually sentences. In distinction, expressive style is described as the use of phrases that have a more personal-social context. These differences are really seen in the early years before 3 years of age, but may be seen later in life as the child's preference in communication. Shore also noted that when birth order of children is looked at the oldest child tends to have a more referential style, that is, single words progressing to multiword sentences; whereas, the younger child in the family has a more expressive style, that is, the use of phrases heard in the environment. It is unclear if the differences are due to the fact that parents will spend more time with the first-born teaching words, and this attitude may be more relaxed with the second child.

Socioeconomic classes are also examined to see if there are different language acquisition styles. Middle-class mothers tend to be more verbally responsive to their children, and have higher linguistic expectations of the children than did the lower socioeconomic mothers. However, this could not fully account for the range of language acquisition in children of the same socioeconomic class. Another interesting finding was that children of parents with higher education tended to have a more referential style. And referential children tended to play more with books, records, and manipulatable toys.

Another reason for studying language acquisition is to understand the learning process of a second language. It is generally believed that second languages learned prior to 12 years of age will be spoken without a foreign accent. Scovel noted that learning the rules of a language is an intellectual process and can be learned at any age; however, pronunciation is a neuromotor process that is completed before puberty, thus making it difficult for a postpubertal learner to speak a foreign language without an accent. This is a generality and not an absolute. Thus, learning languages entails more than just memorizing words and sentence structure.

Language Acculturation

Jaina Amin
Department of Psychiatry, University Hospitals Case Medical Center, Cleveland, OH, USA

Acculturation is the process of two cultures blending, generally seen when an immigrant or minority culture acclimates with the dominant culture. Not only is there a blending of the cultural traditions, there is also a blending of the languages. Newer generations may initially substitute in words from the dominant culture with an eventual progression to full substitution of only speaking the dominant language, as in the example of "Spanglish." Initially, this is seen in a positive light where the family blends, fits in, and can advance in the dominant culture by predominately using the dominant language.

There are approximately 6,000 oral languages spoken in the world. The vast majority of those languages are spoken by communities of 10,000 speakers or less, representing approximately 5% of the world's population. And only 300 of the 6,000 languages are spoken by the majority of the world, representing approximately 95% of the world's population. Thus, one can see that the more than 5,000 languages spoken in the smaller communities are in danger of extinction through the process of language acculturation.

Language acculturation not only affects the diversity of languages, but it also affects the culture. Maffi noted that native Mexicans were losing centuries of knowledge of native medicine and relying solely on modern medicine. This is not to say that one practice is better than the other, but to look at the loss of this cultural aspect. Generally, folk tales, fables, and native medicinal remedies are passed on in the native tongue as they have cultural implications. It is important to note that languages and traditional customs are intertwined and as such when there is a loss of one, there inevitably will be a loss of the other. This process is subtle where the younger generations are exposed to more of the dominant culture's customs and languages, whether by a conscious choice or circumstance.

Across the world, children not only learn their native language(s) but they may also learn a dominant language that will make them more competitive and successful in the world job market. And as the future generations learn more of the dominant culture's language, and media information is in the dominant language, there is less of a need to continue speaking the nondominant language. Initially, people start to substitute in words that are more easily recognized and used from the dominant culture, and then as future generations are born they might not even be taught the minority language as it is so broken through the substitution of words. The concern with the loss of language is the subsequent loss of diversity in our cultures. Many traditions and customs are relayed in the native language, when only the elders speak these languages fluently then the traditions and folk tales die with them.

However, there are some benefits of language acculturation. The process of taking on the dominant language and attributes allows for professional advancements as well as personal advancements, that many not be obtainable if individuals were not able to change. More job opportunities are afforded to individuals that can speak multiple dominant languages. For individuals that come from small villages where they only have a few thousand people speaking their language, learning a dominant language offers them opportunities to advance in life.

While the need for preservation of cultural diversity and languages has been discussed, the reality is that by the simple act of interacting with one another we are influencing each other's behaviors. Everyone we meet will be affected by us and us by them. In order to maintain our diversities while learning and growing in a culturally rich environment, we need to be cognizant of our diversity and the need for it.

Language Barriers

C. Javier González, Francesca Gany
The Center for Immigrant Health, Division of Primary Care, New York University School of Medicine, New York, NY, USA

The provision of linguistically appropriate health care is essential in the prevention, diagnosis, and treatment of disease. To deliver equitable health care for all, the language barrier must be addressed. Numerous strategies exist to tackle the challenge of language discordance during the medical encounter.

According to census data, 33 million people who reside in the USA were born abroad. Of these, it is estimated that 22 million have "a limited ability to listen, speak, read, and write in English, and [speak] English less than 'very well'." They are considered limited English proficient or as having Limited English Proficiency (LEP). With the increase in the nation's plurality, the language barrier is no longer a challenge for metropolitan areas alone. It is a salient and growing national challenge. From 1990 to 2000, 46 states experienced an increase in their LEP population, 15 of which had an increase of over 100%, and 14 others of over 50%.

In the USA, health care facilities are mandated to address interpreting needs. Title VI, 1964 Civil Rights Act, requires that all federally funded institutions make "reasonable" attempts to provide meaningful access to services. States are increasingly adopting measures requiring health care providers to overcome language barriers. Forty-three states have laws to address health care access and quality for LEP patients.

Tasked with facilitating appropriate health care for its LEP populations, and cognizant of the quality and legal implications of not providing adequate and equitable health care for all, health care facilities employ a multiplicity of methods to bridge the language gap when caring for the foreign-born, limited English-speaking population.

The adequacy and quality of these methods and systems vary greatly. They include sophisticated systems composed of properly trained and qualified interpreters, telephonic in-house or commercial services, agency and trained staff interpreters, and the use of untrained bilingual staff members, volunteers, other patients, and family members, including children (the latter despite existing federal and state laws and regulations). Such nonprofessional practices are generally unaccepted in most settings and are regulated by state legislation and policy. Exceptions may include emergent or other special cases dictated by the patient's own choosing.

The failure of health care facilities to provide linguistically appropriate services has considerable costs, both medical and financial. The consequences of miscommunication, such as delayed health care seeking, diagnostic errors, missed appointments, the failure of patients to understand and adhere to treatment recommendations, and the failure of providers to obtain truly informed consent and to be sensitive to a patient's own cultural understanding of health and illness, can be costly and severe. Indirect costs can also result from a reduction in physician productivity, lack of patient adherence, and the ordering of unnecessary tests. The lack of widespread interpreter services poses a serious health and public health threat.

It is important to note that the provision of adequate language services may pose a financial challenge to institutions and providers who in many states do not receive reimbursement for the provision of interpreter services. As such, the following elements should be considered when devising strategies to facilitate linguistic access for the LEP patient population: (1) the development of a corps of, or access to, trained/qualified medical interpreters; (2) ensuring that the body of practitioners, health care staff, and administrators are cognizant of the issue generally and are trained in how to work with medical interpreters specifically; (3) advocacy for policy and legislative change at the state and federal levels to augment the implementation of effective systems; and (4) creation of innovative and diverse systems of interpreter service delivery that enable both efficiency and effectiveness.

Administrators should also be informed about national and state regulations and laws and urged to support innovative programs to accomplish such mandates. Successful programs designate LEP offices led by language experts. These experts usually educate the facility and institute internal policies to move their programs forward. Successful programs, as well, do not deny the multiplicity of approaches needed to face the challenge. These approaches may be comprised of trained interpreters, trained volunteers, and trained staff members, and may include use of telephonic interpreting services and remote simultaneous medical interpreting.

The field of medical interpretation has a relatively short history in the USA. While notable efforts are underway in more and more areas of the country, medical interpretation has not yet achieved the stature or widely acknowledged importance of other forms of interpreting (e.g., court, conference, ASL). A trained medical interpreter is someone who has been tested for bilingual proficiency and undergone a minimum of 40 h of training. Training should include: knowledge of the role of the interpreter in health care; ethical decision-making strategies; memorization, linguistic and cultural competency skills; self-evaluation and interpreting techniques; and learning of specialized terminology (medical and colloquial). Whereas much progress has taken place in the areas of training and professionalization, true standardization and curricula are fast approaching. National efforts such as the Certification Commission for Health Care Interpreters (CCHI) – a national certification process for medical interpreters – and the National Council on Interpreting in Health Care (NCIHC) have greatly contributed to the conceptualization of the young profession as well as toward the creation, lobbying for, and adoption of state and national policy to bring it to life.

As emphasized by the US Department of Health and Human Services, Office of Minority Health, overcoming the language barrier is an integral part of being culturally competent. Nationally, there is a growing recognition of the importance of incorporating education on cultural competence into undergraduate medical curricula, residency programs, and continuing medical education for practicing physicians.

The language barrier poses a serious impediment in the delivery of equitable health care for all. The professionalization of medical interpreting in the USA will lessen racial and ethnic disparities in health care, by increasing access, effecting patient and provider satisfaction, lessening medical errors, and producing improved medical outcomes. State and federal policy and funding, as well as research, that support this effort is of outmost importance.

Late-in-Life Migration

Isabel N. Schuermeyer
Department of Psychiatry & Psychology, The Cleveland Clinic Foundation, Cleveland, OH, USA

People who leave their country of origin later in life face a unique set of challenges. Compared to most immigrants who moved for work opportunities or political refuge, elders tend to move in order to join their adult children who had previously immigrated. Many times, these elders feel lonely and have a sense of family disruption that are the driving forces for their immigration. Much of the research in late-in-life immigration has been conducted in Sweden with Iranian immigrants.

Medical

People who immigrate as elders, as any other aged population, have a higher prevalence of chronic medical problems than younger cohorts. The ability to adequately care for these problems is largely influenced by the cultural competence of the health care system in their new country, and its interaction with the health care seeking characteristics of each individual. While health care seeking behavior is certainly influenced by the individual's culture, it is important to recognize that people from another country express as much variance, from individual to individual as persons from one's own nationality.

Psychological

Psychological Distress

As mentioned in the introduction, many times people who immigrate late in life do so to reunite with their adult children. Unfortunately, although there is this reunification, it does not necessarily mean that there is a restoration of the family as it was in the country of origin. It has been observed that elders and their children may experience a reversal of their traditional, previously held roles. The elders, had they remained in their country of origin, would often have been in a position of authority and respect, and they may now be expected to defer to, or even be subservient to, their children. This is likely a result of the elders being financially dependent upon their children upon arrival in a new country, as well as the greater familiarity with the local language and cultural norms and customs that their children will have acquired from their relatively greater exposure to their new cultural environment. This can, in itself, cause significant psychological distress. Their family may be one of the few things that may not be alien to migrant elders, but that one anchor to what was familiar has also changed as a result of immigration.

These elders can often have a sense of isolation. They may not speak the language and may not have many opportunities to learn it. Further, they do not know the normal, expected behaviors for elders in that culture, which can restrict these seniors from even attempting to decrease their isolation. This can create a self-reinforcing cycle of separation preventing familiarization with the new culture, and this lack of familiarization leading to ongoing seclusion.

Not only can elders be homesick, but they may also feel that they have no purpose in life. Most elders who migrate have retired and do not return to the workforce upon their emigration, which can easily contribute to a feeling of purposelessness. Also, the dependence upon their adult children that may occur as a result of immigration may lead some elders to go so far as to believe that they are a burden on their families.

Depression

Depression is common in the elderly, even without the stresses associated with immigration. Two studies have been conducted examining rates of depression in late in life Asian immigrants. One study was of Chinese immigrants to Canada, and a second study was that of Chinese immigrants to the United States. Both studies found that depression was higher in elders who had a shorter length of residence. This is somewhat reassuring, in that it suggests that, given time, elderly immigrants are able to adapt and cope better with the stressors they experience. It does not suggest, however, that depression in this population is something that is best left ignored. While there are few data on suicide rates amongst elderly immigrants, the elderly within our own culture experience a relatively high suicide rate, and there is little reason to expect that immigrants would be an exception. Unfortunately, the barriers to general health care that this population experiences also impede their ability to receive adequate mental health care. Cultural stigma regarding mental illness may be an even greater barrier.

Summary

People who choose to migrate later in life often face more and more varied challenges compared to their younger counterparts. This transition can lead to emotional distress, a reduction in quality of life, and, potentially, depression.

Terminology

To be categorized as Latino in the USA means that a person has origins in one of the Spanish-speaking countries of the Americas or Spain. Latino is considered synonymous with the term "Hispanic." However, there are notable differences between the origins and meanings of the two terms. The term Hispanic was coined and put into official use in 1974 by the Office of Management and Budget, part of the Federal branch of the US government. The term was specified in *Statistical Policy Directive No. 15: Race and Ethnic Standards for Federal Statistics and Administrative Reporting*. It is used by the US Census Bureau in the collection of self-identified population level data. The Census Bureau defines "Hispanic or Latino" as "a person of Cuban, Mexican, Puerto Rican, South or Central American or other Spanish culture or origin regardless of race." In the USA, Latino is considered an ethnicity by the government, not a race. In the USA, race and ethnicity are considered separate and distinct, and Latinos, being a pan-ethnic group, can thus be of any race.

The term "Latino" is a grassroots term that emerged in contrast to the term Hispanic adopted by the US government. The term emphasizes self-definition and a desire to separate symbolically from Spain, the former colonial power throughout much of the western hemisphere and a historical commonality shared by all peoples from the world's many Spanish-speaking countries. People of Latin American origin also refer to themselves as Spanish, Latin, *Hispana/o,* Latin American, or *Latino Americana/o*. The term "La Raza" is also used. The term has origins in Latin American literature from the early twentieth century. The term literally translates into "the race," but more closely and accurately means "the people" in English. It is a concept that underscores the common heritage peoples from Latin America share with diverse people from around the world, and denotes the mix of cultures, races, and ethnicities that characterize Latin Americans. Regardless of the term used, "Latinos" are a distinct US demographic group and the term Latino is only used in the USA; it is not relevant or applicable to people outside the US context or in the Spanish-speaking countries of the Americas or Spain.

Demographic Characteristics

Latinos are a diverse pan-ethnic group that is immigrant, migrant, and native born. It is a young population with high birth rates, which along with a steady stream of immigration and migration is driving its rapid and sustained population growth. According to the 2006–2008 American Community Survey (ACS) estimates, Latinos comprise 15.1% of the population, making Latinos the largest minority group in the USA (Blacks and Asians account for 12.3% and 4.4%, respectively). Although the total US population grew by 13% during the 1990s, the US Latino population experienced a significantly faster growth rate of 61% during that period. This trend is projected to continue as the Latino population grows steadily throughout the twenty-first century. From 2008 to 2050, the Latino population is projected to triple and its share of the total population to double and account for a projected 30%. Thus, by mid-century, approximately one in three US residents would be Latino. The Latino population is expected to continue growing past 2,100 and continue to grow thereafter. Therefore, Latinos are and will remain the largest minority and ethnic group in the USA well into the future.

The median age for Latinos was 26.9 in 2004, 13 years younger than that of non-Latino Whites (40.1 years), and one in three Latinos is a child under 18, illustrating the youthfulness of the population. Latino children accounted for 17% of all children under age 18. This means that Latino children constitute a small, but nevertheless greater percent of the population under 18 than Latinos as a group account for in the total US population, illustrating the young age of the population. Latino children will soon constitute the largest segment of the overall child population, as it is projected that 39% of all children (<18 years) will be Latino by mid-century.

In 2004, the vast majority of Latinos (80%) lived in nine US states. The largest populations are found in California (30.3%), Texas (18.9%), Florida (8%), and New York (7%), accounting for approximately two-thirds of all Latinos. Among Latinos age 25 and older, 60% had graduated high school compared to 89% of non-Latino Whites. About 13% had earned a bachelor's degree or higher compared to 30% of non-Latino Whites, while 40.4% of Latinos had completed less than a high school education. Latinos had a lower median income, $36,000, which was less than three-quarters that of non-Latino Whites. A larger proportion of Latinos lived in poverty (22%) compared to non-Latino Whites (9%). Latino children had a higher poverty rate, about 29% compared to 11% of White children. The poverty rate among Latinos age 65 and older was 20%. More Latinos rented instead of owned their homes, 52% compared to 48%, respectively.

More than half of Latinos age 15 and older were married in 2004, and were less likely than non-Latino Whites to be divorced (8% compared to 11%). Latino women have higher fertility rates than non-Latino White women. Approximately 75% of 1,000 Latino women ages 15–50 had given birth in the past year, compared to about 50% of Whites. Additionally, about 33% of Latino women who gave birth were unmarried, compared to 20% of non-Latino women. Latinos had larger household sizes on average, 3.4 people compared to 2.5 for non-Latino Whites. Fifty percent of Latino households were headed by a married couple, and 19% were single-female headed households.

In 2004, most Latinos spoke only English at home (22.8%) or did not speak English at home but spoke English very well (38.5%). Not all Latinos speak Spanish; however, the USA has a large Spanish-speaking population and more than 75% of Latinos speak Spanish, many of whom are monolingual Spanish speakers. In 2000, of the 47 million people in the USA who spoke a language other than English, more than half (59.8%) spoke Spanish. Many, but not all, Latinos are Spanish–English bilinguals. Of more than 75% of Latinos who spoke a language other than English, all (99%) spoke Spanish. Thirty-nine percent of Latinos reported speaking English less than very well, much more than the 8.1% of the general US population who reported the same low level of English proficiency.

Immigration

Because the USA is adjacent to Latin America, and because of the unique historical, political, and economic relationships between the USA and Latin American countries, immigration to the USA since 1965 has been primarily from within the hemisphere. 1965 is an important milestone in US immigration policy because it was the year the US government amended the Immigration Act, repealing the national origins quota system and replacing it with a system based on family reunification, and with a focus on attracting immigrants with needed skills to the USA. It was the most extensive revision of US immigration policy since the 1920s.

Immigration to the USA from Latin America, and to a lesser degree Asia, has been driving profound changes in the racial/ethnic composition of the US population in the last 40 years. These changes have been exacerbated by a relative decrease (aging and decreased birth rates) among the majority White non-Latino demographic. In 2007, more than half (53.6%) of the US foreign-born population was from Latin America; 39.8% of Latinos are foreign born compared to 12.6% of the overall US population. However, this indicates the majority of Latinos (60%) are born in the USA and are thus not immigrants. Children of immigrants are the fastest growing subpopulation of US children, the vast majority of whom are Latino. In 2000, more than half (56%) of children living with a foreign-born householder were Latino.

Latino National Origin Groups

Although Latinos have origins in many diverse countries, people of Mexican, Puerto Rican, Cuban, Salvadoran, and Dominican origin comprise close to two-thirds of the US Latino population.

People of Mexican origin constitute the largest share (64%) of the Latino population. The majority of Mexican immigrants (62.6%) came to the USA in 1990 or later. Puerto Ricans are the second largest group of Latinos, comprising 9% of the mainland Latino population. In 2007, the 4.1 million persons of Puerto Rican origin living on the US mainland exceeded Puerto Rico's population of 3.9 million. Because Puerto Rico is a US territory, all Puerto Ricans are US born, have US citizenship, and are entitled to a US passport at birth. Thus, Puerto Ricans who move from the island to the US mainland are considered migrants, not immigrants. Cubans are 3.5% of the Latino population and are the third largest Latino national origin group, concentrated in Florida. Sixty-one percent of Latinos of Cuban origin are foreign born. People of Salvadoran origin account for 3.2% of the Latino population and Dominicans represent 2.6%.

Although Mexicans are the largest Latino national group, they are overwhelmingly concentrated in the southwest. This largely reflects the population characteristics of a large swath of land that once was part of Mexico. Because of the historic immigration and migration patterns of Latinos from the Caribbean to the mainland USA, Dominicans and Puerto Ricans are primarily concentrated in the northeast and south Florida, particularly in urban areas such as New York City, New York, Boston, Massachusetts, Providence, Rhode Island, and Hartford, Connecticut. In the northeast, Puerto Ricans are the largest Latino ethnic group and Dominicans are the third largest immigrant group. Between 1990 and 2000, the northeast Dominican population doubled, illustrating the high rate of immigration from the island to the mainland.

The Historical Incorporation of Latinos of Mexican, Puerto Rican, and Cuban Origin

Not all Latinos are of immigrant backgrounds, as Latinos have lived within the modern-day political borders of the USA since before the inception of the country. That the Latino demographic is so large and growing is in no small part the result of US intervention in Latin America since the 1800s, and in considerable part reflects lengthy political and economic ties to three countries in particular, Mexico, Puerto Rico, and Cuba, representing the three largest Latino national groups.

That the Latino demographic is concentrated in the southwest is a function of historical events that in significant ways have come to characterize the demographic composition of the USA. As the USA expanded westward to the Pacific Ocean during the 1840s, *Mexicanos* (Mexicans), *Tejanos* (Texans), and *Californios* (Californians) in what today is the US southwest – but which then was the territory of the sovereign state of Mexico – were squeezed by US settlers and eventually incorporated into the USA when their land was annexed by the US government when Mexico lost the Mexican-American War (1846–1848). US westward expansion was in part driven by the belief in *Manifest Destiny*, which also prompted the Mexican-American War. *Manifest Destiny*, meaning obvious or undeniable fate, was the nineteenth-century belief that America was created to be expanded, and that the USA had a divine mission to expand across the continent of North America. The Mexican-American War ended with the Treaty of Guadalupe Hidalgo. This entailed that Mexico sell almost half its land to the USA, including what is today Texas, New Mexico, Arizona, California, Nevada, Utah, most of Colorado, and some small parts of Kansas, Oklahoma, and Wyoming. Mexicans living in the newly acquired land that became the US southwest were involuntarily incorporated into the USA. The profound impact of Mexican culture on US culture is evident in the southwest today, as the region was infused with and, to some degree, culturally determined by Mexican culture. Many people of Mexican origin in the USA, particularly the southwest Texas and California, are not immigrants, but rather US citizens by birth who are the descendants of people who have lived within the borders of the USA since before such borders formed the political boundaries of what is now the USA.

The unique relationship between the USA and Latin American countries, and that Latinos comprise a key demographic group in the USA today, in part reflects US military, political, and economic intervention in the region from the 1800s through the present day, as enshrined in the Monroe Doctrine. The Monroe Doctrine was issued in 1823 by President James Monroe. It declared that sovereign states in the Americas should be free from European interference, and that furthermore the Americas should be closed to future colonization by Europeans. It also proclaimed that the USA would view European interference with sovereign states in the Americas as a hostile act toward the USA. Although the Monroe Doctrine was intended to declare US opposition to colonialism, the USA assumed colonial rule over Puerto Rico, as it continues to have to this day.

Like much of Mexico, the island of Puerto Rico became a US territory after military conflict. The Spanish-American War of 1898 ended with a peace treaty between the USA and Spain, under which Puerto Rico was ceded to the USA after its victory. The Foraker Act of 1901 formally established the territorial relationship between Puerto Rico and the USA and the Olmstead Act of 1909 gave the US president a direct role in Puerto Rican affairs. The Jones Act of 1917 made Puerto Rico an unincorporated US territory and granted Puerto Ricans US citizenship. Because of their citizenship, Puerto Ricans were included in the World War I draft as well as future military conflicts in which the draft was in effect. Puerto Rico became a self-governing commonwealth in 1952. Puerto Rico has no voting representative in the US Congress; however, US federal laws apply to Puerto Rico. Although Puerto Ricans are US citizens by birth, Puerto Ricans living on the island may not vote in federal elections and thus may not vote to elect the President. Only Puerto Ricans living on the mainland USA can vote in federal elections. Puerto Ricans living on the island periodically vote in nonbinding plebiscites. Puerto Ricans not living on the island may not participate in plebiscites, which present a choice between independence, becoming the 51st US state, or remaining a US territory. The last plebiscite was held in 1998.

Like Puerto Rico, Spain ceded control of Cuba to the USA at the end of the Spanish-American War in 1898. US military rule of Cuba continued until 1902 when the island was granted independence. US troops were withdrawn from the island after adopting the Platt Amendment, which gave the USA the right to intervene in the political, economic, and military affairs of Cuba. The Cuban economy was dominated by the USA through the mid-twentieth century. When General Batista became President of Cuba in 1940, a period of cooperation between the USA and Cuba was ushered in. However, the Batista government was overthrown by the Cuban Revolution, led by Fidel Castro, in 1959, after which Cuban–US relations deteriorated. Trade restrictions on Cuba were imposed by the US President Nixon in 1959. Diplomatic relations with Cuba ended in 1961, the year of the Bay of Pigs, a failed, armed invasion of Cuba by Cuban exiles launched by the US government. Tensions escalated in 1962 with the Cuban Missile Crisis, which led to a complete US ban on all trade with Cuba and prohibition of US travel and financial transactions. The US embargo against Cuba continues to this day. It is in large part viewed by the international community as a key factor sustaining the profound poverty and lack of opportunity in Cuba, which, along with resistance and opposition to communism in Cuba, have been the primary forces driving Cuban emigration.

Cuban immigration to the USA is the result of a complex mix of political and economic factors, and can be summarized in four waves. The first wave followed the Cuban Revolution from 1959 to 1962, and consisted of upper and upper-middle class professionals, such as lawyers and doctors (those who, simply, had the most to lose after the Revolution with the establishment of a socialist/communist economic and political system). The second wave between 1965 and 1974 consisted of “freedom flights” organized by the USA and Cuba, and primarily brought middle- and working-class Cubans to the USA. The third wave began with the Mariel boatlift in 1980, which brought approximately 125,000 Cubans from every class and segment of Cuban society to the USA. People who came during this wave of Cuban immigration became known as the *Marielitos*. The fourth wave began in 1989 with the fall of communism in Europe and continues to this day. Cuban emigrants headed to the USA during this wave include people known as *balseros* (rafters) who take to the sea and head for Florida (which at its closest point is only ninety miles from Cuba) in boats, rafts, and various other forms of vessels. Immigrants today also come through a visa lottery system implemented by the Cuban and US governments in 1994. US policy toward Cuban immigrants has been much friendlier compared to immigrants from any other Latin American country. Unlike other immigrants from Latin America, Cubans are admitted under a unique parole power of the US Attorney General that puts Cubans on a path to citizenship and grants them full legal status. Under the so-called wet-foot/dry-foot policy, all Cubans who manage to land on US soil are permitted to stay in the USA, but Cuban immigrants seized at sea are returned to Cuba.

Conclusion

Latinos are a diverse pan-ethnic group, and their growth is driving dramatic population changes in the USA. As with population changes earlier in the country's history, such as those driven by the influx of Irish, Italian, German, and Jewish immigrants, Latinos today, whether US or foreign born, will be decisive in shaping the political and economic future of the country as they come to define a significant portion of the US social fabric.

Lead Poisoning

Jerri A. Rose
Division of Pediatric Emergency Medicine, Rainbow Babies and Children's Hospital, Cleveland, OH, USA

Lead is a naturally occurring metallic element found throughout the environment in all parts of the world. High levels of environmental lead have resulted from human activities such as mining, industrial processes, and burning fuels. A variety of commonly used products – including gasoline (in countries where leaded fuel is still permitted), batteries, paints, solder for food cans, ceramic glazes, ammunition, cosmetics, traditional medicines, mini blinds, and even toys and trinkets for children – may contain lead as a component. Drinking water delivered through lead or lead-soldered pipes may also become contaminated with the metal.

Despite its usefulness in multiple processes and products, lead is toxic to humans. Children are particularly susceptible to lead's toxic effects, and lead poisoning is a serious child health concern worldwide. Numerous physiologic and behavioral characteristics place young children – especially those between 12 and 36 months old – at higher risk. Children's bodies absorb greater proportions of lead than adults' bodies, and their developing brains and other organ systems are more permeable and sensitive to the metal's detrimental effects. Young children typically explore their environments through behaviors such as crawling, playing on the floor or ground, and placing their hands and other objects in their mouths; while these behaviors are developmentally normal, they magnify environmental lead exposure.

Upon entering the body, lead is distributed to organs including the kidneys, brain, liver, and bones. The body does excrete some lead, but it also stores the metal in the bones and teeth, where it may accumulate over time. Effects of lead exposure vary widely among individuals and are influenced by factors including the level and timing of exposure, age of the exposed individual, and the person's underlying nutritional and health status. Individuals with significantly elevated blood lead levels may display no symptoms in some cases, while seizures, coma, and even death may occur in the most severe cases of acute lead poisoning. Potential symptoms of lead poisoning are diverse and nonspecific, including impaired thinking, delayed language development, hearing loss, behavioral problems, decreased IQ, vomiting, abdominal pain, decrease in kidney function, poor growth, and decreased red blood cell production. Exposure of pregnant women to environmental lead may negatively impact fetal brain development and has been associated with miscarriage, premature birth, and low birth weight.

Lead exposure occurs mainly through breathing in dust and air contaminated by lead particles, as well as through ingestion of lead in dust, soil, and paint chips (a major route of exposure in children). Although lead exposure occurs worldwide, there is significantly less environmental lead exposure (and therefore a lower prevalence of lead poisoning) in countries which have mandated the removal of lead from gasoline, paints, and soldered cans, and that have focused on reducing other sources of lead exposure, such as in drinking water and children's products. In the United States, for example, the prevalence of blood lead levels greater than 10 micrograms per deciliter in children aged 1–5 years fell from 88 % to 1.6 % between 1976 and 2002. This dramatic decrease resulted from the mandated removal of lead from gasoline and paints, preschool screening programs, and increased public awareness.

Because automobile fumes containing lead particles are such an important source of lead poisoning in children, many countries worldwide have implemented fuel policy changes, eliminating the use of leaded gasoline. In 2002, the World Summit on Sustainable Development called for the removal of lead from gasoline globally, and the World Bank has worked with countries to help achieve this objective. Despite these global calls, numerous countries, primarily in African and Eastern Mediterranean regions, continue to use lead to boost octane levels in gasoline.

Average blood lead levels in many developed countries have fallen drastically over the past three to four decades due to implementation of public policies designed to reduce environmental lead, lead poisoning screening programs, and increased public awareness of the disease. Despite these successes, lead poisoning continues to be a major global health concern. Poor children in developing countries are at especially high risk for lead poisoning. Approximately 20% of the world's disease burden from lead poisoning occurs in the Western Pacific nations, while another 20% occurs in Southeast Asia.

In developed nations, non-White individuals with low educational levels and those living in poorer areas are at the highest risk for lead poisoning. In the United States, the prevalence of elevated lead levels is highest among African-American children living in the inner city, especially among those living in housing structures built prior to the 1970s when lead-based paint was still used. In addition, recently arrived refugee children and those children entering the foster care system are groups with a high prevalence of lead poisoning in the United States.

Legal Services

Zenobia Lai
Asian Pacific American Legal Resource Center,
Washington, DC, USA

The history of American civil legal services began with the German Legal Aid Society in New York founded in 1876 to provide legal assistance to German immigrants. Chicago became the second city to establish a legal aid office in 1890, followed by Boston in 1900. It was Reginald Heber Smith, a young lawyer at the Boston Legal Aid Program, who brought forth the concept of free legal aid for the poor and put the responsibility of providing such service squarely in the private bar. In his seminal work on legal services published in 1919, Smith stated that without equal access to the law, the system gave the most ruthless and powerful weapons that the oppressors of the poor could ever invented. By mid-twentieth century, almost all major U.S. cities had legal aid offices. But many of these offices were tiny with barely one paid staff, often operated in conjunction with local charities, and mostly relied on private attorneys who donated their time to provide legal assistance to the indigent population. When the Ford Foundation began funding the National Legal Aid and Defendant Association (NLADA) in 1959 to launch law school clinical programs, there were barely 400 full-time lawyers scattered among 157 legal aid organizations operating in isolation from one another. Access to justice for many poor people remained elusive.

The Civil Rights Movement ushered to the forefront the plight of the poor and minorities. In 1964, President Lyndon B. Johnson unveiled his Great Society ideal in which he envisioned “abundance and liberty for all. It demands an end to poverty and racial injustice.” He created a new federal agency, the Office of Economic Opportunity (“OEO”) and appointed Sargent Shriver to wage War on Poverty. The OEO administered most of the antipoverty programs such as food stamps, Medicaid, Medicare, Head Start, Community Action Programs, Work Study, VISTA, and Job Corps. However, local politicians did not welcome the new antipoverty forces and fought to block their progress. When Shriver found his programs politically blocked, he turned to the law and created the legal services programs to make law an ally to the poor to challenge obstinate and uncaring government entities and institutions.

The OEO created a legal services system that utilized staff attorneys working in private, nonprofit entities that were full-service legal assistance providers each serving a specific geographic area. The legal services programs were required to take a broad range of cases except fee-generating cases and criminal matters. They were also charged with advocating for law reform and making preventive law and client education high priorities. The OEO also created an infrastructure of national and state support centers, training programs, and a national clearinghouse for research and information in support of the field offices. Despite vehement opposition from all quarters, the first storefront neighborhood legal services began operation in January of 1966. The OEO-funded programs marked the beginning of modern day legal services in the United States.

During the early years, OEO-funded legal services programs brought landmark cases to challenge school boards for discrimination, sued employers for engaging in unfair labor practices, and took government agencies to court for violating the rights of poor people. Notable cases include *Shapiro v. Thompson*, 394 U.S. 638 (1969), which prohibited welfare agencies from arbitrarily denying benefits to poor people; *Goldberg v. Kelley*, 397 U.S. 254 (1970) in which the U.S. Supreme Court held that due process required welfare agencies to give recipients the right to pretermination hearings; and *Javins v. First National Realty*, 428 F.2d 1071 (D.C. Cir. 1970) that established warranty of habitability for renters. Legal services lawyers also advocated behind the scenes in enacting or modifying local, state, and federal legislation. Legal services' success in challenging powerful business and government interests to advance the rights of the poor earned them many enemies, among them powerful political figures.

In 1973, President Nixon proposed the dismantling of the OEO and the creation of a private, nonprofit legal services entity that would receive an annual appropriation from Congress which then distributes the funds to the field. In summer of 1974, President Nixon signed into law the Legal Services Corporation Act of 1974 (LSC Act), creating the Legal Services Corporation (LSC) overseen by eleven board members appointed by the President and confirmed by the Senate. The LSC Act placed new restrictions on legal services programs and staff, such as restricting staff from engaging in the outside practice of law and political activities, and prohibiting programs from engaging in certain kinds of advocacy and lobbying. The new LSC developed a "minimum access" goal, aggressively increased funding, and expanded programs to reach as many poor people as possible. The goal was to fund two lawyers for every 10,000 poor people, defined as someone whose household income was at or below 125% of federal poverty set annually in February. By 1981, the "minimum access" goal was almost a reality with LSC funding 325 programs across 50 states and the territories, with a budget that increased from $71.5 million in 1975 to $321.3 million by 1981.

The 1970s and 1980s marked the heyday of growth for legal services: there were field programs established in every county in the country; a network of migrant and Native American programs; a system of state support centers and national support centers; LSC began a national training program for lawyers; paralegals, including some who were former legal services clients, community activists, or social workers, became full-fledged advocates. On the advocacy side, law reform work that used to reside in specialized programs became more integrated with basic service work; programs expanded into new fields of poverty law, such as advocacy for persons with disabilities, veterans, nursing home residents, and other groups with special problems accessing legal services. The significant legal victories of the 1960s that established constitutional, statutory, and common law rights for the poor finally became a reality with the new legal services system.

The election of Ronald Reagan in 1980 as President of the United States marks the beginning of almost three decades of restrictions and defunding of federally funded legal services programs. President Reagan initially sought to eliminate LSC and to replace it with law student clinical program and a judicare system using private attorneys funded through block grants. Although Congress did not pass the law calling to eliminate LSC, it cut LSC funding by 25% for FY 1981, leading programs to close offices and lay off staff. The following year, the House of Representative passed a LSC Reauthorization Bill that would provide the blueprint for restrictions that Congress in subsequent sessions sought to impose on LSC. Though the Senate did not adopt the House Bill, in 1982, Congress passed new laws and restricted the use of LSC funds for lobbying and rulemaking; it also added new procedural requirements for class action and restricted LSC-funded programs' ability to represent certain classes of immigrants. At the same time, new LSC board members mostly appointed through recess appointments and new LSC staff were openly hostile to the legal services programs they were charged with overseeing. For example, LSC began a highly intrusive and exhaustively detailed monitoring program that sought access to client files and confidential client information. Instead of focusing on the quality of client representation or program performance, the monitoring process focused on the technicalities such as board vacancies and the like. These monitoring processes caused programs to spend inordinate amount of time and resources that could have been used to assure equal justice for the poor.

In the face of reduced federal funding, programs sought funding from foundations, the bar associations, the private bar, the United Way, private donations, and non-LSC federal grants. By the mid-1980s, a new source of funding called the Interest on the Lawyer Trust Account (IOLTA) emerged through new cooperation with the banking industry. By capturing pooled interest on small amounts or short-term deposits of client trust funds used for court fees, settlement proceeds, or similar client needs that were previously held in non-interest-bearing accounts, IOLTA became a significant source of funding for legal services. By 2000, all 50 states, plus Washington, D.C., and Puerto Rico had an IOLTA program.

A temporary respite to legal services came with the election of President William Clinton in 1992: LSC funding reached $400 for FY 1995. The midterm election of 1994 changed the political landscape for the USA and the short-lived fortune of legal services. While the new Congress did not succeed in eliminating LSC and federally funded legal services, it succeeded in imposing significant restrictions on LSC-funded programs. In addition to more stringent restrictions on what kind of work legal services could engage in, the new law prohibited LSC-funded programs from using other sources of funding to engage in restricted activities. The new law directs LSC to distribute funding based on a strict Census formula, which led many programs to close shop or merge. It also requires attorneys and paralegals in LSC-funded programs to follow a time-keeping system and allows LSC expanded access to recipient and client records. These restrictions prohibit LSC-funded programs from representing prisoners, specific groups of immigrants, or public housing tenants being evicted on drug-related charges. The new law also restricts programs from participating in class actions, welfare reform advocacy, and most affirmative lobbying and rule-making activities. In addition, until its repeal in January of 2010, programs were prohibited from claiming or collecting attorney's fees, thus removing a potentially significant source of funding for programs and an effective strategic tool in litigation. To further handicap programs from engaging in law reform work, Congress eliminated funding for national and state support centers and all other entities that had provided support, technical assistance, and training to LSC-funded programs.

In essence, Congress redefined the role of federally funded programs from one that engages in law reform advocacy seeking to address systemic problems to ameliorate poverty to one that provides access to justice only on a case-by-case basis through individual representation. Between 1980 and 2010, LSC funding has hovered between the low of $241 million in 1982 to a proposed high of $400 million for FY 2010. Even at the highest level of funding of $400 million reached in 1995, it still represented a 28% actual reduction in funding compared to the base year of 1980.

During the period when Congress passed law to severely restrict the activities of federally funded legal services, LSC, the American Bar Association (ABA), NLADA, the Center on Law and Social Policy (CLASP), and State Justice Commissions engaged in state planning efforts to focus on developing a state justice community that can provide access to justice to all eligible clients across entire states. Although the number of LSC-funded legal services programs decreased from 325 in 1995 to 138 in 2006, new, non-LSC-funded entities emerged to work alongside the LSC-funded counterparts, including centralized intake programs that provide single points of entry to legal services. During the same period, funding for the new state justice system has increased significantly. New sources of funding include those from the Department of Justice under the Violence Against Women Act (VAWA), the Department of Housing and Urban Development, the Internal Revenue Service, and other federal agencies. Local initiatives such as court filing fees surcharge, attorney registration fees, state bar dues, *cy pres* awards (funds held in trust accounts that are redirected per court order to substitute agencies that can most closely fulfill the original intent of the trust whose initial purpose has become impracticable or infeasible) and attorney fees awards pursuant to fee-shifting statutes also supplemented funding for legal services.

Despite the draconian restrictions imposed on LSC-funded programs, new generations of lawyers continued to enter legal services seeking to fulfill the original intent of legal services by making the law and lawyers allies to low-income people in their struggle for equal justice by engaging in community lawyering practice. Teaming up with other professionals, these legal services lawyers use the law as a powerful tool to support community-initiated advocacy for environmental justice, equitable land use policies, preservation of affordable housing, containment of institutional expansion, access to equitable education, fair labor practices, and enforcement of voting rights. In addition, legal services programs have engaged in developing a comprehensive and integrated system that enhances collaboration across programs on community legal education, client outreach, and statewide advocacy through email listservs, task forces, and cocounseling arrangements to address clients' needs across the state. At the same time, courts have also taken significant steps to make access easier by simplifying court forms, instructions and procedural information, and translating documents into languages other than English to address the needs of pro se litigants (individuals who appear before the court without a lawyer) who have limited English proficiency.

More than four decades since the modern legal services system was created, it has grown significantly in numbers and funding and has evolved continuously to fulfill its overarching goal of equal justice for all. Depending on the local priorities, most legal services programs provide legal assistance in the following areas: abuse prevention, disability, elder law, employment, family, housing, immigration, Medicaid/Medicare advocacy, and public assistance. Clusters of programs also provide legal representation in care and protection, education, bankruptcy, and, recently, foreclosure prevention. However, because there is no law in the USA that guarantees the poor's right to court-appointed counsel in civil matters per a U.S. Supreme Court decision in *Lassiter v. Department of Social Services*, 452 U.S. 18, (1981), civil legal assistance will continue to be challenged by the ebb and flow of resources and the political whim of those that control funding decisions.

Unlike the American legal assistance system, most other countries where such assistance is available adopt the judicare model, where individuals seeking legal assistance apply to a government or quasi-governmental entity for legal assistance. Once approved, these individuals will be represented by private attorneys either for free or for an established fee. In most cases, civil and criminal legal assistance are administered by the same agency. In Europe, the right of the indigent to access legal assistance is provided under the European Convention on Human Rights that makes "equality of arms" between the state and the individual or between parties in the case a guiding principle for legal aid. Cases interpreting the right to free legal assistance under Article 6 of the Convention instruct the courts to weigh three factors: (1) the potential consequences faced by the applicant, (2) the complexity of the case or the procedure, and (3) the capacity of the applicant to effectively exercise his or her right to access to court.

Various international treaties provide considerable guidance on the government's obligation to provide legal assistance to those who cannot afford it. For example, comments adopted by the Human Rights Committee in association with Article 11 of the International Covenant on Civil and Political Rights concerning the right to adequate housing and protection against forced eviction recommends the provision of legal aid to persons seeking redress from the court. Article 37(d) of the Convention on the Right of the Child requires State Parties to ensure "[e]very child deprived of his or her liberty . . . to have the right to prompt access to legal and other appropriate assistance." Principle 3.3 of the United Nations Basic Principles on the Role of Lawyers asks government to ensure the provision of sufficient funding and other resources for legal services to the poor. The treaty establishing the European Community instructs The Council of Europe "to adopt measures in the field of judicial cooperation in civil matters." (Article 61). The Council proceeded to adopt a Directive on January 27, 2003, "to improve access to justice in cross-border disputes by establishing minimum common rules relating to legal aid for such disputes" (Council Directive 2002/8/EC of 27 January 2003). These international treaties affirm the core belief that the provision of civil legal assistance is crucial for the progressive establishment of freedom, security, and justice for the member states and beyond.

Leisure-Time Physical Activity

Amy N. Sharpton
Department of Veterans Affairs, Louis Stokes DVA
Medical Center Cleveland, Brecksville, OH, USA

The US Department of Health and Human Services reports that regular physical activity, fitness, and exercise are critically important for the health and well-being of people of all ages. Physical inactivity is associated with premature mortality, obesity, and increased risk for chronic diseases such as cardiovascular disease, certain cancers, and diabetes mellitus. In the USA, women, older adults, and the majority of racial/ethnic minority populations have the greatest prevalence of leisure-time physical inactivity.

Research has demonstrated that all individuals can benefit from regular physical activity. Mobility and functional health can be improved through physical activity – even for those who are very frail. Regular physical activity has been shown to reduce the morbidity and mortality from many chronic diseases. Millions suffer from chronic illnesses that can be prevented or improved through regular physical activity. In the USA, currently 12.6 million people have coronary heart disease; 1.1 million people suffer from a heart attack in a given year; and 17 million people have diabetes – approximately 90–95% of cases are type 2 diabetes. Notably, in a 1993 study, 14% of all deaths in the USA were attributed to inactivity and diet, while another study associated inactivity and diet to 23% of deaths from major chronic diseases.

Physical Activity Guidelines

Published by the US Department of Health and Human Services, their *Physical Activity Guidelines for Americans* provides guidance to help Americans aged 6 and older improve their health through appropriate physical activity. The content of the *Physical Activity Guidelines* complements the *Dietary Guidelines for Americans* – one of the outcomes from a joint effort between the US Department of Health and Human Services and the US Department of Agriculture (USDA). Together, the two documents provide guidance on the importance of being physically active and eating a healthy diet to promote good health and to reduce the risk of chronic diseases.

Children and a Healthy Lifestyle

Physical activity is essential to a healthy lifestyle. In combination with healthy eating, it can help prevent a range of chronic diseases, including the three leading causes of death: heart disease, cancer, and stroke. Physical activity helps control weight; builds lean muscle; reduces fat; promotes strong bone, muscle, and joint development; and decreases the risk of obesity. Children need 60 min of vigorous physical activity every day to grow up to a healthy weight.

Over the past 30 years, childhood obesity rates in America have tripled. Today, nearly one in three children in America are overweight or obese. It is estimated that one-third of all children born in 2000 or later will suffer from diabetes at some point in their lives; many others will face chronic obesity-related health problems like heart disease, high blood pressure, cancer, and asthma. The *Let's Move* Campaign is a nationwide initiative to solve the challenge of childhood obesity within one generation so that children born today will reach a healthy weight at adulthood. The four pillars of the campaign are empowering parents and caregivers, providing healthy food in schools, improving access to healthy and affordable foods, and increasing physical activity.

Immigrants and Physical Activity

Researchers have recently begun to examine the association between acculturation and physical activity among first-generation immigrants. Researchers found that immigrants are faced with four unique barriers to leisure-time physical activity. They call for the following barriers to be addressed.

There is a needed focus on the overall health benefits of physical activity, not just weight loss. Cultural differences exist related to weight and body image. Emphasis should be placed on the benefits of physical activity as it relates to overall well-being, disease prevention, increased vitality, and mood enhancement.

Cultural influences and the impact of acculturation should be examined. For example, the Hispanic culture may place more value on rest and relaxation. Therefore, they may view leisure as a sedentary activity. In the acculturation process, it is important to value the importance of both.

Stressing the importance of physical activity in the aging process is essential to the education of immigrants. Osteoporosis, arthritis, and other bone and joint problems are sometimes viewed as synonymous with aging. It is well documented that regular physical activity is especially important for people with joint and bone problems and that weight-bearing exercise and walking help to strengthen bones.

It is critical to promote the value of life-long physical activity for immigrant girls. Cultural influences may deter girls from leisure-time physical activity. This issue needs to be addressed so that girls learn skills related to physical activity that can be carried over into adulthood and old age.

Leprosy

Elie Saade
Department of Internal Medicine, University Hospitals
Case Medical Center, Cleveland, OH, USA

History of the Disease

Leprosy, or Hansen's disease, is an infectious disease caused by the bacterium *Mycobacterium leprae*, closely related to *M. tuberculosis*, the microbe responsible for tuberculosis. The microbe was discovered by Armauer Hansen in 1873, before Koch's discovery of *M. tuberculosis*, but the inability to grow the microbe in the laboratory allowed for Koch to be credited with the discovery and for the germ theory of disease, one of the backbones of modern medicine. Leprosy is one of the most dreaded diseases because it is contagious, deforming, and was untreatable previously. Its history dates to biblical times; it was recognized by the oldest civilizations of China, Egypt, and India. Historically, persons who contracted leprosy were quarantined in Leprosaria, or leper colonies, which were widespread during the Middle Ages. A nongovernmental organization (NGO) (IDEA – International Association for Integration, Dignity, and Economical Advancement) is interested in conserving leprosy heritage sites such as leprosara and leprosy hospitals. Remnants of these sites of quarantine can be found on every continent; already some have been turned into museums.

Disease Status: Twenty-First Century

Despite efforts by the World Health Organization (WHO) to eliminate the disease by the start of the twenty-first century, it continues to be a global health threat. However, the number of cases worldwide is declining steadily, with approximately 212,802 cases reported to the WHO at the beginning of 2008. In that year, three countries with a population greater than 1,000,000, Brazil, Nepal, and Timor-Leste, had not achieved the goal of elimination – considered accomplished when at any given time the disease is present in fewer than 1 out of 10,000. Areas of high disease occurrence remain in regions of the Amazon forest in Brazil, the Central African Republic, Angola, the Democratic Republic of Congo, parts of central and west India, Madagascar, Mozambique, Nepal, and the United Republic of Tanzania.

Leprosy in the United States

In the United States, the disease persists mainly through immigrants, although it is reported occasionally in native-born Americans. There is an endemic focus in Texas, around the western Gulf Coast. Armadillos, which have a low body temperature that serves to facilitate the growth of the microbe, can harbor the disease. Infected armadillos have been identified in parts of the United States, such as Louisiana and Texas, and, to a much lesser extent, in Arkansas and Mississippi. It remains controversial, however, whether they transmit the disease to humans. Autochthonous, or local, transmission of the disease was recognized also in Hawaii; Puerto Rico; and, possibly, California.

Effects of the Disease

Leprosy affects the skin and peripheral nerves; it can cause irreversible impairment of nerve function and chronic disabilities. It is suspected that only a small percentage of persons is susceptible to the infection and will develop the disease after contact. While the degree to which one is prone to the disease is determined by the individual's genetic background, at present, there is no publicly available method to determine if a specific individual is at risk. Furthermore, onset can be latent, with many years passing between exposure and the arrival of disease symptoms.

Leprosy can affect children and adults of any age. Although the manifestations are variable depending on the disease subtype, usually a skin lesion presents with or without nerve involvement. Skin lesions can be flat or raised, reddish-brown or pale colored, with raised, well-defined edges and loss of hair. Usually, there is local absence of sensation to pain, temperature, and touch. The lesions can be found anywhere on the body, but they involve rarely the scalp, axillae, or perineum. The specific number of lesions appearing can range from one to many, reflects the number of infecting germs, is key in determining the disease type, is related to other manifestations of the disease, and is a determinant in selecting the most appropriate treatment.

Forms of Leprosy

The disease can take on a variety of forms, in mild forms manifesting as simple, painless, red bumps on the anterior legs. In more severe forms of leprosy, those affected may experience abnormal sensations in their limbs, called peripheral neuropathy, which can lead to deformities and ulcers that will not heal. In advanced disease states, patients may suffer from involvement of the eyes (blindness), nose (septal perforation and nose deformity), larynx, liver, kidneys, testicles (infertility), and bone, leading to disfiguration, disability, and death.

Leprosy Diagnosis

Doctors suspect the presence of leprosy based on the appearance of the skin lesions, the associated complaints and findings, and, most importantly, the patient's exposure history, which makes of utmost importance places and dates of travel, special activities, and contact with sick people or with certain animals. While other methods are still under development and testing, the most reliable means to determine the presence of the disease are examining skin samples under the microscope and looking for the culprit bug.

Treatment

A combination of specific antibiotics is used to treat leprosy. Rarely, one dose of an antibiotic combination is sufficient; in most cases, a prolonged course is necessary, frequently up to 2 years and rarely as long as 10 years, to assure cure and to prevent the emergence of mutant resistant germs. Adequate response to treatment is determined by the disappearance of skin lesions and the reversal of nerve disease. Resolution is slow, and some manifestations are irreversible and can be ongoing; reoccurrence is possible also after ceasing treatment.

Precautions

To inhibit progression of the disease, a physician who is knowledgeable of leprosy and the disease process should examine all household contacts and first-degree and second-degree relatives to detect and treat leprosy cases. Awareness is necessary of the modes of transmission to avoid exposure, occurring mostly through respiration but with the potential for transmission via contact with the skin. Although tuberculosis vaccine is active partially, still there is no reliable way to prevent transmission of leprosy.

Progress of Medicine and Disease Resilience

Leprosy is an ancient disease of which worldwide occurrences have been reduced substantially by the efforts of international organizations, local authorities, local community involvement, and active health care workers. This illustrates the progress of medicine, which has transformed this long-lived dreaded disease surrounded by a nebula of myths into an object of science, with well-defined diagnostic and treatment procedures. It demonstrates also the resilience of certain diseases and the difficulty to control them despite international effort. Finally, it exemplifies the necessity of international cooperation in order to control global health threats.

Liberia

Maura Busch Nsonwu
Department of Social Work, School of Human Environmental Sciences, University of North Carolina, Greensboro, NC, USA

Located on the west coast of Africa, Liberia has a population of 3,441,790 and is surrounded by the Atlantic Ocean on the southwest, Sierra Leone on the northwest, Guinea on the east, and Côte d'Ivoire on the southeast. Guinea, Sierra Leone, and Liberia are known as the three Mano River Union countries of West Africa.

Liberia was named using the Latin word, liber, meaning "free." In 1820, the first groups of repatriated slaves from the United States, referred to as Americo-Liberians, and a second group of former slaves from the West Indies and Africa, the Congoes, were sent to this West African country, inhabited already by a variety of indigenous Africans. These newcomers did not govern themselves initially; the country was run by wealthy, White administrators from the American Colonization Society. In 1839, Liberia was declared the Commonwealth of Liberia, and in 1841, Joseph Jenkins Roberts was elected the first black governor. Liberia received independence in 1847, becoming the Republic of Liberia. In 1870, the True Whig political party was created, and governance was controlled by the Americo-Liberians. With the True Whig party in power, the Americo-Liberians continued to be heads of state until 1980, when Samuel Doe, a Krahn tribesman, became the first indigenous ruler of the country. Of the Liberian population, 3% is Americo-Liberian and 97% is indigenous.

Liberia's indigenous population is comprised of 18 ethnolinguistic groups. These groups, or official tribes, include: Kpelle, Bassa, Gio, Kru, Grebo, Mano, Krahn, Gola, Gbandi, Loma, Kissi, Vai, Bella, Dei, Gbe, Mende, Sapo, and Mandingo – with the Kpelle and Bassa comprising the largest ethnic groups. Although the official language of Liberia is English, many Liberians speak their tribal languages and/or Liberian Pidgin English. The linguistic groups are subdivided into four ethnic cluster groups: the Kwa, the Mande-Fu, the Mande-Tan, and the Mel (or West Atlantic), and each cluster group is comprised of multiple tribal affiliations. Many of these tribal groups have ethnic ties to other West African countries. The Mandingo, Krahn, and Gio are affiliated with tribal groups in Côte d'Ivoire; the Mende and Vai with Sierra Leone; and the Kissi, Kpelle, and Loma with Guinea.

Liberia has experienced years of strife and civil war. Examples include: Rice Riots in 1979, the Doe's coup d'etat in 1980, and a bloody civil war from 1989–2003 when President Charles Taylor's rule ended. Taylor is being tried for war crimes and crimes against humanity due to his brutal rule of the country. Currently, Liberia experiences peace under the rule of the first woman president of an African country, Madame Ellen Johnson-Sirleaf. Despite a period of peace, Liberia is experiencing severe hardship as it struggles to recover from the devastating civil war.

The fighting within Liberia killed more than 250,000 Liberians and caused almost 1,000,000 more of its people to flee their homes and become internally displaced persons (IDPs) or refugees in the neighboring African countries of Sierra Leone, Guinea, Côte d'Ivoire, Ghana, and Nigeria. Population statistics remain fluid and unpredictable as there is significant movement in West African countries due to economic and governmental instability. The United Nations High Commissioners for Refugees (UNHCR) statistics report over 75,000 refugees originating from Liberia during 2009 who are living outside of their homeland. Many Liberians began the process of repatriation to their homeland from neighboring countries in the mid-2000s as the UNHCR's goal was to provide reintegration. Due to conflicts that have spilled over from neighboring West African countries, Liberia hosts over 15,000 refugees from Côte d'Ivoire and 1,500 from Sierra Leone.

Currently in a state of peace, Liberia continues to struggle with the effects of war and abject poverty. An approximately 14-year civil war has produced economic instability, a lack of infrastructure, and significant unemployment. Government programs, humanitarian support, and peace building initiatives are partnering to rebuild social service and educational programs, as well as to develop safeguards against future outbreaks of violence. The declining health and well-being of Liberians is reflected in significantly high rates of infant mortality, shortened life expectancies, a high death rate for adults, low literacy rates, and high infectious disease rates.

Nearly all Liberians have experienced some level of trauma, and many have been victims of torture and rape because of wartime atrocities in their own country or in their country of asylum. Also, it is important to recognize the high incidence of personal, physical, and sexual violence, especially in the lives of Liberian women and children. Often the perpetrators of this violence were rebel fighters, soldiers, or others who had the responsibility to protect vulnerable refugees and IDPs. Some Liberian children were drugged, forcibly recruited to be child soldiers, and forced to commit violent acts and murder against their own family or community. Fears, anxiety, depression, and familial conflict/abuse are a frequent result of the individual and collective suffering of the Liberian war victims. Physicians and mental health practitioners should be alert to stress symptoms and psychosomatic disorders in their Liberian clients. Professionals should utilize culturally relevant support systems such as the Liberian reliance on deep religious faith and their community/familial support systems that may be crucial to assisting these traumatized victims of war. Programs promoting literacy and education should be high priority interventions that will promote self-sufficiency and increase self-esteem.

Life Expectancy

Philipp L. Dines
Geriatric Psychiatry, University Hospitals Case Medical Center, Cleveland, OH, USA

Life expectancy is affected by many factors. The common causes of death vary as a function of age. For example, in data from Canada, that may be representative of many regions globally, the most common cause of death from birth to approximately 44 years of age is injuries and the second most common cause in this age group is malignancies. In the 14-year-old-and-less age group, the third most common cause of death is congenital abnormalities, while in the 15–19 year age group, cardiovascular disease is the most common cause of death. From 20 to age 24, the third greatest cause of death was neurological disease and, in the 25–44 year age group, it was cardiovasculator diseases. In the age group of 45–64, the three leading causes of death are malignancies, cardiovascular illness, and injuries. In age groups from 65 and older and across all age groups, the three leading causes of death are cardiovascular illness, malignancies, and pulmonary disorders.

In addition to age, the number of comorbid illnesses and functional limitations are important predictors of life expectancy. Congestive heart failure, advanced renal disease, severe chronic obstructive pulmonary disease, and significant functional dependencies in ordinary activities of life lower life expectancy. Reduction in functional status and mobility are associated with decreased life expectancy. Life expectancy is negatively correlated with diabetes and the resulting increase in cardiovascular illness. Smoking, hypertension, poor blood glucose control and increased body fat contribute to increased mortality and decreased life expectancy from cardiovascular diseases and malignancies. Cognitive decline and neurodegenerative disorders have a negative correlation with life expectancy. Now 50% of individuals over 85 years of age have Alzheimer's disorder. Additionally, in the age group of 65 years of age and older, suicide is a significant risk to life expectancy. Higher suicide rates have been reported in this group for both men and women.

In men, life expectancy has been lower attributable to higher risk behaviors and using health services less. Further, in older men, it has been reported that work plays a key role in their health and life expectancy as does work-related exposures that may cause ill health and adversely affect the health of men. It has been reported that there is a strongly positive correlation between civic participation and life expectancy. In comparisons between similar populations in the United States and Canada, where health care is more widely accessible compared to the United States, there were findings of greater life expectancy in Canada. Also, measures of quality of health were better in Canada than in the United States for those over 40 years of age and the same for those less than 40 years of age. Health management issues affect life expectancy. Race, ethnic background, and neighborhood socioeconomic status have been found to be associated with life expectancy. In another study, life expectancy and material deprivation were inversely related. Social disparities are widespread and continuing, affecting quality of health and life expectancy.

In the history of life expectancy, the major advance in life expectancy is due to major decline in perinatal, infant, child, and maternal mortality along with increased survival rate for those past 65 years of age. Current trends in life expectancy indicate that in the twenty-first century life expectancy continues to advance although at a slower pace than the rapid increase that occurred in the twentieth century. Men have made gains in life expectancy but continue to lag women. The 80–89 year of age subgroup is the fastest growing age group. As a result of longer life span, major illnesses that affect the increasing aging population are malignancies, cardiopulmonary illnesses, and dementia. The aging process itself is probably related to an accumulation of body and genetic damage. Increasing life expectancy has been associated with decreasing fecundity. Recently, it also has come to light that single genes have extended the life of laboratory animals and that these findings have been found in a wide range of organisms. Life expectancy in the future may involve greater substantial gains.

Regarding immigrants in general, this population tends to be a selected population secondary to multiple screenings that many times occur before arriving at the country of immigration. It has been reported that male and female immigrants to the United States have a 3.4 and 2.5 year longer life expectancy respectively than citizens born in the United States. Most immigrant groups had lower risks of infant mortality. At the same time, the longer the residence of immigrants, the more their pattern of chronic illness and disability approximates, in the case of this report, the United States born. Immigrants continue to be a growing segment of the population of the United States. The disparity in life expectancy advantage of immigrants compared to US-born population has been increasing. From 1979 to 1981, immigrants had a 2.3-year advantage over the US-born population. Explanations put forth for immigrant advantage in life expectancy have been heterogeneity of the immigrant population, selectivity by virtue of the process of immigration, and behavioral characteristics of this population.

An estimation of life expectancy becomes an important component of medical management when a given individual may be nearing the last stage of life. In this case, the physician needs to allocate resources in the best interest of the patient based on weighing the risks and benefits of interventions. Unfortunately, physicians tend to overestimate the remaining survival time of their patients. In addition, the more they know their patient, the more physicians tend to overestimate. As a result a number of tools have been developed to provide better estimation of remaining life span. In estimating life expectancy, the factors that affect life expectancy involve the well-known parameters of age, disease, and functional status. In addition, the physician must weigh the time needed for an intervention to have impact and whether the outcome of that intervention is likely to be effective. A useful construct for thinking about prediction of end stage life expectancy is to consider an algorithm that separates estimated survival time as greater than 6 months, less than 6 months, or a matter of days. A tool to estimate survival in heart failure is the Four-Year Mortality Index for Older Adults. In cases of expected life span of less than 6 months in advanced dementia, a useful tool is FAST, the Functional Assessment Staging Test. In this time span, estimating when to refer for hospice services can be a clinical decision point of significant import as both patient and family may be in significant need of support. Late referrals to hospice have been associated with family perception of reduced quality of care. As determining when a hospice referral is indicated can be difficult, a palliative referral can be a prior step in the process. The PPS (Palliative Performance Scale) is a useful tool for predicting 6-month mortality and was developed for patients with oncological disease. With very low scores on the PPS, this can be an indicator that death is imminent. Cheyenes–Stokes respiration (a pattern of breathing characterized by several rapid breaths followed by a period of no breathing) or protracted apnea are also indicators of impending death.

Life expectancy is determined by many factors. These include age, comorbid illnesses, and psychosocial determinants. Life expectancy has improved drastically over the twentieth century largely thanks to simultaneous advances in public hygiene and medical advances. Life expectancy continues to show gains, but reduced fecundity may occur with an increase in life expectancy in the general population. Recent understanding in aging suggests that life expectancy may experience significant advances as genetic and medical understanding and care progress.

Immigrants are a special select population that have had in the United States and Canada characteristics with advantaged life expectancy to date. However, the longer the immigrant residence, the more chronic illness and disability approaches the US population.

In medical practice, estimating the last stage of life becomes an important process for assessing appropriate interventions in the best interest of patients. Physicians tend to overestimate patient survival time. Several tools have been developed to estimate life expectancy effectively.

Lifestyle

Amy N. Sharpton
Department of Veterans Affairs, Louis Stokes DVA Medical Center Cleveland, Brecksville, OH, USA

The evidence is overwhelming for the importance of a healthy lifestyle; there is an unmistakable relationship between lifestyle and health status. A healthy lifestyle includes not smoking, limiting alcohol intake, physical activity, consuming a higher amount of fruits and vegetables, an overall healthy diet, low belly fat, and maintaining a proper weight. Unhealthy lifestyle factors have been linked individually to chronic disease and premature death.

Chronic diseases are long-lasting conditions that can be controlled but not cured; they have generally a slow progression. Chronic illness affects the population worldwide and is the leading cause of death and disability in the USA. It accounts for 70%, or 1.7 million, of all deaths in the USA each year. Data from the World Health Organization show that chronic disease is the major cause also of premature death around the world – even where infectious diseases are rampant. Chronic diseases are among the most common, costly, controllable, and preventable of health problems. Chronic diseases, such as heart disease, stroke, cancer, chronic respiratory diseases, and diabetes, are by far the leading cause of mortality in the world, representing 60% of all deaths. Out of the 35 million people who died from chronic disease in 2005, half were under 70 and half were women.

Four modifiable health risk behaviors – lack of physical activity, poor nutrition, tobacco use, and excessive alcohol consumption – are responsible for much of the illness, suffering, and early death related to chronic diseases. The results of countless recent studies show that overall lifestyle modification, to include a healthy lifestyle, is critical in disease prevention.

Simple lifestyle measures have been shown to be effective in preventing or delaying the onset of type 2 diabetes and other chronic diseases. Health authorities recommend that people should achieve and maintain healthy body weight; be physically active, including at least 30 min of moderately intense activity on most days of the week, with more activity required for weight control; eat a healthy diet of between three and five servings of fruit and vegetables a day, reduce sugar, and reduce saturated fats intake; avoid tobacco use; and limit alcohol consumption.

Limited English Proficiency

Amy N. Sharpton
Department of Veterans Affairs, Louis Stokes DVA Medical Center Cleveland, Brecksville, OH, USA

Limited English proficiency (LEP) is a term used to describe individuals living in the United States (US) who do not speak English as their primary language and who have a limited ability to read, speak, write, or understand English. The precise number of LEP persons in the US is difficult to estimate because LEP is defined generally, lacking clear qualifying criteria. Furthermore, as in the cases of the decennial US Census and the annual American Community Survey, often respondents are required to self-assess and self-report their English language proficiency in terms of imprecise categories. For example, persons age 5 and older are considered LEP who report speaking English "not at all," "not well," or "well," while persons are considered proficient in English who report speaking only English or speaking English "very well." Although some experts raise concerns over the origin of the data, surveys conducted by the US Census Bureau are accepted as providing the most comprehensive information on the current LEP population and trends.

LEP and Other than English at Home

It is presumed that prior to age 5, language ability is limited for foreign and native-born speakers of all languages; therefore, the figures that follow pertain only to the US population age 5 and older, unless otherwise noted. The US Census Bureau 2000 reports that at home 80.3% of the US population spoke English only. Of the remaining 19.7% who reported speaking a language other than English, Spanish was by far the most commonly spoken (61.9%), followed by Chinese (4.4%), Tagalog (2.7%), French (including Cajun, 2.4%), Vietnamese (2.1%), and German (2.0%). In 2008, slightly over half of the foreign-born population – 19.6 million – was considered LEP; this compares to 15.6 million in 2000. Furthermore, the percentage of persons in the entire US population considered LEP has trended upward in recent years, from 4.8% in 1980 to 6.1% in 1990 to 8.1% in 2000.

English Ability by Language Group and Geography

There are approximately 380 unique languages in the US, each falling within one of four larger language groups: Spanish, other Indo-European, Asian and Pacific Island, and all other languages. According to US Census 2000, the percentage of each group who were identified as LEP included Spanish, 48.9%; other Indo-European, 33.8%; Asian and Pacific Island, 51.6%; and all other, 31.4%. Persons who are LEP are not distributed equally across or within regions of the US. In 2000, while the West had only slightly more than one-fifth of the US population age 5 and over, it was home to more than one-third (37%) of all non-English-language speakers – the highest proportion of any region. Within regions, the proportion who spoke a non-English language at home was 29% in the West, 20% in the Northeast, 15% in the South, and only 9% in the Midwest.

Federal LEP Policy: Brief Timeline

Federal policy relative to LEP has been shaped by three key legislative events: Title VI of The Civil Rights Act (1964), Lau *v.* Nichols (1974), and Executive Order 13166 (2000). The cornerstone is Title VI of The Civil Rights Act, which prohibits discrimination on the ground of race, color, or national origin. Second, in *Lau v. Nichols* (1974), the Supreme Court prohibits national-origin discrimination, denial of equal access to programs or services because of an individual's limited proficiency in English. Most recently, on August 11, 2000, was signed Executive Order 13166 (EO 13166) – *Improving Access to Services for Persons with Limited English Proficiency.* As each federal agency is tasked with taking reasonable steps to provide meaningful access to its own federally conducted activities, EO 13166 was designed to provide persons who are LEP with greater access to federally conducted and federally assisted programs and activities.

Implications for Healthcare Institutions

The evolving federal policy on LEP has specific implications for healthcare, including all non-federal entities that receive federal financial assistance, for example, state agencies, hospitals, physician practices, community clinics, pharmacies, and nursing homes. Federal financial assistance may include training, grants, donations or use of property or equipment, receipt of Medicare or Medicaid funds, and other assistance. The Office of Civil Rights (OCR) within the Department of Health and Human Services is responsible for enforcing Title VI, while the Coordination and Review Section of the Civil Rights Division of the Department of Justice oversees the implementation of EO 13166. According to OCR, in terms of compliance with Title VI, the focus is on whether an institution's policies and procedures support LEP individuals in participating meaningfully in health and social services.

As compared to other US institutions, especially healthcare must be poised to respond quickly to emergent situations and variable environments. In this context, EO 13166 has significant impact, as information frequently must be drafted in multiple languages and disseminated quickly. Of those who speak a language other than English at home, a high percentage of persons in various ethnic groups are LEP. The Centers for Disease Control and Prevention (CDC) reports the following data concerning the portion considered LEP of various groups in the US: Latinos, 39.4%; Hmong, 76%; Cambodians, 70%; Laotians, 68%; Vietnamese, 61%; Koreans, 52%; Chinese, 51%; Tongans, 39%; and Samoans, 22%, while high percentages of LEP individuals exist also among other immigrant communities, such as those from Africa and Eastern Europe.

To assist health centers in providing language services, the Department of Health and Human Services has created access grants. These funds aid health centers so that they can provide translation, interpretation, and other services to assist LEP persons in overcoming language barriers. Studies show that the quality of care increases dramatically when there is clear communication between the healthcare provider and LEP persons. The aim of the access grants is to give those in healthcare the tools necessary to communicate effectively with the LEP populations they serve.

Linguistic Minority Community

Nathalie Piquemal
University of Manitoba, Winnipeg, MB, Canada

In Canada, there has been an unprecedented increase in the number of immigrants from various countries from all continents and representing different categories of immigration (humanitarian, meaning refugees; economic, meaning the labor market needs; and social, meaning family reunification). These immigrants have to negotiate substantial cultural and, often, linguistic discontinuities. Whether it symbolizes a search for adventure or an escape from a war-torn country, immigration generally represents a drastic change in values, customs, society's expectations, language, much of which often leads to significant tensions, feelings of ambiguity, and sometimes a sense of loss. While the process of immigration is, in itself, often intentional, the circumstances leading to the intention of immigrating can range from an enthusiastic search for new (often well-calculated) challenges to a desperate hope for a refuge away from violence, insecurity and instability.

Additional layers of challenges become visible when immigrants who are members of cultural minorities are also members of linguistic minorities. The process of adaptation is more difficult for immigrants whose cultural and linguistic capital is incongruent with what is declared to be the norm, because the immigrant becomes a visible minority within a linguistic minority. As such, parallel to issues of attachment in the development of a renegotiated cultural identity, issues of language marketability and economic health arise as immigrants attempt to secure a job in a social context that privileges English over any other language, even if this other language is the other official language in the country, as is the case for French in Western Canada.

The process of adaptation to a new country involves a number of steps or, to be more to the point, obstacles, some of which are on a systemic and structural level, while others are on a relational and interpersonal level. While a very small minority of immigrants are actively recruited for a well-established purpose (e.g., a well-known scientist, or a high-performing soccer player), in which case settling is structurally organized for them, the vast majority of immigrants struggle (granted, to various degrees, depending on premigration circumstances) to settle. On a structural level, difficulties may include the recognition (or lack of) of prior professional experiences and diplomas, leading to economic hardship such as unemployment and inability to find adequate lodging, systemic inequities in hiring practices, often leading to a low representation of visible minorities in leadership positions, and language barriers, leading to limited meaningful social and political participation. These difficulties potentially threaten the health and well-being of the family, which may have an impact on the most vulnerable, namely the children, and specifically their education. On a relational and interpersonal level, immigrants may experience tensions related to the differing values between host and home cultures. For example, children may be under pressure to behave in a certain way in order to be accepted by their peers at school while feeling an obligation to conform to parental expectations that might be quite different from mainstream values.

While working through these tensions, immigrants often redefine their own sense of cultural identity through two major stages, namely attachment and detachment. Most immigrants experience an immediate sense of attachment toward the host culture, some because immigration represents an adventure and others because it represents peace. However, as immigrants progress through the many, often difficult, levels of adaptation, a sense of detachment from the host culture often follows. In this phase, immigrants may come to miss their home culture, including family members left behind, language, and ways of interaction, and may find it particularly difficult to find a sense of belonging. Feelings of split loyalties may follow until the immigrant is able to emotionally reattach to communities (church, cultural centers, school, etc.) can give him or her a new sense of home comprised of elements of both (or more) worlds.

Additional layers of challenges become visible when immigrants who are members of cultural minorities are also members of linguistic minorities. As such, parallel issues of attachment in the development of a renegotiated cultural identity, issues of language marketability and economic health arise as immigrants attempt to secure a job in a social context that privileges English over any other language, even if this other language is the other official language in the country, as is the case for French in (Western) Canada.

Literacy

Susan Koch-Weser
Department of Public Health and Community Medicine, Tufts University School of Medicine, Boston, MA, USA

Literacy is certainly the ability to read and write, a definition that emphasizes print. The various academic disciplines that have claimed literacy define it more broadly, and conceptualizations of literacy differ across, and even within, disciplines. The variability of definitions is both in terms of the skills included as well as the extent to which literacy is determined by the context in which it is practiced. As a result of the variety of ways literacy has been defined and studied, there are no universal definitions of literacy or standards for determining what it means to be literate. In addition, literacy is rarely considered as a dichotomy, literate versus illiterate, but rather is thought to exist on a continuum.

In the United States, the National Institute for Literacy defines literacy as "an individual's ability to read, write, and speak in English, compute, and solve problems, at levels of proficiency necessary to function on the job, in the family of the individual, and in society." The definition comes from the Workforce Investment Act of 1998, Section 203. Depending on time and context, the reading, writing, and speaking skills required to be considered functionally literate can vary. The literacy skills of a theologian may not be up to the task of reading an article in a physics journal, and the physicist likewise might struggle with an exegesis. Time has also changed our views of what constitutes literacy. During the Civil War, military recruits were judged to be literate if they could sign their name, whereas today's GI is expected to have attained a high-school diploma or GED. When interpreting statistics related to literacy rates, it is important to know how literacy was defined and what criteria were used to assess it.

The United States conducted the National Assessment of Adult Literacy (NAAL) in 2003. The literacy skills of US adults aged 16 and older, including prison populations, were assessed. The NAAL used written materials that might be found at home, in the community, or on the job to assess three types of literacy: prose, document, and quantitative. Prose literacy is the knowledge and skills needed to search for and comprehend information in continuous texts such as editorials, news stories, brochures, and instructional materials. Document literacy is the application of the prose literacy skills, but to noncontinuous texts in various formats, such as job applications, payroll forms, transportation schedules, maps, tables, and drug or food labels. Quantitative literacy is knowledge and skills required to identify and perform computations, either alone or sequentially, using numbers embedded in printed materials, such as a checkbook, a restaurant check, an order form, or a tax form. To characterize the English language literacy of American adults, the NAAL reported results in terms of the following performance levels: nonliterate in English, below basic literacy, indicating no more than the most simple and concrete literacy skills, basic literacy, indicating skills necessary to perform simple and everyday literacy activities, intermediate literacy, indicating skills necessary to perform moderately challenging literacy activities, and proficient literacy, indicating skills necessary to perform more complex and challenging literacy activities. The results for prose literacy among US adults 16 and older indicated that 14% were below basic, 29% were basic, 44% intermediate, and 13% proficient. Results for document and quantitative literacy were similar.

The NAAL provided an opportunity to examine the English literacy of foreign-born adults living in households in the United States. The NAAL data showed that on average, foreign-born adults had lower scores on prose, document, and quantitative literacy. The English literacy scores varied across different background characteristics. Hispanics had the lowest scores compared to their foreign-born peers. Foreign-born Blacks scored above Hispanics, but below foreign-born Whites and Asians. Generally adults who had arrived in the United States at age 11 or younger tended to have higher scores than those arriving at older ages, and more years in the United States were also associated with higher scores. Speaking a language other than English before starting school was associated with lower scores, while higher educational attainment was associated with higher scores.

The NAAL provides an overview of English language literacy among foreign-born adults, but given the great variability between and within immigrant populations, understanding the particulars of each immigrant group will allow for greater insight into potential strengths and weaknesses in terms of English language literacy. Immigrants with strong literacy skills in their native language are likely to quickly develop English language literacy skills if they see the need for them, as many of the skills that contribute to literacy in one language are transferable to another. Immigrants lacking literacy skills in their native language can find it more difficult to learn English literacy skills. It is important to keep in mind that any cognitively normal adult can learn to read at any age; however, as with all adult learning, they must see a purpose.

There are a number of sources of information about literacy levels in other countries that can help provide insight into the literacy levels in the country of origin for various immigrant groups. The International Adult Literacy Survey (IALS) was a large-scale cooperative effort by governments, national statistical agencies, research institutions, and the Organisation for Economic Co-operation and Development (OECD). Using a similar definition of literacy and assessment strategy to the NAAL, the IALS has been conducted in Canada, France, Germany, Ireland, the Netherlands, Poland, Sweden, Switzerland, the United States, Australia, the Flemish Community in Belgium, Great Britain, New Zealand, Northern Ireland, Chile, the Czech Republic, Denmark, Finland, Hungary, Italy, Norway, and Slovenia. Because the same methodology was used, the IALS allows for comparisons across participating countries.

For countries that have not participated in the IALS reliable and comparable cross-national data on literacy rates is often lacking. The United Nations Educational, Scientific and Cultural Organization (UNESCO) has programs in place to develop viable systems to define, monitor, and evaluate literacy across the developing world. Potential sources for international literacy statistics include UNESCO, US Agency for International Development (USAID), and the Central Intelligence Agency (CIA). In 2006, UNESCO published a global monitoring report focused on literacy. The MEASURE DHS project, funded by USAID to collect data on health and population trends in developing countries, includes brief measures of literacy practices (such as frequency of reading) as well as level of education. The CIA compiles country-reported literacy rates in its Fact Book.

Liver Cancer

Robert J. Stern
Department of Medicine, Case Western Reserve
University School of Medicine, Cleveland, OH, USA

Cancers of the liver, or hepatobiliary malignancies, are a growing health care problem around the world. These cancers include malignancies of the liver cells themselves as well as malignancies arising from the passageways, or tracts, within or just outside the liver. Cancerous tumors of the liver cells are called hepatocellular carcinoma, whereas biliary tract cancers include cancer of the cells lining the biliary ducts, termed cholangiocarcinoma, and gallbladder cancer. All of these types of hepatobiliary cancer are strongly associated with inflammation within the liver, the biliary ducts, and the gallbladder. This inflammation is frequently the result of chronic infections or ingestion of various toxins, especially alcohol.

The most common factors associated with the development of hepatocellular carcinoma are chronic infection with hepatitis B virus or hepatitis C virus and chronic ingestion of excessive quantities of alcohol. This is so because chronic viral hepatitis and chronic alcohol abuse can lead to inflammation of the liver, which can lead to cirrhosis, or scarring of the liver, which, in turn, often precedes hepatocellular carcinoma. In the United States, an estimated 30% of new cases of hepatocellular carcinoma likely are to be related to alcohol abuse. Worldwide, however, new cases of hepatocellular carcinoma vary according to the prevalence of chronic hepatitis B and chronic hepatitis C infections. Currently, Asia and sub-Saharan Africa have the highest rates of infectious hepatitis and the highest incidences of hepatocellular carcinoma in the world. As such, immigrants from Asia and sub-Saharan Africa to other regions of the world frequently have higher rates of chronic hepatitis and hepatocellular carcinoma than those born to these other regions.

Hepatocellular carcinoma is the fifth commonest cancer in men and the eighth commonest in women, with an estimated 560,000 new cases diagnosed annually worldwide. The number of new cases of hepatocellular carcinoma is rising due to the prevalence of chronic hepatitis C infection. Many expect incidence may decline over time, however, with more widespread use of vaccination against the hepatitis B virus. People with hepatocellular carcinoma usually present to physicians late in the course of their disease, and median survival is only 6–12 months. Additionally, the surgical cure rate is estimated at 5%. The most common symptoms of hepatocellular carcinoma include jaundice, generalized itching, significant weight loss, and an increase in abdominal girth.

Diagnosis of hepatocellular carcinoma is usually made by its characteristic appearance on imaging, with ultrasound, CT scanning, or MRI; characteristic blood tests; and, frequently, a liver biopsy. If present, the cancer is staged based in its size, location, number of masses, involvement of lymph nodes, and presence of distant metastasizes. Unfortunately, surgical resection and liver transplantation offer the only hopes for a cure and are appropriate for only a small minority of patients. Other treatments, like local or systemic chemotherapy, or radiation treatments, among others, may be helpful to prolong life and decrease symptoms, but their rates of success are poor.

A far less common cancer of the liver is cholangiocarcinoma, which arise from the cells that line the biliary ducts. In the United States, there are approximately only 2,500 cases of cholangiocarcinoma each year. However, in some areas of the world, this type of cancer is very common and accounts for a great number of deaths annually. For instance, in Northeast Thailand and Southern Laos, cholangiocarcinoma is among the leading causes of death each year. This is because infection with the liver fluke, Opisthorchis viverrini, is endemic in these areas of Southeast Asia and is strongly associated with the development of cholangiocarcinoma. Additionally, in areas of the world where another liver fluke, Clonorchis sinensis, is common, like China, Taiwan, Vietnam, and Korea, rates of cholangiocarcinoma are relatively high. Both of these parasites (Opisthorchis and Clonochis) are acquired through eating raw, undercooked, or fermented fish, which allows passage of the metacercariae (or immature stage) of the parasite into the stomach, intestines, and, ultimately, bile ducts of the human host. Once in the bile ducts, this parasite develops into its adult form and lives out its life within these small ducts of the biliary tree. It is thought that a specific type of immune response is directed against this adult worm, and after many years, this inflammatory response leads the cells that line the biliary ducts to transform into cancer cells.

People with cholangiocarcinoma develop symptoms similar to those of hepatocellular carcinoma. Similarly, surgical cure rates of cholangiocarcinoma are generally low, approximately 10%, and median survival is approximately 6 months from the time of diagnosis. Symptoms can be temporarily relieved with use of biliary stents, photodynamic therapy, and radiation therapy – used alone or in combination with chemotherapy.

Cancerous tumors may occur in the gallbladder, but these are uncommon as well, with only 5,000 new cases per year in the United States. Gallbladder cancer usually is associated with chronic inflammation of the gallbladder. This type of cancer is more common in women, and usually begins after the age of 50. These tumors usually grow into adjacent structures in the abdomen, making surgical cure very difficult. The further the tumor has spread, the worse the prognosis. In patients with gallbladder tumors that have spread beyond the gallbladder itself, only 5–10% will live another 5 years. However, sometimes gallbladder cancer is found incidentally at the time of cholecystectomy or removal of the gallbladder. If this is the case, the prognosis is very good, with only a 5% chance of death in the next 5 years.

Liver Cirrhosis

Clifford D. Packer
Department of Veterans Affairs, Cleveland,
OH, USA

Cirrhosis is the replacement of normal liver tissue with fibrosis, scar tissue, and regenerative nodules. It is the final common pathway of many types of liver disease. Complications of cirrhosis can include ascites, peritonitis, esophageal varices, encephalopathy, liver cancer, and liver failure. Hepatitis B, Hepatitis C, and alcoholic liver disease, all common in various immigrant groups, are the three leading causes of cirrhosis and primary (hepatocellular) liver cancer worldwide. Screening, vaccination, and treatment for liver disease are complex issues for physicians, health care researchers, and immigration officials.

Hepatitis B

Hepatitis B (HBV) is the commonest type of viral hepatitis, with an estimated two billion persons exposed and 350–400 million with chronic infection. Of these, 25–40% will eventually develop cirrhosis or liver cancer, causing up to one million deaths annually. Vertical transmission (mother-to-infant) leads to chronic infection in 90%. Consequently, there are high rates of infection in infants and children in endemic areas. Horizontal transmission (via sexual contact, bodily fluids, transfusion of blood products, intravenous drug use) occurs at a 6% rate in adults. HBV is 50–100 times more contagious than HIV. Cirrhosis develops in 15–20% of actively infected HBV patients within 5 years. Endemic areas, with >8% rates of chronic infection, include much of Asia, sub-Saharan Africa, and parts of Central and South America. Between 1997 and 2006, approximately three million Asians and 600,000 Africans emigrated to the United States. Assuming infection rates around 8%, 290,000 new cases of HBV were introduced into the United States over that decade from Asia and Africa alone.

Prevalence studies suggest that this estimate may be low. A study of Chinese immigrants in Chicago's Chinatown showed that 11.1% were hepatitis B surface antigen (HBSAg) positive, indicating chronic hepatitis. A study of Vietnamese immigrants in the 1990s showed a 13.8% prevalence rate. In 2006, the New York Times reported "staggeringly high" rates of chronic HBV infection (around 15%) among recent Chinese and South Asian immigrants to New York City. Recent studies of sub-Saharan African immigrants to Australia showed 19–22% rates of chronic Hepatitis B. In Minnesota, 8% of sub-Saharan African refugees tested in 1999 were HBSAg positive.

Although 40–65% of people with chronic hepatitis B have no symptoms, serious illness is common. In one cohort of Chinese immigrants, severe disease – fibrosis or cirrhosis – was found in 34%. In those who are aware of their illness, cultural taboos and prejudices often make them reluctant to disclose their hepatitis for fear of being rejected and isolated from their families and communities. "Our culture is not to talk about disease," commented a California State Assembly member of Chinese descent with chronic HBV disease. "I was walking around for 20 years not knowing what to do about my own health. I have a one in four probability of developing liver cancer. . .People should not keep this a secret."

The World Health Organization has recommended universal immunization for hepatitis B.

An effective hepatitis B vaccine has been available in the United States since 1982. Vaccination of children and high-risk adults has decreased new cases of hepatitis B by 70%. However, there are still approximately 1.25 million people in the United States with chronic hepatitis B infection, many of whom are immigrants. The US Centers for Disease Control (CDC) recommended in 2008 that people born in either Asia or Africa who currently live in the United States should be tested for HBV. The CDC also recommends testing for refugees, immigrants, and adoptees from countries where HBV infection is endemic. For those who are chronically infected, treatment is expensive ($2,000–$9,000/year), lengthy, often poorly tolerated, and complex because of multiple HBV genotypes and increasing drug resistance. Annual health care costs for the 150,000 US HBV patients with significant liver damage (many of whom are immigrants) have been estimated at $360 million.

Although screening of immigrants is recommended, hepatitis B is not on the US Health and Human Services "List of Communicable Diseases of Public Health Significance" that make a foreign national inadmissible to the United States.

Hepatitis C

Hepatitis C (HCV) has been called "a viral time bomb." It is transmitted chiefly by intravenous drug use, blood transfusions, and infected medical equipment. Unlike hepatitis B, sexual and maternal-fetal transmissions are rare, and adults are far more likely to be infected than children. According to the WHO, 3% of the world's population (170 million people) have been infected with HVC, of whom 80% have chronic hepatitis C. Of these, 20–50% will eventually develop cirrhosis, and about 5–7% may die from complications of the infection. Eighty percent of patients infected with hepatitis C have no symptoms, and most are not aware that they have the disease.

Hepatitis C prevalence is highest in Africa, Latin America, and Central and Southeast Asia (5–10%). The prevalence of HCV is lowest in Northern European countries, including Great Britain, Germany, and France. In the United States, about 1% of the population (3.6 million) are infected. There are pockets of very high prevalence among some immigrant groups. For example, 28.3% of a cohort of immigrants from the former Soviet Union to New York City were found to be seropositive for HCV. This was attributed mainly to inadequate sterilization and reuse of medical equipment. Approximately 20% of Egyptian blood donors test positive for the HCV antibody, probably because of a past practice of mass treatment with parenteral therapy for schistosomiasis. In Italy, the prevalence is >5% in some communities, likely associated with dental therapy and past use of glass syringes. Before HCV screening of blood donors began in 1990, blood transfusion was the leading cause of HCV transmission. Since then, the leading cause of new infections has been high-risk drug behavior (intravenous drug use, intranasal cocaine) and unsafe injection practices. Overall, new cases of HCV in the United States have decreased by 80% since 1990.

Unlike hepatitis B, there is no immunization available to prevent Hepatitis C. Treatment with interferon and ribavirin can induce viral remission, but it is expensive ($10,000), takes 24–48 weeks, and is often poorly tolerated. Response rates vary from about 45% to 80%, depending on the viral genotype. Genotypes 2 and 3, which are more common in Asian, African and European immigrants, generally have better treatment response rates (70–80%) than genotype 1 (<50%), which is most common in US natives. Annual health care costs for the 3.6 million US patients infected with HCV have been estimated at $9 billion.

Hepatitis C is not on the US HHS “List of Communicable Diseases of Public Health Significance;” presence of the HCV antibody does not bar prospective immigrants from admission to the United States.

World Health Organization Recommendations

The WHO has recently published recommendations for prevention and control of viral hepatitis. These include immunization of children and health care workers for hepatitis B, ensuring safety of blood supplies, promoting safe injection practices, supporting development of new vaccines, increasing awareness among communities and health care workers of the opportunities to prevent viral hepatitis, and expanding care and treatment services for people with chronic viral hepatitis.

Alcoholic Cirrhosis

Cirrhosis caused by excessive alcohol consumption is the most common cause of liver cancer in the developed world. Epidemiologic studies show that Europe has the highest per capita alcohol consumption worldwide, and that the highest rates of alcoholic cirrhosis are found in Germany, Italy, Spain, France, and Russia. Immigrants from these countries may be at particularly high risk for cirrhosis and its serious complications. Intermediate rates of alcoholic cirrhosis are seen in the Americas and Australia, and the lowest rates are in Africa, Asia, and the Middle East.

Rates of alcohol use may change as immigrants become acculturated to their new countries. Studies of Asian-American and Mexican-American immigrants, for example, show that their drinking behaviors conform to those of the general US population over time. On the other hand, some ethnic groups and individuals may cling to their pre-immigration drinking habits. In general, rates of alcohol consumption depend on a complex combination of physiologic, cultural, social, religious, and legal factors that are beyond the scope of this article.

Though data on alcoholic cirrhosis in immigrants are limited, the general pattern appears to be that alcoholic cirrhosis is more common in industrialized countries, and hepatitis B is a far more common cause of cirrhosis in less developed countries. For instance, an Australian study of causes of hepatocellular cancer found that excessive alcohol intake was a risk factor for 46% of the Australian-born patients and only 13% of immigrants. Sixty-four percent of the immigrants, however, had markers for hepatitis B infection.

Another factor limiting the significance of alcoholic cirrhosis in immigrants is its higher prevalence in middle-aged and older populations. Immigrants are often somewhat younger than the general US population. About half of new immigrants are 25–44 years old (average age below 37), compared to less than 40% of the overall US population between 25 and 44 (average age above 37). And immigrants may be getting younger: in New York City, the average age of recent Irish immigrants was 24; Mexican immigrants to the United States are now entering at an average age of 21.5. Alcoholic cirrhosis is almost always diagnosed in patients over 35, often substantially older. Therefore, immigrants might be less likely to have alcoholic cirrhosis than natives for two reasons: they are younger on average, and most (with the exception of some European immigrants) come from countries where per capita alcohol consumption is lower and cirrhosis from alcohol less common.

Locura

Mary Jo Garcia Biggs
School of Social Work, Texas State University – San Marcos, San Marcos, TX, USA

Locura has been referred to as a culture-bound syndrome; it is a term used by Latinos in the United States and Latin America to describe a severe form of illness. The term describes a concept of deviance from the norm due to mental illness. A person with locura may exhibit a variety of symptoms, including auditory and visual hallucinations, agitation or possible violence, inability to follow rules of social interaction, incoherence, and unpredictability. Locura is not considered a part of normal life. It is sometimes thought to be the result of supernatural maneuvers (*mal puesto*) of another person but may also occur naturally and without reason to the individual due to the effects of life difficulties. La locura is said to be stronger and more severe than a case of *nervios*. Within the culture, immigrants with locura are believed to have some sort of nervous system weakness. Mental health disorders such as schizophrenia are commonly defined as locura in many Latin American countries and by Latino immigrants in the United States. While others do not blame the individual for their physical illness, there is a stigma associated with locura as there is with most mental health issues. It is understood that the individual does not have the power to control his/her actions one-way or the other but indicates a physical problem. Latinos diagnosed with locura, or a severe mental disorder like schizophrenia, most often live with their families. Thus, families should be considered in the treatment and diagnosis of the illness.

Cultural anthropologists who researched the term "locura" have found that there are vast arrays of differences concerning its meaning within the culture. The various subcultures reported that la locura could occur as the result of child abuse, heredity, accidents, and brain tumors. Conditions such as a weakened mind (the result of thinking too much), and having nerves on the edge are thought to be other contributing factors to the syndrome. Locura is said to be weak or strong, in regard to its impact on the individual. Those with strong locura may not be cured and may commit suicide.

As there are various interpretations of locura, there is also a variety of treatment modalities that an individual may seek. Medical attention and psychiatric treatment or commitments are some of the recommended treatment options. However, consultation and treatment by a curandero (traditional healer) may be considered part of the treatment either alone or a combination with one of the above. It is important that factors in the Latino culture, such as the role that family plays in fostering specific values and beliefs, be considered in order to treat and assess locura. In treatment and diagnosis, culturally informed health care providers must recognize the role and influence of cultural factors, including patient beliefs, values, behaviors, and complementary health practices.

Loneliness

Susan Hatters Friedman
Departments of Psychiatry and Pediatrics,
Case Western Reserve University School of Medicine,
Cleveland, OH, USA

Loneliness means much more than merely a state of being alone. Environment alone does not define loneliness. Loneliness includes unwanted feelings of solitude; it may occur in the presence of others. It may include feeling forsaken, lack of identification with others, or feeling abandoned by others.

Loneliness is based on the person's subjective view, rather than necessarily being related to the objective view of others. Some feel lonely for psychological reasons, some for sociological reasons, and some for biological reasons. A review of over 8,000 people in twin and sibling studies found that genetics accounts for approximately half the difference in loneliness. The rather large research on the importance of attachment and bonding in early childhood has potential implications for loneliness later on in life.

Those who are experiencing true loneliness may experience an overwhelming feeling of separateness from others. They may experience anxious symptoms, depressive symptoms, and feel hopeless, meaningless, or resentful. These feelings, left unchecked, could progress to full-blown syndromes of depression and anxiety. Scales to measure loneliness have been developed. For example, the UCLA Loneliness Scale includes questions about having no one to talk to, feeling a lack of understanding, and feeling shut off from others.

Loneliness represents a public health problem and may be a particular problem for immigrants. One study evaluated the experience of loneliness among hundreds of immigrants from the former Soviet Union to Israel. They compared "distress-related loneliness" and "distress-free loneliness." They noted that while loneliness without distress was considered a normal reaction to a lack of satisfaction with the level of support they were receiving from others, distress-related loneliness was a more general negative experience in which the immigrant experienced other symptoms as well.

Another study followed almost 200 recent immigrants from the former Soviet Union to Israel for a 1-year time period. While 44% of the people demonstrated a normal pattern of permanent low-level distress, 33% had a positive pattern (showing decreasing distress or persisting moderate distress), and the final 23% had a negative pattern with persisting high distress or actually increasing distress. Those with a negative pattern had less social support, and increased stressors related to personality factors and lack of acceptance of the new host culture.

Many people have few close friends or relatives to confide in. Some may need to immigrate due to religious persecution or problems in their homeland. They may need to leave their support system and may become lonely in their new homeland.

Loneliness does not just occur in underpopulated areas. Indeed, those immigrating to large cities may feel cut off from others, and rather feel anonymous in a crowd. In industrialized large cities, there may be many rather temporary residents of various groups.

In the long term, loneliness has been correlated with mental health issues such as anxiety, depression, and alcoholism, as well as physical problems such as cardiac disease, cancer, stroke, elevated blood pressure, and sleep problems. Treatment when a person is lonely or socially isolated may include psychotherapy, which would explore negative feelings, and help the person to reach out and feel connection with others. Establishment of a support system in one's new area is also of importance. Additionally, the social aspects of various religions may be helpful for people experiencing loneliness.

Low Literacy Level

Suzanne Carreker
Neuhaus Education Center, Bellaire, TX, USA

Low literacy refers to limited ability to read, write, and comprehend. Low-literacy adults may be able to read and understand signs, box labels, and simple texts, but they lack the reading, writing, and inferential skills that are necessary for educational advancement, which promotes access to health care, economic improvement, and civic contributions. Furthermore, low-literacy adults cannot provide literacy experiences in the home environment that lead to reading and academic achievement.

Approximately half of adults who are of Limited English Proficiency (LEP) have low levels of literacy skills in English. These adults may have low literacy skills (1) because English is not their primary language, (2) due to limited educational opportunities in their primary language, or (3) because of unidentified language learning disabilities. Important predictors of a child's reading and academic success are the literacy levels of the parents or guardians and the quantity and quality of literacy activities in the home environment (e.g., books read by adults and to child or language interactions between adult and child). Hence, children in LEP immigrant home environments are at risk for reading and academic failure.

The challenges of providing intensive language education were highlighted by an elementary school in a rural agricultural community in northern California. With 48% of its students from LEP immigrant families, the school prepared a plan to improve the literacy skills of all students. In accordance with California Proposition 227, the school was an English-only school. English was not the home language for 98% of the children from the immigrant families. In a district with eight elementary schools, the school ranked eighth in reading achievement on state- and district-mandated measures. Previously, the school had employed literature-based reading curricula that had little emphasis on the teaching of sound-symbol correspondences and other language patterns (e.g., syllable division rules, spelling rules). Moreover, the critical role of oral language in developing comprehension and higher-order thinking skills was not completely understood by all the teachers. A major part of the school's improvement plan was to provide an intensive 30-hour professional development session to all teachers on research-based reading instruction as delineated by the National Institute of Child Health and Human Development. A master reading specialist observed the teachers to ensure fidelity of implementation.

In third grade, two teachers were rated as having high levels of implementation, and two teachers were rated as having low levels of implementation. The achievement of 46 third-graders was measured on a standardized reading test. Seventy-one percent of these students were from immigrant families. On the pretest, no statistically significant difference between classroom groups was found. All classroom groups demonstrated statistically significant gains on total reading scores on the posttest. Furthermore, a statistically significant difference between the reading achievement of students whose teachers demonstrated fidelity of instruction and the reading achievement of students whose teachers taught with less fidelity was found. Students, including those from immigrant families, made greater gains with teachers who had high levels of implementation. Although the sample sizes of teachers and students were small, preliminary data from an ongoing longitudinal study suggest that teachers who deliver explicit reading instruction with fidelity can help to close gaps created by low home-literacy environments.

Certainly, improving home-literacy environments would further enhance the results of the explicit reading instruction. Recent reviews of family literacy programs have advocated the development of programs that increase parents' literacy skills and provide parents with skills to support the literacy of their children. For example, parents in the aforementioned school could participate in literacy classes aimed at providing the most appropriate instruction to help them become more proficient readers and writers. In additional sessions with parents and children, teachers could model literacy strategies for parents, and parents could practice the strategies with their children and then use them at home. Thus, both parents and children would gain the literacy skills necessary for educational and economic advancement and full participation in society.

Machismo/Macho

Marysol Asencio
The Institute of Puerto Rican and Latino Studies,
The University of Connecticut, Storrs, CT, USA

The Spanish term *machismo* is a common reference to Latino masculinity, in particular, the gender construction of extreme traditional masculinity or of the characteristic of the "true" man ("macho") in Latin American and Caribbean societies. The term is commonly employed within Latina/o communities inside and outside of the USA to refer to such males or the behaviors associated with those males. It has been theorized as a form of masculinity derived from the Spanish conquistadores. The complementary gender construct for Latin American women is referred to as *marianismo*.

While the term machismo has become part of the lexicon of lay people and social scientists, the exact definition, associated decontextualized characteristics, and applicability to most Latino men, is a matter of debate. Some researchers have noted that the initial social science descriptions and focus on machismo were obtained from particular populations of Latin American men and then simplified and generalized through an ethnocentric lens. Several scholars have studied the use of the term in the social sciences and have found that machismo as a concept is not well defined or consistently defined in the literature with various characteristics being attributed to the concept without a systematic approach to understanding the larger social context and the diversity among Latino masculinities.

In some of the earliest research, machismo is represented as a constellation of characteristics (referred to as the "machismo complex") while in more recent works it may simply refer to any form of sexism or attitudes that place males in a dominant position over females and other males. The various characteristics attributed to machismo in the social science literature include: male domination and female subordination; the control of female behavior and sexuality; the use of physical and verbal aggression; drunkenness; the refusal to do anything perceived to be feminine; a strong sexual drive with little social constraints; and a desire to father many children, in and out of legal unions, as a sign of virility and conquest of women. Machismo has also been linked to concepts such as invulnerability, courage, honor, respect, and dignity, in particular, around issues of the family, veneration of their mothers, and a sense of obligation to protect and provide for their family. While these characterizations have been seen by some researchers and programs as positive attributes of Latino masculinity, some feminist scholars have cautioned about the underlying power and gender inequality issues also related to these attitudes and behaviors.

Machismo does not prevent men from engaging in sexual intercourse with other men as long as the man takes on the active ("activo") or inserter role in sexual intercourse. The male who is sexually receptive ("pasivo") is placed in the role of the woman and is therefore, the homosexual. This conceptualization of Latin American same-sex sexualities and behaviors is also beginning to be questioned in terms of the rigidity of these roles.

The lack of a clear and consistent definition of machismo as well as the simplistic use of the term leads to its application in research and programs in contradictory ways. For example, research findings that show Latino men do not use condoms can be attributed to machismo. Yet, when Latino men use condoms to protect their partners, it can also be attributed to machismo. Therefore, machismo can

Sana Loue & Martha Sajatovic (eds.), *Encyclopedia of Immigrant Health*, DOI 10.1007/978-1-4419-5659-0,

be seen as both the problem and the solution. Yet, both sets of findings are attributed to a concept that is not directly being studied within the research. Another issue associated with US research utilizing the concept of machismo is the assumption that those behaviors are more likely to be found among immigrants, and that through acculturation males shed machismo and become more egalitarian. This assumption does not take into account the various forms of masculinities in Latin America, the Caribbean, and the USA as well as the social structural factors contributing to particular forms of masculinity. Characteristics similar to machismo are described among Puerto Rican youth born and raised in urban centers in the USA. These characteristics (referred to as Coolin) have been linked to inner-city masculinity, which developed as a response to social inequities within the USA.

In any given population of Latino males, the elements described as *machista* may vary in magnitude or be absent. Latino males may subscribe to different male roles, standards, and types of masculinities. The social science literature shows that the behaviors and beliefs associated with machismo vary across Latin American regions, ethnic groups, age cohorts, socioeconomic status, sexual orientation, geographical locations, and historical periods. Although machismo commonly is presented as a unique phenomenon of Latina/o culture, researchers also have used this term to describe masculinity in a variety of non-Latino cultures. It is a product of the relationship between masculinity and power and framed by the larger socioeconomic and political terrain. The colloquial and frequent usage of the term macho by the media and the general population to describe any form of sexism or hypermasculinity by any individual from a variety of cultural or social groups implicates Latinos as the reference point for such behaviors. Thus, it can create the danger of reducing all Latino men to a decontextualized stereotype.

Mal de Ojo

Konane M. Martinez
Department of Anthropology, California State University San Marcos, San Marcos, CA, USA

Mal de ojo is a Spanish term meaning "evil eye," which is frequently used to refer to a culturally specific illness common in Latin Americans and Latino immigrants in the United States. The origin of mal de ojo has been traced to the Eastern Mediterranean and Greco-Roman traditions, although many variations of this syndrome have existed for thousands of years. The widespread belief of the evil eye in Latin America is credited to the Spanish colonizers who brought it to the continent, amid combinations that resulted from indigenous and folk-healing systems. In Brazil, the equivalent for the evil eye is called "olho gordo" or "mau olhado," that is translated as "fat eye." Among Latin American popular cultures mal de ojo is generally believed to be caused by a strong stare full of jealousy, envy, or admiration directed at either vulnerable or perceived weaker individuals such as women or children. Certainly, babies and infants are considered at special risk for the evil eye, given the fact that childless parents and women may admire and want them. Mal de ojo typically occurs when the child is the object of a strong stare without being touched by the person. Smiling or paying too much attention to a child can also result in mal de ojo. Therefore, protective measures include allowing, and even encouraging, strangers to touch children.

Different symptoms, preventive measures, and methods of treatment have been associated with this syndrome. Symptoms of mal de ojo often consist of fatigue, headache, weight loss, exhaustion, and malaise. Gastrointestinal symptoms may also include desiccation and dehydration, as well as crying and irritability. Wrapping children's wrists with red laces and ribbons are considered as affective talismans against mal de ojo. In addition, it is widely accepted that some people can unintentionally cast a curse on others. The mere act of *ojear* is actually understood as giving someone the evil eye as an involuntary act that is rooted in deep envy or jealousy. In fact, individuals with "mirada fuerte" (heavy look) are considered as potential doers of mal the ojo. They may *ojear* babies, animals, or inanimate objects just by staring and wanting them.

The evil eye may result in diseases, and even death, among the living and in failure of working inanimate objects, such as cars. The figure of the *curandero* is sought to prevent and cure the evil eye among other folk illnesses. A curandero is an important community-based folk healer held in high regard by Latin American transnational communities and Latino immigrants. Curanderos usually treat this illness through a series of rituals aimed at ridding the victim from the strong power caused by the stare. "Cleansing" is one of the preferred healing methods that involves saying prayers while passing a raw chicken egg over the body, in order to absorb the evil power of the person who casted the spell. In Southwestern United States and some regions in Mexico, the egg is then broken and left in a bowl of water under the victim's bed overnight. Finally, the egg is examined the following morning to assess success – the shape of the yolk will tell the curandero if the aggressor was a man or a woman. Other treatments involve a *barrida*, or ritual sweeping of the individual with medicinal herbs.

While mal de ojo has historically been dismissed by conventional medicine as a benign folk disease, research has shown that individuals suffering from this condition have very real physical symptoms that often need immediate medical treatment. In some cases, this syndrome can be life threatening if not addressed. Researchers are currently investigating mal de ojo in relation to diseases readily diagnosed in conventional medicine. In this vein, several studies have found that the evil eye is thought to be the cause of several medical conditions including upper respiratory infections, the flu, and viruses.

Malaria

Douglas W. MacPherson
Department of Pathology and Molecular Medicine,
McMaster University, Hamilton, ON, Canada

Immigrants are also distinguishable from other mobile populations by several characteristics that determine health and disease outcomes. One of these characteristics is directly related to the process of migration and the source and transition countries through which they have moved prior to arrival at their destination. For diseases like malaria that have a defined geophysical limit to the areas of endemic transmission and biological limitations on their incubation periods, the impact of this disease on incoming immigrants is both predictable and inevitable. There are four species of human malaria: *Plasmodium falciparum*, *Plasmodium vivax*, *Plasmodium ovale*, and *Plasmodium malariae* all of which are transmitted by the bite of a mosquito. Blood transfusion, shared equipment during intravenous drug use, and maternal-to-child transmission of malaria occur very rarely.

Of the 108 countries with endemic malaria, only 31 are considered "high impact" countries, most of which are in sub-Saharan Africa. The adverse impact of endemic malaria is almost completely due to *P. falciparum* and its associated morbidity and mortality particularly in children and pregnant women.

In low-transmission but malaria endemic countries, adults may not develop semi-immune or immune status due to frequent exposure to *P. falciparum* and as a consequence may also experience severe illness and death due to this infection. This includes many urban dwellers particularly in sub-Saharan Africa and those who use personal protective measures against mosquito bites and malaria; they may have a similar risk as nonimmune travelers for serious or fatal malarial infections.

Public health epidemiological reports from low to middle income immigrant recipient countries may be challenging to interpret for several reasons. The immigrant-receiving country may also be a malaria endemic area and differentiating where the infection was acquired may be difficult. Epidemiological reporting requirements may not include either malaria or the administrative classification of the affected person. Several epidemiological reporting systems exist in high income countries where malaria generally is not transmitted so that virtually all cases of this disease must be imported. In the USA, approximately half of all reported cases of malaria occurred in immigrant travelers. Immigrant travelers, often also called "visiting relatives or friends" (VFR) travelers, are foreign-born nationals, and sometimes their spouses and locally born children, who return to ancestral homes. Their travel characteristics differ from other travelers such as businesspersons or tourists in location (more often rural), accommodation (non-hotels), duration (longer), and the intent (to visit friends or relatives), as well as other characteristics. In the US report, 70% of VFR-associated malaria was acquired in West Africa, reflecting the immigration source region and risk for return travel to a hyperendemic malaria transmission zone.

Management Considerations

Fever in a migrant (of any nature) to any malaria transmission area should be considered a medical urgency. Appropriate clinical assessment, diagnostic testing, and treatment are essential. Incoming immigrants rarely arrive *in bulk* as occasionally occurs with planned refugee movements that provide a window of opportunity for mass treatment of incubating diseases like malaria. For many reasons, immigrant or VFR travelers do not access, do not have available, or cannot afford pretravel advisory services for the prevention of malaria.

Prevention of malaria in immigrants and the prompt and professional management of malarial illness will reduce personal morbidity and mortality, and also minimize adverse impacts on health care service and delivery systems.

Mammography

Griselda Chapa[1], Antonio P. Linares[2]
[1]Tulane University, New Orleans, LA, USA
[2]Anthem Comprehensive Health Solutions, Walnut Creek, CA, USA

Breast cancer is the most common cancer diagnosed in women worldwide. In low- and middle-income countries (LMC), also referred to as underdeveloped and developing countries, the incidence of breast cancer has increased in the past few decades. This has been associated with risk factors linked to the Westernization of dietary patterns as well as changes in physical activity. Also, infectious disease, which was responsible for a large portion of deaths in lower resource countries, has declined. People who would have died from infectious disease are growing older and age is a well-documented risk for breast cancer. Recent global efforts to promote breast cancer detection identify more cases; newer data collection systems, such as cancer registries and atlases, are better equipped to record breast cancer events. Thus, the coupling of reduced death from competing risk with improved screening and recording systems has contributed to increased breast cancer rates globally.

Mammography screening is the best method of breast cancer detection. Implementing breast cancer detection programs in LMC as well as in resource-poor areas of developed countries is difficult. In recent decades, policy makers and providers have made notable inroads to changing this. Still, even when poor, immigrant and minority women do have mammograms, they continue to be diagnosed for breast cancer at later stages when treatment is either more complex and sometimes near impossible. Consequently, the 5-year survival of breast cancer varies widely from 81% for the general population in the United States to 32% in sub-Saharan Africa.

Well-intended efforts seeking to promote mammography screening face substantial barriers beyond structural and access issues. Cultural barriers are particularly difficult to overcome. The target population may perceive mammography screening as the beginning of a process leading to disfigurement, disability, and death. Cultural barriers are especially apparent where mammogram screening is widely available. In Europe, Israel, and North America, for example, researchers have documented screening disparities in immigrant and minority women.

Remennick details structural and organizational barriers to mammography screening with an emphasis of immigrant women to Israel but cites similar barriers in the United States. She describes qualitative research demonstrating poor women are socialized to be caregivers. Therefore, any behaviors that would potentially cause them to become burdens to their families are typically avoided. This reiterates the need for efforts to promote and increase mammography screening to address sociocultural issues. She provides a concise table enumerating barriers to mammography screening; these barriers include structural, e.g., lack of transportation; organizational, such as language; psychological, such as a fear of cancer; and sociocultural, which includes women's subservience in the household and family. Many of these same barriers have been recently documented as being pertinent to Asian immigrants in the United States.

The focus of this paper will be Latin American women and women of Latin American origin residing in the United States and henceforth referred to as Latinas who face both structural and cultural barriers to mammography screening. The United States Census designation for this population is "Hispanic" and the terms may be used interchangeably depending on the original source cited. These women, for the purposes of health services research, are classified as minority in the United States; a subset of these women is immigrant with diverse levels of acculturation. This distinction is made as much of the available literature cites acculturation as affecting adherence to mammography screening even though the relationship is modified or confounded by other variables such as English language proficiency. English language proficiency helps navigate the health care system but more importantly allows women to be employed in the primary labor market where they are more likely to have access to health insurance. Moreover, there is evidence that only a third of Latina immigrant women residing in the United States less than 10 years have had a mammogram in the past year. Further examination reveals that Latina immigrant disparity differs by country of origin and is attenuated by higher socioeconomic status.

According to the American Cancer Society and the National Cancer Institute, breast cancer is the most common cancer diagnosed in women in the United States. It is the second cause of cancer death in White women and the primary cause of cancer death among Latinas. In other words, Latin American origin women living in the United States have cancer mortality rates that mirror those of women living in low- and middle-income countries. Although mammography rates, which affect incidence and mortality, have been repeatedly shown to be slightly lower in Asian immigrant women, breast cancer mortality is currently higher among Latinas.

Previous to 1989, in the United States, national mammogram rates were lower than 50% and not available by Latin American ethnicity. Since 1989, expanded media coverage coupled with public, private, national, and local efforts have championed the use of mammography to reduce breast cancer morbidity and mortality. Despite the resulting increases in mammogram screening rates, Latinas continue to be diagnosed at later stages, when breast cancer treatment options are more limited.

Data from 2002 to 2006 indicate 55% of breast cancers among Latinas in the United States were diagnosed at the local stage, compared to 63% of cases among White women. They are also more likely to be diagnosed with larger breast tumors and approximately 20% more likely to die of breast cancer than White women diagnosed at a similar age. Many reasons have been suggested for this difference in breast cancer outcomes. Historically, Latinas in the United States have had lower mammogram rates than their White and African American counterparts. The screening and treatment differences have been attributed to various causes and parallel results from studies done with other immigrant and minority groups both in the United States and in other Western countries. These range from cultural belief systems, health care access issues, and insurance status. More recent research has focused on immigration status and citizenship.

PubMed, a service of the United States National Library of Medicine, as of this writing, registers 237 articles found using search terms "Latinas and mammogram" and 312 using search terms "Hispanic women and mammogram." These go back to the 1980s and cover diverse subtopics. Most studies rely on self-reported data from surveys. A large number of studies involve secondary data analysis from national surveys. These include the National Health Interview Survey (NHIS). Screening data from the NHIS are depicted in Fig. 1.

The NHIS is the principal source of information on the health of the civilian noninstitutionalized population of the United States. It is a household survey. A subcomponent of the NHIS, the The Medical Expenditure Panel Survey (MEPS) collects additional data on respondent health care expenditures. This includes data collected from the respondents' medical insurance providers, as well as employers. Other self-reported mammogram data are compiled from the Center for Disease Control (CDC)'s Behavioral Risk Factor

	1987	1992	1998	2000	2003	2005

Surveillance System (BRFSS). The BRFSS is the world's largest ongoing telephone health survey system, tracking health conditions and risk behaviors in the United States yearly since 1984.

Smaller surveys have been conducted and analyzed as primary data sources. Focus groups have helped gather qualitative data not easily available from surveys. Finally, a very small portion of published studies are derived from insurance claims. When claims data have been evaluated compared to self-reported data, the latter have been consistently higher. These diverse data sources contribute to our knowledge base and might best be evaluated as pieces of information that may be helpful in better understanding this health care gap, thereby allowing us to design more appropriate interventions. They should also, however, be evaluated with caution and a clear understanding of potential biases including, but not limited to, recall and selection bias. Recall bias is not relevant to insurance claims data but Latina women are less likely to be insured than their African American or White counterparts.

The United States federal government supports two initiatives to help improve access to mammography services. The Breast and Cervical Cancer Mortality Prevention Act of 1990 established the Centers for Disease Control and Prevention (CDC)'s National Breast and Cervical Cancer Early Detection Program. Under this program, the CDC makes grants to states to provide mammography services to medically underserved women, especially those with low incomes and without health insurance coverage. Although the program has historically covered only about 20% of eligible women, the goal is to cover all eligible women. Program availability, however, has been hampered following the new United States Preventive Services Task Force guidelines recommending screening start at age 50. The second national public initiative relates to coverage for screening mammography under Medicare, the federal government's health insurance program for people age 65 and older and certain disabled people. Additionally, in 2000, the United States Congress passed the Breast and Cervical Cancer Treatment and Prevention Act to facilitate follow-up services, through individual state-managed Medicaid programs, to medically underserved women who are found to have breast or cervical cancer or a related precancerous condition.

Eliminating mammogram disparities became a national Healthy People 2010 goal. Healthy People 2010 provides a framework for prevention for the United States. Additionally, compliance with mammography screening became a quality metric (in the private sector under HEDIS or the Health Employer

Data Information Set) used to compare health plans. The Healthy People 2010 goal of screening 70% of eligible women was not met and disparities continue even among privately insured women.

Before further summarizing the literature on mammogram compliance and Latin American origin women in the United States, it may be useful to acknowledge the diversity of the population. Latin American individuals originate from one of more than 40 countries and may speak a language other than Spanish, such as Portuguese, French, English Patois, and Dutch, as well as an indigenous language. Since the largest and first immigrant group is Mexican origin, much of the available research has focused on this group. Generalizing to other groups should be done with caution. Within-group variation, due to variables ranging from longer residency in the United States to civil status (e.g., refugee, documented, citizen), also affects subgroup heterogeneity.

The second point worth discussing before exploring more research on Latinas and mammography utilization relates to a technological divide between the United States and Latin America. Mammogram technology was introduced in the United States in 1960, but modern mammography has been available only since 1969 when the first x-ray units dedicated to breast imaging were available. By 1976, mammography as a screening device became standard practice and a guideline of the American Cancer Society. Mammogram technology continues to improve as lower doses of radiation now detect even smaller potential problems earlier.

Mammogram facilities and licensed radiologists are common in the United States. This is largely due to the Mammography Quality Standards Act (MQSA) – a Federal law passed in 1992 intended to guarantee mammograms be safe and reliable. Through the MQSA, all mammogram facilities in the United States must meet stringent quality standards, be accredited by the Food and Drug Administration (FDA), and be inspected annually. The FDA ensures that mammography facilities across the country (and Puerto Rico) meet MQSA standards. These standards apply not only to the facility but also to (1) the technologist who takes the mammogram, (2) the radiologist who interprets the mammogram, and (3) the medical physicist who tests the mammography equipment.

In 1997, Mexico's public health department documented that there were 330 mammogram facilities in all of Mexico and 43 radiologists who were certified to read a mammogram. To put this in perspective, California has 729 FDA-approved mammogram facilities; New York, Texas, and Florida, where a large part of the Latino population reside, have 561, 520, and 508, respectively. The United States General Accounting Office (GAO) reports that from October 1, 2001, to October 1, 2004, the number of mammography facilities nationwide decreased from 9,306 to 8,768 but is still adequate, albeit not in all areas.

According to 2005 mid-decade United States Census across ethnic subgroup, 40% of all Latinos in the United States were foreign born and most were of Mexican origin. Among Central American and South Americans approximately 67% and 72%, respectively, are foreign born. Recent immigrant women may not have had access to mammogram technology or may not have had a relative in their countries of origin that had a mammogram. More information on this has become available as a result of the Pan American Health Organization's Salud, Bienestar y Envejecimiento (Health, Well-Being, and Aging) also known as the "SABE" survey.

The SABE study population was 6,207 women aged 60 years or older living in various Latin American and Caribbean cities. Older age, higher education, and health insurance status were strong predictors of mammography use. Women without insurance and with public insurance had 70% and 46%, respectively, lower odds for having a mammogram than women with private insurance. Table 1 presents the survey variables associated with mammogram utilization. An odds ratio greater than one means a woman was more likely to have a mammogram. An interesting finding is that being married, which tends to be associated with having a mammography, had the inverse effect on women in Mexico, where married women were less likely to have had a mammogram. Much has been written on the topic of male Mexican machismo and, in this situation, because spouses would have been older, machismo may have played a role. Moreover, this is consistent with Remennick's qualitative research documenting that women in male-dominated societies are less likely to have mammograms. Across all Latin American sites, medical conditions increased the

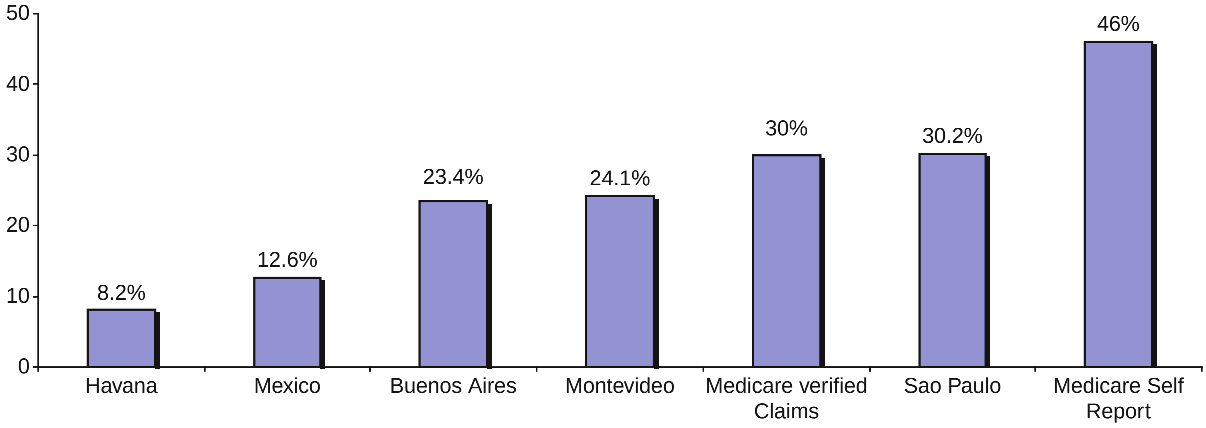
[a] The comparison group is private insurance

likelihood of having a mammogram probably because the woman had a usual source of care. Across studies, having a usual source of care whether that is a private physician or a clinic has been overwhelmingly associated with mammogram compliance. Alternatively, women with functional disabilities were less likely to have mammograms probably due to competing priorities.

Predictors of mammogram in the first SABE survey parallel those in the United States where women with higher levels of education and private insurance have higher screening rates. Two more issues related to the SABE study merit attention. These involve geography and knowledge. The SABE study sampled cities. Women from smaller cities or rural areas are not likely to have easy access to mammogram facilities. Also, the data were self-reported and still very low. This suggests that most women did not see value in (falsely) reporting something they may not have recognized as important. The mean age of the SABE study participants was 70 across study sites. This is comparable to the United States Medicare population. Figure 2 depicts the proportion of SABE survey participants who reported having a mammogram in the past 2 years and compares them to a Latina Medicare population where self-reported data were verified with claims data. The graph underscores the risk of recall bias and demonstrates that Medicare claims data mirror self-reported data from at least one SABE site, Sao Paulo.

A notable finding from the SABE survey is that privately insured women are more likely to have had a mammogram. Most women in Latin America have public insurance. However, in the United States, Latinos are less likely to have any insurance coverage compared to their White or African American counterparts. Still, much of the research published on the Latino population points to the protective effects of having insurance. That protective effect may be linked to the fact that, since the early 1990s, United States health plans have reported quality metrics to the National Committee for Quality Assurance (NCQA) and mammogram compliance for women ages 50 and older is a quality metric.

A Harvard study analyzing NCQA quality metrics across ten health plans discovered that sociodemographic characteristics associated with individual member's area of residence were related to performance measures such as mammogram screening.



Mammography. Fig. 2 Mammogram prevalence within the last 2 years SABE survey participants and medicare Latinas (source: Pelaez et al. 2000)

Sociodemographic data were not specific to each enrollee but rather were estimated from Census data. The findings, however, do reiterate that minorities, low-income and poorly educated individuals, immigrants, are less likely to have recommended medical services. These findings are especially salient because screening differences were found among commercially insured members within the same health plans and therefore were not attributable to differences in insurance coverage.

A number of possible factors may be associated with these detrimental neighborhood effects. Low-income, recent immigrant, and minority populations are concentrated in geographic areas that may have difficulties in recruiting and retaining physicians; poor transportation to health facilities may affect screening rates. Additionally, lower-income, less-educated health plan members may be less aware of the importance of mammogram screening. This finding does not undermine the importance of insurance coverage but does suggest the need to better understand other potential screening barriers.

The research on acculturation and sociodemographic variables has recently taken a new angle. Historically, English language usage was used as a proxy for acculturation. More recent studies have operationalized the concept of acculturation by using citizenship as a proxy. Citizenship requires legal residency in the United States for 5 years and a basic level of English proficiency. This is not only a cultural variable but affects a woman's ability to find work and, therefore, improves her chances of securing health insurance. Women with greater English proficiency are more likely to be eligible for employment that allows them to take time during their work day to have medical care. These are jobs where employees are salaried and not paid in hourly wages. Finally, English proficiency helps a woman better navigate the health care delivery system.

Citizenship is associated with higher mammogram rates. However, the American Cancer Society reports that Central and South American women, who according to census data are more likely to be recent immigrants than Mexicans, have higher mammogram rates than Mexican women. Foreign born women are more likely not to have had a mammogram but this is reversed when socioeconomic status and insurance coverage are evaluated. Recent analyses of National Health Interview survey data reiterate the role of acculturation in mammogram screening compliance.

The older literature on Latino health issues espoused cultural models that described a fatalistic world view that could be equated with an external locus of control. For example, Hazuda, Stern, and Haffner characterized Hispanics as prone to use unconventional medicine and being fatalistic: “Mexican Americans as a whole had a certain ‘cultural tenacity’ about maintaining a religious orientation which places a high value on doing God's will, an outlook about factors influencing one's state in life which emphasizes luck and living for the present, and an attitude toward health and death which is largely fatalistic.” The older research placed more emphasis on belief systems, which in the absence of access to medical care, would have been protective and may have made sense to a low-income, low-literacy immigrant population. Recent research involving focus groups and Latino scholars has examined fatalistic beliefs and found that, in light of other variables, these are less related to noncompliance with health issues than was once believed. Given the elapsed time between the fatalistic studies and more “modern” beliefs, this may be a sign of later generational acculturation.

Mammography data has been available by Latin American ethnicity for approximately two decades. In that time period, mammogram rates have improved but the gap between Latina and White women persist. The more recent literature has examined structural variables affecting access to care and once these are examined, differences in screening are significantly reduced. Having health insurance has been widely cited as being a predictor variable as has having a usual source of care. These are important because they are characteristics that policy and decision makers can affect. But as many researchers have discussed, less acculturated women into the host society require culturally relevant interventions. Table 2 provides a summary of recommendations made elsewhere by Remennick that may help improve breast cancer screening among minority and immigrant women.

Mammography. Table 2 Approaches to improving use of breast-screening services among immigrant and minority women in multicultural societies (source: Remennick, 2006)

Macrolevel approaches
Conduct community needs assessments
Ensure women’s access to breast-screening services
Motivate health care providers to perform screening and to ensure follow-up
Train providers in culturally competent care for immigrant and minority women
Include more immigrant and minority providers in screening activities
Train community outreach workers
Increase the involvement of men in breast cancer and early detection
Involve alternate and traditional healers in breast cancer advocacy
Engage breast cancer survivors in educational and screening efforts
Microlevel approaches
Empower women and improve their self-efficacy and self-care
Educate women about navigating complex health systems
Dispel popular myths about cancer and breast cancer
Encourage a proactive approach in cancer detection
Educate women about contemporary cancer therapies
Elevate the ranking of breast health on the list of women’s health concerns

Managed Care

JAMES T. WALKUP[1], FIONA S. GRAFF[2]
[1]Graduate School of Applied and Professional Psychology, Institute for Health, Health Care Policy, and Aging Research, Rutgers, The State University of New Jersey, Piscataway, NJ, USA
[2]Clinical Psychology, Graduate School of Applied and Professional Psychology, Rutgers, The State University of New Jersey, Piscataway, NJ, USA

Just how managed care impacts immigrant health or how the facts regarding immigrant health have implications for managed care practices are not issues easily analyzed. One challenge comes from neglect by researchers of the conjunction of the two. Managed care has been extensively studied, and excellent reviews exist. While far from comprehensive, an empirical basis also exists for profiling health-related characteristics of immigrant populations, including modest attention to issues potentially related to managed care, such as access, costs, and quality of care. Nevertheless, investigations reporting on both immigrant status and managed care remain very much the exception. A second, more far-reaching challenge comes from the complexity, variety, and constantly changing character of the social phenomena falling under the "managed care" and "immigrant" labels which, we discuss in what follows.

Managed Care

The term "managed care" describes a motley and controversial collection of administrative practices designed to eliminate wasteful health care spending while promoting practices that save money and/or improve health outcomes. It is motley because, historically, the term has been applied to a variety of business and organizational strategies that typically share little more than an intention to alter behavior to promote efficiency. It is controversial because, although most observers would agree that some cost-saving strategies come from superior health care such as better preventive care, patient education, or monitoring of chronic conditions, critics charge that some cost-containment measures deny payment and limit liability even for needed care through tactics sometimes referred to as "rationing by hassles."

In most respects, managed care is a development of the US health care system. While health care systems outside the USA confront many of the same challenges that motivate managed care – the need to use limited resources efficiently, integrate and rationalize care, and organize incentives to promote system priorities – the most characteristic features of managed care reflect the distinctively American reliance on widespread high-cost technologies, an insurance system whose tight connection to employment is supported by tax policy, a fee-for-service delivery system that produces higher revenues for providers who deliver more services, and a historical aversion to direct government influence on costs of care (outside public insurance programs).

Several types of organizational arrangement have been described as managed care. The name Health Maintenance Organization (HMO) dates from the 1970s and refers to an organized care delivery system supported by premiums, either for profit or nonprofit. An HMO may own hospitals, lab services, and the like and employ MDs to treat members (a "staff model"); contract with hospitals and a physician group that pays MDs (a "group model"); or contract with multiple physician groups (a "network model"). A combination of federal incentives and regulation initially encouraged the creation of HMOs, but further evolution in managed care was driven by corporations' efforts to respond to the impact of rising costs, which forced them to devote more and more of their labor costs to health insurance. The resulting demand for cost-containing organizational innovations was more often met by for-profit firms supplying administrative oversight than by HMOs supplying health care. (An example is the decision by individual medical practices to form Independent Practice Associations (IPAs) to contract as an organization for per capita fees.)

Over the past decade, managed care organizations have come to resemble distinct types less than various ways of bundling an assortment of strategies and techniques. A review of these illustrates how the logic of efficiency has developed under managed care.

One set of strategies uses oversight to stop provision of more, or more expensive, care than is really needed. While the problem of excessive care (by some definition) may partly reflect patient demand, the assumption of managed care is that it reflects the incentives of a fee-for-service system in which providers make more money when they provide more procedures (including some that may not be strictly necessary). "Utilization review" requires examination of medical procedures by a third party who can challenge or authorize payment. Specialty care is a particular target. It is expensive, and most efficiently used when reserved for cases that require additional levels of training and technology. Cases that can be effectively treated by a primary care physician should be. When care is managed, a payer may require patients to get a referral from their primary care physician, whose job it is to determine whether the more expensive service is warranted, a function called "gatekeeping."

"Capitation" combines organizational and financial strategies to reverse the incentive structure by contracting with a physician or provider group to supply needed care to anyone in a designated group in exchange for a set amount for each person in the group. With this arrangement, unnecessary procedures reduce the providers' income, making them both more likely to provide no more care than is needed and to keep patients healthy. In practice, capitation may require providers to assume more financial risk than can be efficiently managed, since the costs of a given provider's patients may be hard to predict and prone to fluctuate significantly from year to year based on the very high costs of a small number of patients. A consequence is that providers may use part of the capitated fee they receive to purchase insurance to limit their liability for these very high cost patients.

Other strategies focus on increasing patient engagement in care by promoting prevention, fostering self-care, and trying to make sure patients do not "fall through the cracks" of an often fragmented and poorly coordinated delivery system. A "case manager" is someone who tries to make sure a patient gets the services they might need from a number of different sources. For example, a patient just discharged from the hospital may need to keep a range of appointments, arrange for transport, get complex prescriptions, arrange for consultations, and the like. A case manager's job is to make sure these things get done. Sometimes primary care doctors are expected to provide a medical home that coordinates care among many providers. (This coordination function is not always sharply distinguished from the resource management "gatekeeping" function mentioned earlier.)

Disease management interventions and groups may be provided to educate patients about their illness, medications, and desired behavioral changes – particularly for chronic illnesses. These range from simple, low-cost innovations such as reminders for medication refills, vaccinations, and check-ups, to more extensive investments, such as nutritional consulting or subsidies for exercise programs. Financial disincentives for preventive care may also be reduced by lowering or eliminating co-payments or reducing deductibles.

Immigrant Health

According to Larsen (2004), approximately 12% of the US population is foreign born, and this group is quite heterogeneous. Immigrants differ considerably in characteristics likely to exert direct or indirect influence on health and health care utilization, including country of origin, race/ethnicity, religion, family structure, language, educational attainment, and occupational and socioeconomic status. Differences in legal status are also important, with estimates suggesting the 12% figure is approximately equally distributed among naturalized citizens, legal permanent residents, and undocumented immigrants.

Insofar as managed care strategies represent efforts to control payer costs through oversight, care integration, and health promotion, the first questions to be answered concern how health care for immigrants is financed and how much it costs. The most important generalization in this discussion – that most evidence indicates immigrant health care costs are lower, not higher, than native born – is doubly significant because it is often unrecognized, and is poorly understood. Indications that, overall, immigrants are less costly users of health care services than are US natives are particularly striking, since figures include low frequency, high-cost utilization, such as in emergency room settings, which sometimes are used as a first point of contact for those with no usual source of medical services. Despite concerns over costs of caring for undocumented immigrants sometimes voiced in political disputes, a study by Goldman and colleagues found that figures based on the Los Angeles County Family and Neighborhood Survey suggested per capita costs for undocumented patients were 39% of their native-born counterparts for men and 54% for women. Extrapolating from these data, these researchers estimated a national health care price tag of $6.4 billion for undocumented individuals, 17% of which is funded by public sources.

There is little disagreement that health care spending by immigrants is likely influenced by multiple factors, although the contribution of each is difficult to determine. One influence is dubbed the “healthy immigrant” phenomenon. Most studied among Latino groups, data suggest immigrants arrive in the USA in better health than US natives as measured by indices such as mortality rates, despite exposure to a variety of risk factors for poorer health (e.g., higher rates of poverty, lower education, lower insurance, and less access to care). Hypotheses for this effect include selective migration, in which those who chose to emigrate are particularly healthy; additionally, there may be home-country protective factors that are lost with acculturation in the USA. A second influence that depresses spending may be high rates of uninsurance, with especially sizable rates among low-income and nonnaturalized citizens. These rates reflect, in part, the US linkage of the health insurance system to employment; again, with the caveat of considerable heterogeneity, immigrants are less likely to work in employment settings where insurance coverage is offered through the workplace. For example, they may be more likely to work in smaller or family-run businesses, which cannot afford to provide coverage, and are also disproportionately represented in agricultural and migrant farm work. Legal status determines federal eligibility for public insurance programs, including Medicaid-managed health care plans, although essentially all are eligible for Emergency Medicaid. Low-income legal immigrants who do not receive insurance through employment qualify for Medicaid, but only after 5 years of residence in the USA (in accordance with the 1996 Personal Responsibility and Work Opportunity Reconciliation Act).

A third influence may be culture-specific factors, such as reliance on care delivered outside the formal health care system from traditional healers, combined with a US health care system that can fall short in cultural sensitivity. Costs associated with care received from traditional healers are almost always out of pocket, and utilization is difficult to estimate. (Problems can sometimes arise when patients, concerned about disapproval or a lack of cultural understanding, prefer not to make providers in the formal care system aware of their use.)

If the prototypical target of managed care is the excessive service use of costly insured populations, the profile of immigrant health and utilization might seem singularly unpromising as a focus of concern. A closer examination of the facts suggests otherwise, at least to some degree. First, “healthy immigrant” status is not a stable trait. With increasing time in the USA, immigrants increasingly resemble native-born counterparts across a range of health indicators. For example, among Latinos, more group members smoke, use alcohol and other substances more, and become overweight or obese with adoption of a US diet. This trend co-occurs with increasing service utilization as time in the USA increases. Second, studies suggest rates of recommended vaccinations are lower among foreign-born children and adults. Third, if scrutiny of service use patterns is combined with independent evidence for the existence of access barriers, it is apparent that lower utilization and costs likely coexist with considerable unmet need and fragmented care.

In principle, managed care strategies tailored to promote health and integrate care have the potential to have a positive impact on immigrant health outcomes. Correlations between duration in the USA and increases in certain unhealthy behaviors are an obvious target for prevention and harm reduction strategies, as are low immunization rates. Immigrants are more likely than native born to lack a "medical home" or usual source of care, suggesting managed care's emphasis on primary care could benefit health status and utilization outcomes. Superior rates of preventive care have been found for Latinos in managed care compared to those in fee-for-service. Improved primary care and disease management could offset a perverse incentive to utilize high-cost emergency care. Recent or undocumented immigrants ineligible for Medicaid may have services financed by Emergency Medicaid. Spending for this may be increasing, particularly among elderly and disabled patients, with a significant contribution to their need from chronic illness complications. A potentially significant barrier to care is posed by a cluster of social psychological effects indicative of the social distance between providers and immigrant patients, including communicative style, language barriers, and cultural mismatch. While the construct of "acculturation" has correctly been criticized for collapsing the complexities of identity management into a single dimension, studies find even after controlling for a range of demographic and clinical variables, foreign-born patients who are less "acculturated" often receive inferior care. A patient-centered approach advocated by proponents and defenders of managed care would seem well-positioned to improve health outcomes by stressing cultural competence for providers, provision of skilled translators, and other strategies. Development of these may also create tensions with managed care's cost-containment strategies.

The future relevance of managed care for the delivery of health care to foreign-born populations can be anticipated only in the most general terms. Under any imaginable policy scenario, cost containment will be a pressing priority for the delivery system as a whole. More and more care is likely to be managed toward this end. While the 1990s saw some patient-driven pushback against managed care economies, the prospects for this seem poor today. Economic insecurity provides employers with leverage over employees who prefer to accept limitations on their medical care to unemployment. Uncertainties about immigration policy and how various immigrant groups will fare in the economy only compound the difficulty of predicting how the impact of managed care may be distinctive for the foreign born.

Maquiladora

JENNIFER BURRELL
Department of Anthropology, University at Albany,
The State University of New York (SUNY), Albany,
NY, USA

Maquiladoras are factories or export assembly plants, usually foreign-owned. They are generally contracted by transnational corporations (TNCs) to conduct the final stage of a production process, often assembling and packaging products for export. TNCs provide maquiladoras with materials, including preassembled cloth, electronic components, and chemicals. Maquiladora employees finish or semi-finish products. One hundred percent of maquiladora products are then exported back to TNCs. TNCs import machinery and materials duty-free and export finished products around the world.

In the past 40 years, maquiladoras have taken root on the northern and southern sides of the USA–Mexico border and throughout Latin America, although they also exist in other parts of the world where cheap labor is plentiful. As centers of production in what is referred to as the global factory system, maquiladora workers now provide a significant share of the world's industrial labor. Some 60–80% of maquiladora workers are thought to be women and are subject to low wages and extreme forms of discipline inside of factories.

Maquiladoras were first established along the USA–Mexico border in 1965 as part of the Mexican government's Border Industrialization Program. This program was meant to address wide-scale unemployment prevalent following the end of the Bracero Program, which allowed Mexicans to work under short-term contract in the USA. The growth of maquiladoras skyrocketed following the implementation of the North America Free Trade Agreement (NAFTA) in 1993. By 2003, there were close to 3,000 maquiladoras along the US–Mexican border employing well over 1,000,000 workers. Maquiladoras functioned as a source of employment for people living in the region as well as tens of thousands of Mexicans migrating from other parts of the country and from Central America and Latin America. More recently, they have become temporary sources of employment for migrants who encounter difficulties crossing an increasingly militarized border.

Environmental, Health, and Immigration Issues

According to environmental watchdog organizations, this high concentration of maquiladoras together with loosened enforcement of environmental regulations has led to what the Council on Scientific Affairs of the American Medical Association has called a "cesspool" that breeds infectious disease. The high cost of removing hazardous waste contributes to illegal dumping and the pollution of surrounding water, air, and land. Meanwhile, inside of these factories, workplace safety and exposure to toxic chemicals have alarming health implications for workers. Skin and respiratory protection are not provided, and workers report that drinking water and toilet facilities are inadequate to serve all employees. In one maquiladora, employees reported that there was no lunchroom and they were forced to eat on the floor where their food was at risk of contamination. In another, one employee reported that the workers were yelled at, were not permitted to use the bathroom, and were provided with food that made them sick. These occupational and workplace hazards are have been a linchpin for action and advocacy on the part of many border and labor solidarity activists, particularly the Maquiladora Health and Safety Support Network, a volunteer network of 400 occupational health and safety professionals.

Marginalization

Keren Mazuz
The Department of the Sociology and Anthropology,
The Hebrew University, Mount Scopus, Jerusalem,
Israel

A dynamic range of practices, shaped by an aggregate of factors, most important of which are government migration laws and policy, labor market conditions and the politics of otherness in the host society. The marginalization sustained by migrant workers potentially embraces all aspects of their lives. Marginalization is enacted by classifying, sorting, and regrouping migrant workers through two simultaneous and interrelated practices of bureaucratic categorization and socio-geographic segregation.

Bureaucratic Categorization

Migrant or foreign workers are divided into sharply defined bureaucratic categories of legal workers and illegal aliens. These categories are constructed and reified by host government migration laws and policies. Legality and illegality are juridical statuses in relation to the host state. The boundaries of these statuses determine the ease with which the migrant worker moves between the two, as well as limit his/her socioeconomic mobility. Foreign workers become illegal in one of two ways: if they are found working for an unauthorized employer or without a valid work visa. Those who become illegal may be deported to their countries of origin. Bureaucratic categories produce the marginalization of foreign workers by locating them as noncitizens within the state, with restricted opportunities for socioeconomic mobility, cultural acknowledgment, family reunification, and social security benefits. Additionally, they are often exposing them to civil rights violations.

For the common migrant worker, legal status is often a fragile state and almost inevitably gives way to periods of illegality, due to limited access to legal sources of income. Described as "the servants of globalization," most foreign workers are mainly employed in transient low-wage, low-status positions in secondary sector manufacturing and construction and tertiary sector nonprofessional services, regardless of their education, skills, or qualifications. The nature of their low-skill jobs renders them disposable in the fluid work market, making them vulnerable to exploitation by their employers, who may threaten to withhold payment or fire them if they do not comply with illegal demands. The bodies of migrant workers become their instruments of work. For example, Filipina work migrants worldwide are employed in mothering and care-giving roles such as household servants and geriatric and child care workers. The globalization of care and domestic services from the Philippines illustrates the feminization of the system of care which is based on the stereotypic notion of feminine empathy. Thus it is the Filipina's gendered body which keeps her employed. Often the confluence of gender, race, and ethnicity with migration serves to deepen and intensify the marginalization of migrant workers. This contrasts with the foreign professionals employed in specialized fields such as international business, academia, sports, or the arts who benefit from high-wage and high-status labor even though they are noncitizens within the host state.

Socio-Geographic Segregation

Most foreign workers are segregated into somewhat self-contained sociocultural and geographical enclaves. These enclaves are generally located near state borders or on the periphery of large cities, made invisible to the host country's citizens, in neighborhoods designated specifically and exclusively for the foreign worker, the literal outsider, and proverbial "other." Such neighborhoods are typically low-cost, overcrowded, underdeveloped, and neglected. As a result, they develop into threatening sites for the host society. Sub-enclaves often emerge within these neighborhoods, along ethnic and racial or legal and illegal lines. Marginalization becomes an inherent and practically inescapable state of existence characterized by invisibility, exclusion, discrimination, and exploitation. Therefore, even in countries which grant citizenship on the grounds of *jus soli* (right of soil, i.e., automatic citizenship to those born in the country), as opposed to *jus sanguinis* (right of blood), systematic marginalization may still be inherited by second-generation migrant workers.

Access to health care is an issue which highlights the all-encompassing nature of migrant worker marginalization, and the connection between bureaucratic categorization and socio-geographic segregation. The significance of health care is paramount, because as a low or unskilled laborer, the foreign worker's body becomes his/her primary work instrument. However when this body breaks down due to illness or injury, it can be easily replaced by younger, stronger, healthier bodies from the tireless flow of migrant workers. From the perspective of the migrant subject, falling ill becomes a cost-prohibitive luxury. In addition, most foreign workers as noncitizens do not receive national medical insurance. At best, legal migrants are covered by a private policy purchased by their employers. Even then several issues arise: Does the private health insurance cover only emergency treatment or also pregnancy, well-care, and chronic sicknesses? Does the policy ensure reasonable access to quality care? Does the migrant worker lose his or her medical immunity if the employer is the owner of the health insurance policy? Thus, migrant vulnerability and marginalization, which are consequences of migration laws and policies, become taken for granted as natural exigencies of the social order. Hence, the marginalization of the migrant worker becomes a potentially endless, self-propagating cycle of practices, performed and patterned along two axes: an *external* axis between the host society citizens and the foreign worker noncitizens, and an *inner* axis between the foreign workers themselves (in their work sites, neighborhoods, or even within their families), delineating professional and nonprofessional, legal and illegal.

The marginalization practices emerge along both axes from complex connections between migration laws and policies, economic conditions, and social relations which shape the daily reality of the migrant worker. For the host state, the marginalization process is a double bind. In order to maintain their high standards of living, developed countries demand cheap and plentiful labor, while keeping the laborers themselves at arm's length. At the same time the host countries feel threatened by the growing number of foreign, marginalized people within their borders.

Marianismo

Marysol Asencio
The Institute of Puerto Rican and Latino Studies,
The University of Connecticut, Storrs, CT, USA

Marianismo is a Spanish term used as a reference for the prototypical woman among Latin American and Caribbean people. It is also the complementary gender construct to machismo. Marianismo is an obsolete concept used to explain Latinas' gender norms and sexuality. The term is much less frequently used in the social science literature as a gender construct than machismo. Yet, the characterization associated with this term frames the discussions on Latinas, culture, and gender.

Marianismo (or Mariolatry) is linked with the deep worship of the Virgin Mary. Marianismo ("the cult of the Virgin Mary") has been thought to influence the female ideal in many cultures (including non-Latina/o cultures) where Catholicism has been dominant. The characteristics associated with the Virgin Mary are assumed to provide the example for women to emulate. As such, marianismo confers on females a spiritual superiority over men which can provide them with a place of power in their personal relationships.

Marianismo includes the expectation for women to be virgins, asexual, submissive, humble, tolerant, faithful, and devoted to the male partner and assume the sole responsibility for childrearing and caregiving to the family. Motherhood in particular is exalted. A female's love for a male is demonstrated through complete trust and martyrdom. Although the honor of the family is connected to the sexual purity of females, virginity in perpetuity is not supported unless women enter a religious order. As with many societies, women who never marry or have children may be perceived as strange, problematic, or objects to be pitied. Marianismo also frames the madonna/whore dichotomy of womanhood. It represents the madonna (Virgin Mary) and therefore, it distinguishes itself from the whore category (which in Catholicism is a reference to Mary Magdalene). The characterization of Latina womanhood (as a well as in other societies) is predicated upon expectations of female sexual behavior. Most commonly, a female who is sexual or has sexual intercourse outside of marriage is labeled "a bad woman" (*mujer mala*) or "a whore" (*puta*). The madonna (virgin) is supposedly protected under machismo, but the whore can be a target for male lust and abuse. This creates the necessity to have a relationship with a man, in particular through marriage or a committed recognized union, for a woman to be perceived as "respectable" to the larger society. There is a societal expectation that women do not talk about sex with men since this may not only be seen as vulgar behavior in women but as a sign of sexual promiscuity. The label puta (whore) is also used as a way to silence women.

Another gender construct associated with marianismo is "hembrismo" (femaleness). Although some scholars have used it synonymously with marianismo, others have characterized it as a different gender construct altogether. In the latter case, hembrismo is a reference to a Latina woman who is of strong character, perseveres, and is a survivor. She is neither submissive nor passive as with marianismo. This gender construct, unlike marianismo that privileges the colonial influences in Latin America, derives from depictions of strong indigenous women of pre-Columbian times and represents a matriarchal figure whose actions are geared to benefit family and community. This gender construct explains female's agency in negotiating oppressive sociopolitical environments, such as the Latina who provides financially for her family or fights against social injustices. A more recent usage of the term hembrismo defines it as being the female version of machismo. As such, it has been connected to beliefs of female superiority and dominance over males, discrimination against males, or devaluing males. In some popular writings, it has been equated with the Latina feminist. Hembrismo, regardless of its varying conceptualizations of Latinas, is even less prevalent in the social science literature than marianismo. In the portrayals of Latina womanhood, what seems to remain consistent is the centrality of motherhood.

Marianismo (*and hembrismo*) are often broadly defined with multiple characterizations and based on limited research with Latina populations. To characterize all Latinas as marianas diminishes the range of femininities ascribed to by Latinas and makes invisible the larger socioeconomic and political environment that frame their attitudes and behaviors. Modernity, urbanization, and other economic and political changes have influenced the expectations and characteristics of womanhood for Latinas in the USA, Latin America, and the Caribbean. There has been a long history of women's rights movements across Latin American and Caribbean nations. Age, socioeconomic status, ethnicity, geographical status, generational status, and region have been shown to play important roles in how gender is enacted by Latinas. Moreover, some of the same marianista characteristics associated with Latinas are also found among women in non-Latina/o societies and non-Catholic societies including non-Latina White women in the USA.

While the actual term marianismo is less frequently used in the literature, the associated characteristics such as passivity, lack of agency or voice, lack of employment or career focus, sexual naïveté, and the bearing of (many) children are present in popular images of and research references to cultural values, in particular those of immigrant Latinas. The term and accompanying characteristics rely on a narrow and uncritical perspective of culture and gender, including the idea that there is such a thing as a Latina/o culture rather than Latina/o nationalities and cultures. As such, it creates a stereotype of all Latinas that feeds into ethnocentric beliefs about Latin American and Caribbean societies. It also reinforces the beliefs that Latinas are embedded in tradition-bound systems that are impervious to change and less evolved than other Western societies, in particular that of the USA and Europe. As such, when a Latina in the USA shows agency or more egalitarian beliefs, she is a product of acculturation rather than representing the diversity of gender perspectives found among Latinas and Latin American women. In addition, ethnocentric images of Latinas as highly fertile and passive also support concerns about them being a drain on the welfare system and an immigration "threat."

Marijuana

Timothy P. Johnson
Survey Research Laboratory, University of Illinois
at Chicago, Chicago, IL, USA

Marijuana is a psychoactive substance derived from the cannabis plant. Its documented use dates back several thousand years, and it is currently considered the most commonly used illicit substance in the world. It can be ingested in several ways, most commonly being smoked as a cigarette or in a pipe. It can also be smoked as a "blunt" (i.e., a cigar that has been emptied of tobacco and repacked with marijuana and sometimes other drugs), mixed with food, or brewed into a tea. Acute effects of marijuana use may include impaired motor coordination and balance, increased heart rate, short-term memory loss, and other impairments to cognitive functioning. Chronic use may lead to several long-term effects, including respiratory problems such as chronic cough, bronchitis, and emphysema, a weakened immune system, heart problems, and increased risk for some cancers. Marijuana is considered to be addictive and it may also be associated with several mental health conditions, including anxiety, depression, suicidal ideation, and schizophrenia, although causality has not been established. There is currently ongoing debate in some nations as to whether marijuana also has medical applications, primarily for alleviating the symptoms associated with a variety of chronic medical conditions such as AIDS, cancer, and multiple sclerosis.

There is a growing body of evidence linking international migration with the risk of marijuana use initiation and increased frequency of use. Numerous empirical studies conducted in the USA have documented increased use of marijuana within US-born and English-speaking minority populations, relative to members of the same groups born elsewhere and having immigrated to the USA. The longer the immigrants reside in the USA, however, the greater their patterns of marijuana use come to resemble those of the native-born population. Similar associations between immigration status and marijuana use have been found in Western Europe. There are several potential explanations for these findings.

One commonly cited explanation is the assimilation, or acculturation, hypothesis, which suggests that immigrants will over time adopt the social values and norms of the dominant national culture as their exposure to it increases and they acquire new language skills. To the extent that immigrants' transition from more traditional and conservative societies to more modern and liberal ones, the risk of initiation of marijuana and other illicit substance will also increase.

A contrasting view, known as the acculturative stress hypothesis, holds that the multiple psychological, social, cultural, and economic stresses associated with migration, along with feelings of marginalization, experiences of discrimination, and pressure to rapidly adapt to a new cultural environment, may encourage maladaptive coping among immigrants via marijuana and other substance use behaviors. The increased stress characteristic of neighborhoods with high levels of social disorganization, poverty, and crime into which many immigrants are consigned further contributes to this process.

A third hypothesis, known as the segmented assimilation theory, posits that there are multiple pathways by which immigrant populations adapt to new social environments, and that these pathways may mediate the risks confronting immigrants. According to this model, some immigrants are able to successfully acculturate to the values of the host society and, consistent with the acculturation hypothesis, become more vulnerable to illicit drug use as they do so. In contrast, other immigrants fail to successfully acculturate, possibly due to the stresses and pressures central to the acculturative stress theory, and become permanently marginalized on the fringes of society, where substance use may be a more normative coping strategy. A third group consists of immigrants able to successfully preserve their traditional cultural values and relationships while navigating the new host society. The traditional values and strong family and ethnic social ties available to these individuals may provide important buffers that offer protection from the stresses and pressures confronting immigrants, thereby decreasing the risk of marijuana and other substance use initiation. Supporting this hypothesis, empirical research has identified protective effects of living in neighborhoods with high concentrations of recent immigrant populations by documenting the association between residence in these "immigrant enclaves" and reduced risk of marijuana use.

The risks associated with increased marijuana use among immigrant populations may thus be best understood as a consequence of multiple, reinforcing social processes taking place concurrently at individual, family, and social structural levels. Within Western nations, immigrants largely gain access to marijuana via the same illicit market channels as do nonimmigrants.

Marijuana and other substance use norms in nations of origin may also be influenced by immigration, as some evidence exists that returning immigrants, and families reporting having members who have immigrated to nations with more permissive substance use cultures, are at increased risk for marijuana use initiation.

Finally, in addition to the known health risks and domestic legal penalties associated with marijuana use, there are many nations in which the possession, marketing, and/or smuggling of marijuana may lead to deportation for immigrants and other noncitizens. In the USA and some other nations, anti-immigration politicians often accuse immigrants, among other things, with the smuggling of marijuana and other substances into the country.

Marriage

Cristina Gavrilovici
Department of Legal Medicine, Medical Deontology and Bioethics, University of Medicine and Pharmacy "Gr. T. Popa", Iasi, Romania

There are far more international immigrants in the world today than ever previously recorded, and their number has increased rapidly in the last few decades. There were an estimated 214 million international immigrants in the world in 2010, representing an increase of almost 40 million in the first decade of the twenty-first century, and over double the number of international immigrants in 1980. Europe hosts the largest number of immigrants, followed by North America and Asia, which host nearly 25.3 million. Most of today's immigrant workers come from Asia. Migration marriages remain an intriguing phenomenon in many parts of the world. Since 1974, family migration has become the most popular way of settling in Western Europe. Many immigrants from South Asia (i.e., India, Pakistan, Bangladesh, and Sri Lanka) form today one of the fastest growing immigrant groups in Canada and USA.

A vast majority of immigrants enter the host country on the basis of family migration, more specifically, on the basis of marriage migration. The popularity of marriage migration is often explained by its instrumental role in making migration possible. The tendency within immigrant communities is to marry someone who grew up in the country of origin.

Macroeconomic factors, such as globalization, unequal economic development between countries, and feminization of poverty are the driving forces in most of the international marriages. According to economic migration theories, it is assumed that people leave their country in order to improve their socioeconomic situation. However, there is also a lot of evidence that the socioeconomic situation of such immigrant communities is many times problematic compared with that of mainstream society. Men are particularly motivated to immigrate in order to improve their socioeconomic situation. They are quite sure that earning a living will be much easier in Western countries. While women also share this view, they often stress the broader advantages of living in a democratic, prosperous country with a sound social security system: access to health care; more social rights for women; better financial provisions in case of sickness, unemployment, and retirement; and also more sociocultural opportunities. Women also share a lot of admiration for the Western health system. Not only young people from poor countries perceive immigration as a relevant project, but parents also dream of having their children immigrate to Europe. The socioeconomic security for their children in combination with easier access to the West for them are the most appealing elements that apparently seem to counterbalance the potential settlement challenges due to systemic, informational, cultural, and linguistic barriers. One can thus notice that there are totally different values that are supposed to be shared between the two partners within an immigrant marriage.

However, once they arrive in the host country, immigrant women may experience multiple oppressions not only from their own community (e.g., gender and class-based norms) but from the dominant society as well, based on their immigrant and ethnic minority status.

Once arrived in their host country, many women often become financially dependent on their husbands and stay at home, thereby limiting their opportunities to socialize, learn the second language, and develop skills to access available jobs. Moreover, the loss of an extended family system after migration increases their social isolation along with a greater burden of housekeeping tasks, which used to be shared in the extended family.

South Asian immigrant women commonly endure culturally prescribed rigid gender roles and patriarchal norms. If they secure employment, those women who work outside the home report triple workloads of paid work, unshared household everyday jobs, and care giving, unlike their male counterparts. Due to a small circle of family and friends, the magnitude of their multiple work responsibilities is also higher than among native born women. This new reality is likely to limit their opportunities to integrate in the host country.

Migration opportunities have a major impact on changing the concept of "family" and "marriage" not only in countries of origin, but also in the host country communities. Especially in Islamic communities, marriage plays a crucial role. Islamic tradition legitimizes the existing gender roles and family values. The spouses are expected to fulfill the tasks related to their gender role and to assure the continuity of the family. Marriage is primarily an alliance between two families. Traditionally, it is the family and not the future spouses who negotiate the marriage arrangement. This conception of marriage which is foremost a negotiated contract between two families fits well within the context of migration where spouses-to-be have far fewer chances of being acquainted with each other than if they lived within the same country, let alone the same community. From a traditional perspective, this is not considered problematic. It is assumed that parents know best whom their children should marry. However, parents have no direct information about the personality and behavior of the future son/daughter-in-law when they live in another country. In the case of migration marriages, it is not unusual for there to be no more than a few days between the decision to marry and the wedding. The parents sometimes take advantage of this situation to hide negative aspects about their children from the future family-in-law, such as disease, drug addiction, "shameful" behavior, or delinquency.

Another issue that may affect the married immigrants' health more than non-immigrants is domestic violence. Although the "battered spouse protection" under the immigration laws is worded in gender-neutral language, it is aimed clearly at women who suffer abuse. The prevalence of physical abuse among South Asian immigrant women varies from 35% to 41% and for sexual abuse is around 19%. The reality of partner abuse is sociohistorically built, women's oppression arising out of the social structures, such as women's gendered inferior roles through societal norms of men's superiority. There is a long delay in seeking help from professionals among abused women of all backgrounds and generally low rates of help-seeking from medical, social, and legal professionals. Many Asian women, like women from many parts of the world, are taught to keep a tight lid on things that might bring dishonor to the family, either her birth family or her family by marriage. The reasons for such a prolonged delay include: social stigma, women's gender roles (silence, marriage obligations, subordination), children's well-being, and lack of social support. Disclosing facts about domestic violence is perceived to bring suffering and loss of respect especially for their family and parents. On the one hand, they may use silence as a strategy to divert attention away from themselves, and view this practice as an indicator of their own strength, as opposed to their weakness. On the other hand, women may feel that the social prescription of "silence" enhances their vulnerability to abuse because their husbands take advantage and the situation worsenes. In the context of an arranged marriage and a desire for harmony, women may feel obliged to maintain the bond and, hence, be able to identify themselves as a "real woman."

Women in an arranged marriage may be hesitant to apply for "battered spouse" protection under the US immigration laws, for fear that it will bring her shame. Quite often, such women are told (and believe) that the INS (Immigration and Naturalization Service) will order them deported if they complain about their spouses or that the conduct of the abusive spouse is somehow their fault or their responsibility. While these beliefs are not limited to women from Asia, quite often the conservative religious and cultural values in Asia contribute to them. It is often difficult to prove the mental or physical cruelty necessary to establish a battered spouse petition.

When the time comes to file the application with the INS, there is little or no proof evidence supporting wife's testimony. If the husband is especially vindictive, he can claim that a traditional marriage dowry was actually a payment for him to immigrate the wife – something that appears to be marriage fraud. A woman unfamiliar with US immigration laws or US culture can accidentally make things worse if she agrees that money was paid for her husband to marry her. Unless it is immediately clarified that she is talking about a traditional dowry or bride price, the INS can assume that the wife married the husband solely for the purposes of evading the immigration laws. This conclusion on the part of the INS results in the wife becoming ineligible to immigrate to the USA for life.

Maternal Dietary Intake

Margaret D. Larkins-Pettigrew
University Hospitals MacDonald Women's Hospital,
Cleveland, OH, USA

Maternal dietary health is the corner stone for predicting the survival of mothers and their newborns. The mother's pre-pregnancy weight is a key factor in predicting the survival of the mother and her newborn. Immigrant women are usually underweight and therefore are at increased risk for producing newborns that are at low birth weight and more vulnerable to infectious disease. Subsequent weight gain or loss during pregnancy may result if health choices are unavailable or if there are limited food sources.

The recommended dietary allowance for pregnant women consists of 3 servings of milk, 3 servings of fruit, 4 servings of vegetables, 6–12 servings from the bread group, and 3 protein portions. Folate supplementation is often needed to equal 600 micrograms (1,362 nanomoles) in addition to foods to reach the recommended intake of folate. Several small meals per day and a minimum of eight glasses of water are recommended.

Diets that lack dairy products or a variety of vegetables have placed many women at risk for vitamin D, folate, and iron deficiencies. In one study, Pakistani women in Oslo were found to have the poorest vitamin D intake but all women from Turkey, Iran, India, Sri Lanka, and Vietnam had significant deficits as well. African-American women in the United States who experience the highest rates of low birth weight newborns have also been found to have a diet that lacked dairy products. This is a significant concern for immigrant women who find themselves in communities where traditional foods and ingredients are not readily available. The early pregnancy hormonal challenges that cause nausea and vomiting may be accentuated when new foods are attempted.

Pica, the disorder of intentionally ingesting nonfood substances, is another dietary challenge in many ethnic groups; pica may result in lead poisoning. Geophagia, the consumption of clay dirt, remains a common practice in African-Americans in the United

States. The consumption of pottery ingredients by some Hispanics groups, “tierra,” is believed to add supplemental iron and calcium resulting in healthier babies. As a result of pica, many newborns suffer long-term cognitive and social development disorders resulting in difficulty in later life when they attempt to enter into the mainstream workforce. Impaired growth of female neonates often results in short statured adult females who encounter complications during the delivery of their own children such as obstructed labor, damage to bowels and bladder, and neonatal death.

Prenatal health care facilities that are sensitive to the challenges of immigrant population have developed programs that attempt to eliminate barriers to care, such as language and transportation. Grants and monetary support of such programs have increased the opportunity for immigrants to receive early prenatal care and nutritional counseling. Early prenatal care that includes dietary counseling may dispel myths, reduce harmful practices, and result in improved neonatal outcomes and maternal well-being.

Maternal Employment

Margaret D. Larkins-Pettigrew
University Hospitals MacDonald Women’s Hospital,
Cleveland, OH, USA

Employment of expectant mothers who have uncomplicated pregnancies is a reasonable expectation especially if she has other children that must be cared for. Many immigrants find themselves in economically challenged positions and work is necessary for day to day survival. Women who are not expecting a child fare better when attempting to find employment but may often have to settle for low-paying domestic jobs.

Legal challenges are the limiting factors in the United States, but these challenges may not exist in other countries. US employers are bound by the Immigration and Naturalization Act of 1990 to employ qualified workers in a safe environment. They may also be penalized for hiring undocumented workers and may be subjected to fines and/or incarceration.

Immigrants must meet legal requirements to work and/or receive medical care. For example, in the United States individuals who enter as nonimmigrants, meaning that they are not going to remain in the United States permanently and are entering for a specified purpose, must hold specified visas to be able to work legally. Individuals who are asylees or refugees can request permission to work. Specific documents that support the right of employment and proper identification must be kept current to avoid the risk of deportation. In some countries displaced persons have no legal restrictions and may seek employment that is consistent with their skill level.

The workforce for immigrants with a low skill level is often limited to housekeeping, janitorial, and child-care opportunities. The pregnancy state itself does not limit the mother's ability to work but some jobs may be difficult as long standing, heavy lifting and body habitus prohibit some job opportunities. Jobs that place the pregnancy at risk, such as those that involve chemical exposure and heavy machinery work, should be avoided.

Women who work and enjoy healthy lifestyles during their pregnancy have fewer complications and outcome data show reduced labor stressors and improved neonatal outcomes. Postpartum recovery periods are shortened and postdelivery depression is minimized.

Matrifocal Family

Laila Prager
Institute of Ethnology, University of Münster,
Münster, Germany

Usually this term is used to refer to a residential kinship group with no male in the role of husband/father being regularly present, and where women constitute the focus of the family. Comparative anthropological research has shown that matrifocality can be a culturally preferred or accepted feature, often but not exclusively in connection with matrilineal descent, as among the Minangkabau in Indonesia, the Na in China, or in some societies of the Afro-Caribbean region (e.g., Barbados). Presently, however, there are many other societies that display a tendency toward the emergence of matrifocal families, though officially such a family structure is still deemed as a social anomaly. Examples include the Middle East where men are expected to wield authority over the female family members, or in parts of China where fathers are the uncontested head of the family, or Cuba with its idea of machismo. Despite the overall value of male domination, these and other regions are witnessing an increasing number of matrifocal families bringing about new challenges with regard to long-established gender roles and intra-familial authority.

The reasons for the emergence of matrifocality in traditionally male-dominated societies are to be found in social transformations, which lead to different forms of social instability, such as diasporas and armed conflicts (married women living alone while their husbands are fighting or being imprisoned), or economic pressures entailing the large-scale work migration of men who usually leave their wives and children behind "at home." This "home" can either be situated in the country of origin or in the immigration context, as the Chinese case indicates. In China, during the second quarter of the twentieth century, matrifocal families increasingly came into being as a corollary of the US Immigration Act of 1924, under which the wives of Chinese labor migrants were forbidden to follow their husbands to the USA. As a consequence, while working and living in the USA, the men had to marry in China and leave their children to be raised there. Later, this pattern was reversed, so that Chinese wives and their children now live in the USA while their husbands seek employment in other countries and only come back once or twice a year to see their wives and children.

Health problems evolving as a direct consequence of matrifocality are most likely to emerge in those cases in which matrifocal families are situated in male-dominated societies where such a type of family structure is usually devalued compared to the socially acknowledged ideal of the two-parent family, or among immigrants from male-dominated societies (i.e., Middle Eastern immigrants). Under such circumstances, women not only have to cope with the sole upbringing of their children, but they are also frequently struggling with an “inappropriate” gender role and suffering from exclusion from the major social and/or religious activities, be it in the home or in the host society. This exclusion has been emphasized by psychologists and sociologists as constituting the major factor for the emergence of mental health problems among single-parent immigrants. Clearly, this applies less to those immigrants originating from societies where matrifocality is a culturally accepted feature. Nevertheless, it is highly relevant for female immigrants who live matrifocally in a male-dominated host society or among male-centered social immigrant networks in the USA or in Europe.

In terms of potential health problems, the matrifocal family to a certain extent is comparable to the phenomenon of single mothers. In 2006, 10.4 million single mother families were estimated to live in the USA, including both native-born Americans and immigrants. In the case of both single mothers and mothers in matrifocal families – if the latter are not situated in a three-generation household (grandmother, mother, children) but are living alone with their children – the major health problems suffered by these women are usually attributed to exposure to higher stress levels than those experienced by women who live together with their husband or partner. Many of these women are at risk of becoming economically marginalized; one half of the single mothers in the USA end up in low-wage income and poverty. The higher stress level, as psychologists have maintained, results from the twofold burden of raising the children and earning money as well as from anxieties about the overall financial situation. Statistically, as surveys have shown, immigrant women are less likely to live in single-parent households; however, immigrant women living under such conditions, together with native-born and women of color, are most likely to belong to the low income-level groups. In the USA, single mothers with children may be eligible to participate in government-funded assistance programs such as Medicaid, Food Stamps, and the State Children’s Health Insurance Program (SCHIP). However, the US welfare and immigration reform laws promulgated in 1996 and later severely restricted immigrants’ access to cash assistance and Food Stamps. Undocumented immigrants are ineligible for most government-funded assistance programs. Additionally, eligibility of legal immigrants to participate in several such programs is restricted in most cases to those who have been permanent residents for not less than 5 years and can meet several additional eligibility criteria, and to those who have been granted asylum or refugee status.

Older psychological surveys often attributed children’s retardation to the matrifocal family. Recent psychological reports continue to maintain that children from single-mother families evidence more mental or psychosomatic disorders (such as enuresis, neurosis, stuttering, and various conduct disorders) than other children. This is particularly evident where single-parent families are considered anomalous by the wider social environment or if an immigrant mother has been expelled from her social group. These reports also emphasize that the precarious economic situation appears to have no significant impact on the children’s mental health.

Additional health problems may arise for immigrant single mothers if language barriers impede their understanding of medical staff’s treatment recommendations, potentially resulting in less effective health care for their children (and for themselves). Moreover, language barriers may also complicate their communication with social welfare institutions. However, recent surveys undertaken in the USA and Europe indicate that children from matrifocal families or single-parent families, regardless of their origin, do not display a higher risk of suffering from physical health problems than children from two-parent families.

However, significant differences have been found in the occurrence of physical diseases among women living alone or as part of a couple. Contemporary research in Europe revealed that single mothers of any origin have statistically fewer preliminary checkups compared to women living with a partner. This is even more striking for immigrant women who, due to the above-mentioned language barriers, are often excluded from the health care system. A German survey found that single mothers compared to those living with a partner suffer three times more often from bronchitis; two times more often from renal infections, hepatitis, or liver diseases, 10% more frequently from migraine; 15% more frequently from mental health problems such as neuroses, anxieties, and depression; and 8% more often from diseases affecting the reproductive system. Moreover, single mothers tend to refrain from seeking the help of physicians to a much greater extent than other women, even when they experience a need for care.

An amelioration of the general health condition of single mothers/women in matrifocal families has been recently achieved in the framework of various US and Canadian state-financed test programs. Many of these programs support the establishment of organizations to assist these women with child care responsibilities and their reintegration into social activities as a means of raising their awareness of health care issues. Additionally, the greater availability of interpreters within health care systems could help immigrant women to communicate and negotiate with medical staffs and social welfare institutions, particularly during the period immediately following their immigration to their new host country.

Media

Martha Womack Haun
Valenti School of Communication, University of Houston, Houston, TX, USA

Media communication involves messages that are transmitted from one message source to many. One source of communication, often institutional, sends either written/print or oral/broadcast messages to many at one time. This communication results in minimal or zero feedback from the recipients. Radio, television, magazines, newspapers and numerous web sites are examples of media. For example, television and radio provide the *medium* (singular) for large institutions/organizations such as NBC National Broadcasting Corporation), ABC (American Broadcasting Corporation), CBS (Columbia Broadcasting Corporation), BBC (British Broadcasting Corporation), Fox News, and CNN to reach the general public.

This one-to-many form of communication also occurs in social networking where one person may via Facebook, Twitter, Linked-In or MySpace, or some other computer applications reach a large network of friends through combinations of communication loops. Such applications are also useful for persons in the job market as they are venues for recruiting and marketing. Persons may post credentials, resumes, endorsements, and recommendations on some of the sites. As news media and private corporations use these social networks to get feedback, they attempt to establish a two-way communication with the viewers or listeners. Many people reported networks of friends or special interest groups that reach hundreds for the average person and thousands or millions for celebrities. Individuals are responsible for the management of their own spaces and these may or may not be managed. Major networks, for example, employ gatekeepers who control the flow of information in an intermediary role, much like the floodgates at a dam control the amount of water that passes through the floodgates and moves on. These gatekeepers may also function as opinion leaders commenting on particular information and news. Whether in print or broadcast journalism, editors prioritize the vast amount of information submitted by reporters and citizens. Editors who serve as gatekeepers determine which information will be shared. Other editors serve as the agenda-setters who prioritize the news that flows from the gatekeepers. The amount of airtime indicates the significance and priority of the news as do the size of headlines and story location in print journalism (front page, bold headline or small story on page 32, etc.). Is this the lead story or the final human interest story of the evening on the broadcast news? An oil platform explosion in the Gulf of Mexico receives major coverage compared to an area traffic accident and so on. Because of these reporters, gatekeepers, and agenda-setters, we are able to stay informed about an earthquake in Haiti or Chili, tsunamis, war events, or the destruction of the World Trade Centers on 9/11. This information is communicated and disseminated by the media.

Computers and webcasts and live streaming of videos provide alternative means for accessing these broadcasts. IPods and smart telephones provide further recent extensions of personal access to media. Reading devices such as Kindle and Nook provide access to millions of books and access to blogging sites. Message posting and blogging of one's personal thoughts provide a recent extension to electronic print journalism. The public is able to view and listen to current events through multiple mechanisms. Political candidates may now reach voters through social networks. Advertisers have extended beyond print and television/radio broadcast, especially to social networking sites.

To some I-Phones and I-Pads may seem merely toys or gadgets but they have further facilitated news gathering and social networking along with many other activities (games, downloading music, etc.). George Gerbner's cultivation theory addresses how media effects build up over time. Marshall McLuhan recognized in the late 1960s that technology has key effects on its user from extensions of the senses (glasses/eye, cars and planes/feet, computer/brain, etc.) and as such remolds societies from agrarian to industrial to electronic. The world became a "global village" through television, then split into "cultural islands" via Cable (cooking channel, weather channel, sports channels, sitcom reruns, NCIS reruns, etc.). Social networking has reduced some social stratification and linked people separated by thousands of geographical miles.

Conclusion

Media can have positive effects by providing information about storms or hurricanes that are approaching, by providing information about health and nutrition, cultural events, entertainment opportunities, keeping a person connected to one's homeland, and so on. However, it can also have negative effects through advertising or behavior modeling in comedies or dramas that encourage bad eating habits, poor money management, or other irresponsible behaviors. Media is often more influential in times of stress.

Under normal, day-to-day condition, the media may be taken for granted. In times of stress, the media connect us to homelands, provide information from points around the world so that we can be up-to-date on natural disasters and other events that affect us, loved ones, friends, and homeland. The media coverage is often very specific to immigrant interests – new immigration laws in Arizona, related court rulings, immigrant protest about laws, profiling, or working and housing conditions. Internationally, media coverage of disasters and political events, for example, directly affects the health and safety of immigrants. Culturally specific talk shows from Hispanic to Chinese report specific news, provide social networking, provide talk, cooking, shopping, or game shows, and other venues of special interest. These reveal ways that they might participate in special language news and social networking. All of these increase opportunities for native language communication and provide critical health and social information to immigrant populations.

Medicaid

BETH E. QUILL[1], JENNIFER DURAND[2]
[1]Children's Defense Fund - Texas, Bellaire, TX, USA
[2]School of Public Health, University of Texas Health Science Center, Houston, TX, USA

Established in 1965 through Title XIX of the Social Security Act, Medicaid was developed to help finance health care for low-income persons; this federal-state program helps individuals with little or no medical insurance by paying for part or all of their health care. In 2009, approximately 47 million people received services through this program. People who are eligible for Medicaid fall into one of two groups: the "categorically" and "medically" needy. Categorically needy individuals are those receiving aid because they are aged, blind, or disabled. Those who are medically needy have enough money to live on, but cannot afford to pay for medical care. In general, eligibility requirements include US citizens or permanent residents, people 65 years old or older, low-income children under the age of 19, all children under 6 years of age, and pregnant women with incomes up to 133% of the federal poverty level.

Medicaid is a joint program between the states and federal government, in which each state operates its own system but must follow certain government guidelines to receive matching funds. The program's funding, which is generated through tax revenues, varies according to each state's poverty level. Additionally, patients' eligibility and benefits are determined by each state. For example, each state defines the scope and cost of services but must comply with services for mandatory eligible groups.

State Medicaid programs must provide services for mandatory eligible groups. These groups include: (a) limited income families with children as described in Section 1931 of the Social Security Act who meet certain eligibility requirements in the state's Aid to Families with Dependent Children plan in effect July 1996, (b) Supplemental Security Income recipients (or in states using more restrictive criteria – aged, blind, and disabled individuals who meet the criteria which are more restrictive than the SSI program), (c) infants born to Medicaid eligible pregnant women through the first year as long as she remains eligible, (d) children under the age of 6 and pregnant women whose family income is at or below 133% of the federal poverty level, (e) recipients of adoption assistance and foster care under Title IV-E of the Social Security Act, (f) certain people with Medicare, and (g) special protected groups who may keep Medicaid for a period of time such as families who may have lost eligibility for specified reasons.

At a minimum, a state's Medicaid programs must provide the following services: (a) inpatient and outpatient hospital services; (b) skilled nursing facilities; (c) physician services; (d) home health care; and (e) early and periodic screening, diagnosis, and treatment for children under 21 who are eligible. Medicaid also provides coverage for mental health and substance abuse services, expensive drugs for treatment of AIDS, and rehabilitation services not covered by private insurance. Dental services, prescription drugs, eye glasses, intermediate care facilities, and other services are considered optional services and states may offer any or all of these. These services must be provided to children and pregnant women at no cost. Deductibles (a set amount the patient must pay before Medicaid pays) are not permitted and co-payments (a percentage of the total charges paid by the patient) generally do not apply.

States do have discretion in some program eligibility. The option to have a "medically needy" program, for example, allows states to extend Medicaid eligibility to additional qualified persons who may have too much income to qualify under the mandatory or optional categorically needy groups. This option allows them to “spend down” to Medicaid eligibility by incurring medical or remedial care expenses to offset their excessive income and reducing it to below the maximum allowed by the state’s Medicaid plan. They may also elect to include the medically needy under their plans for certain children under 18 and pregnant women or other groups, for example.

Categorically needy groups can also be given extended benefits under state programs. Such groups may include: (a) infants up to 1 year of age and pregnant women not covered under mandatory rules whose family income is below 185% of the Federal poverty level; (b) low-income children; (c) certain aged, blind, or disabled adults who have incomes requiring mandatory coverage but above the Federal poverty level; (d) children under 21 who meet the income requirements for AFDC but are otherwise not eligible for AFDC; (e) institutionalized individuals; (f) persons who would be eligible if institutionalized but are receiving home or community-based care under services waivers; (g) tuberculosis-infected individuals who would be financially eligible at the SSI level; (h) recipients of SSI; (i) low-income, uninsured women screened and diagnosed through a Centers for Disease Control Breast and Cervical Cancer Early Detection Program and in need of treatment. States may always provide more services than required. In 2005, without Medicaid there were 28 million low-income children, 15 million parents, as well as 9 million people with disabilities without health care coverage.

Children and their parents constitute the majority of the program’s beneficiaries. Enrolled children comprise 48% of enrollees and 19% of the expenditures. Adults comprise 27% of enrollees and 43% of the expenditures. Individuals with disabilities and older people who are poor incur the highest per capita expenditures and consume disproportionate amounts of Medicaid dollars. Sixteen percent of Medicaid enrollees were disabled expending 43% of the total expenditures. The elderly comprise 9% of enrollees and generated 26% of expenditures. Forty percent of Medicaid’s costs are associated with “dual eligibles,” people who are covered by Medicare and Medicaid. More than 90% of elderly are dual eligible as are about one third of Medicaid enrollees with disabilities. Medicaid’s role as a primary source of long-term care, gap coverage for Medicare, and coverage for the disabled is likely to continue with the increasing growth of the elderly population.

Funding Medicaid has become a critical issue for many states because of increasing expenditures as a result of higher program enrollment and medical inflation. There were nearly 3.3 million more people enrolled in Medicaid in June 2009 than in the previous June, the largest ever 1 year increase in absolute numbers. As economic conditions have declined, enrollments have increased with Medicaid’s costs growing faster than state and federal revenue. On average, the federal government pays 57% of all Medicare expenses. The federal government spends more than $300 billion annually on Medicaid services. States fund their 43% from state revenues and while states may expand coverage under Medicaid, many states are seeking to reduce program expenditures. Forty four states report higher than expected enrollment and expenses due to the large demand for services and the limited resources. Enhanced federal matching money for Medicaid through the federal stimulus law is set to expire December 31, 2010, further stressing state budgets.

Governmental actions to address these concerns have influenced the benefits available to Medicaid beneficiaries. In the 1990s, in reaction to the growing number of uninsured people and increasing medical costs, states submitted applications for waivers through the Social Security Act. This waiver allowed states flexibility in modifying eligibility requirements, payment methods, and other program characteristics. For example, it allowed beneficiary enrollment into managed care plans. Another outcome was the extension of health coverage to the working poor and their families who were not previously eligible for Medicaid. As a result of this change, the State Child Health Insurance Programs expanded to provide coverage to children whose family income is too high for Medicaid support and the Personal Responsibility and Work Opportunity Act (1996) redefined the scope of welfare benefits, which set the stage for the work requirements linked to these benefits. More recently, the federal government has used its 42 year experience with Medicare and Medicare to assess the benefits and challenges of the intersection of multiple programs at the federal and state level to assess the role of these programs in health care reform.

The Medicaid program, actually many programs in one, is the largest health care program for low-income families, elders, and people with disabilities. Medicaid has enabled low-income populations to have access to quality health care. In particular, pregnant women and children have received enhanced or special services as part of their enrollment. One study notes that 75% of the children in the Medicaid or State Children's Health Insurance Program had a preventive or well-child visit within the past year, compared to 46% of uninsured children. Further, Medicaid has acted as "gap" insurance for society's sickest and frailest. Medicaid provides mental health and substance abuse services and expensive drugs for treatment of AIDS. Approximately 44% of nursing home care is paid for by Medicaid. Despite this progress, with increased funding issues, Medicaid is a topic of public policy debate now and will be in the foreseeable future.

Since 1996, federal law has generally excluded from Medicaid undocumented immigrants as well as most legal immigrants who have been present in the USA less than 5 years. These groups may receive Emergency Medicaid, however. Immigrants continue to have high rates of uninsured compared to citizens, with 44% of legal Mexican immigrants and 77% of undocumented immigrants lacking health insurance with the notable consequences of lack of access to needed services. While immigrant populations are increasing, relatively little is known about their health status and health services utilization except in local circumstances. Data from North Carolina highlight the utilization of Emergency Medicaid, noting that 94% of eligible individuals were pregnant and 93% were Hispanic. Outside of pregnancy, one-fifth of hospitalizations and one-third of all Emergency Medicaid spending were for injuries. Emergency Medicaid provides critical services for childbirth but fall short of providing the necessary preventive and chronic disease management care required to maintain the health of immigrants and their families.

Immigrants receive limited public benefits. For example, a child born here is a citizen and eligible for coverage, although noncitizen parents may not generally receive benefits or be eligible for Medicaid. In 2007, 23 states chose to use state funds to provide additional services for recent legal immigrants or for undocumented women and children. Passage of the landmark Patient Protection and Affordable Care Act of 2009 has only minimally impacted access to public or private employment-based insurance for immigrants and continues to leave the enrollment of legal and undocumented immigrants into expanded programs like Medicaid at the discretion of states. High growth immigrant states with strained state budgets and anti-immigrant sentiment are unlikely to allocate funds for this population through programs like Medicaid. Further, immigrants, especially those who are undocumented, are reluctant to inquire about public programs and leery of program benefits that might disclose their status. Thus, children born in this country of immigrant parents may be primary beneficiaries while many immigrants will remain without coverage and in many cases without care.

Medical Examination (for Immigration)

John Welshman
Department of History, Lancaster University,
Lancaster, UK

Medical examinations for migrants, asylum seekers, and other entrants are currently high on political and public health agendas in many countries around the world. In the USA, for example, the Secretary of Health and Human Services frames regulations under the Immigration and Nationality Act, and the Public Health Service Act, for the medical examination of migrants seeking admission to the USA. The Division of Global Migration and Quarantine provides the Department of State and the US Citizenship and Immigration Services with medical screening guidelines for all examining doctors. A medical examination is compulsory for all refugees going to the USA, all applicants applying for an immigrant visa, and for aliens applying to become permanent residents. Outside the USA, medical examinations are performed by around 400 selected doctors. Health-related grounds for ineligibility for visas or admission include communicable diseases, absence of documentation of vaccination, physical or mental disorders, and drug abuse and addiction. Technical instructions are provided to these doctors by the Centers for Disease Control and Prevention, and for immigrants and refugees these examinations (which consist of a physical examination, skin test or chest X-ray examination for tuberculosis, and blood test for syphilis) are done overseas. The purpose of the examination is to identify those applicants with health-related conditions that render them inadmissible.

Similarly in the UK, the British Thoracic Society's Code of Practice recommends that all immigrants or other entrants from all countries other than the European Union, Canada, the USA, Australia, and New Zealand, and all refugees, be screened for specified illnesses or conditions. The ten Port Health Units based at major ports and airports see themselves as having a dual responsibility – to provide immediate health care for asylum seekers and migrants, and to protect the wider community from any risks to public health. Infectious disease and migration remain important political issues, with the Conservative Party arguing that infection should not be imported into the UK, and the Australian experience demonstrating the value of medical examinations in controlling the incidence of tuberculosis. Thus, screening continues to have a symbolic and metaphorical value, over and above any claims to clinical effectiveness.

Nevertheless, despite guidelines, studies have highlighted widespread variations in policies for screening of migrants. There is no national policy on screening migrants to the UK for tuberculosis. The Port of Arrival system operates only at international ports with Port Health Units attached, and relies upon Immigration Officers identifying certain categories of travelers and referring them for screening by Port Health Officers. Details are then forwarded to Consultants in Communicable Disease Control and Primary Care Trusts within which the destination address lies. However, many Trusts do not arrange screening for the new entrants referred to them on the grounds that they do not have the resources or have other priorities. Many migrants do not present for screening due to changes of address, language difficulties, and mistrust of authorities. It has been argued that compulsory screening of migrants for tuberculosis and HIV is not based on adequate evidence, and has practical and ethical problems.

It has been suggested that the specific immigration history of Australia in the twentieth century has strong links with public health policy and practice. The theme of the "immigrant menace" has been similarly influential in histories of migration and public health in the USA. In his important early history, *Silent Travelers*, Alan Kraut identified four key themes: the relationship between health, disease, and nativism; the advances and perceived limitations of scientific medicine; the institutional response of national, state, and local governments to immigration and public health; and migrant responses to differences between their own conceptions of therapy, health care, disease prevention, and hygiene, and those of native-born Americans. In the case of the UK, the theme of "port health" has again been the most influential concept on earlier (mainly sociological) writing on the history of migration and health. Yet against this, Amy Fairchild has argued that the procedure that migrants endured at Ellis Island was part of a process of inclusion. Only when groups of migrants failed to conform to social expectations about the fit industrial worker did the migrant medical examination exclude those groups at the nation's borders. She argues that officials placed little emphasis on racial distinctions between people, with the goal of exclusion; rather, the impulse was to absorb migrants into the laboring body.

In the UK, after the Second World War, it was partly epidemiological evidence, but more importantly professional bodies, notably the British Medical Association (BMA), and political actors (Conservative and Labour MPs and Ministers), that sought compulsory medical examinations at the Ports of Entry. The 1962 Commonwealth Immigrants Act gave powers to Port Health Authorities and Immigration Officers to refer certain categories of people to Medical Inspectors for examination. Furthermore, from February 1965, chest X-rays were introduced on an experimental basis at London's Heathrow Airport. Nevertheless, the emphasis on screening at the Port of Entry was gradually subverted in favor of a policy whereby the addresses of arriving migrants were forwarded to Medical Officers of Health in the district of intended residence. Evidence indicates that neither the experimental X-ray scheme at Heathrow Airport nor the Port of Arrival system were effective as mechanisms for detecting early cases.

Many of the same factors seem uppermost in the debate on medical examinations and immigration today. These include the close association in the popular mind between migration and infectious disease, the emphasis on the importance of "protecting" public health, the stress on the costs of care for patients, the importance to the economy of migration, and the interest in the experience of other countries. While legislative frameworks in the UK remain essentially the same, their coercive nature may change to incorporate pre-entry screening on the US model. Historical perspectives throw long shadows on contemporary debates, and are helpful in explaining how the screening systems that exist today were created; relationships between science, politics, and policy; and continuities in different framings of immigration and medical examination.

Medical Interpretation

Izabel S. Arocha
International Medical Interpreters Association (IMIA), Cambridge Health Alliance, Boston, MA, USA

Introduction

As the immigrant population in the United States becomes more diverse, there is greater demand for medical interpreters. For legal, medical, and ethical reasons, a reliable and accurate medical interpreter is necessary in any medical setting where the provider and the patient do not share the same language. Medical interpreters are especially needed to ensure the legal rights of those who are linguistically diverse and are not able to communicate their symptoms to their healthcare providers so that these professionals can accurately diagnose and treat them. The profession has evolved, as well as the different technologies to provide language services. There are also barriers such as the lack of certified medical interpreters and the lack of reimbursement for language services across most states. Medical interpreters play a pivotal role in meeting the communication needs of the immigrant populations and are integral components of a comprehensive immigrant health policy.

Medical Interpreter Profession Overview

Translation refers to the written word while interpreting refers to the spoken word. While the interpreting profession is well established in the conference and business settings, medical interpreting, or health care interpreting, as it is sometimes called, is a relatively new specialization. According to the Bureau of Labor Statistics, Employment of interpreters and translators is projected to increase 22% over the 2008–2018 decade, which is much faster than the average for all occupations.

There is more to medical interpreting than just simply repeating what the physician has said in another language. While the interpreter seems to simply be "stating" in one language what was "said" by another speaker in another, the interpreter actually has to convert the messages by rephrasing them into the other language, which is the act of interpreting. It requires that the interpreter have a high fluency in both languages, and be very attuned to active listening in order to be able to properly "interpret" the message uttered. They are responsible for ensuring that the patients and providers understand everything that is being discussed. This is done primarily in the consecutive mode (the interpreter will interpret after a speaker finishes their utterance), and also in the simultaneous mode (the interpreter will start interpreting and continue as the speaker continues as well to speak so that both parties are speaking with a small time lag called *décalage*). There is also sight translation, when an interpreter reads a document, such as a discharge instruction, in one language, and interprets it orally into the other language.

In addition to interpreting for patients and providers, they engage in other activities. As other allied health professionals, interpreters document their work to produce statistics that will be later utilized for regulatory, operational, and quality measure purposes. They develop glossaries, engage in terminology research, provide cultural consultation to providers in situations where cultural issues take place, assist providers in identifying medications from other countries, provide medical translations, and many other tasks related to ensuring linguistic access to patients. Most medical interpreters state that their work is varied and interesting as they are able to participate in varied medical interactions, from a cesarean delivery (c-section) to an emergency stab wound treatment, to a psychological assessment. Staff interpreters see as many as 15 patients a day or as few as 5. Remote interpreters working primarily over the phone might interpret for many more interactions as phone interpreting encounters tend to average under 20 min and there is no travel time required from one interpretation to the other.

Interpreter Education

Medical interpreters are trained in their target language and culture and also in medical terminology and procedures. They must complete specialized training in the techniques of interpreting in various modes, and also in the knowledge of specialized medical terminology, standards of practice, ethical codes, and more. Many interpreters are nationally certified, and receive the CMI credential (Certified Medical Interpreters). The level of education and certification required to work varies from state to state.

Universities, community colleges, and training organizations offer different types of educational programs for medical interpreters. Some specialize only in medical interpreting while others work from a generalist-specialist model, where the student is trained to interpret in different settings. There are also different associations, both medical and language related, that provide continuing education opportunities. The programs vary in length and intensity depending on the school itself and where it is located.

Medical interpreters work for health care organizations, health plans or physician organizations, and translation and interpreting companies. There are both freelance interpreters and those that work for hospitals/health care facilities or organization. Those who work for hospitals will have more consistent hours and a more stable pay but sometimes do not get paid as much. Freelance interpreters are essentially on constant call so they must be available at a moment's notice, and they generally do get paid more. Many hospitals around the country are now hiring interpreters for staff positions, as well as hiring individuals to work on a per diem basis or as independent contractors. Telephone interpreting companies are hiring interpreters to work in their call centers or to work from home.

Standards of Practice

There are several published standards of practice for the medical interpreter profession. *Medical Interpreting Standards of Practice*, by the International Medical Interpreters Association and Educational Development Center, was the first to be published and is the most well known. If all that the provider and patient need to achieve the goals of the clinical encounter is this linguistic conversion, then simply providing such a conversion fulfills the interpreter's role. The standards, however, go beyond the skills of conversion and recognize the complexities of interpretation and the clinical interview. The medical encounter is a highly interactive process in which the provider uses language (the provider's and the patient's) as a powerful pool to understand, evaluate, and diagnose symptoms and to mutually inform and instruct. The interpreter, therefore, cannot simply be a "black box converter" but must know how to engage both the provider and the patient effectively and efficiently in accessing the nuances and hidden sociocultural assumptions embedded in each other's language, which could lead to dangerous consequences if left unexplored.

These standards of practice also recognize the importance of the medical encounter in establishing a therapeutic connection between the provider and the patient. The formulation of a therapeutic relationship is especially difficult when parties cannot communicate directly, and it becomes even more complex when different culturally based belief systems are involved. A competent interpreter can mediate these barriers by attending not only to the linguistic but also to the extra-linguistic aspects of communication. The standards are organized into three major task areas: (1) interpretation, (2) cultural interface, and (3) ethical behavior. They are intended for use by all stakeholders, with varying levels of knowledge in the field of medical interpreting.

Ethical Guidelines of Medical Interpreters

There are several codes of ethics that interpreters abide by. The International Medical Interpreters Association was the first organization to author an ethical code of conduct specifically for medical interpreters. It has been translated into 11 languages and has worldwide adoption. Multiple codes of ethics have since followed. The various interpreter codes of ethics include tenets of confidentiality, transparency, professionalism, advocacy, and impartiality.

Interpreter Roles

There are four roles that are well established in the medical interpreting field. The first role is that of *linguistic conduit role*; and that is the role in which the interpreter primarily focuses in listening to messages from one party in one language and recreating them in another language. The second role involves the *clarification role*, which is paramount for interpreters to completely understand the messages they are to interpret. This is when an interpreter will request any type of clarification to ensure understanding. The third role has been labeled as *cultural interface role*, also called cultural clarifier. This role involves identifying, exploring, or clarifying for either party a cultural context or belief or tradition that could be interfering with understanding. Culture is embedded in language and often a literal interpretation will simply not suffice for mutual understanding. The fourth role is that of *patient advocate*.

The Interpreter's Role of Patient Advocate in Immigrant Health

Most in the field agree that the role of patient advocate is a role that needs to be addressed with much professional maturity and care and not simultaneously with the act of interpreting, as it interferes with the ethical code of impartiality. Patient advocacy in the interpreting field refers more to advocacy and patient education for their language rights, access to health care, and intervening mostly when patient care is compromised. This is a role which is very sought out by immigrant patients who are at different levels of acculturation into the dominant culture and therefore need more assistance to navigate a new health care system from an operational as well as cultural perspective.

There are also other newer interpreter roles that are beginning to be explored in the field such as that of facilitator, navigator, and educator.

Language Access Laws and Regulations

There are several laws and regulations which form a framework for language access and they vary by state. At a federal level, Title VI of 1964 prohibits discrimination against national origin. The Americans with Disability Act covers the communication rights of the deaf and hard of hearing. The United States Health and Human Services Office of Minority Health Standards for Culturally and Linguistically Appropriate Services (CLAS) published in 2001 gave health care organizations across the country very specific guidelines. The Joint Commission which accredits hospitals values effective communication as a means to deter medical errors and has taken special interest in issues of language access. This legal framework has been very helpful in the provision of language services, but there are anti-immigrant sentiments and English-only laws that threaten these services to immigrants.

The Triadic Encounter: How to Work with an Interpreter

Physicians themselves clearly find that language barriers have a strong impact on services to patients who do not speak English. Here are important guidelines when working with a medical interpreter:

- Ensure proper introductions and pre-sessions
- Avoid high register, speak to the patient in lay terms
- Look directly at the patient, not the interpreter
- Speak to the patient in the first person
- Pause for the interpretation
- Ensure that instructions are understood by asking the patient to teach back
- Document interpretation or how the language need was met in the medical record

Mental Health Interpreting

Mental health interpreting requires more advanced skills from interpreters for several reasons. Providers of mental health are relying on subtleties of communication to make their diagnosis and tone and affect are difficult to ascertain from someone who is speaking a different language. Mental health providers and medical interpreters need to work as a team in order to have the same effect as if there were no language or cultural barrier. The interpreter needs to interpret these subtleties in a way that the provider can understand the patient well. Sometimes, depending on the case, continuity with the same team can affect the treatment positively while a sudden change in the triadic composition can take the patient back a few steps due to the trust and comfort level with the new interpreter. Mental health providers often request that the same interpreter interpret throughout a case to achieve a more effective result.

Language Access Technology: Remote Interpreting

Technology allows medical interpreting to be provided via telemedicine, or remote interpreting, as it is called in the language field. Several health care organizations are utilizing remote interpreting as a means to effectively offer medical interpreting services in a larger variety or languages 24 hours a day, 7 days a week. When a face-to-face interpreter is not available, sign language interpreting for deaf and hard of hearing patients needs to be provided remotely via video as the patient needs to see the interpreter signing on the screen. Both remote modalities are becoming more common as health care professionals become more comfortable with the technology and understand the importance of relying on a professional medical interpreter. Remote services have certain advantages such as greater reliability of service, availability in remote areas or emerging languages, and timeliness, as the interpreter becomes available within a minute or less. The newest modality is the mobile phone interpreter service applications available now to the general public, making a professional interpreter directly accessible to the consumer.

Common Barriers to Language Access

1. *Providers or Patients Interacting with Limited Proficiency* – Some health care professionals know enough to get through a basic conversation with the patient but, without a good understanding of the patient's culture or language, inaccurate communication can create further confusion or misunderstandings or result in negative health outcomes. In order to have an effective conversation with the

patient, the health care professional should understand the patient's culture, how the culture affects the patient's language, and how to directly translate meaning, not just words. Immigrant patients have different levels of language acculturation and their understanding of English might suffice for one type of appointment whereas a discussion of treatment options might require a medical interpreter. Likewise, a provider with limited Spanish vocabulary will certainly not know what they did or did not understand and such types of communications are fertile grounds for miscommunication.

2. *Lack of Reimbursement for Medical Interpreter Services* – Only 14 states have Medicaid reimbursement and very few insurance companies pay for language services. This is changing and there is legislation in progress in US Congress advocating for this reimbursement. Without it, hospitals and small provider practices are left to pay for these services out of their administrative budgets, making this an unfunded mandate.
3. *Lack of Training on Cultural and Linguistic Issues in Health Care* – Medical schools are starting to incorporate stronger components of cultural competency into their curriculums and internships or residency programs. Most health care organizations do not have cultural and linguistic educators, but more is being done in this area than ever before.
4. *Reliance on Unqualified Interpreters* – When a qualified interpreter is not available or has not been scheduled, the provider is often left with the difficult decision of how to proceed. The provider may resort to relying on a bilingual staff member, family members, or friends as facilitators to the communication. These options are wrought with inadequacies, such as the confidentiality of personal health information and also the inability for most of these people to interpret medical terminology or act in an impartial and objective manner when a loved one's health is being discussed. Often the provider will, in effect, have a conversation with the facilitator and not the patient. When the family member or an untrained bilingual staff person does this, there is nobody to interpret for the patient who is simply left out of the equation. Remote interpreting is rapidly becoming a preferable option when a face-to-face interpreter is not available.

Conclusion

Medical interpreters certainly play an important role in immigrant health due to their unique position: they are knowledgeable in the culture of the patient and the Western health care system. They facilitate the delivery of linguistically and culturally appropriate health care services to newcomer populations and providers strive to eliminate ethnic and racial disparities in health care.

Medically Indigent

BETH E. QUILL
Children's Defense Fund - Texas, Bellaire, TX, USA

"Medically indigent" is a term used in the USA that refers to individuals who do not have health insurance and are not eligible for other health care coverage such as Medicaid, Medicare, or are not able to afford private insurance. States, counties, and municipal agencies have established under legislative authority Medically Indigent Programs to provide critical medical services to the population. Funded by state and county or local taxes, they are usually authorized under a state public health or health and social services state code. The codes specify eligibility requirements, services allowed, acceptable providers and facilities, and application and administrative processes. The programs are considered the "last resort" when other options for coverage have been exhausted and are usually administered by agencies at the state or county level.

Eligibility

Eligibility requirements vary from state to state but most provide coverage for adults and children. Programs are designed for residents (and often specifically citizens) and applicants must document financial status, usually based on the Federal Poverty Guidelines, as well as non-eligibility for public programs and insurance. If eligibility changes, enrollees will be transferred to another program for which they are eligible. Eligibility may need to be reviewed and reapproved periodically. States vary in their eligibility requirements. Colorado includes residents, migrant farmers, and US citizens or legal immigrants. Virginia covers residents, citizens, or lawful aliens, while California covers undocumented residents only for emergency care.

Services

Eligible services are specified by type, duration, and place. Public facilities such as public hospitals or designated general hospitals in the patient's residential area are the primary source of services. Services include hospitalization (medical or surgical), emergency treatment, and psychiatric admission. In addition, skilled nursing and intermediate care services are often included. Some outpatient services may be offered such as laboratory diagnostic tests; dialysis; prescription drugs; physical, occupational, or respiratory therapy; mental health services; and dental care. Home health services may also be covered along with durable equipment. Childbirth and child health services may also be paid services.

Administration

Medical Indigent Programs are under strict requirements to verify eligibility requirements, proper facility, and provider care and optimal use of these resources dedicated as a last resort for care. Therefore, documentation of residency, income, and household composition and enrollment in other programs are the responsibility of the applicant. If the applicant is identified as a noncitizen, for example, additional verification information will be required.

This program provides important care for those without access to care through traditional public programs or private insurance. Immigrants will be limited in the ability to utilize this program, however. Since social security numbers, birth certificates, and income statements and residence verification are required, this may be a deterrent to enrollment. Legal immigrants and refugees may qualify in some states. A first effort would be to determine if Emergency Medicaid is an option. If the applicant is not eligible then the Medically Indigent Program criteria for eligibility will be applied. The variability of programs across states suggests that residents must explore the requirements within their resident state to determine the benefits for which they may be eligible. Since the intent of these programs is to provide care as a last resort to needy residents and citizens, the expansion of services to immigrants is unlikely. This is underscored by the strains on state budgets and the anti-immigrant sentiment in some states.

Medicare

BETH E. QUILL[1], JENNIFER DURAND[2]
[1]Children's Defense Fund - Texas, Bellaire, TX, USA
[2]School of Public Health, University of Texas
Health Science Center, Houston, TX, USA

Medicare is a federal health insurance program administered by the US government. Signed into law on July 30, 1965 as Title XVIII of the Social Security Act, Medicare is the major health insurance for those over 65 years of age who are covered by the Social Security system, regardless of income. Amendments to the Social Security Act in 1972 extended the benefits to those who do not meet the criteria for the regular Social Security Program, but who are willing to pay a premium for coverage. In 1973 a further amendment extended benefits to those entitled to Social Security disability benefits or those who suffer from chronic renal disease requiring a kidney transplant or routine dialysis. Many beneficiaries who qualify for Medicare also receive Medicaid. In 2008, the Medicare program had 45 million enrollees, and that number is expected to grow to 78 million by 2030, making the program a major national healthcare expenditure. Citizenship and payment into the Social Security System requirements preclude immigrants from participation in this program.

The Medicare program consists of four parts: Part A (hospital insurance), Part B (supplemental medical insurance), Part C (advantage plan), and Part D (prescription drugs). Part A coverage includes hospitalization, care in a skilled nursing facility, and home health or hospice care. Part B of Medicare, supplemental medical insurance, is an optional plan and must be paid for as a Social Security deduction. It pays for reasonable physician charges, inpatient and outpatient medical and surgical services such as renal dialysis, supplies, limited ambulance transportation, physical and speech therapy, ambulance and diagnostic tests, clinical laboratory tests, home health care, and outpatient diagnosis and treatment. Part B also covers patients' medical equipment (such as wheelchairs and walkers), prosthetics, and oxygen for home use. Parts A and B are generally less costly than additional private insurance and beneficiaries have a lower average out-of-pocket expenditures spending than Medicare beneficiaries overall. Under Part C, beneficiaries are given the option to receive Medicare benefits through their private health insurance plans and pay a monthly premium to cover costs not covered by Parts A (hospital insurance) and B (medical insurance), such as dental and vision care. With Part D, which went into effect on January 1, 2006 as part of the Medicare Prescription Drug, Improvement and Modernization Act, the program helps to subsidize the costs of prescription drugs for Medicare beneficiaries. Individuals can join Part D of the Medicare program or a private prescription drug plan for coverage.

Medicare beneficiaries are often required to pay out-of-pockets expenses such as premiums, deductibles, and co-payments through private insurance healthcare plans. Under Part A, most Medicare patients do not pay a monthly premium because they have paid Federal Insurance Contributions Act taxes. For those who have not, they must pay a monthly premium. However, all Part B enrollees must pay an insurance premium for coverage. The amount paid per monthly depends on household earnings; the higher the household income, the more one pays. Deductibles are set amounts patients must pay before Medicare begins to pay. For example, under Part A, patients must pay a deductible of $1,068 for a hospital stay of 1–60 days and $534 per day for 91–150 days of a hospital stay. Under Part B of the plan, after a patient meets the yearly deductible of $135, he or she is required to pay a coinsurance of 20% for all services, except for laboratory services that are completely covered. Co-payments are a percentage of the charges paid by a patient and may be required at the time of service. These expenses for deductibles, co-pays, and supplemental insurance for elderly persons may pose a significant financial burden and contribute to beneficiaries not seeking care when it is indicated. One in seven elderly Medicare beneficiaries does not have a usual source of care or has not seen a physician when they needed medical care.

Supplemental insurance, Part B has emerged as an option for the patients to lower co-payments, covers more services and decreases out-of-pocket expenses. The majority of elderly purchase this benefit. Beyond this, Part C (often referred to as Advantage), "Medigap insurance" was designed to cover what Medicare does not. Beneficiaries purchasing this insurance must already be enrolled in Parts A and B of Medicare and will continue to pay for Part B. While only standardized policies are sold under this benefit, private insurance requires premiums, deductibles, and co-pays to be paid by the beneficiary. Policies may vary substantially in cost. Medigap policies sold before the enactment of Part D in January 1, 2006 do provide coverage for prescription drugs, while Medigap plans sold after this date do not cover prescriptions since Part D was enacted. While these efforts have been developed to minimize financial barriers to care, many elderly may not enroll in the programs when their resources are insufficient to make these additional out-of-pocket expenses or they do not understand the program benefits.

Part D of Medicare, the prescription drug component, was instituted after a public outcry regarding the increasing costs of prescription drugs and the plight of the elderly, who reported high out-of-pocket expenses that often competed with the expenses of daily living. Part D, a low-cost drug program, was a major advance in the benefits offered by the Medicare program. Medicare beneficiaries must apply for this benefit to obtain medications through a private drug program subsidized by Medicare. They must have Parts A and B and be a permanent resident in a state with prescription drug programs. Medicare beneficiaries may also select their own prescription drug plan such as one offered by their former place of employment or through unions instead of Part D. Part D includes deductibles and not all medications may be covered. While there were obstacles in the implantation of this, such as deductible and a benefit gap, Medicaid patients were transferred to the program and an option for drug coverage became available subsidized by the Medicare program. Current efforts in the program are focused on access for the elderly who are poor and ensuring availability of acceptable programs in both quality and quality.

In addition to the type of service covered, Medicare benefits are paid for a specific period of time. For example, hospital care expenses that comprise over 55% of Medicare expenditures and skilled nursing home expenses that are increasing their share of the expenditures annually are not paid by Medicare beyond a specified number of days. Typically, the benefit period begins on the day a patient is admitted to a hospital and ends after 60 days in the hospital or facility care. When secondary insurance fails to cover the expenses beyond Medicare, patients pay out of pocket for the ongoing expenses. In many cases, this is beyond the capacity of many families and the elderly are enrolled in the Medicaid program, a state-federal program, to cover the nursing home costs. Medicaid and personal resources are the primary financial resources for nursing home care. With nursing home costs increasing and an aging population, long-term care will continue to be a major expenditure of healthcare resources.

The Medicare program receives its revenue through various funding sources: payroll taxes levied on employed personnel, general revenue, beneficiary premiums, payments from states, taxation of social security benefits, and interest earned on the trust funds. Part A received the majority of its funding through payroll taxes (85%), while Parts B and D receive most of their funding through general revenue, 73% and 77%, respectively.

In 2009, Medicare paid $484 billion in benefits payments: more than one-third of the payments were for patient care at inpatient hospital and nursing facilities (Part A), while 28% covered Part B services, including outpatient and physician care.

Medicare spending is growing steadily in absolute terms and as a proportion of the federal budget. In 2009, Medicare spending reached $511 billion, or 3.5% of the gross domestic product. Also, Medicare spending is expected to increase to $926 billion in 2018 and become 6.4% of the gross domestic product in 2030. Further, the Part A trust fund is projected to be depleted by 2017 and the monthly Part B premium is expected to increase to $111.50 in 2012. Going forward, Medicare will have difficulty maintaining financial viability, especially as the population continues to age and the number of enrollees increases each year. Fundamentally speaking, the ratio of personnel paying Medicare taxes to retirees who are receiving benefits is reducing. At the same time, the cost of providing healthcare services to individuals is increasing. Each year for the next 10 years, Medicare spending is expected to increase by 7%. The challenge for officials is to keep Medicare program efficient, effective, and equitable in providing coverage for a broad scope of services. A recent inclusion of preventive services such as immunizations in coverage suggests this process is continually being reviewed.

Benefits for immigrants as beneficiaries in public health programs have ignited a debate over the past decade. As a federal program, Medicare does not provide benefits for noncitizens and those who have not paid into the Social Security system. While some states may elect to provide benefits for the elderly, Medicare cannot be relied on to provide care for the immigrant elderly. The public health challenge is to maximize the functioning of this program, despite the financial and administrative setbacks. Notably, quality-of-life and end-of-life issues will influence the public policy discussions and the status of immigrants as an increasingly diverse population reaches age 65. The heart of public policy debates regarding Medicare and how to pay for it is expected to continue as health care in the USA undergoes reform.

Melting Pot

Paraic McCormack
Department of Psychiatry, Auckland District
Health Board, Greenlane Hospital, Greenlane,
New Zealand

The melting pot is an analogy for the idealized process of immigration and colonization whereby people of different national and cultural origin purportedly "melt together" into a new, harmonious, and egalitarian community. It was particularly used in the early twentieth century to describe utopian visions of the assimilation of immigrants in the United States, foretelling the emergence of an American "new man." The metaphor was popularized by the 1908 play

The Melting Pot by Israel Zangwill, though others had used similar imagery in the nineteenth century.

The suitability of the melting pot model in present-day society is somewhat contentious. The more contemporary analogy, the salad bowl, suggests that different cultures mix, but their distinct identities remain intact. Similarly the more widely used term of multiculturalism proposes that cultural differences within society are valuable and should be preserved.

Quantifying various dimensions of social integration such as culture and language may present some challenges to the social scientist; however, data on the health and economic well-being of immigrants is relatively easy to collect. Furthermore, while to most modern observers attempts to eradicate differences in the former dimensions in immigrant people would be considered objectionable, eradication of health and economic disparity would seem to be a desirable, if elusive, end.

One study looking at the effects of a melting pot policy in Israel clearly demonstrated an increase in socioeconomic disparity in second-generation immigrants. There is also a growing body of evidence that demonstrates increased morbidity in immigrant populations subject to socioeconomic disadvantage. A striking example of this effect is the high rates of serious mental illness, such as schizophrenia, in the British African Caribbean population. This effect would not appear to be due to the potentially stressful process of migration itself, as the native-born immigrants are less affected than subsequent generations. While it is likely to be multifactorial, a plausible mechanism for this adverse effect on immigrant health is yet to be demonstrated.

Menopause

Renee Sorrentino
Massachusetts General Hospital, Quincy, MA, USA

Menopause is defined as the cessation of ovarian function or of menstrual cycles. The diagnosis of menopause is made when a woman has not had a menstrual cycle for 12 consecutive months. The diagnosis can also be made by laboratory studies, which indicate a pattern of persistent elevation in follicle-stimulating hormone (FSH) and luteinizing hormone (LH). Menopause occurs because the ovary stops producing the hormones estrogen and progesterone. It is a normal process of aging with a median age of 51 years. The normal aging process involves the progressive decline in the number of oocytes, or eggs by atresia (degeneration of eggs) or ovulation. This is a gradual process, which occurs over an average of 4 years. The years prior to menopause are referred to as the menopause transition. During this time, fluctuations in FSH and LH cause irregular menses and a series of symptom complexes.

Common symptoms associated with the menopause transition are hot flashes, night sweats, and vaginal dryness. These symptoms are thought to be associated with the menopausal hormonal changes. Hot flashes and night sweats are referred to as vasomotor symptoms. Vasomotor symptoms typically occur around the final menstrual period and then gradually decrease in frequency. Vaginal dryness is a symptom of vaginal atrophy (wasting). Vaginal dryness is less common than vasomotor symptoms, affecting approximately one third of menopausal women. Other symptoms reported during menopause that are not directly related to changes in hormone levels include sleep disturbances, mood swings, cognitive difficulties, joint pain, headaches, and palpitations. The symptoms of menopause vary greatly between individuals. Studies suggest that a woman's educational levels, cultural background, acculturation, and lifestyle influence her perception of menopausal symptomatology. Immigrants in general were found to have lower rates of visiting physicians for menopausal symptoms or discussing health care maintenance such as hormone replacement therapy.

The diagnosis of menopause is confirmed by laboratory tests. An elevated FSH (greater than 30 mIU/mL) in the setting of absent menstrual cycles is diagnostic of menopause. LH levels are elevated in menopause but typically rise slowly over the menopause transition.

Menopausal women are at increased risk of osteoporosis, breast cancer, and endometrial cancer. These health problems are associated with the reduced hormone levels of menopause. Postmenopausal women should be regularly monitored for these health problems.

The treatment of menopausal symptoms includes both pharmacological and nonpharmacologic interventions. Hormone therapy is an effective treatment for many menopausal symptoms; however, controversy surrounds its use because of its many side effects including cardiovascular events, breast cancer, and thromboembolism (blood clots).

Mental Health

Rob Whitley
Douglas Mental Health University Institute, McGill University, Montreal, QC, Canada

Research into the mental health of immigrants has been a significant subspecialty of psychiatry for almost 100 years. Odegaard could be considered one of the founding fathers of this subspecialty. In his famous 1932 paper "Emigration and Insanity," he notes that Norwegian immigrants to the United States have higher rates of "insanity." He argues that this can be explained by the selective migration of "weak" people from Norway, as evidenced by histories of poor social adaption prior to migration. This hypothesis reflected popular beliefs at the time that European immigrants (especially those from Southern and Eastern Europe) to the United States were predisposed to "insanity" and other forms of "weakness" such as alcoholism. Unfortunately, these popular beliefs were somewhat perpetuated by significant figures within mainstream psychology and psychiatry, backed up by dubious empirical and theoretical scholarship. As cogently argued by Stephen Jay Gould, this was used to justify restrictive immigration policies to the United States in the name of "science." This misuse of psychiatric theory remains a stain on the investigation into immigrant mental health.

Fortunately, since the time of Odegaard, research and theoretical development in the field of immigrant mental health has multiplied and diversified, with a variety of perspectives and models going far beyond the stigmatizing "moral weakness" explanations of yesteryear. Teams of well-funded and sophisticated researchers in countries such as the United States, Canada, the United Kingdom, the Netherlands, Sweden, and Australia have emerged with their sole focus on the investigation of the mental health of immigrants.

Smaller teams continue to examine migration within the non-Western world, for example, from East African countries to Middle Eastern countries. The investigation of immigrant mental health has become a global phenomenon.

Mental Health and Immigrants

Contrary to Odegaard's theory, some research suggests that immigrants are mentally healthier than (1) the general population of the places from where they migrate and (2) the general population of the place to where they migrate. This phenomenon has become known as the "healthy migrant effect." It is explained by theory suggesting that in order to migrate, individuals must have a high level of resiliency and psychological resources. Furthermore, many Western countries also have strict medical requirements for immigrants. Potential immigrants face medical screening prior to the issuance of papers, which prevents those with preexisting health problems from emigrating.

However, other research suggests that this "healthy migrant effect" is temporary in terms of mental health, with immigrants soon suffering mental illness at a rate at least similar to the host population. Furthermore, the healthy migrant effect may be applicable only to skilled immigrants with preexisting economic, social, and symbolic capital. Vulnerable groups of immigrants, for example, refugees, asylum seekers, and those from predominantly Black populations, may be at higher risk.

Indeed, much research implies elevated levels of various mental disorders, especially schizophrenia, among immigrant populations in the Western world. This especially appears to be the case among dark-skinned immigrants and those coming from a developing country. Evidence is overwhelming that certain immigrant groups in Western Europe suffer a greater incidence of schizophrenia. This includes first- and second-generation Afro-Caribbean immigrants to the United Kingdom, first- and second-generation Surinamese and Moroccan immigrants to the Netherlands, and East African immigrants to Sweden. A recent meta-analysis of the incidence of schizophrenia in immigrants to various Western countries (of various nationalities and ethnicities) found strong evidence of significantly increased rates in both first- and second-generation migrants. A common finding is that risk increases with length of residence in the host country, and that this risk is even more severe in the second generation. This suggests a dose–response relationship. There is something toxic in the sociocultural environment for some immigrants to Western countries.

Models seeking to explain the relationship between immigration and mental illness have moved away from Odegaard's simplistic notion that elevated rates are accounted for by preexisting vulnerabilities. Though acknowledging the role of premigratory factors, newer models also emphasize postmigratory experience in the host country, as well as the nature of the process of migration itself. These models also emphasize resilience, acutely aware of the stigmatizing nature of the pathological emphasis that plagued early investigations into immigrant mental health.

Instead of focusing on preexisting *vulnerabilities* before migration, many contemporary researchers into immigrant mental health focus on premigratory *experience*. Many immigrants, especially refugees and asylum seekers, come to Western countries from war-torn regions, ravaged by poverty, persecution, civil violence, food shortages, drought, and violence. Some may have witnessed widespread death and destruction (even genocide). Experience of violence and/ or persecution may further leave people vulnerable to posttraumatic stress disorder and other mental disorders. They may carry the physical and psychological scars from such events with them as life progresses after migration. Indeed much therapy attempts to focus and reinterpret premigratory experience in immigrants in order to combat mental health problems such as posttraumatic stress disorder.

Other researchers have also focused on the *process* of immigration. Many refugees and asylum seekers have spent time in refugee camps or have traveled to their host country via circuitous and arduous journeys. In such camps, potential immigrants face crushing and chronic problems such as poor diet, inadequate physical activity, and lack of work. They may be tormented by uncertainty regarding the fate of loved ones, as well as uncertainty about the future. They may experience the loss, entrapment, and humiliation which are associated with depression and anxiety, especially among women. Such experience can be psychologically damaging and an ongoing risk factor for psychopathology.

In terms of the role of postmigratory experience in the development of mental illness, numerous common risk factors have emerged from the literature. One emerging risk factor that has received much attention is the concept of "social defeat," which has been posited as influential in the development of psychosis in migrants. Social defeat is an umbrella term that refers to various sociocultural (and economic) acute events and chronic processes often experienced by immigrants. These processes and events share in common aspects of subordination, humiliation, entrapment, thwarted expectations, and marginalization. What common experiences amount to social defeat for immigrants? First is the experience of obvious and subtle racism and discrimination. This may come in many forms, for example, being passed over for a job or being harassed by law enforcement. Second is a phenomenon known as aspiration-achievement discrepancy. This can refer to immigrants being unable to find a job commensurate with qualifications and experience – the proverbial doctor driving a taxi. Such discrepancy might be due to issues of language, nonrecognition of foreign qualifications, and other structural discrimination. Immigrants may have arrived with dreams of large cars, spacious houses, and well-paid jobs; the reality of immigrant life might be quite different. Third, social defeat may come about due to deliberate and subtle denigration of cultural identity. This is a plight facing many religious immigrants (and nonimmigrants) in Western countries today, where core symbols that express that person's identity are being questioned, and in some extreme cases, even outlawed. It should be noted that social defeat, and indeed other risk factors for immigrant mental illness, may vary by sociodemographic variables. Evidence suggests that factors such as gender, age, and ethnicity may mitigate (or worsen) the impact of these risk factors.

While the discussion so far has focused upon risk factors for mental illness, it should be noted that some studies suggest that numerous protective factors commonly exist among immigrant populations. A widely studied factor is known as "the ethnic density effect." This refers to a phenomenon whereby adverse mental health outcomes among individuals from ethnic minorities are higher in neighborhoods where they comprise a lower proportion of the population. In other words, living in neighborhoods with a high density of similar immigrants is good for immigrants' mental health. These neighborhoods may be more inclusive and welcoming, with less opportunity for social defeat. Dense social networks within these neighborhoods may also provide salutogenic social support and cultural validation.

Another protective factor for immigrants is religion and spirituality. Many immigrants hold a deep and abiding religious faith, which they continue to practice on arrival in a new country. Religious congregations may provide new arrivals with a ready-made community into which they can enter and find social, instrumental, emotional, and practical support. These "gateways" can even help immigrants find work and integrate into the host society. This is a resource which may have been underexploited in mainstream psychiatry, but which is undoubtedly protective for mental health.

Mental Health Services and Immigrants

Every Western country has developed its own mental health service system. All Western countries (except for the United States) provide basic mental health services that are free at the point of use. Regardless of the configuration of health services within a country, a common finding is that immigrants tend to underutilize mental health services. Numerous reasons have been put forward for this underutilization. These explanations tend to focus on either (1) individual-level factors, (2) community-level factors, or (3) service-level factors. There is a large overlap between these three factors – they are not orthogonal. In terms of individual-level factors, issues such as inability to speak the language of the host nation, or lack of health insurance, can prohibit use of conventional mental health services. Immigrants living in trying circumstances may also find it difficult to take time off work (which is often only paid hourly) to visit a mental health clinic regularly. In terms of community-level factors, stigma and the possession of differing explanatory models for mental illness are often identified as influential.

Explanatory models refer to notions held by individuals regarding the causes, nature, and consequences of emotional suffering. These are often shared within cultures. Many immigrants will consider emotional suffering as a moral or religious problem, or as part of everyday life unworthy of medical attention. They will thus seek help from family and friends first, religious and folk healers second, and mental health services last.

Another common explanation for immigrant underutilization of mental health services is stigma. It is posited that in certain communities, the manifestation of a mental health problem, and consequent use of mental health services, can indelibly stigmatize not only the individual concerned but also his or her entire family. It may affect secondary factors such as their job opportunities and marriage prospects (for them and their family). As such, stigma may be a prohibitive impediment to the use of mental health services in some immigrant groups.

In terms of systemic factors, many themes emerge accounting for immigrant underutilization of mental health services. Many have cited lack of cultural, linguistic, or religious competence in services as influential in deterring their use among immigrants. Some studies suggest that many immigrants find mental health professionals unsympathetic to “talk” and more interested in hastily dispensing psychiatric medication. This leads them to drop out of services in search of more holistic or respectful (to their eyes) models of health care.

More worryingly, some research suggests that mental health services are inherently Eurocentric and may even have some characteristics that could lead them to be accused of “institutional racism.” For example, a growing body of research suggests that dark-skinned first- and second-generation immigrants are significantly more likely to be brought to emergency psychiatric services by the police or ambulance, in comparison to the general population. Other studies suggest that dark-skinned first- and second-generation immigrants are less likely to be offered “talking therapies” and more likely to be over-medicated. Additionally, they are more likely to receive restraint and seclusion.

Though the situation for immigrant mental health may sound bleak, there are positive signs of progress. Transcultural psychiatry clinics now exist in various cities around the world, including Montreal, Toronto, London, Stockholm, and Amsterdam. These clinics provide culturally sensitive psychiatric services in a multicultural milieu to a multicultural population. They often make manifold use of culture brokers, interpreters, cultural psychiatrists, and other experts to assist in individual cases. These models are spreading throughout the world.

Another cause for optimism is that many national and regional governments have made commitments to improving knowledge and practice regarding immigrant mental health within their jurisdictions. For example, establishing greater knowledge and practice in this area has been highlighted as a key priority by various commentators and agencies concerned with immigrant mental health in the United Kingdom, Canada, and Australia.

Conclusion

Some clear themes have emerged from the study of immigrant mental health. Key findings include the elevated rate of schizophrenia for immigrants and the underutilization of mental health services by immigrants. Various explanations have been put forward accounting for these differences, and various strategies are in place to address these inequalities. The study of immigrant mental health faces a set of specific conceptual and methodological challenges. Social, cultural, religious, linguistic, geographical, and economic variables have all been hypothesized as important in determining mental health and health-service utilization among immigrants. Debate is ongoing regarding the relative influence of pre- and postmigratory factors in determining mental health outcomes. Unpacking the impact and interaction of these variables is difficult, and they may apply with differential weight to immigrant subgroups. Fortunately, the arena of immigrant mental health is occupied by dedicated and gifted teams of researchers and practitioners in various centers across the world. Many of these researchers and practitioners are themselves first- or second-generation immigrants and have developed vital links with community organizations in order to develop a strategy to improve community mental health. These teams meet regularly at conferences throughout the year to exchange findings and discuss emerging models of best practice. This situation gives cause for optimism vis-à-vis the promotion of mental health among immigrants.

Mental Illness

Holly C. Sienkiewicz
Department of Public Health Education, The
University of North Carolina at Greensboro,
Greensboro, NC, USA

Immigrants, including refugees, face unique stressors that contribute to mental illness prior to, during, and after migration to a foreign country. Many factors affect immigrants' abilities to cope with these stressors. Diagnosis and treatment of mental illness is complicated due to accessibility barriers and cultural differences in the display and acceptance of mental health conditions.

Premigration Factors

Premigration trauma experienced in the country of origin may include environmental triggers such as war, torture, genocide, terrorism, natural disasters, and famine. The effects of these factors are exacerbated by the loss of family members and social networks through separation and/or death. The immediate residence prior to migration can also affect the mental health of immigrants and refugees. Prolonged stays in refugee camps and detention centers impact one's mental health in very different ways. For instance, the majority of refugee camp dwellers have sufficient cause to worry over their physical safety and material possessions. In addition to safety fears, refugees residing in camps often become dependent on ration cards and handouts which can perpetuate a felt loss of identity, independence, and self-sufficiency.

Expectancy bias is another premigration risk factor for mental illness. Expectancy bias ensues when life in the receiving country is not as one thought it would be.

Immigrants and refugees often have unrealistic expectations of their future in the USA, and are subsequently disappointed when they discover the realities of their postmigration situation. The disconnect associated with the reality of lived experiences and romanticized expectations amount to an increase in current stress levels that may exacerbate prior and contribute to nascent mental health afflictions.

Perimigration Factors

The process of migration can impact mental health outcomes. Immigrants face challenges leaving their country of origin that may include fleeing dangerous conditions, traversing geographical obstacles, and witnessing death and/or separation from loved ones. The formal application process and immigration status can also impact the mental health of immigrants. Polygamy, the practice of having multiple spouses, is practiced in various regions of the world. Polygamy is not legal in the USA; therefore, the USA will not accept multiple wives from the same family to be resettled as one family unit or as part of family reunification programs. Families seeking placement in the USA must either lie on their application forms or elect to leave certain members behind. Either of these options greatly affects family dynamics and can impact mental health.

Postmigration Factors

Postmigration stressors also play a pertinent role in the mental health status of immigrants. Postmigration stressors include issues such as financial concerns, acculturation, prejudice and discrimination, worries about family back home, loss of traditional ways of life, and dismal housing conditions. Postmigration difficulties in conjunction with premigration trauma and perimigration challenges coalesce to contribute to the mental health status of immigrants.

Finding gainful employment is the primary concern for immigrants and refugees immediately after migration. Immigrants to the USA are expected to quickly achieve a degree of financial self-sufficiency. Due to current economic conditions, it is difficult for non-English-speaking immigrants to obtain any type of employment. When immigrants obtain jobs, they are often overqualified for the position and receive minimal compensation for their efforts. Immigrants not only pay for the many expenses of life in the USA, but many also send money to family members still residing in their country of origin.

Another postmigration challenge that causes significant stress is the process of acculturation. Acculturation is especially difficult for individuals migrating from developing countries to industrialized societies. It is difficult to learn the nuances and fully engage in a culture different from one's own. Those that have gained proficiency in the dominant culture may still experience stress stemming from loss of cultural identity. Immigrants may also display signs of "margination," or opposition to acculturation. Elderly immigrants in particular maintain their original culture at the expense of the host culture and encourage younger family member to do the same. Margination is not an option for youth and adolescents, however, as they are immersed in school and struggle to fit in.

Not all immigrants have experienced prejudice and discrimination as a result of race or ethnicity prior to migration. While this is clearly not the case for refugees who may have fled due to racial or ethnic persecution, this is something that many immigrants did not account for prior to relocating to the USA. Most immigrants fit in and looked like the majority of other people in their country of origin. Upon arrival to the USA, however, many are dealing with discrimination and prejudice for the first time. Discrimination is increasingly recognized as a risk for mental illness.

Traditional ways of life and family dynamics also change dramatically as a result of migration. In many societies the elderly are the decision makers in their households and communities. Their knowledge and wisdom is appreciated and advice sought from the younger generations. After migration, however, the elderly feel that they have little wisdom to impart on the younger generations. The knowledge they have acquired throughout their life is no longer useful. The elderly also have difficulty adjusting to new ways of life, whereas children and adolescents adapt more quickly. Children learn English more quickly and often serve as the family interpreter – an essential service valuable for the migrating family. Where the elderly were once given the highest honor in the family, the power dynamic has shifted in favor of those who are able to learn English the quickest, thus altering traditional family structures.

Housing conditions also greatly affect the mental health of immigrants. Immigrant populations often have a limited income and subsequently reside in neighborhoods with low-cost housing. These areas tend to be urban, have higher crime rates, and lower performing schools compared to areas where nonimmigrant populations reside. Limited income also drives many immigrants to live in overcrowded conditions. The neighborhood environment and the quality of living conditions impact one's mental health status.

Protective Factors

It is important to note that not all immigrants experience mental illness. In fact, some immigrant groups have better mental health than nonimmigrant populations. For instance Mexican immigrants to the USA experience less mental illness than nonimmigrant populations in the USA. Many groups have protective factors associated with their culture that serve as a barrier to mental illness. Current studies are further investigating the concept of protective factors. The protective factors that some immigrant groups possess decline as families acculturate to life in the USA and these factors do not necessarily shield the second generation. Second-generation Hispanic adolescents have a dramatically higher rate of suicide and suicide attempts in the USA than nonimmigrant populations in the same age bracket.

Resilience is a factor with a positive impact on mental illness. Immigrants endure the challenges of relocating due to a strong desire for a better life for themselves and future generations. Immigrants have the resilience to move forward and achieve their goals. Indigenous religious and culturally prescribed practices among immigrant populations may have the ability to enhance resiliency and recovery efforts.

Illness and Diagnoses

Immigrants and refugees experience different mental health afflictions to a degree. Due to the inherent nature associated with a refugee's history, it is common for refugees to experience negative mental health effects after migration such as posttraumatic stress disorder (PTSD), anxiety, depression, and somatization. Statistics pertaining to psychiatric diagnoses within refugee populations in the USA have yet to be determined. Immigrants arriving in the USA primarily for economic reasons are less likely to experience PTSD and anxiety disorders, but are more likely to suffer from chronic stress and depression.

Barriers to Care

Immigrants and refugees face many barriers to effective care and treatment of mental illness. Barriers to care fall into two main categories – accessibility and acceptability. Accessibility barriers pertain to logistical barriers such as cognizance of services, the location of services and transportation to services, documentation, language barriers, and traversing a complex health care system. Acceptability barriers include the use of cultural healing modalities and the stigma associated with mental illness. For better outcomes with diagnosis and treatment of such illnesses, there is the need to consult cultural advisors when addressing mental illness in immigrant and refugee populations.

Metabolic Syndrome

Paul Lewandowski
School of Medicine, Deakin University, Waurn Ponds, VIC, Australia

Metabolic syndrome is a disorder characterized by a cluster of the most dangerous heart attack risk factors: diabetes and prediabetes, abdominal obesity, high cholesterol, and high blood pressure. A consensus worldwide definition of metabolic syndrome, including ethnic specific criteria was compiled by the International Diabetes Federation. In the case of migrants, the country of origin or ethnic background is used to define the appropriate group.

It is estimated that around 20–25% of the world's adult population have the metabolic syndrome and they are twice as likely to die from and three times as likely to have a heart attack or stroke compared with people without the syndrome. In addition, people with metabolic syndrome have a fivefold greater risk of developing type 2 diabetes (adult onset). The clustering of cardiovascular disease (CVD) risk factors that typifies metabolic syndrome is now considered to be the driving force for a new CVD epidemic.

Each year, 3.2 million people around the world die from complications associated with diabetes. In residents and migrants from countries with a high diabetes incidence, such as those in the Pacific and the Middle East, as many as one in four deaths in adults aged between 35 and 64 years is due to the disease. Type 2 diabetes, which accounts for 90% of all diabetes, has become one of the major causes of premature illness and death, mainly through the increased risk of CVD which is responsible for up to 80% of these deaths.

However, even before levels of blood glucose (blood sugar) are high enough for a person to be diagnosed with diabetes, hyperglycaemia (elevated blood sugar) and related changes in blood lipids (increase in triglycerides and decrease in the "good" cholesterol HDL-c) increase a person's risk of CVD. The more components of the metabolic syndrome that are evident, the higher is the cardiovascular mortality rate.

High-risk migrant populations for the development of metabolic syndrome are those from South Asia (people from Pakistan, India, and Bangladesh). The prevalence of metabolic syndrome has been shown to be much higher in South Asian migrants when compared to African-Caribbean and White European migrants. It has been established that metabolic syndrome can increase the risk of developing cardiovascular disease fourfold in Punjabi Indians. According to reports primarily from the UK, the prevalence of metabolic syndrome ranges from 29% to 50% in migrant South Asians. It has also been shown that South Asians are twice as likely to develop cardiovascular disease when they suffer from metabolic syndrome, in comparison to non-sufferers. Although studies on migrant South Asian women are limited, the data that do exist suggest that the rate of mortality due to cardiovascular disease is higher in migrant South Asian women, when compared to men. As a subset of the South Asian population, Pakistanis tend to have a higher rate of hyperinsulinemia (elevated blood insulin) and insulin resistance when compared to people of other ethnic backgrounds. Furthermore, the prevalence of cardiovascular disease in migrant Pakistanis living in the UK, USA, and South Africa is 50% higher when compared to the general population of the host country.

Generally, migration and lifestyle change (such as an increase in energy dense foods and a reduction in physical activity) leads to a higher prevalence of metabolic syndrome in migrant populations, when compared to the host population. As weight gain has been shown to be the strongest predictor of metabolic syndrome, weight control is important in preventing the onset or reducing the severity of the syndrome. It has been shown that losing weight or stopping weight gain using an improved diet and increased physical activity may reduce the overall risk of the disorder.

The treatment of metabolic syndrome must be a multifaceted process with a primary focus on therapeutic lifestyle change; in more advanced cases, however, pharmacological intervention may also be required. Diet and lifestyle modification is the first line of defense against various chronic diseases, metabolic syndrome inclusive. When using therapeutic lifestyle change to treat metabolic syndrome in migrant groups, a culturally competent approach must be used. Culturally appropriate diet and lifestyle intervention programs ideally should be implemented at an early stage (preferably on migration) so as to encourage healthy eating and physical activity. Education in the migrants' native language is necessary in order to create awareness about metabolic syndrome and preventative measures so as to reduce the impact and effects of obesity on various populations. Furthermore, leisure activities in which individuals from culturally sensitive backgrounds can participate should be promoted as a means of endorsing a physically active lifestyle.

Mexico

Julio Guerrero[1], Ranjita Misra[2]
[1]Department of Health & Kinesiology, Texas A&M University, College Station, TX, USA
[2]Center for the Study of Health Disparities (CSHD), Department of Health & Kinesiology, Texas A&M University, College Station, TX, USA

Introduction

The United Mexican States, more commonly known as Mexico, is a federal republic located in North America. It is bordered by the United States of America to the north, the Pacific Ocean to the west and south, Guatemala and Belize to the southeast, and the Caribbean Sea and Gulf of Mexico to the east. In total, its land mass covers 761,600 square miles (1,972,550 km^2), making it the third largest country in North America behind Canada and the USA, and the third largest Latin American county behind Brazil and Argentina. Mexico is divided into 31 states and a federal district.

Mexico gained independence from Spain on August 24, 1821, after being ruled by the Viceroyalty of New Spain for nearly 300 years. However, independence was first declared on September 16, 1810, which serves as Mexico's Independence Day and one of the most celebrated patriotic events in the country. In 1521, Spanish explorer Hernan Cortez landed on the Mexican shores in search of wealth and eventually conquered the great Aztec empire, which ruled Mexico at the time. Spain and other European nations began colonizing the New World and forced the indigenous peoples into inferiority, which began the separation of social classes. This separation widened over time and unfair practices eventually became so intolerable that Mexico finally demanded its independence from Spain.

In 1836, American settlers in northern Mexico demanded independence due to the unfair practices of Mexican president Antonio Lopez de Santa Anna. Santa Anna sent troops to defend the territory, but after losing some key battles, he surrendered and lost what became the Republic of Texas. This altered the northern Mexican boundary and significantly decreased the area ruled by Mexico. In 1845, the USA annexed Texas, but disputes over the southern boundary culminated in the US–Mexican War, which resulted in another defeat for Mexico. Consequently, Mexico ceded most of the current southwestern USA, further altering the northern Mexican border. Finally in 1853, the Mexican government sold a strip of land to the USA in the Gadsden Purchase, which extended the southern boundaries of the US states of Arizona and New Mexico. This was the last significant boundary alteration of the Mexican Republic.

The Mexican Constitution was adopted on February 5, 1917, but has been amended several times. It established three levels of government - the federal, the state, and the municipal governments - and mandates that all officials are either elected by voters or appointed by elected officials. It also established that the president serves as the head of the government and is elected by the citizenry to a nonrenewable 6-year term.

Mexico has a free market economy in the trillion dollar class and has experienced a series of economic booms and recessions that have affected the middle- and lower-classes. The country's economy is fragile despite creating strong ties with the USA and Canada through the North American Free Trade Agreement (NAFTA) and 12 additional free trade agreements with over 40 countries. Mexico's current president, Felipe Calderon, has placed reducing poverty and creating jobs at the top of his economic priorities.

Spanish is Mexico's official language and the most widely spoken language, though several indigenous languages are also spoken throughout the country. Spanish is also the language of instruction in schools and universities, though many offer instruction in English as well.

Mexico City, located in the Federal District, is the nation's capital city and undisputed urban apex. It serves as the economic, social, educational, and industrial capital of Mexico and attracts millions of tourists and new residents annually. Also, its population of 22 million residents accounts for approximately one-sixth of the nation's population and ranks not only as the largest metropolitan area in the Western Hemisphere, but also one of the largest urban centers in the world.

One of Mexico's most iconic symbols is its national flag. Known as "El Tri" for the flag's three color bands (red, white, and green), it symbolizes the foundation of the country and represents the pride of the people. According to myth, an Aztec god ordered the tribe to search for a permanent home, which would be indicated by an eagle perched on a nopal cactus with a serpent in its beak. The tribe ultimately spotted the eagle, the cactus, and the serpent on an island in the ancient Lake Texcoco. There they established Tenochtitlan, which became the power Aztec capital city and eventually Mexico City. Today, the eagle, the cactus, and the serpent are depicted on the center white band of the flag, in remembrance of the foundation of the capital city.

History

The Americas was inhabited by people who many believe migrated from Asia tens of thousands of years ago via a former land bridge in the Bering Strait. Highly organized civilizations developed throughout North and South America and existed for thousands of years before Europeans arrived in the 15th and 16th centuries. The area that is now Mexico produced a string of great early civilizations, including the Olmecs, Toltecs, and Mayas. But when Hernan Cortez arrived in 1521, most people lived under the Aztec empire. Cortez sought wealth from the New World and felt threatened by the Aztecs. So he conquered the empire and claimed the land for the Viceroyalty of New Spain.

By 1525, Spanish rule had extended as far south as Guatemala and Honduras and as far north as the western USA. Spanish expansion was motivated by the hope of discovering precious metals and the need for defense against nomadic indigenous raiders and against the perceived threat of British and French invasion.

Following the arrival of Europeans, intermarriage between European settlers and the Natives resulted in an increasing mestizo population, which over the centuries, became the dominant ethnic group in Mexico.

However, the smaller group of direct European descendants and lighter-skinned Mexicans dominated the wealthiest echelons of Mexican society and controlled economic, political, and social policies. In contrast, mestizo and indigenous Indians belonged predominantly to the poor and working classes and seldom advanced to higher classes.

Centuries' worth of social, political, and economic inequalities eventually stimulated revolts by the lower classes, the most important occurring on September 16, 1810. On that day, a priest named Miguel Hidalgo y Costilla called for the end of Spanish rule, which began the Mexican War of Independence. War ensued and lasted for a decade before Mexican forces finally ousted the Spanish. Independence was eventually recognized on August 24, 1821, and Miguel Hidalgo has since been known as the "Father of Mexico."

Mexico's new and inexperienced government urged equality among all Mexican citizens with no distinction between Mexican and European, that Roman Catholicism would be the national religion, and that an imperial form of government would be implemented. On July 21, 1822, Agustin de Inturbide was crowned Mexico's first emperor, but his reign only lasted until 1824, when Mexico's first Constitution was adopted and a democratic form of government was established. On October 1, 1824, Guadalupe Victoria was elected president in Mexico's first national election.

The Mexican government endured several hardships throughout the nineteenth and twentieth centuries. Economic and political instability made borrowing money from foreign nations expensive, resulting in an escalating national debt. The Mexican government became incapable of providing funds for education and other social improvements, which many Mexican leaders thought were urgent requirements. Furthermore, the government was constantly overturned by revolting armies angered by insufficient compensation, which led to greater instability.

In addition to the economic and political instability plaguing the country, Mexico also suspended debt payments to its European lenders. Though tensions rose between Mexico and its lenders, France retaliated most aggressively. French ruler Napoleon III had been seeking expansion opportunities and was interested in Mexico's strategic location and economic potential. So when Mexico suspended payments to France, he seized his chance to gain control and launched an invasion. His forces eventually captured the capital and he established Mexico's second monarchy. Maximilian of Austria was appointed emperor and was expected to comply with Napoleon's scheme. At the same time, clerics in both Mexico and Europe welcomed Maximilian, hoping he would reestablish Roman Catholicism as the Mexico's exclusive religion and restore the Church's authority. Maximilian defied both Napoleon's and clerical request and operated his own agenda, which proved to be ineffective at securing governmental control or economic prosperity. Foreign nations began pressuring Napoleon to withdraw from Mexico. France withdrew in 1867, leaving Mexico once again vulnerable to rival armies.

Benito Juarez, who was president when the French invaded Mexico, was able to reestablish his presidency. He was greeted by an enthusiastic public that welcomed the end of the long and devastating civil war and the reestablishment of a government under the Constitution. He launched "La Reforma," a set of policies that eventually stabilized the Mexican government for the first time in its history. The aims were to improve public education, establish a sound economy, and ensure equal rights for all Mexicans. Juarez modernized Mexico's economy, established peaceful relations with foreign countries, and stabilized Mexican society. He was elected twice more before his death in 1872 and has been regarded as one of Mexico's greatest leaders.

The next major political figure to emerge was Porfirio Diaz, who was elected president in 1876. His progressive agenda dominated 35 years of Mexican history and modernized Mexico into a world economy. He emphasized economic development and social progress, but his policies only benefited rich Mexican supporters and foreign investors. He used European and US funds to build railways, provide electricity and streetcars for the cities, create industrial complexes, rehabilitate port facilities, and develop the mining of industrial metals. The Mexican petroleum industry was also created under Diaz, but concessions were only made to foreigners, which laid the groundwork for serious problems later. On one hand, Diaz propelled Mexico into the world market and greatly improved Mexican society. But on the other hand, his regime repressed and controlled the lower classes by maintaining low wages and long working hours. Urban workers were deprived of rights and most were unable to keep their land. Elites enjoyed most educational opportunities while indigenous groups were often shipped to plantations for cheap labor. Diaz also overrode elections and appointed officials who favored his policies. Diaz instilled fear and intimidation into the Mexican public, but the younger generation voiced dissent. Finally, when Diaz fraudulently won reelection in 1910, opponents revolted and the Mexican Revolution began.

Diaz was ousted almost immediately, once again leaving the presidency open for rival armies. Violence continued throughout most of the decade, but in 1917, several sides joined together to create a constitution to stabilize the government. Though the exact end of the Revolution remains speculative since skirmishes continued until the 1940's, the Constitution of 1917 still serves as Mexico's constitution.

World War II shifted Mexico's attention from domestic dilemmas to foreign affairs. Mexico aided the USA by supplying raw materials for the manufacture of war equipment and machinery. Also, the two sides signed a trade treaty, in which the USA agreed to buy Mexican silver at world prices, provide long-term loans to strengthen Mexico's economy, and provide military aid to professionalize Mexico's army, all of which stabilized the Mexican economy. The treaty also resolved strained relations between Mexico and the USA.

Mexico enjoyed considerable economic growth until the 1980's and 90's, when the economy was stricken by plummeting worldwide petroleum prices. Unemployment and inflation soared, private and foreign investment dropped, and the population began migrating from rural areas into the cities. Mexicans also began migrating to the USA in search of opportunities, but the flow of illegal immigrants became problematic and relations were strained again. But the creation of the North American Free Trade Agreement in the late 1990's helped Mexico's economy recover and eased the border tensions.

Society

Mexico's population is 112.5 million (2010), which ranks as the 11th highest in the world and the highest among Spanish-speaking countries. Its population growth rate is 1% and life expectancy is 76 years. The majority (65%) of Mexicans are between 15 and 64 years of age, while 29% are between 0 and 14 years of age and 6% are 65 years of age and older. More than 60% of the people are mestizo, about 20% is Native Indian, and most of the rest are European descendants. Though Mexico has no official religion since the Constitution guarantees separation of church and state, Roman Catholicism is practiced by more than 90% of the population.

Mexico's northern border cities have grown rapidly since the 1970s, largely because migrants from central Mexico have been attracted to jobs in the USA and in "maquiladoras," which are export-oriented manufacturing plants where duty-free imported parts are assembled on the Mexican side of the border. Migration has also helped to maintain Mexico's population at optimal levels. Remittances average around $21 billion (USD) per year and are the second-largest source of foreign revenue behind oil. Thus, migrations has served as a safety value for Mexico's social and economic pressures.

Mexican society experiences extremes of wealth and poverty – with a limited middle class wedged between elites and investors and masses of rural and urban poor. The largest segment of the urban population is the lowest socioeconomic class. Many city dwellers' incomes are below poverty level, whereas the relatively affluent middle- and upper-income groups enjoy the amenities of urban life and control most social, political, and economic activity.

Health

The Mexican population grew more than sixfold from 1910 to the early twenty-first century. The rapid rise of the population in the 1940s was primarily due to improvements in health care and food supplies. The death rate and infant mortality have drastically declined, but are still high when compared to other developed countries. The growth rate also slowed during the late 20th century, but the Mexican population is still increasing.

Disparity in health status is noted by difference in social classes. Poor and indigenous Mexicans tend to suffer from illnesses associated with unsafe water supplies, infections, and respiratory diseases. Also, rural areas have much higher mortality and morbidity than urban areas. But in general, the leading causes of death in Mexico are cardiovascular diseases, diabetes, cancers, accidents and violence, and diseases of the digestive and respiratory systems.

Mexico's health care system is comprised of public and private programs. Federally subsidized hospitals and clinics are available to all Mexican citizens and are found throughout the country. In rural areas, modern medicine is often considered too expensive, difficult to obtain, or is not trusted. Private care is superior to public care and is preferred by higher social classes. Overall, the quality of medical care in Mexico lags behind that available in the USA and Europe, so many Mexicans elect to travel outside the country for more sophisticated surgical procedures or treatments.

Education

Mexico strives to provide quality educational opportunities for its people by increasing the number of schools for children. School attendance is required for children ages 5 to 18. Adult literacy programs have also been promoted vigorously since the 1970s. Mexico's efforts were evident at the beginning of the 21st century when its literacy rate was 91%.

Mexican public schools are mostly located in rural areas and are poorly funded by the Mexican government. Many only offer a primary education, so citizens migrate to the cities for better schools and social opportunities that derive from higher education. Despite increases in the numbers of classrooms, teachers, and educational supplies, about one-seventh of all school-age children do not attend school, and almost one-third of adults have not completed primary school and over half have not complete secondary school.

Private schools are vastly superior to public schools, but are only afforded by upper-middle and upper class families. This contributes to the socioeconomic imbalance that greatly favors the middle and upper classes.

Universities are found only in the largest cities. Most college students study in Mexico City, where 20% of all Mexican universities are located. Less than 12.5% of the Mexican population has earned a college degree.

Immigration/Emigration

Mexican migration into the USA has increased sharply since the 1970's and has contributed to the largest US immigrant group. Between 8 and 13 million immigrants entered the USA between 1970 and 2000, with more than 170,000 in 2000 alone. Many cross the US-border illegally in search of jobs and better opportunities, while others are highly qualified professionals.

American migration into Mexico has also increased in recent decades. Most Americans simply commute daily for work or leisure, but many live in Mexico permanently since several US companies operate in Mexico and employ millions of US citizens.

Policies and Issues

A lack of adequate housing is one of Mexico's most serious problems. The federal government has built multiunit housing projects, but urban populations have increased more rapidly than new units can be constructed. Also, economic difficulties have reduced the funds available for new construction. The poorest social classes have resorted to building makeshift housing on unoccupied city lands that usually lack water, electricity, and sanitation. Widespread rural poverty is also a serious problem with a high proportion of the rural populations relying on limited means for survival.

Mexico's environmental issues include scarcity of hazardous waste disposal facilities, polluted natural fresh water resources, deforestation, widespread erosion, and desertification. Land subsidence around Mexico City causes destruction of homes and buildings and air pollution affects the capital city and urban centers along the US–Mexican border.

Illegal immigration from Mexico to the USA has been a source of tension between the two countries, especially in recent decades. Former Mexican president Vicente Fox tried to loosen strict US immigration policies to allow undocumented Mexicans to work in the USA. But the 2001 terrorist attack in the USA prompted the US government to strengthen its national defense.

Illegal drug trafficking is another issue of concern for both Mexico and the USA. Despite conducting the largest illicit-crop eradication program in the world, Mexico serves as a major producer of illegal drugs and a transport channel for most US-bound illegal drugs produced in South America. Millions of pounds of heroin, marijuana, and cocaine are smuggled into the USA every year, as violent drug cartels battle to control Mexico's drug-trafficking operations. These cartels are responsible for some of the highest annual death tolls in Mexico and in the world. Efforts by both Mexican and US governments have been ineffective in alleviating the problem.

Summary

Mexico is an upper middle-income and industrialized country located in North America. It has the 11th largest population in the world and the largest among Spanish speakers. Its history is extensive and dates far before European arrival to the New World. The economy is frail and relies heavily to its NAFTA partners, especially the USA. Finally, Mexico experiences several domestic and international issues, which are largely impacted by US legislature.

Traditional midwives (TMs) or traditional birth attendants (TBAs) exist in most societies. Often, TMs are members of the local community and share culture and traditions with others. They also have high social standing and considerable influence on health practices of local people. More importantly, they play a vital role in pregnancy and birth in many societies. Newar women in Nepal, for example, give birth with the assistance of *aji*, a grandmother in local term, who can be an experienced older relative or a neighbor. For each family, there is a strong relationship between the family and a particular *aji*, who can be called upon whenever the birth takes place.

Lefeber and Voorhoever suggest that a TM does not just only deliver babies. Rather, she is familiar with the woman and her family. She also shares cultural ideas about the birth and the preparation of the birth with the woman. TM is knowledgeable about the traditional medicines and rituals which are required before, during, and after birth. As such, the work of a TM is adapted to the social and cultural matrix of which she is a part and her beliefs and practices are consistent with the needs of the local community.

The number of TMs has reduced dramatically in many traditional societies although there are still TMs delivering infants, particularly in remote areas where modern health care is not accessible to many poor women. It has been suggested that approximately 90% of poor women and those living in rural areas in India continue to give birth with the help of *dais*, or local TMs. Indeed, recent studies have pointed to the existence and persistence of traditional midwives in different societies.

In Thailand, a TM is called *mor tamyae* in some parts but referred to as *mae jang* in the North, is a caregiver of women in childbirth. *Mae jang* delivers babies in the villages, and assists women with postpartum practices during the first month after birth. When the labor begins, *mae jang* will be summoned to the woman's home. A husband is expected to assist *mae jang* and the laboring woman. The birth mostly takes place in the kitchen, where hot water can be prepared. Mattresses are folded up for the woman to prop her back up against when pushing. A husband provides physical support to a laboring woman. He sits behind her with his legs astride her shoulders so that when contractions are intense she holds on to his muscled thighs, which give her strength to push. A piece of strong wood or bamboo is tied to a post or a wall where the woman can push her feet against. If there is no husband assisting a woman at birth, a piece of long cloth or rope is hung onto the rafters of the room. This is for the woman to cling onto when contractions are intense. The TM squats at the woman's thighs and waits to catch the baby when it emerges so that the baby will not drop. After the birth, the husband boils the water which the midwife will use to wash the placenta, clean the body of the new mother and the newborn. He also cleans up the remnants of the birth and the floor, prepares a bed for his wife who must observe a postpartum ritual for the whole month, and buries the placenta of his newborn infant.

Mae jang may also help a woman to have an easy birth by manipulating her abdomen and uterus during pregnancy. This is known as "*klang tong*" or "*kwag tong*" in northern Thai. Essentially, the midwife massages and pushes the uterus upward to make it "loosen up." This will create enough space within the uterus, not only to make the baby move more easily in the womb, and hence, make it easy to emerge, but also to ensure that the baby is not squashed and deformed inside the womb. This ritual is done two to three times per week from the sixth month onward.

The Safe Motherhood Initiative has advocated, in a bid to reduce maternal mortality, for an increase in the number of skilled birth attendants including TMs, so that women in rural areas and resource-poor settings who have limited access to modern maternal health services and care may have safe births. Although attempts have been made in many societies, it seems that there are still many obstacles to achieving this outcome. Births assisted by TMs are still largely seen as unsafe. In societies where discourses of modernity are pervasive, such as in most Western societies, TMs would still be perceived as not only ignorant, but also dangerous and dirty. Thus, the presence of TMs in Western societies would still be unimaginable to many women, and there are lots more to be done to bring back TMs in many societies.

Immigrant women who reside in Western societies where TMs are not recognized face difficulties when they become pregnant and give birth in Western hospitals. They have to rely on the medical model of care and are isolated from familiar faces during a critical time. Most maternity hospitals in Western societies permit a husband to be present at birth. However, in a society where men are not culturally permitted during birth, it can lead to conflicts and emotional turmoil in the women, their husbands, and families. Also, women may wish to have other people such as their mothers, sisters, and particularly TMs who can provide culturally sensitive support during this critical period. Therefore, the lack of acceptance of TMs and their support in Western hospitals can impact on the well-being of many new mothers from immigrant backgrounds.

In many societies, traditional births are replaced by modern and medicalized birth. Although there is no denial that modern birth can be beneficial to many women, overmedicalized birth has made other types of birth, such as births assisted by TMs, irrelevant. It has, however, been evidenced that TMs can provide support during pregnancy and birth in clinical settings so that a more "humanized birth" can be achieved. In order to make birth less frightening to many women including immigrant mothers, there is a need for a trusting collaboration between modern obstetric and traditional midwifery care. Ultimately, this will lead to culturally sensitive birthing care to many women in traditional societies in general, and to immigrant mothers in particular.

Migrant Day Laborers

Il-Ho Kim[1], Carles Muntaner[2]
[1]Social Aetiology of Mental Illness (SAMI) CIHR Training Program, Centre for Addition and Mental Health, Toronto, ON, Canada
[2]Bloomberg Faculty of Nursing and Dalla Lana School of Public Health, University of Toronto, Toronto, ON, Canada

With the decline of the formal economy, especially since the 2008–2010 global economic crisis in the competitive global labor market, the health risks engendered by the rapid growth in migrant day labor have become a central occupational health problem. Migrant day labor can be defined as a type of work in the informal sector that holds no guarantee of future work and employs mainly recently arrived immigrants. In the search for better jobs and higher wages, immigrant workers have traditionally migrated from poor to rich countries primarily in Europe, Asia, and North America. During the past three decades, immigrants have filled day labor work positions and particularly migrant day laborers have constituted a large portion of their host country economy as agricultural, construction, manufacturing, and domestic-service workers. They create jobs and greatly boost the economy by producing cheap farm products and home goods. Nonetheless, migrant day laborers suffer from very low wages and repetitive, strenuous work in an unsafe, underground economy. Accordingly, the majority of migrant day laborers face high health risks as they toil in hazardous, exploitative working conditions.

The Characteristics of Migrant Day Laborers

According to an ILO report, there were approximately 86 million economically active immigrants worldwide in 2004, and a large proportion of them tended to work as unskilled day workers at the bottom of the employment ladder. Until now, the characteristics of migrant day laborers, their true size, and magnitude, have been difficult to establish. However, the ILO and EU Commission have recently estimated that globally the number of undocumented migrants was roughly between 20 and 30 million. Undocumented migrants, though ubiquitous around the world, are most populous in America (11.9 million), Europe (1.9–3.8 million), Russia (1.5 million), Canada (0.5 million), and Korea and Japan (0.5 million). Migrant day laborers mainly perform manual, labor-intensive work – work that is described as dirty, degrading, dangerous, and unappealing to native workers. They work excessive hours with inadequate safety equipment and no compensation insurance. Migrant day laborers who cannot obtain work permits are especially vulnerable to exploitation and employer abuse since they fear losing their jobs, incarceration, and deportation; thus they are hired at extremely low wages and are often underpaid or not paid at all. As the most vulnerable workers, female migrant laborers toil primarily in retail, housecleaning, or consumer services. Their working condition can be regarded to being exploited like a slave. Female undocumented migrant day laborers are often trapped into smuggling, sex trafficking, or servitude by migration agents or criminal organizations. The global economic crisis may force migrant laborers to face even greater challenges: large unemployment, xenophobic fear that they will "steal" local jobs, and non-renewal of work permits. Accordingly, the remittance amounts that migrant workers send to families in their home countries have decreased concomitant with their families' increased poverty.

The Health of Migrant Day Laborers

Migrant day laborers are exposed to a variety of work-related hazards (such as chemicals, pesticides, dust, and other toxic substances) without proper protective equipment, compensation insurance, and on-the-job training. The health issues to be considered for these workers are: (1) occupational safety, injuries, and diseases, (2) mental health, (3) barriers to accessing health services, and (4) health risks for their families. Because of their high-risk working conditions, injuries among migrant day laborers are all-pervading. For instance, the 2004 ILO report suggested that, worldwide, these workers fall victim to 335,000 accidents per year in the most dangerous of industries – agriculture, mining, and construction. Valenzuela and colleagues reported in 2006 that in the USA, one in five migrant day laborers had suffered from on-the-job injury, and that agricultural hazards accounted for 7.4% of their work-related deaths. Daily unstable working conditions and social isolation also induce a risk of poor mental health such as chronic stress, anxiety, and depression. Moreover, female undocumented workers are often victims of sex trafficking, exposing them to a great risk of contracting HIV/AIDS or other sexually transmitted diseases. While only a few of these laborers, when injured, received medical treatments covered by employer-sponsored insurance, the majority of these injured workers obtained no medical treatment. The most well-known barriers that prevent immigrant day workers from accessing the healthcare system are discriminatory government policies and financial constraints and, to a lesser extent, language barriers. Moreover, immigrant day laborers often conceal their need for medical care because they are afraid of being laid off or deported. Another important consideration is the enormous health effect on migrant workers' families and children. In particular, pregnant women are forbidden from accessing prenatal care. For children who have day laboring parents, being excluded from medical services and the educational system can lead to serious mental and physical problems. The global economic crisis has aggravated an already horrendous situation for these deprived, vulnerable workers – that is, has aggravated their hazardous working conditions and, correspondingly, their health.

Recommendations and Conclusion

For migrant day laborers, the excessive risk of injury and disease, linked to their dangerous employment and working conditions, is a global phenomenon. To reduce the employment-related health inequalities affecting laborers, future legislation backed by research, evaluation, and monitoring, country by country, is urgently needed because of insufficient understanding of (1) what are the true magnitude, mechanisms, and pathways underlying health inequality's relation to their employment conditions, (2) how health effects vary according to the hosting county's labor regulations and policies, and (3) how the current global economic recession amplifies health inequalities for these legal and undocumented migrant day laborers.

Being one of the most vulnerable groups of workers in the global labor market, migrant day laborers face common health-related challenges such as systematic exploitation and exclusion from health protection in dangerous workplaces. To ensure their health and safety, governments, unions, and international organizations should collaborate to implement fair labor standards by (1) administering adequate supervision, safety training, health surveillance, and work-related insurance for legal and undocumented laborers on par with citizen workers, and (2) standardizing labor migration policies while instituting legal support for these undocumented laborers to help eradicate sexual trafficking, smuggling, forced labor, and poverty wages.

Migrant Farmworkers

Pilar A. Parra
Division of Nutritional Sciences, Cornell University,
Ithaca, NY, USA

Agricultural work accounts for half of the labor force in the world, but in advanced industrialized countries it is much less than 10%. Agricultural work with mining and construction are considered the three most dangerous occupations worldwide. In 2005, the highest incidence of fatal (13 deaths per 100,000) and nonfatal accidents at work (about 6,700 per 100,000) were among skilled agricultural and fishery workers

There is no accurate census of hired agricultural workers. Epidemiological research that aims to report their health status is limited by the absence of a reliable numerator and cross-sectional assessments of health outcomes. Quality of data collection by fatalities and injury by occupation varies by country. Data on the health status of agricultural workers is reported by occupation, and includes farmers and family members as well as hired workers. The temporary and transient characteristic of the hired farmwork-force makes it difficult to present an assessment of their health status. This entry will focus on migrant farmworkers in industrialized countries where more reliable and recent data can be found.

Migrant farmworkers are part of the hired agricultural force, defined as "a worker temporarily engaged during harvesting periods, who come from other regions in the country or neighboring countries."

Agricultural workers' health, in general, is negatively affected due to occupational risks and labor conditions. Occupational risks include use of heavy machinery and sharp tools, lifting heavy weights, long repetitive movements, exposure to pesticides, and working under adverse weather conditions. In many countries, labor laws protecting workers in other industries exempt agricultural workers. Comprehensive legislation on occupational safety and health is limited and poorly enforced. Cultural and language barriers add to the likelihood of injury and disease when workers do not receive adequate training in the use of machinery or pesticides.

In the European Union (EU), year-around, seasonal and migrant wage earners account for approximately 40% of persons involved in agricultural work. The EU employs 4.5 million seasonal and migrant workers, and about half a million come from countries outside the EU. Migrant workers in agriculture there are entitled to some protections. The International Labor Organization (ILO) since 1982 promoted Convention No. 184 that specifically states that "measures shall be taken to ensure temporary and seasonal workers receive the same health safety and protection and adequate and appropriate training. . . taking into account their level of education and differences in language." France, with one of the largest agricultural workforces in the European Union, has health coverage for 98% of farmers and agricultural workers. However, farmers, due to the high costs of social contributions, may not list hired migrant workers on their payrolls. Greece, Italy, and Spain also include some protections, but temporary workers are many times excluded.

In 2007, the US census reported three million people working in agriculture, where 1.1 million were hired farmworkers and about half a million were migrant farmworkers, who migrate from their homes to a single location, crossing state lines or an international border. Only 12% are follow-the-crop migrants and will work in several farms following specific geographical streams.

Among developed nations, the USA has the largest proportion of seasonal and migrant farmworkers who are foreign born (80%) and more than half lack working permits. In the European Union, one in ten workers comes from countries outside of the EU, and unauthorized workers account for a relatively small proportion of migrant farmworkers. In general, foreign-born migrant workers in the European Union and in the USA face more obstacles in obtaining health care due to access, high costs, transportation, language barriers, and legal status.

Access to Health Services

Since 1962, the US government established health coverage under the Migrant Health Act for migrant agricultural workers, and later in 1970 included seasonal workers. Health coverage for migrant farmworkers in the USA is restricted to accidents and illness at the workplace. Access to services is further limited due to the relatively small number of Migrant Health Centers in the nation. In 2008, there were about 500 Migrant Health Centers nationwide, and cover about one quarter of all migrant and seasonal farmworkers and their families.

Occupational Risk: Fatalities and Injuries at the Work Place

In the USA, agricultural workers overall account for 3% of the workforce but were 7.4% of work-related casualties. Data from 1996 to 2006 Department of Labor's Census of Fatal Occupational Injuries for the agricultural sector report that fatality rates increased from 22.2 to 29.4 per 100,000 workers. In 2007, there were 25.7 deaths per 100,000 in agriculture compared to an average rate of 3.7 deaths in other industries. As the number of foreign born increased in the farm workforce, so did the number of fatalities. In farming and forestry, 84 deaths occurred in 1992, a sharp increment of 54% by 2002. Many of these fatalities are the result of lack of training and difficulties following instruction for lack of English language.

Pesticides Illnesses

Governments have implemented rules and guidance on substances that can be used in agriculture. Pesticides are applied to prevent, destroy, or mitigate any pest, including insects, mice, and other animals, and weeds, fungi, and some microorganisms. In the USA, the Environmental Protection Agency regulates pesticide safety training for workers. Safety measures are not always enforced and language barriers impede full understanding of handling of pesticides with safety. Inhalation, ingestion, and absorption by the skin are ways through which pesticides can enter the body. Fields may not have available the sanitation facilities to wash themselves and their contaminated clothes. Under these conditions, pesticides can be brought home and affect workers' families, especially children. Also farmworkers' housing is exposed to drifts of pesticide applications in nearby fields. Immediate effects of smaller doses of pesticides include rash, dizziness, nausea, vomiting, eye irritation, headache, and muscle weakness. Long-term effects include increased risks of several cancers, sterility and neurological decline in adults, and other chronic health problems such as respiratory problems, memory disorders, and dermatological conditions. Pregnant women who are exposed face the danger of spontaneous abortion and deformed babies, and retarded neurobehavioral development in children.

Heat and Sun Exposure

Heat stress is an occupational risk that is the result of long hours under the sun and great physical exertion that causes body heat to rise, and if not attended to can lead to dehydration, electrolyte imbalance, neurological impairment, multi-organ failure, and death. Crop workers have a heat-related death rate of 0.39 per 100,000 workers compared to 0.02 for other civilian workers. These deaths could be easily avoided if appropriate clothing, shade, breaks, and drinking water were readily available in the fields. The 2005 National

Agricultural Workers Survey reported that one in five workers did not have access to drinking water and cups.

Musculoskeletal Injuries

Farmwork requires constant bending, climbing, crawling, twisting, overexertion, repetitive motions, excessive loads, and carrying heavy items. Moreover, because most are paid by piece rate, workers are pushed to labor for long hours, with no breaks and at high speed. All these factors increase the likelihood of injury. There are two main groups of musculoskeletal injuries: (a) peripheral neuropathies, e.g., carpal tunnel syndrome and (b) tendonitis. Others include strains and muscle pain, rotator cuff injuries, and bursitis. These disorders account for half of all agricultural occupational injuries and 30% of absences. Also, inadequate tools play a role in their injuries. These problems can be reduced by altering work procedures and by redesigning agricultural tools (ergonomics). Musculoskeletal injuries not attended may become a permanent disability.

Other serious health conditions that are more difficult to diagnose and implement a follow-up treatment are mental health and chronic conditions. These conditions are exacerbated by the isolation, job insecurity, long periods of family separation, and poverty. Health centers report increasing numbers of severe mental stress and depression and chronic conditions such as hypertension and diabetes.

Military-U.S.

Tambra K. Cain
Barrett, Twomey, Broom, Hughes & Hoke, LLP,
Carbondale, IL, USA

Roughly 8,000 noncitizens enlist in the US military every year. As of 2005, the Defense Manpower Data Center (DMDC) estimated that about 35,000 noncitizens currently serve in some branch of the active US military. Additionally, approximately 12,000 noncitizens were serving in the National Guard and Reserves. In 2003, the four services had the following numbers of noncitizens: Navy – 15,880 noncitizen sailors; Marine Corps – 6,440 noncitizen marines; Army – 5,596 noncitizen soldiers; Air Force – 3,056 noncitizen airmen.

The treatment of noncitizens across the US military services is not uniform. Each service branch has different policies regarding noncitizen service members. While limited English proficiency may impose a practical hurdle to potential noncitizen recruits, several of the services offer special enlistment programs for those seeking to enlist with limited English proficiency. Each branch has a differing proficiency requirement. Additionally, occupational choices available to a noncitizen may be limited. The greatest current limitation on noncitizens in the US military is their ability to obtain a security clearance, which requires US citizenship. Many military jobs require a clearance for entry and/or promotion. There are clearance-free jobs; however, the number varies from branch to branch. Reenlistment standards for noncitizens also vary among the services. Neither the Navy or the Marine Corps have restrictions on the reenlistment of noncitizens, the Army allows noncitizens to serve up to 8 years, either consecutive or not, and the Air Force limits noncitizens to one enlistment term of either 4 or 6 years, then requires a noncitizen to get their citizenship in order to reenlist. All enlistees, regardless of the branch of military service, must take the Oath of Enlistment and swear to support and defend the US Constitution.

Selective Service System

Conscription in the United States (more commonly known as “the draft”) has been used several times in US history. It was discontinued in 1973, with the transition of the US military to an all-volunteer force. However, the Selective Service System remains in place as a contingency plan. The Selective Service System is a means by which the United States maintains information on those potentially subject to the draft.

All males between the ages of 18 and 25 are required by law to register within 30 days of their 18th birthday. Currently, the law exempts women from registration. The issue of women being exempted was addressed in 1981 by the US Supreme Court in *Rostker v. Goldberg*. The Supreme Court determined that since women are excluded from combat, they would not be needed in the event of a draft, and therefore decided not to register them.

Selective Service (and the draft) in the United States is not limited to citizens. Noncitizen males between the ages of 18 and 26 living in the United States, who are permanent residents (holders of green cards), seasonal agricultural workers, refugees, parolees, asylees, and even illegal immigrants, are required to enlist in the Selective Service. Refusal to do so is grounds for denial of a future citizenship application. Foreign males in the United States as lawful nonimmigrants (international students, visitors, diplomats, etc.) are not required to register.

Naturalization

Noncitizens who serve in the United States military enjoy several naturalization benefits which are unavailable to noncitizens who do not serve. Members and certain veterans of the United States Armed Forces may be eligible for naturalization through their military service under Sections 328 or 329 of the Immigration and Nationality Act (INA).

A person who has served honorably in the US armed forces at any time may be eligible to apply for naturalization under Section 328 of the INA. The military community sometimes refers to this as “peacetime naturalization.” An applicant for peacetime naturalization under Section 328 of the INA must be aged 18 or older; have served honorably in the US armed forces for at least 1 year and, if separated from the US armed forces, have been discharged honorably; be a permanent resident at the time of examination on the naturalization application; be able to read, write, and speak basic English; have a knowledge of US history and government; be person of good moral character; have an attachment to the principles of the US Constitution and be well disposed to the good order and happiness of the US; and meet the residency and physical presence requirements. If the applicant has filed an application while still in the service or within 6 months of separation, the applicant is not required to meet the residence and physical presence requirements.

Members of the US armed forces who serve honorably for any period of time during specifically designated periods of hostilities are eligible for naturalization under Section 329. An applicant for naturalization under Section 329 must have served honorably in active-duty status, or as a member of the Selected Reserve of the Ready Reserve, for any amount of time during a designated period of hostilities and, if separated from the US armed forces, have been separated honorably; have been lawfully admitted as a permanent resident at any time after enlistment or induction, or have been physically present in the United States or certain territories at the time of enlistment or induction – regardless of whether the applicant was admitted as a permanent resident; be able to read, write, and speak basic English; have a knowledge of US history and government; be a person of good moral character; and have an attachment to the principles of the US Constitution and be well disposed to the good order and happiness of the United States. There is no minimum age requirement for an applicant under this section. Additionally, the Immigration and Nationality Act provides for posthumous naturalization under Section 329A. Posthumous naturalization can greatly impact the status of the deceased person's spouse and dependents.

Current members of the US armed forces who qualify for naturalization under Sections 328 or 329 of the Immigration and Nationality Act can proceed with their naturalization application either in the United States or overseas. For active-duty service members, the fees are waived.

Mixed Methods

Katherine K. Bedard, Amy Kerivan Marks
Department of Psychology, Suffolk University, Boston, MA, USA

Mixed methods research can be defined as the intentional combination of qualitative and quantitative methods within research. Qualitative research aims to gather an in-depth understanding of human experience and investigate *why* people have the attitudes, behaviors, values, and motivations that they do through a nonnumeric analysis of the world. Qualitative research mainly utilizes words, such as observations, interviews, and focus groups, to understand the contexts in which events occur. Conversely, quantitative research aims to gather a breadth of knowledge about a specific topic in a controlled context that can be generalized to the larger community. Quantitative researchers utilize questionnaires, surveys, physiological measures, and other standardized assessments that can be analyzed using numbers and advanced statistical techniques. These differing approaches to research are thought by many to be incompatible due to differences in their techniques, goals, scientific rigor, and overall philosophy. However, proponents of mixed methods research feel strongly that the combination of these techniques can overcome the weaknesses of qualitative and quantitative methodologies alone. When working with immigrant populations, the combined strengths of these methods allow investigators to obtain a complete look at the immigrant health experience – gaining an in-depth understanding of the specific experiences within a culture from the individuals themselves, while also gathering a breadth of general knowledge that may be generalized to the larger community.

Strengths of Mixed Methods Research

Many believe there is a strong case to be made for utilizing an approach that combines qualitative and quantitative methods. For one, combining these methods in order to study the same phenomenon serves to gain convergence and increase the validity of the results (triangulation). Also, this approach uses the strengths of each method to overcome the weaknesses of the other in order to enrich the study of a particular topic (compensatory). Lastly, using two methods increases the researcher's understanding of the findings through allowing a more complete picture of the phenomenon to be gathered (expansion). By using varied methods, one is encouraging inclusivity and demonstrating value in gaining as much knowledge as possible. There is no need to pick one method over another; all methods are imperfect and can be enhanced with the addition of methodology that complements its weaknesses.

One of the leading supporters of mixed methods research, Tom Weisner, explains that human development takes place along an endless amount of different pathways based on everyday cultural and community contexts. Behaviors and experiences do not take place within the control of a laboratory, but are a part of a complex environmental system, or context, that has reciprocal affects on one another. Research often neglects the questions of *why* outcomes are occurring, failing to understand what people's actual experiences are and what they mean to them. A mixed methods approach provides an opportunity to learn about the personal experiences of people within their contexts, including their cultural beliefs, motives, thoughts, and behaviors. Based on this, he believes that a mixed methods approach that combines scientific rigor and standardized assessments with in-depth methods that allow one to more closely examine the experiences of people within their contexts is the best practice for trying to understand development. Immigrant populations are just one example of a group whose health depends on many social contexts (i.e., culture of origin, new culture); because of this, researchers may benefit greatly from utilizing a mixed methods approach in order to learn more about the specific health, mental health, and developmental experiences of immigrants.

Mixed Methods as a Way to Understand Culture and Immigration: Etic Versus Emic

In considering the use of mixed methods research, it is important to think about the theoretical distinction between investigating culture from an *etic* perspective or an *emic* perspective. Those who consider culture through an *etic* lens see culture as "universal" and applicable to all. In other words, an *etic* account would be a description provided by an outside observer in a way that can be applied to other cultures (i.e., culturally neutral). An example within research is the creation of a measure to be utilized across cultures, based on the understanding that the items are applicable to those from all cultural backgrounds. Quantitative research often takes an *etic* approach.

Conversely, those who consider culture through an *emic* lens see outcomes as "culture specific." An *emic* account would be a description provided by someone within the culture, speaking to his or her specific cultural experiences. An example within research is the implementation of focus groups to speak directly to the population of interest due to the belief that using a standardized measure would likely not capture important cultural nuances in the psychological or health construct measured. Qualitative research often takes an *emic* approach. In combining these two approaches, mixed methods allows investigators to gather varying cultural beliefs, customs, and experiences from both a local (in-depth; emic) and universal (broad; etic) perspective. Taking the ideas of Weisner into account, it becomes clear as to how mixed methods can truly integrate the *etic* and *emic* perspectives in order to gather the most complete information about how immigrants from varying cultures, on varying developmental and health pathways, experience their lives.

Mixed Methods Used to Study Immigration: Examples from the Literature

A recent study by Corona, Gonzalez, Cohen, Edwards, and Edmonds in 2009 used a mixed methods approach to investigate the health concerns and service needs of Latino youth in Richmond, Virginia. Considering the growing number of children of Latino immigrants throughout the US, and specifically to the Richmond area over the last 10 years, the authors believed that additional culturally responsive services for children and their families were critically needed in the Richmond area. A mixed methods approach was chosen because very little health information was available regarding Latino youth. Additionally, mixed methods allowed for an in-depth investigation of health concerns and service needs in Latino youth, as well as provided the opportunity to gather information that could be generalized and applied more broadly. Using this approach, the study aimed to identify (1) the specific health concerns and service needs among Latinos in their community and (2) factors that may promote and inhibit Latino youth health. Quantitative data were collected through a community survey given to 212 self-identified Latino adults; 96% were immigrants and 99% completed the survey in Spanish. The survey inquired about family composition, educational attainment, ethnic origin, length of time in the US, socioeconomic status, perceived health and safety concerns, service needs, and suggestions for addressing those needs.

Qualitative data were gathered through interviews with identified key informants that represented a variety of organizations from the community (e.g., faith-based organizations, schools, law, media), as well as focus groups of Latino parents and youth. Interviews lasted approximately 90 min and focused on perceived community concerns, service needs, service barriers, and ways of promoting adolescent safety and health. Focus groups lasted approximately 2 hours and topics covered included (1) problems and barriers faced by adolescents, (2) violence and safety prevention needs, (3) family communication patterns, (4) difficulties parents and adolescents have with each other, (5) attitudes and beliefs about drugs, delinquency, AIDS, and sexual behavior, (6) suggestions for programs or services to address health, child development, and safety needs, and (7) feelings and attitudes about the changing racial/ethnic demographic and subsequent effect on interactions with other individuals. An additional qualitative piece of the study involved the creation of a steering committee of Latino adults and youth from the community. This group met twice and worked together to develop the questions to be included in the survey, interviews, and focus groups, as well as to come up with a plan for recruitment that would address barriers identified by these community members.

The use of mixed methods in this case was critical in order for the researchers to obtain a detailed picture of the perceived health concerns and service needs identified through the quantitative community survey. The use of the steering committee to formulate the topics to be addressed throughout the varying assessment methods ensured culturally appropriate content, as well as a sufficient overlap of topic area between the qualitative interviews and quantitative surveys. This consistency in topic area served to increase the depth of the information gathered in the topic areas across methodologies. In addition, the steering committee made suggestions regarding recruitment procedures that allowed increased accessibility to the population of interest by addressing community barriers that may have been previously unknown to the researchers. This mixed methods approach created a detailed picture of Latino immigrant health concerns and service needs, a topic lacking understanding throughout the research. It provided a quantitative numerical look at the survey results that could then be supported through the qualitative descriptions of actual immigrant experiences within the interviews/focus groups.

An additional example that utilized a mixed methods approach with immigrant populations was a study done by Sirin, Bikmen, Mir, Fine, Zaal, and Katsiaficas in 2007 that explored the dual identification of Muslim-American emerging adults. The authors of this study aimed to learn more about the identity negotiation process between identifying as Muslim and American within the context of post-9/11 New York area. The authors were less interested in which ethnic or racial boxes these emerging adults might select when asked how they identify, but more about the *process* of *how* they formulate and *experience* the identity they have chosen within their varying contexts. Past research suggests that the construction of identity for immigrants is based on the balance (or lack of balance) of two domains: (1) the degree to which one is willing/able to identify with one's home culture (e.g., Muslim) and (2) the degree to which one is willing/able to participate in one's host culture (e.g., American). The ability to balance these two domains well indicates biculturalism and often leads to more positive psychological and physical health outcomes.

Within this mixed methods study, the authors aimed to increase their knowledge of the Muslim-American identity through specifically exploring (1) the degree to which Muslim and American identities are related among a group of emerging young adults in post-9/11 New York, (2) the degree to which discrimination-related stress, religiosity, and social and cultural preferences shape Muslim and American identities, and (3) the effect of gender in the relationship between Muslim and American identities. All 97 participants within the study were self-identified Muslim-American youth who were children of recent immigrants or who themselves immigrated to the US at a young age and live in the post-9/11 New York area; 44% were first-generation immigrants and 56% second-generation.

Quantitative data were gathered through self-report measures of identity, acculturation practices, religiosity, frequency of discrimination, discrimination-related stress, and a demographic questionnaire. As a means to add to this quantitative data, qualitative data were gathered by asking participants to "draw a map" of their multiple identities. More specifically, participants were provided a blank piece of paper and drawing materials and given a standard description of their task: *Using the materials provided with this survey, please draw a map of your many ethnic, religious, and social identities. This should be an illustration of how you see yourself as a Muslim-American person. You are free to design the map as you wish. You can use drawings, colors, symbols, words. . .whatever you need to reflect your multiple selves.* Two independent raters used a previously established protocol with Muslim youth to code the identity maps into three categories: those that reflected an "integrated," "parallel," or "conflicted" identity. Initial agreement between raters was 87% and disagreements were discussed until full agreement could be reached.

The use of mixed methods was critical in this study for several reasons. First, coding based on the qualitative identity maps was used to form meaningful categorical groups (e.g., those Muslim-Americans with an integrated, parallel, or conflicted identity), which were used in quantitative statistical analyses to look at how they were similar and different in other components of identity that had been collected through quantitative measures. Using this method, participants' identity maps provided the authors with a unique look into their experiences, allowing them to learn that the majority of their participants successfully balanced the coexistence of both their Muslim and American identities, with only a small portion expressing conflict between their identities. Overall, similar to the study mentioned above, utilizing a mixed methods approach allowed an in-depth look at the actual experiences of dual identity from the participants within the study, while combining with a quantitative analysis of other immigrant constructs, such as acculturation and discrimination-related stress.

Overall, the topic of immigrant health is an area of growing importance and concern within the US due to the increasing number of immigrants within the country and much more research is needed. Due to the unique contexts and experiences of these individuals, researchers need to focus a piece of their investigation on the knowledge that can be gained directly from the immigrants themselves. When working with immigrant populations, the combined strengths of qualitative and quantitative methodologies truly allow investigators to obtain a complete look at the immigrant experience – gaining an in-depth understanding of the specific experiences within a culture from the individuals themselves, while also gathering a breadth of general knowledge that may possibly be generalized to the larger community.

Mood Disorders

Kristin L. Hicks
Department of Psychiatry, Mount Carmel Health
Providers, Columbus, OH, USA

Mood disorders are a group of psychiatric disorders in which the primary symptom is disturbance of mood, which may be defined as one's sustained emotional state. The disturbance must be severe enough to cause subjective distress and usually results in impaired social, interpersonal, and occupational functioning. Mood disorders are classified in both the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders* (DSM-IV-TR) and the World Health Organization's *International Statistical Classification of Diseases* (ICD-10). Though it is widely accepted that mood disorders are a cross-cultural phenomenon, the experience and expression of mood disturbance vary widely across cultures.

There are two general categories of mood disorders. Depressive disorders are characterized by episodic or chronic low mood, while bipolar disorders involve periods of abnormally elevated, expansive, or irritable mood. According to the World Health Organization, depression is the leading cause of disability worldwide. In the USA, approximately one out of ten adults has a mood disorder in any given year. Depression is an important risk factor for suicide and it is estimated that 90% of people who die by suicide have a mood disorder, substance abuse disorder, or both. Primary depressive disorders, as classified in DSM-IV-TR, include major depressive disorder, dysthymic disorder, and depressive disorder not otherwise specified. Primary bipolar disorders include bipolar I disorder, bipolar II disorder, cyclothymic disorder, and bipolar disorder not otherwise specified. Mood disorders can also be substance-induced or occur secondary to a general medical condition. For example, depressed mood is a side effect of certain medications for hypertension. Secondary mood disorders typically resolve with treatment of the underlying cause or withdrawal of the causative substance.

Major depressive disorder is an illness characterized by periods of low mood called major depressive episodes. A major depressive episode is a period of at least two weeks in which a person experiences low mood or loss of interest in normal activities plus several of the following symptoms: sleep disruption, change in appetite, feelings of guilt or worthlessness, change in energy level, and suicidal ideation. If a person has one or more major depressive episodes, he or she may be diagnosed with major depressive disorder. If left untreated, the frequency and severity of depressive episodes tend to increase with age. Depressive episodes can become so severe that individuals experience symptoms of psychosis, including auditory hallucinations and paranoia. Dysthymia is a depressive disorder characterized by at least 2 years of depressed mood for more days than not, accompanied by other depressive symptoms that do not meet criteria for a major depressive episode.

The best treatment for depressive disorders is a combination of psychotherapy and antidepressant medication. Selective serotonin reuptake inhibitors (SSRIs), including sertraline, fluoxetine, fluvoxamine, citalopram, and escitalopram, are considered first-line treatment. In concordance with the hypothesis that people with depression have a relative deficiency of serotonin, SSRIs block reuptake of this neurotransmitter so that more is available to neurons in the brain. Norepinephrine has also been implicated in the etiology of depression and another class of first-line medications for depressive disorders work by blocking reuptake of both serotonin and norepinephrine. These are called serotonin norepinephrine reuptake inhibitors (SNRIs) and include duloxamine and venlafaxine. Bupropion, which blocks reuptake of norepinephrine and dopamine, is another option. While SSRIs and SNRIs are generally not combined with each other or other serotonergic medications, bupropion may be safely added to as an adjunctive medication to either class.

Older classes of antidepressants, including the tricyclic antidepressants (TCAs) and monoamine oxidase inhibitors (MAOIs), are as effective as newer drugs but typically cause more side effects and have a higher risk of toxicity in overdose. In the case of psychotic depression, antipsychotic medications are always indicated in addition to an antidepressant.

St. Johns Wort is a popular over-the-counter herbal supplement for depression. It has serotonergic properties similar to the SSRIs and may be effective in the treatment of mild to moderate depression. It is very important for individuals to tell their healthcare provider if they are taking over-the-counter agents because of drug interactions. For example, combining St. Johns Wort with prescription antidepressants can lead to serotonin toxicity, a potentially life-threatening condition.

Side effects commonly limit the use of antidepressants. Sexual side effects, including decreased libido and orgasmic dysfunction, are the primary reason people discontinue SSRIs. There are several strategies for minimizing side effects, including lowering the dose, changing the class of medication, or even adding a medication. For example, bupropion may help reverse sexual side effects caused by SSRIs. Antidepressants are most helpful when combined with regular psychotherapy or counseling, which may be provided by a psychiatrist, psychologist, social worker, or licensed counselor.

Bipolar I disorder, commonly referred to as “manic depression,” is diagnosed when a person experiences one or more manic or mixed mood episode. A manic episode is a period of abnormally and persistently elevated, expansive, or irritable mood lasting several days, and characterized by several of the following symptoms: decreased need for sleep, inflated self-esteem or grandiosity, racing thoughts, a sense of pressure to continue talking, distractibility, and impulsivity. In a mixed episode, the criteria for both a manic episode and a major depressive episode are met nearly every day for several days.

In addition to manic and mixed episodes, people with bipolar I disorder usually experience major depressive episodes. The mood episodes in bipolar I disorder are often so severe that individuals lose touch with reality and become psychotic. For example, a manic individual may have grandiose delusions that he or she is the president of the USA. A patient experiencing a mixed or depressive episode may become paranoid that others are trying to poison his or her food, or hear self-deprecating voices. Bipolar disorder is different from schizophrenia and other psychotic disorders in that the psychosis only occurs within the context of a mood episode.

Bipolar II disorder is characterized by one or more hypomanic episodes, and at least one major depressive episode. Hypomania may be considered a less severe form of mania in which individuals typically do not perceive subjective distress or experience much impairment in occupational or social functioning. Cyclothymic disorder is characterized by at least 2 years of numerous periods of hypomanic symptoms that do not meet criteria for a manic episode and numerous periods of depressive symptoms that do not meet criteria for a major depressive episode. Bipolar disorder NOS is diagnosed when individuals have bipolar features that do not meet criteria for any of the above bipolar disorders.

There are several treatment options for bipolar I disorder. First-line agents include lithium, valproate, and carbamazepine, which are mood-stabilizing medications. Antipsychotic medications such as risperidone, quetiapine, and ziprasidone also have mood-stabilizing properties and may be used alone or in combination with mood stabilizers. Antipsychotics are always indicated when psychotic symptoms are present during a mood episode. The exact mechanism of lithium, valproate, carbamazepine, and other mood stabilizers is unknown, but they are thought to target hyperactive signaling pathways in the brain. Antidepressants are typically avoided in bipolar I patients as they are thought to induce mood cycling and may exacerbate mood episodes. Bipolar II disorder and cyclothymic disorder are also treated with mood stabilizers and sometimes antipsychotic medications. Antidepressants may be helpful in select cases. Mood-stabilizing and antipsychotic medications commonly cause unpleasant and sometimes dangerous side effects and require regular blood draws and other forms of monitoring. While depressive disorders are frequently diagnosed and treated in primary care settings, bipolar disorders are most often treated by psychiatrists.

The etiology of mood disorders involves a complex interaction of biological, genetic, social, psychological, and cultural factors. Some disorders, such as bipolar I disorder, have a strong biological and genetic basis. Young, poor women, especially those who have suffered abuse or neglect, appear to be at greatest risk for depression compared with all other population groups, thus implicating social factors. Psychological factors include personality style and coping skills. Cultural factors are extremely important in that culture heavily influences one’s subjective experience of life. A thought, feeling, or behavior becomes a symptom of mood disturbance only when it is interpreted as such based on cultural norms. For example, the conceptualization of depression as an illness is related to the modern, Western notion that individuals should rightly pursue and achieve their own happiness.

Research on the prevalence and experience of mood disorders among immigrants is limited by several factors including undocumented migrants and poor funding for mental health research. According to the World Health Organization, 27% of countries have no system for reporting mental health data. Existing studies reveal conflicting findings. Some support the hypothesis that stressors associated with immigration increase a person's risk for development or exacerbation of a mood disorder, while others show the opposite. In Israel, a society made up largely of immigrants, migration is considered a significant risk factor for mental illness including mood disorders. However, a study of 12,376 respondents living in Ontario, Canada showed a higher prevalence of depression among Canadian-born respondents than foreign-born respondents. Research conducted since the early 1980s has consistently found that immigrants to the USA from Latin America have a lower lifetime prevalence of mood disorders than US-born Hispanics. One study looked at two immigrant groups: one included 706 individuals born in Mexico who immigrated to the USA and the other included 538 individuals born in the USA but of Mexican descent. The group born in the USA had more depressive symptoms, even after adjustments were made for differences between the groups, including socioeconomic status, amount of stress, and social resources. One possible explanation for these results is a selective migration pattern in which foreign-born persons in good health are more likely to immigrate than those in poor health. This pattern also suggests that the process of adjustment to American society leads to an increasing risk for mood disorders. Another US study involving a survey of 3,056 immigrants found that downward social mobility was linked to an increased risk of depression. Thus, it appears that specific stressors associated with immigration, such as the process of cultural transition, may increase a person's risk for development or exacerbation of a mood disorder.

In summary, mood disorders are a group of psychiatric disorders characterized primarily by mood disturbance that result in significant morbidity and mortality worldwide. Mood episodes, whether depressed, manic, or mixed, represent emotional states outside the bounds of normal fluctuations from sadness to elation. Although sustained mood disturbance and associated symptoms are recognized in most cultures, mood disorders, as classified in the DSM-IV-TR and ICD-10, are primarily diagnosed and treated in cultures that subscribe to a Western, medical model of psychiatry. The etiology and course of mood disorders involves a complex interaction of genetic, biological, psychological, and sociocultural factors. There are several effective treatments for mood disorders including medication and psychotherapy; however, the relationship between the affected individual and his or her healthcare provider seems to be one of the most important factors in determining outcome. Immigrants face a unique challenge of having to integrate native cultural beliefs about mental illness with those of their host country while undergoing a broader process of cultural transition.

Mortality and Morbidity

Ravi K. Sharma
Department of Behavioral & Community Health Sciences, Institute for Evaluation Science in Community Health, Graduate School of Public Health, University of Pittsburgh, Pittsburgh, PA, USA

Mortality and morbidity are often used as indicators of health status. Mortality is a unique and final event that is clearly defined and measurable. Morbidity events refer to diseases and illnesses. Both of these indicators can be used to look at the immigrant health.

Assessing immigrant health in terms of mortality and morbidity is a complex issue for a number of reasons. First, there are major deficiencies in national health statistics. Often the immigrant population as recorded in the official statistical systems does not differentiate between naturalized immigrants, permanent residents, nonimmigrants (e.g., temporary workers, students, and visitors), and illegal immigrants. Second, immigrant populations are heterogeneous, not only in terms of national origin but also racial, ethnic, and socioeconomic composition, even from within the same country. Third, migration selectivity renders the interpretation of immigrant health problematic. Finally, due to limitations of data, it is often not possible to compare immigrants' health with that of their counterparts in their country of origin. Most studies assess immigrant health in terms of the country of destination.

Despite variations in patterns and profiles for different immigrant groups in different countries, a few broad generalizations are still possible. Immigrant mortality and morbidity patterns are influenced by both their country of origin and their destination, and by the very process of migration itself. The immigrant mortality/morbidity rates for a particular cause of death or disease may remain similar to their country of origin, worsen in relation to their native country, improve in relation to their native country, or fluctuate in comparison to the host country. The stability of migrant mortality/morbidity rates may be attributable to genetics or factors such as diet, smoking, alcohol, and other health-related behaviors and practices that are brought from the native homeland. These may lead some immigrant groups to experience higher mortality rates from certain diseases such as cardiovascular diseases.

Some immigrant groups, however, may experience a better health outcome than the native-born individuals of their country of destination. This is often explained by reference to the "healthy migrant hypothesis." It states that migrants represent a selectively healthy group that is not representative of all potential migrants from origin societies. As a result, their health advantage stands out when they are compared with the general population at their destination. There is also the possibility that, over time, migrant mortality and morbidity rates might converge to the rates of the host population due to migrants' acculturation, that is, their acquisition of the health behaviors of their adopted country. However, studies on how acculturation affects health are often difficult to interpret because there are few well-validated and consistent measures of acculturation.

In summary, mortality and morbidity are indicators of health status and provide some clues to migrant health status but more studies that assess immigrant health comprehensively are needed. Understanding migration health is paramount in the context of global health but also to understanding and eradicating health disparities.

Multiculturalism

Rosalyn Negrón
Department of Anthropology, University of
Massachusetts-Boston, Boston, MA, USA

There are at least two meanings of multiculturalism. Multiculturalism can be defined as a demographic condition in which diverse cultural groups coexist within local or national boundaries. Multiculturalism also describes a sociopolitical philosophy that promotes respect, understanding, and preservation of cultural differences. Both of these multiculturalisms have important consequences for the equitable provision of healthcare. As a demographic reality, multiculturalism demands public health policy that provides healthcare access to multiple and growing subpopulations. Multiculturalism as a sociopolitical ideal entails that such provision of healthcare be sensitive to different cultural practices and worldviews. As such, multiculturalism attunes health practitioners and policy makers to both the quantity and quality of healthcare for diverse populations.

Especially since the 1960s, when civil rights and independence movements and shifts in immigration policies helped to reconfigure and intensify global immigration flows, a number of countries have seen steady and rapid increases in their foreign-born populations. Today, countries with long immigration histories, like Australia, Canada, and the USA, have between 13% (US) and 24% (Australia) of their populations foreign born. Even historically ethnically homogeneous countries, like Ireland and Denmark, have received significant numbers of immigrants since the 1990s. Thus, immigration has been a major force in changing the racial, ethnic, and cultural composition of a number of increasingly multicultural societies.

Nations differ in their official responses to these demographic shifts. Canada and Australia have federal policies to encourage multiculturalism, sponsoring programs that respect cultural differences, and protect cultural groups' rights to maintain their customs and languages. In the USA, where no established multicultural policy exists at the federal level, the prevailing national narrative has favored assimilation over multiculturalism. However, since the lifting of national origin quotas with the Immigrant and Nationality Act of 1965, mass immigration from non-European countries has led to the emergence of large immigrant communities, especially in major cities. While individual immigrants follow different paths to incorporation in American societies, immigrant communities throughout the USA have been important for the maintenance of immigrants' cultures and languages.

Medical practice has been significantly impacted by these socio-demographic trends. Multiculturalism has exposed the limits of the one culture, one language model at the core of Western medicine. New approaches to healthcare attend to cross-cultural differences in how health and healthcare are perceived, how health services are utilized, and the ways that culture impacts health outcomes. Multiculturalism in healthcare relates to providing culturally competent healthcare to diverse populations and being aware of cultural differences that could impact the ways that healthcare is perceived, accessed, and adhered to. Within a multicultural framework, health practitioners are encouraged to understand and affirm patients' cultural similarities and differences while avoiding overgeneralizations. Multicultural approaches to healthcare also encourage health practitioners to be aware of their own culturally mediated frames of reference, beliefs, and behaviors as they interact with patients from different cultural backgrounds. Hiring choices made in the interest of multiculturalism can help ensure that health workforces reflect the diversity of the communities that they serve.

Hospitals, health clinics, and doctors' offices have applied the multiculturalism concept in a number of ways. Given the potentially life-threatening consequences of miscommunication between patient and provider, among the most common multicultural accommodations has been the provision of translation and interpretation services through bilingual staff, professional interpreters, and/or on-demand telephone translation services. Delivered effectively, language services in healthcare settings go beyond translating words, to the ideas and worldviews that can impact health outcomes. Whether translating between two languages or not, multicultural staff are often called upon to provide knowledge about cultural differences in how illness is perceived, folk models for the causes of disease, and the ways to treat illness, traditional healing systems, and different cultural scripts that guide patient–doctor relationships and interactions. Another increasingly common extension of the multicultural approach to health practice is the use of community health workers (CHW) – for example, *promotoras* – to provide basic health services in diverse communities. These lay health providers come from the communities they serve and are trained to be liaisons between fellow community members and professional healthcare providers. In this capacity, CHWs provide outreach, basic health information, referrals, advocacy, and support. This community-based, multicultural approach to healthcare has been used as a way to ensure that underserved communities have access to basic primary and preventative health services.

While shifts to multicultural models of healthcare have improved access to culturally competent healthcare, multiculturalism has its limits. Multiculturalism's emphasis on differences among culturally distinct ethnic minority groups assumes that such groups are internally homogeneous, bounded sets. This could lead health practitioners and policy makers to gloss over socioeconomic and linguistic variation within one cultural or ethnic group. In addition, with its emphasis on the cultural dimensions of healthcare, multicultural approaches risk ignoring political and structural forces that mediate the impacts of culture on health and healthcare access. Applied to the strategies and services described above, drawbacks of the multicultural concept can do more harm than good. For example, relying for translation on staff who are not fully bilingual or inadequately trained can lead to misinterpretation of patient's complaints or a provider's treatment plan and counsel. Even for fully bilingual staff, problems can arise if they lack knowledge about dialectal differences within one language group – differences in word meanings, pronunciations, or idioms. Simplistic use of cultural concepts thought to be relevant to particular cultural groups is also potentially harmful. As an instance, the concept of fatalism – assumed to be a deterrent to preventive behaviors among Hispanics – may lead health providers to focus blame on patients for their health problems rather than on persistent structural barriers that lead to disempowerment.

The adequate provision of multicultural health services hinges on providers' ability to identify, classify, and count the various groups that they serve. Race and ethnicity measurement errors, and poorly defined ethno-racial categories, lead to misclassification and miscounting, which, besides producing poor estimates of health resources needed, could also result in inadequate estimates of mortality and health outcomes among various ethnic and racial populations. Thus, proper accounting of demographic diversity requires understanding the ethno-racial labels that people use to identify themselves and the ways that people respond to ethno-racial identification questions in health questionnaires and patient intake forms. Along with multicultural healthcare approaches, accurate population counts are fundamental for understanding and eliminating health disparities in multicultural societies.

Music Therapy

Ronna S. Kaplan
The Music Settlement Department of Music Therapy,
American Music Therapy Association, Cleveland,
OH, USA

According to the American Music Therapy Association, "music therapy is the clinical and evidence-based use of music interventions to accomplish individualized goals within a therapeutic relationship by a credentialed professional who has completed an approved music therapy program." Music therapy interventions may be systematically designed to promote wellness; manage stress; and improve communication/language, social/emotional, cognitive, and/or perceptual/motor skills, and more. Research in music therapy supports its effectiveness in a wide variety of healthcare, educational, and social service settings.

As early as the 1970s, pioneers in the music therapy field began to identify the role that music therapy could play for immigrants. Schorsch suggested the use of music to promote cultural integration, particularly as an aspect of a family therapy approach for immigrant and minority group members, as a future orientation in music therapy. Euper also suggested considering the role of music in family life and how musical activities could serve the needs of families who are disorganized or emotionally unbalanced. Parents in immigrant families may have difficulties adapting to their new environment, and children are often caught between values of the two cultures. Rather than treating patients individually, music therapy may be an excellent means to strengthen intrafamilial ties and help all family members become integrated into their new dominant culture. Music therapy might make a family's own ethnic music a respectable source of pride and unity for that family, while at the same time utilizing local music as an avenue to understanding of and participation in the life of a new community.

More recent studies have addressed the use of music therapy to teach English as a Second Language. Immigrant adults who transplant their families to the USA often seek enriching educational and occupational opportunities. However, their success with these opportunities is typically defined by their language abilities or limitations, and, thus, "immediate language acquisition" for their children is critical for academic, social, and economic integration. Comprehension and accurate expression of English is important not only to communicate thoughts, feelings, and needs but to gain new information, particularly vocabulary, in order to facilitate all other learning. Schunk found that pairing sign language with singing yielded the highest gain in receptive vocabulary skills for elementary students learning English as a Second Language, as compared to spoken text paired with sign, sung text, and spoken text only.

Kennedy utilized music therapy as a supplemental teaching strategy for kindergarten ESL students. While both of his groups performed well on story retelling and English speaking skills, the after-school group performed better than the public school group. Story retelling skills consisted of retelling most of the story; understanding the characters' roles; understanding ideas in the story; using conjunctions, verbs, and adjectives correctly; and using compound sentences. English speaking covered sticking to the topic, speaking clearly, taking turns and waiting to talk, talking loudly so others could hear, using courteous language, volunteering to answer, and speaking only to classmates. Music experiences included chanting and call and response, playing rhythm sticks, singing, moving to music, listening, and lyric analysis. Kennedy further suggested that perhaps the community setting might be more relaxed and less intimidating an environment for young children learning English, possibly because the after-school groups were held in the students' own neighborhoods and parents often were present in the room.

Schwantes conducted case studies of kindergarten, 4th grade, and 6th grade Latino students referred for short-term music therapy services by the ESL teacher. The younger students used traditional Spanish language children's music translated into English, with the premise being that music from the children's culture would help them retain their culture and also be more familiar to them as they worked to acquire English. However, the older students' sessions utilized Western "pop-culture" music because (a) it was thought that this music would help serve as a bridge between them and their peers and (b) they were very motivated to fit into American culture. Music experiences included singing, fill-in-the-blank activities, moving to music, and instrument playing, as well as identifying vocabulary words in the context of the song. All students progressed in acquiring receptive and expressive English abilities, increasing their vocabulary, answering "wh" questions with longer phrases, sequencing song events with greater accuracy, and increasing receptive language skills.

Not only are some music therapy programs, such as the ones mentioned above, specifically designed for immigrants, but any person, regardless of immigrant status or not, may derive benefit from music therapy services. Those with medical issues or special needs may be appropriate candidates, as are individuals who might wish to participate in wellness programs. Music therapy researchers have addressed current issues regarding multicultural training for and practices of music therapists, a topic very pertinent to immigrants being served in the field. Toppozada asserts that as cultural diversity continues to grow in our country, it is vital that music therapists be trained to be aware of and respond to needs and values of clients from a variety of cultures. Seventy-eight percent of professional music therapists responding to her survey supported multicultural training for music therapy students. Chase found the need for research of specific clinical issues in multicultural music therapy and offered the following clinical considerations for work with culturally diverse clients: (1) Know yourself. (2) Engage in new cultural experiences. (3) Treat each person as an individual. (4) Be musically flexible. (5) Ask for help if you need it. Music therapists working with immigrants, above all else, need to be respectful of that person's culture and familiar with appropriate music and customs.

Muslim

Lucia Volk
Department of Anthropology and Middle East
and Islamic Studies, San Francisco State University,
San Francisco, CA, USA

Background

A Muslim is a follower of Islam, one of the three monotheistic religions to emerge out of geographic South West Asia. Muslims see themselves as a community of believers that descended from Abraham, whom they consider a prophet, and they profess actual and metaphoric kinship with members of the Jewish and Christian faith. A practicing Muslim follows the teachings of the Qur'an, which include references to people and events in the Old and New Testaments, and tries to emulate things Prophet Mohammad said and did during his lifetime, which were recorded in a set of writings called Hadith. Based on the Qur'an and Hadith, Muslim jurists throughout history established a body of law, called the Shari'a, to which believers turn to settle everyday questions and disputes. A pious Muslim will profess that there is only one God, pray several times daily, fast during the month of Ramadan, give alms to the poor, and, if health and income permit it, embark on a pilgrimage to Mecca at least once during her or his lifetime.

Muslim Migration

In the world today, there are an estimated 1.3–1.5 billion Muslims. Most of them live in the region that spans South Asia (Pakistan, India, Bangladesh), Southeast Asia (most importantly, Indonesia, Malaysia, and Thailand), South West Asia (also referred to as the Middle East), and North Africa. As such, most Muslims originate in the "global south," and as many of their non-Muslim, global southern fellow-citizens have migrated to Western Europe and the United States, where they constitute immigrant communities of an estimated 15 million and 7 million, respectively.

The reasons for migration are multiple, including the search for economic and educational opportunities, and the flight from war and political oppression. Moreover, the history of colonialism in much of the Muslim world established commercial and cultural ties between European centers of power and their colonial peripheries, which have enabled and sustained migratory flows. The first Muslim migrants to the United States arrived on slave ships from West Africa. While Muslim migrants constitute the clear majority of practitioners of the faith in the United States, there is a growing number of US converts. Some scholars believe that Islam is the fastest growing religion in the United States.

Muslims in the West

In both the United States and Europe, Muslim immigrants have been viewed with fear and suspicion, even before the al-Qaida attacks of 9/11 raised the specter of global terror. The negative attitudes among citizens of the global north stem in large part from their perception of religious and cultural practices among the immigrants. For instance, pious Muslims promote modest dress codes for men and especially women, a family structure that emphasizes the complementarity rather than the equality of spouses, and may practice polygamy. These norms do not mesh easily with Western notions of freedom, equality, and justice. So-called "headscarf affairs" have been reported in most European countries, with subtle to outright acts of discrimination against veiled Muslim women. In one instance in a courtroom in Dresden, Germany, in 2009, a veiled Egyptian woman was brutally murdered by the man she had taken to court for insulting her and pulling off her headscarf in public.

Despite these prevailing and dangerous prejudices and cultural misperceptions, Muslim immigrants to the United States and Europe have, on the whole, been able to build economically successful lives, and the majority is resolved to stay. President Barak Obama, in his historic 2009 address from a pulpit at the venerable al-Azhar University in Cairo, Egypt, celebrated the fact that the majority of Muslim Americans enjoy incomes and education significantly above the American average. Yet, with the events of 9/11 and the subsequent wars in Iraq and Afghanistan, as well as more recent tensions with Iran, many Muslim migrant communities have withdrawn onto themselves and live, now more than ever, in tight-knit communities isolated from the mainstream. This political climate of fear and suspicion has implications for Muslim immigrant health.

Muslim Immigrant Health: Reproductive and Mental Health and Culturally Sensitive Care

Because Muslim immigrants to the United States as well as to Europe come from a very diverse set of national, ethnic, and class origins, it is very difficult to classify or aggregate them in any meaningful way. A common misperception is that most Muslims are Arabs when in fact most of them come from South and South East Asia. Religious practices may unite or, quite often, separate the Muslim community, depending on the variety of branches of Islam. Additionally, not every member of the Muslim community is a consistent practitioner of the faith; as with every other belief system, members fall on the spectrum from pious to secular, with many in-between who consider themselves culturally Muslim and celebrate important holidays. In the United States, there are no census questions that track religious affiliation, and therefore Muslims are not quantifiable in the way that ethnic minority groups are. The most immediate implication of the lack of census data is the lack of epidemiological data, which can be derived for other groups. For instance, there is no "Muslim paradox" similar to the "Latina paradox" (favorable birth outcomes despite low socioeconomic status), although there is a solid body of work about reproductive health and fertility among Muslim families.

Yet still, it is possible to discuss Muslims as a community with shared health concerns based on the fact that many of them share a cultural repertoire that includes the importance and closeness of the family; different levels of respect afforded to members of a family according to their gender and age; and concern with a family's reputation within the wider community, which may circumscribe actions of individuals. And while the existing literature in the area of Muslim immigrant health is not as extensive as that of US-born minority groups, there is nevertheless a growing body of work that acknowledges the stresses and effects of discrimination on Muslims in the West that are not unlike those experienced by members of other minority groups. Those stresses may manifest themselves in Muslim individuals in the area of mental health. Discrimination may not only manifest itself in symptoms of Muslim patients, however, but it may lead to Muslim patients receiving lower quality or culturally insensitive care from health care providers.

Reproductive Health

Because families are central to most Muslim individuals, and children are important to the status of both women and men in most Muslim societies, reproductive health is of central concern also among Muslim immigrants. Couples that cannot conceive often go to great length to obtain medical assistance, with or without the blessing of their religious clergy. Couples that can conceive and that would like to have large families often run into host-country norms that prescribe small, nuclear families, and that consider deviations from that norm as backward and primitive. Reproductive choices, across societies, are often read as a yardstick for women's advancement. If a woman has many children, she may be considered less developed; if the same woman also wears a veil, she is very likely to be looked at as oppressed. Muslim immigrant women may receive special reproductive counseling from their doctors, whether or not they ask for it.

Mental Health

Muslims who live in the West face stereotypes and misperceptions that can lead to violence, as we saw, for instance, after the attacks of September 11, 2001, as well as during the current "war on terror." A climate of fear prevails, and Muslims are constantly under suspicion. The pressure to prove themselves to be different from the stereotype of a religious fanatic has led many to abandon religious dress and practice or distance themselves from members of their own community. As a result, community support networks that used to be available no longer operate. Isolation can lead to depression and other mental health conditions. Additionally, existing mental health conditions may get exacerbated, and individuals may be increasingly reluctant to seek help. Mental health problems, moreover, may carry stigma for the patient – a situation that can be found in other immigrant communities as well. Mental health patients may be considered "crazy" or "possessed" by community or family members, which may prevent them from seeking help.

Of course, mental health issues are prevalent among those Muslim immigrants who arrive in the West from a war zone. As war refugees or asylum seekers, they may receive treatment upon their arrival, but rarely do they obtain long-term care. Again, as stated above, existing stigma within the community may prevent patients from seeking such care. Nevertheless, the awareness of the rising number of mental health patients in the Muslim community led, in 2004, to the creation of a nonprofit organization, as well as the journal *Muslim Mental Health* Inc., with the explicit goal of promoting knowledge and awareness on this particular health issue.

Access to Culturally Sensitive Care

The lack of understanding of Muslim belief and practice among the non-Muslim mainstream in the West has repercussions in the health care field. Many providers appear to be ignorant about or insensitive to the cultural and religious values of their Muslim patients. Rarely are families integrated into the treatment process – one that focuses on the individual body instead. Rarely do medical practitioners ask their patients about their medical practices that they learned at home, and that might support or enhance the course of Western treatment. Most Muslim immigrants consider Western medical practice superior to the medical care that they might have received in their countries of origin – especially if those countries are poor – yet this alone is not a guarantee that they will comply with treatment instructions. Of course, there are also Muslim immigrants who have limited or no access to health care, and there are also pious Muslims who turn to their faith rather than to a doctor for help with an illness. Yet the majority does have at least some access to medical care providers, and it is crucial that we pay attention to what happens in the treatment room between doctors, nurses, and patients.

Myanmar

Amy N. Sharpton
Department of Veterans Affairs, Louis Stokes DVA Medical Center Cleveland, Brecksville, OH, USA

History

Myanmar, known historically as Burma, has an ethnic heritage that includes a mixture of Indo-Aryans, who began arriving in the area around BC 700, and the Mongolian invaders, who penetrated the region in the thirteenth century. Anawrahta, who lived from AD 1044 to 1077, was the first great unifier of Myanmar.

In 1612, the British East India Company sent agents to Burma to establish posts along the Bay of Bengal. Although the Burmese resisted efforts of British, Dutch, and Portuguese traders, through the Anglo-Burmese War in 1824–1826 and two subsequent wars, the British East India Company expanded throughout Burma. In 1886, Burma was annexed to India, becoming a separate colony in 1937.

Burma was a key battleground during World War II; the 800-mile Burma Road was the Allies' vital supply line to China. The Japanese invaded and had occupied most of Burma by May 1942, effectively cutting off the Burma Road. After one of the most difficult campaigns of the war, Allied forces liberated most of Burma prior to the Japanese surrender in August 1945.

Although Burma became independent on January 4, 1948, in 1962 General Ne Win staged a coup, banned political opposition, suspended the constitution, and introduced the "Burmese way of socialism." Twenty-five years of economic hardship and oppression followed, culminating in massive demonstrations in 1987 and 1988. In March 1988, in response to the increasing ethnic conflict and deteriorating economic situation, student disturbances broke out in the capital city of Rangoon as they called for a regime change. Despite repeated violent crackdowns by the military and police, the general public joined the students and the demonstration began to swell in number. During mass demonstrations on August 8, 1988, military forces killed more than 1,000 demonstrators. Following the massacre a rally was held during which Aung San Suu Kyi, the daughter of General Aung San, made her first political speech and assumed the role of leader of the opposition.

On September 18, 1988, the military overthrew Ne Win, abolished the constitution, and established a new regime called the State Law and Order Restoration Council (SLORC). Shortly thereafter the SLORC sent the army into the streets to suppress the ongoing demonstrations. It is estimated that an additional 3,000 were killed, and that more than 10,000 students fled into the hills and border areas. The SLORC changed the country's name from Burma to Myanmar after the name of the ruling party. Notably, governments of many countries including Australia, Canada, France, the United Kingdom, and the United States still refer to the country as "Burma," with varying levels of recognition of the validity of the name change itself.

The SLORC ruled by martial law until national parliamentary elections were held on May 27, 1990. Although under house arrest, Aung San Suu Kyi's National League for Democracy (NLD) party won 392 of the 485 seats. However, the SLORC refused to call the Parliament into session and imprisoned many political activists. In 1992 General Than Shwe became leader, claiming the position of prime minister. Subsequently, many political prisoners were released, most martial law decrees were lifted, and plans were announced to draft a new constitution. Despite this, the army gave no sign that it would be returning governance to civilian control. Quickly, this drew the condemnation of the United Nations Security Council. Furthermore, the regime signed ceasefires with the insurgent ethnic groups except for the Karen, with the government launching a major attack against them in 1997.

In 1997, the ruling junta changed its name to the State Peace and Development Council (SPDC); however, the name change did not reflect a shift in policy. In 2000, the SPDC announced it would begin talks with the political opposition led by Aung San Suu Kyi, who numerous times had been under house arrest and released, only to be detained again. Following the talks, a sizable number of political prisoners were released, and there was some increase in political freedoms for Aung San Suu Kyi and the NLD. On May 6, 2002, she was allowed to leave her home and subsequently traveled widely throughout the country. On May 30, 2003, Aung San Suu Kyi and her convoy were attacked by a government-affiliated group. Many members of her convoy were killed or injured, while others remain unaccounted for. Aung San Suu Kyi was detained and put again under house arrest. She remained there until November 2010, when she was released once more.

Geography

Myanmar occupies the Thailand/Cambodia portion of the Indochinese peninsula – a peninsula in Southeast Asia that is roughly east of India and southwest of China. Myanmar is 678,500 km^2 in total area and covers a total land area of 657,741 km^2. India is situated to the northwest of Myanmar, while China is to the northeast. Bangladesh, Laos, and Thailand are also neighbors. The Bay of Bengal borders the southwest coast. In the south is the fertile delta of the Irrawaddy River, which contains a network of interconnecting canals and nine principal river mouths.

Health

Myanmar has an estimated population of 53,414,374 as of 2010; a growth rate of 1%; a birth rate of 19.5/1,000; an infant mortality rate of 50.7/1,000; and a life expectancy of 64.5 years. Rangoon (Yangon) is the capital, with a population of 4,344,100. The World Health Organization reports that approximately two-thirds of the population have easy access to improved water source – with urban and rural coverage being 92.1% and 74.4%, respectively, according to the 2003 MICS Survey. This reflects an increase from 32% in 1990 to 71.5% in 2000.

The World Health Organization's National Health Plan has four projects related to health and environment in Myanmar: prevention and control of environmental health hazards, occupational health and safety, prevention and control of agricultural hazards, and air and water pollution control. Environmental health awareness is increasing and steps to confront hazards are under active consideration; these hazards include impacts of urbanization, air pollution, solid and hazardous waste, traffic congestion, noise pollution, and substandard housing.

Emigration

Over the years, Burma – now Myanmar – has seen several sizable waves of migration. Indians were the largest Asian minority in Myanmar until the start of World War II, during which hundreds of thousands fled the Japanese invasion. Although many returned at war's end, the Indian minority never reached its prewar numbers. After gaining independence in 1948, the Myanmar government established firm restrictions on Indian migration. Between April 1963 and June 1965, the Indian population was reduced by 100,000. During this time, Indian immigrants were repatriated as part of an effort to increase the wealth and holdings of Myanmar nationals – the impetus of the program being the Indians' prominent position in Myanmar commerce.

Although the government sought to curtail both immigration and emigration, it is estimated that as many as 500,000 persons may have exited Myanmar between 1962 and 1971. About 187,000 Muslims fled to Bangladesh in 1978, leaving Myanmar because of alleged atrocities by its soldiers in Arakan State. With the help of UN agencies, they were repatriated by the end of 1981. They lost their citizenship in 1982. In addition to migration resulting from immigration and emigration, forced resettlement continues to be a concern for poor urban residents. Between 1989 and 1992, approximately 500,000 rural residents were subjected to forced resettlement in connection with counterinsurgency operations.

In 1992, 250,000 Muslim refugees claiming human right abuses in Myanmar's Northern Rakhine state began arriving in Bangladesh. Between 1994 and 1997, some 230,000 of these refugees returned home; however, as of October 1996, around 50,000 were still living in one of five refugee camps in the southern part of Bangladesh. Repatriation resumed in November 1998 following meetings between the United Nations High Commissioner for Refugees (UNHCR) and Myanmar authorities. However, due to procedural problems, returns were limited and slow.

Fleeing fighting and political conflicts in Myanmar, asylum seekers increased dramatically during the 1990s; Thailand was and continues to be a popular host country. Recent clashes between an ethnic rebel group in Myanmar and government soldiers pushed a wave of at least 10,000 refugees across a river into Thailand. This occurred in November of 2010, one day after Myanmar held its first election in 20 years. In the attack, ethnic Karen rebels seized a police station and post office in the border town of Myawaddy. The fighting is one skirmish in a decades-long civil war with a number of ethnic groups that have raged in remote mountains and jungles of Myanmar.

In the first election in more than two decades, military-backed candidates took the majority of the Parliament seats. Not surprisingly, as the junta set the rules for the election and the parties and Myanmar's current military leaders were expected to retain power, condemnation from Western nations ensued. While the United States was quick to condemn alleged violations of human rights and call upon the international community to take a similar stance, India and China undercut the sanctions in force by the United States and the European Union. Both neighbors of Myanmar, India and China, are competing for influence and access to raw materials; they have continued trade and diplomatic support for Myanmar's ruling generals. Notably, due to continuing unrest in parts of the minority ethnic areas, 1.5 million persons were excluded from the election.

In one of the world's longest running separatist insurgencies, minority groups in untamed regions of Myanmar have been fighting against government control since the country gained independence in 1948. The most recent wave of refugees has sought safety in camps along the border between Myanmar and Thailand. Thai officials said they would be sent back when the situation returned to normal.

N

Nanny

Sarah Nagle-Yang
Department of Psychiatry, University Hospitals Case Medical Center, Cleveland, OH, USA

The International Nanny Association defines a nanny as one who is "employed by [a] family on either a live-in or live-out, part-time or full-time basis, to undertake all tasks related to the care of children." The history of the nanny can be traced back to the eighteenth- and nineteenth-century England, when virtually all upper-class parents hired nannies to take charge of childrearing. Nannies often had control of their own floor or wing of the house where they shared quarters with children and may have had the assistance of a nursemaid. While nannies and children spent most of their time together, the class difference between the two was always clear. Parents often hired more culturally similar caregivers as their children matured in order to reinforce their upper-class values. The late-twentieth century saw a drastic increase in the employment of nannies. In the United States, this was primarily accounted for by two concurrent social trends: (1) the dramatic increase in the number of dual-career families and (2) a shift in parenting practices to a "child-centered" approach. From 1975 to 2008, the labor force participation rate of mothers of children under age 6 rose by 25%. Furthermore, women increasingly worked in jobs that are well compensated and may require long hours with the expectation that childrearing will not affect their performance. In 2008, over half of all managers and roughly a third of lawyers and physicians were women. This has given rise to what some sociologists refer to as two-career households: a family where both parents hold down professional jobs in which the time demands are excessive or unpredictable.

Alongside this growth of the "professional class" has been a shift in parenting philosophies toward a "child-centered model": one which places the intellectual and developmental needs of a child at the center of a mother's life. This type of "intensive mothering" emphasizes continuous stimulation of a child's development in the form of reading, music, language, and other expert-guided activities. Continuous nurturing by a single energetic caregiver is the ideal. Women operating under this model may seek a nanny to act as a "mother surrogate," to take their place during the working day. Families who hire nannies cite the benefits of increased flexibility of schedule and a sense of control over their children's environment.

In order to meet the needs of the middle- and upper-class, the modern nanny has become part of the fabric of life in developed countries. As a whole, however, their profession is one without much formal statistical data or regulatory activity, prompting one Washington Post journalist to term this a "shadow industry" in the United States. The industry includes many immigrant workers, both legal and undocumented, and employers who may or may not pay taxes. It is estimated that there are 200,000 domestic workers in New York City alone. A survey conducted by Domestic Workers United in 2003 and 2004 found that 99% of domestic workers in New York were foreign-born. This survey did not report the immigration status of these workers. Another study of only 76 nannies in either Los Angeles or New York included women from 29 different countries. In 2006, a survey conducted for a county council outside of Washington DC found that only 28% of 280 nannies surveyed reported that money was deducted by their employers for Social Security taxes.

The unregulated nature of nanny work has raised a number of labor and human rights concerns. Human Rights Watch declares a larger group of domestic workers to be "among the most exploited and abused workers" worldwide. Grievances are many and include:

Sana Loue & Martha Sajatovic (eds.), *Encyclopedia of Immigrant Health*, DOI 10.1007/978-1-4419-5659-0,

exclusion from labor laws in multiple countries, wage exploitation, excessive work hours, unfair termination of contracts, and lack of basic employment benefits such as paid time off, health care, and maternity leave. There are reports of psychological, physical, and sexual abuse. In the United States, domestic workers are excluded from both the National Labor Relations Act and the Occupational Safety and Health Act Civil Rights Laws, which give employees the right to organize and bars employment discrimination on the basis of race, color, religion, sex, or national origin. As "casual employees," many domestic workers are also excluded from the Fair Labor Standards Act, which sets a federal minimum wage, maximum hours, and overtime for employees. The survey conducted in New York by Domestic Worker's United reported that 26% of domestic workers made wages below the poverty line, 67% did not receive overtime pay for overtime hours worked, and 90% of domestic workers did not receive health insurance from their employers. In this same survey, nearly 60% of the domestic workers identified themselves as the primary income earner for their family.

Recognizing the risks of exploitation that nannies and other domestic workers face, many governments have enacted laws to protect the rights of this population. Both Brazil and Mexico have incorporated rights for domestic workers into their constitution. Hong Kong affords domestic workers the ability to organize and join trade unions. Two-thirds of the 66 countries studied by the International Labor Organization have established a minimum wage for domestic workers. In the United States, the National Alliance of Domestic Workers is leading campaigns in both New York and California to enact a Domestic Workers Bill of Rights. Both of these legislative acts address common injustices such as inadequate notice of termination, lack of overtime pay, and paid sick leave. Success in California and New York, which could affect hundreds of thousands of domestic workers, would be a strong precedent for nationwide change.

Narghile

Shannon Moore
The Institute for Palliative Medicine at San Diego Hospice, San Diego, CA, USA

The narghile (also known as a shisha, hookah, hubble-bubble) is a type of water pipe. The device has been used for centuries, most commonly in the Middle East, but also in many other countries, including India, Africa, and China. Moistened and often sweetened tobacco is heated, and smoke is drawn into the lungs through water via a single or multistemmed tubing and mouthpiece. It is thought that globally, over 100 million people smoke tobacco in this way, often in cafés or shops where the social context is comforting and relaxed.

International Spread of the Narghile

Narghile smoking is gaining in popularity. With immigration and cultural adaptation, the use of the narghile has spread through Europe and has been increasing in the USA. Special "cafés" are sprouting up in the Middle East, across Asia, as well as in European and American cities – in college towns and urban settings. The café ("hookah bar") provides the narghile, and the inexpensive sweetened or flavored tobacco is readily available. The cafés are comfortable and provide an inviting, socially acceptable environment which is very attractive. Whereas for women in the Middle East, cigarette smoking is associated with cultural stigma, more and more women (and families) are smoking in the cafés. In the USA, adolescents and college students have been exposed to this form of tobacco use; it has become "trendy." Students say the reason they smoke is that it is "pleasurable," that it "adds to intimacy in a social gathering," that it helps "deal with pressure," and to be "accepted by peers."

Concerns About Narghile Smoking

There is a prevailing misconception that smoking using a narghile is less toxic than smoking cigarettes. Many smokers believe that the water filters out the carcinogens, tar and nicotine, but studies seem to prove otherwise. Tobacco for the various types of water pipes, sold in cardboard or plastic jars decorated with fruit illustrations and mixed with fruit, honey, or fruit oils, attracts the young and health-conscious. The smell, taste, and fragrance reinforce the belief that there is something "healthy" about smoking this tobacco. However in various studies, it has been shown that the percent nicotine content in the water-pipe tobacco is actually higher than tobacco used in cigarettes, increasing exposure to the cancer-causing chemicals, heavy metals, and hazardous gases. Because the smoke is cooled as it passes through a water-filled chamber, smokers take longer deeper puffs and, in the social setting around a narghile, smoke for a longer period. It is estimated that a single water-pipe session may lead to smoking the equivalent of 20–100 cigarettes. Typically, the water-pipe sessions are episodic, but this does not necessarily diminish the risk of developing nicotine dependence; addiction to nicotine may happen rapidly. Some experts believe that smoking tobacco in this way sets up the adolescent or naïve smoker to experiment or become addicted to cigarettes over time. While the data are limited, it appears that like cigarette exposure, the use of these pipes is linked to lung cancer and other respiratory and heart diseases. In addition, when the mouthpiece is shared from smoker to smoker, there may be an increase in orally transmitted infectious diseases.

Narrative Research

Maura Busch Nsonwu
Department of Social Work, School of Human Environmental Sciences, University of North Carolina, Greensboro, NC, USA

Narrative research is an inquiry method that collects and analyzes people's stories; it initially received great attention in the 1980s, in the scholarship of various helping professions including medicine, law, education, and social work. This qualitative research methodology reflects the core values intrinsic to feminist and cultural studies research by permitting the storyteller to guide the inquiry and as such, is a particularly appropriate research methodology for use with immigrant and refugee populations. The research participant or storyteller describes and interprets her/his life to the listener which creates a dynamic where she/he is not simply the object of inquiry, but is uniquely and intimately a part of the research process. In the telling of their story, participants describe and emphasize what is important in their own language and voice, and consequently their story reflects their unique social, political, historical, and cultural perspectives. This research methodology provides participants, who may not normally be part of the dominant discourse in our society, an opportunity to construct, direct, and interpret the meaning of their personal stories.

Narrative research analysis processes are distinctive. First, through a shared analysis, the participant and the researcher co-create a narrative where special attention to the cultural and political idioms used by the participant is important. The analysis consists of considering five specific factors: selectivity, silence, slippage, intertextuality, and the collective subjective. Selectivity recognizes what participants chose to include in parts of their stories (e.g., where to begin and end the narrative), silences are parts of the narrative where the participants chose to omit details; slippage are any inconsistencies or contradictions in the narrative.

Narrative analysis also employs the use of intertextuality – the comparison and analysis within and between different participants' narratives. Individual and group narratives will also be compared to the scholarly literature. The researcher utilizes direct quotations to ground the themes of the data. Throughout this process the researcher becomes both a conduit for the story and a learner about that story.

Researchers and philosophers use different terms to describe what Gramsci defined in 1980 as the collective subjective, the concept of recognizing and valuing the commonalties in participant stories that reflect the shared beliefs, problems, and language of a social group. For example, Bakhtin describes the collective subjective as "social dialect," West identifies it as "discourse," and Fish calls it an "interpretive community." Understanding the collective experiences provides a forum for the voices of the marginalized to be understood in a cultural context and to be valued and honored.

An understanding of self or "subjectivity" in relation to their participants and/or the general area of inquiry is also critical in narrative research. Self-reflection allows the researcher to explore her/his own life experiences and to examine how her/his beliefs and values may positively or negatively influence her/his research.

Narrative research methodology can be arduous and time consuming, requiring extensive time in building partnerships, interviewing, and the process of paying particular attention to fine details in analysis. Consequently, the number of participants is frequently limited.

Narrative research utilizes culturally relevant traditions of oral history when working cross-culturally with immigrants and refugees. Because narrative research does not require the storyteller to possess any specific educational background, it is particularity suitable for immigrants and refugees who may be illiterate or who may have limited language proficiency. From a mental health perspective, the narrative research process can be therapeutic and cathartic for the participant or storyteller. The process may allow the participant to reflect on her/his past struggles and problem-solving skills, acknowledging her/his inherent strength and resiliency.

National Origins Act of 1924 (U.S.)

Karen Manges Douglas
Department of Sociology, Sam Houston State University, Huntsville, TX, USA

The 1924 Immigration Act (National Origins Act or the Johnson-Reed Act) was the crowning achievement of nativists seeking to restrict immigration in the United States at the turn of the twentieth century. Nativists used a variety of scare tactics including health and disability, race, and assimilability to argue for limiting immigration.

Fueled by the eugenics movement and the belief that selective breeding could improve the population, and alarmed over the increasing number of immigrants originating from southern and eastern Europe (considered of racially inferior stock), intellectuals and the power elite began calling for immigration restrictions. For example, T.V. Powderly, the Commissioner-General of Immigration, warned in 1902 that immigration was a menace to the national health and defended the 1891 immigration law which barred certain groups including those suffering from loathsome or dangerous contagious diseases from entering the country. Further he linked certain communicable diseases such as favus and trachoma to immigrants from southern Europe and Asia.

Allan McLaughlin, a doctor for the US Public Health and Marine Hospital Service on Ellis Island, echoed this sentiment in a *Popular Science Monthly* in which he suggested that empirical data supported the view of immigrants as a menace to public health. McLaughlin asserted that the physique of immigrants from southern and eastern Europe represented a marked deterioration compared to that of the sturdy races of northern and western Europe. The result of this deterioration, he argued, was a corresponding increase in loathsome and dangerous diseases in the country. The solution was to mandate a standard physique for all immigrants and exclusion for those not making the grade.

In 1907 the US Congress formed the Dillingham Commission to study the immigration issue. Echoing popular sentiment, the Commission concluded that immigration from southern and eastern Europe posed a threat to the culture of the United States and recommended restricting their numbers. The Commission opined that the relative lack of restrictions from 1819 through 1882 had allowed "the diseased, defective, delinquent, and dependent" to easily enter the country. While the Commission acknowledged that the present immigration policy seemed to adequately identify unhealthy immigrants, it suggested that such screenings be done by American medical officials in the ports of origination.

Newspapers mimicked the theme of diseased and defective immigrants. A 1913 *New York Times* article entitled "Alien Defectives" cited a report by Ellis Island surgeon C.P. Knight who claimed that almost every ship to port in New York contained mentally defective immigrants. To minimize the impact of mental defectives, Dr. Knight supported a three-pronged solution: control procreation, regulate marriage, and limit immigration into the United States. The newspaper began warning of diseases emanating from immigrant processing facilities such as Ellis Island that could spread to the rest of the country.

Anti-immigrant sentiment extended beyond the intellectual and political elite into the mainstream as well. Anti-Asian sentiment further propelled the demands for immigration restriction. Even *Good Housekeeping* published articles on the issue including one in 1921 by then vice-president (later president) Calvin Coolidge entitled "Whose Country Is This?" Prominent novelists like Jack London and F. Scott Fitzgerald included elements of anti-immigrant sentiments in their writings.

Responding to mounting national pressure to act, Congress passed the Emergency Quota act in 1921 meant to temporarily impose immigration restrictions. This emergency bill limited the number of immigrants to 3% of the foreign-born population of a given nationality resident in the United States based on the 1910 census. While significantly curtailing immigration from these regions, the political and intellectual elite was unsatisfied. The author of the act, Albert Johnson, and his colleagues set to establish a more effective way to selectively screen immigrants.

The idea of initial immigrant screening from abroad found support on multiple fronts. Proposals by Johnson to having American consuls abroad prescreen immigrant applications became part of the 1924 National Origins Act. This act established quotas of 2% of the foreign-born individuals of each nationality resident in the United States as determined by the census of 1890. Further, persons deemed ineligible for citizenship (e.g., Asians) were excluded from the quota system.

The shift of immigrant screening abroad resulted in the eventual closing of the medical line inspections at Ellis Island in 1924. A year later a *New York Times* article cited suggestions that if the program of screening immigrants abroad was successful, Ellis Island might be abandoned. Its article in 1934 titled "Busy Ellis Island Now a Thing of the Past" cast support for the earlier prediction.

With the issue involving health screenings taking place abroad settled, attention turned to border control. Nativists were upset that the 1924 act excluded Mexicans from immigration quotas and anti-Mexican rhetoric mounted after the passage of the Act. For example, agencies in California charged that Mexicans were unhealthy, filthy, and prone towards criminality and mental defects. Such demands for greater border control resulted in the establishment of medical line inspections along the US-Mexico border. Mexican border crossers in general had to derobe, have their hair shorn, and clothing and baggage fumigated. Mexicans who commuted to work in the United States were required to report to immigration service weekly for bathing.

In sum, concerns over health were integral to the mounting hostility towards immigrants and calls for restrictions that ultimately culminated in the passage of the 1924 National Origins Act. Nativists unhappy with Mexico's exemption from the quota system began anew the claims of ill-health and mental degeneracy previously aimed at southern and eastern Europeans. Thus, while the law ended the medical line inspections at Ellis Island – the source of overcrowding which generated much negative press – it shifted attention to US borders, and particularly the US-Mexico border.

Nationality

► Identity

Nativism

Lorena Castro
Sociology Department, Stanford University, Stanford, CA, USA

Nativism is opposition to a minority group because of their perceived "foreignness." The underpinnings of nativism are racial, cultural, religious, economic, and political. In general, nativism runs high during times of economic uncertainty. In such circumstances, individuals often scapegoat immigrants, citing concerns about threats to American culture and the fiscal costs of low-skilled immigrants.

The nativist sentiment often draws on myriad, interconnected rationales. Old nativist concerns primarily dealt with immigrant competition in the labor market; however, recent nativist concerns deal with the threat immigrants pose to the established American culture, which is perceived to be Anglo-Protestant. In the USA, most publicly available data regarding nativism is specific to the Latino community. Some scholars see Latin American immigrants, especially those from Mexico, as distinct from immigrants who came during of the turn of the twentieth century. The argument is that Latin American immigrants pose an economic threat because they are slow to assimilate socioeconomically. Latin American immigrants are also seen as a cultural and political threat to an American nation with a "single national language and a core Anglo-Protestant culture." The narrative at the center of nativist concerns has been called the "Latino Threat Narrative." The Latino Threat Narrative suggests that Latinos will not become part of the American nation like previous immigrants did, because they are either unwilling or incapable of integrating socially and culturally. In this way, Latinos are perceived to be an invading force from the south of the border and a threat to the American nation. A recent poll found that 78% of Americans believe that the USA could be doing more along its border to keep unauthorized immigrants out. The fact that nativist rhetoric focuses on the Latino community is problematic because people often cannot differentiate between authorized and unauthorized immigrants, which oftentimes perpetuates discrimination against the entire community.

There are three different anti-foreign sentiments that are at the core of the racialized nativism of the contemporary period in the USA. First, there is extreme antipathy toward non-English languages and a fear that linguistic difference will undermine the American national unity. Second, nativism expresses a concern that multiculturalism and affirmative action are retarding meritocracy and disproportionately distributing resources to non-Whites. Third, contemporary nativism focuses on the perceived drain of public resources by immigrants, both authorized and unauthorized, particularly as it relates to utilization of welfare, education, and healthcare services.

Debates over health care are a flashpoint of nativism in the USA. Because health care is seen as a scarce and expensive resource, many Americans are loath to share this resource with immigrants and unauthorized immigrants in particular. A recent poll found that 80% of Americans oppose providing health care to unauthorized immigrants. Americans view health care as a resource that belongs to legal members of the national political community, and not individuals who are here as unauthorized immigrants. A similar rhetoric was seen during the passage of Proposition 187 (Save our State initiative) in California. The goal of Proposition 187 was to prohibit unauthorized immigrants from using social services – one of the social services being health care. Consequently, the healthcare reform debate is an avenue for defining inclusion and exclusion. It is important to note that nativism is not a phenomenon confined to the USA. Many countries experience a rise in nativism as a result of new immigration.

Naturalization

Adrián Félix
Center for Latin American Studies, University of Florida, Gainesville, FL, USA

Unlike birthright citizenship, naturalization is the legal process whereby immigrants become citizens of the receiving state, gaining membership into the polity and access to its political rights. In some contexts, healthcare access has been construed as an exclusive right of citizens, rather than a universal human right. In the USA a number of local, state, and federal policies have had the effect of conjoining healthcare access with US citizenship. At the state level, Proposition 187, the 1994 California ballot initiative, sought to eliminate social services, including nonemergency medical care, for undocumented migrants. This ballot initiative also required public employees – including schoolteachers and healthcare providers – to report undocumented migrants, or individuals “suspected” of being undocumented, to the US Immigration and Naturalization Service. While the targeted population of this measure was undocumented migrants, criteria for suspicion of “illegality” were arbitrary, and therefore Latinos perceived that characteristics such as language, ethnicity, and skin color were likely suspects, irrespective of nativity or formal citizenship. At the national level, the Illegal Immigration Reform and Immigrant Responsibility Act of 1996 barred undocumented migrants from social security benefits. Such restrictions were extended to the legal permanent resident population with the Personal Responsibility and Work Opportunity Reconciliation Act of 1996, which enacted restrictions on the eligibility of legal migrants for many benefits available under Federal law, and also authorized States to restrict benefits programs. Under these reforms, legal migrants were banned from receiving Medicaid during their first 5 years of residence in the USA. These provisions also allowed state elected officials to renew their attempts at excluding undocumented migrants from access to healthcare, for example California Governor Pete Wilson’s efforts to deny undocumented migrant women access to prenatal care. By seeking to restrict healthcare to birthright and naturalized US citizens these laws not only had implications for migrant health, they also mobilized a sizeable segment of the immigrant Latino population against what they considered an assault on their political and human rights.

Among its political effects, these reforms mobilized eligible migrants to seek naturalization out of fear of losing basic rights and services, among them access to healthcare. In the mid-1990s, naturalization figures soared from over 270,000 to over a million, with Mexican migrants alone accounting for 20.8% of those new citizens. Studies in Latino politics show that this increase in naturalizations was a direct effect of the hostile, anti-immigrant political climate fostered in places like California. The immigrant-targeting legislation of the 1990s, which sought to restrict access to services such as healthcare, triggered a wave of “defensive naturalization,” producing a cohort of politically engaged and informed new citizens. In places like California, these patterns of mobilization had clear partisan consequences, with newly registered Latinos largely registering Democratic. In sum, the rollback of civic and human rights for undocumented migrants and legal residents – healthcare access among them – mobilized eligible migrants to naturalize and turnout to vote, breaking with earlier patterns of low political participation. With the series of mass protests against anti-immigrant congressional legislation in 2006, naturalization rates once again increased significantly. Between January and October 2007, the US Citizenship and Immigration Services (USCIS) received 1,029,951 naturalization applications, a 59% increase from the same period in 2006.

In addition to their political effects, such policies and initiatives also have implications for migrant public health outcomes. Latinos constitute the subpopulation with the highest uninsured rates in the USA and the lowest percentage of individuals with employer-based health insurance. Survey data collected in the lead-up to the healthcare reform legislation under the Obama administration reported that a majority of Latinos (61%) agreed that the federal government should ensure that all people have health insurance. An even larger majority of Latinos (67%) believed that anyone living in the USA should be eligible to buy or receive healthcare regardless of citizenship status, compared to only 30% of non-Latino Americans.

In spite of these patterns, the healthcare reform bill left out undocumented migrants entirely, meaning that millions will continue to face high healthcare access barriers. This outcome is likely to have negative effects on immigrant health and on the healthcare system itself.

Unlike the USA, other immigrant-receiving democracies offer greater social services and benefits for migrant populations. Naturalization rates have historically been higher in these immigrant-receiving societies compared to the USA. For example, in 1997 only 35% of foreign-born residents living in the USA had become naturalized citizens. In Canada, on the other hand, 70% of immigrants were naturalized citizens. While migrants in the USA have been mobilized to naturalize out of fear of losing basic rights and services such as healthcare, higher naturalization rates in places like Canada are a product of greater citizenship promotion programs on behalf of local and federal governments, leading to different configurations between migrants, the state and national identity in the two countries.

Neoplasms

Francesca Gany
The Center for Immigrant Health, Division of Primary Care, New York University School of Medicine,
New York, NY, USA

Neoplasms are masses that develop as a result of abnormal or excessive cell division. These tumors may also form when cells do not die when they should, and thus accumulate into a mass. While malignant neoplasms are cancerous, there are also; benign neoplasms that are not cancerous.

Cancer in immigrants is a complex research and clinical topic. Risk factors for the development of cancer include genetic, environmental, and behavioral factors, including nutrition and exercise, as well as differential rates of infection with cancer-causing pathogens. Our understanding needs to include the factors responsible for changes in cancer risk with migration. For example, there are differences in cancer rates for populations that are similar genetically but living in different locales. These rates change over time and with generation of residence. Cancer rate differentials also exist in similar environments among people with different genetic risk for cancer.

Establishing a deeper understanding of cancer risk factors can lead to a more targeted modification of risk and the application of screening for early detection. For example, recent Latino and Asian immigrants have a high incidence of gastric cancer, partly due to the high prevalence of Helicobacter pylori infection in their countries of origin. Similarly, high rates of liver cancer reflect the chronic hepatitis B infection among these immigrants.

However, despite the need to consider risk by population group, data are too often aggregated (for instance, Asian Pacific Islanders are considered as one group, without regard to immigration status, length of stay, or even at times country of origin), and biologically and environmentally significant denominator data are impossible to obtain. Further, ethnic and racial minorities are underrepresented in cancer clinical trials. Immigrant minorities also face considerable barriers in accessing appropriate cancer care and information, as highlighted by the Institute of Medicine, the Presidents' Cancer Panel, and the National Academy of Sciences. These include systems, financial, and physical barriers, barriers related to language or education, and barriers related to cultural differences and biases in cancer care. Some immigrants may also face the additional barrier of immigration status.

These issues lead to disparities in cancer morbidity and mortality between socioeconomic groups, insured and uninsured populations, and certain racial and ethnic groups. Despite an observed decrease in overall cancer death rates in the USA, immigrants continue to experience disproportionately higher cancer incidence and mortality rates for many cancers, as well as decreased access to treatment, end-of-life care, and survivorship services.

For example, lung cancer among immigrant groups is, in large part, influenced by their use of tobacco. There is a higher smoking prevalence and lifetime smoking rate for Chinese American immigrant men in many areas. Globally, there is significant geographic variation in the incidence of oral cancer; notably, the Indian subcontinent has been cited as having a disproportionately high incidence. In India, the oral cavity is one of the top five leading sites for cancer, with tens of thousands of new cases of oral cancer each year. In the USA, oral cancer accounts for less than 5% of cancers diagnosed annually – yet immigrants from South Asia are at much greater risk. Use of areca nut and smokeless tobacco in the form of paan and gutka contribute to this increased risk.

Breast cancer, after lung cancer, is the second leading cause of cancer death in women. The proportion of Mexican and Dominican women with breast cancer has increased rapidly in New York City, for example. Cultural beliefs and decreased access to care may impede breast cancer screening in minority immigrant women, and can lead to later stage of disease presentation. Cervical cancer is the most common type of cancer among women worldwide. In the USA, deaths and death rates from cervical cancer have increased for foreign-born women and decreased for US-born women. For many immigrant groups, such as the Korean, Chinese, Vietnamese, and Indian populations, the rates of Pap testing are low. Invasive cervical cancer is diagnosed in more advanced stages in Haitian and English-speaking Caribbean immigrants than in US-born Black women in Brooklyn, New York. Mexican immigrants are also at risk. Diagnosis of invasive cancer due to lack of screening and follow-up is one cause of the elevated age-adjusted mortality rate from cervical cancer among minority immigrant women.

Prostate cancer is the leading cancer diagnosed among men in the USA. Although there is a genetic component to its incidence, environmental factors have been suggested to influence its course as well. Blacks, both immigrant and nonimmigrant aggregated, in the USA have rates of prostate cancer approximately seven times higher than Korean-American men, for example. The magnitude of the declines in prostate cancer death rates for Whites and Asian Pacific Islanders have not been mirrored in Blacks.

Colorectal cancer remains one of the top three most common cancers in the USA among all races/ethnicities. Each year many thousands of lives could be saved in the USA by significantly increasing rates of colorectal cancer screening. Disparities persist for minority populations. For Latinos/Hispanics, particularly immigrants, the screening rates are especially low. Efforts directed at providers (working with them to recommend and refer for screening more often) and community members, as well as systemic interventions, must be made to increase screening rates.

Much effort has focused on increasing access to screening for underserved populations. While screening disparities persist, disparities in cancer survival and mortality remain – even after adjusting for diagnostic stage. This indicates that other, post-diagnostic factors contribute to the mortality differentials, such as structural constraints and contextual factors that restrict access to healthcare. As a result, low-income and minority women, for instance, are less likely to receive adjuvant treatment for breast and gynecologic cancers, are more likely to terminate their treatment prematurely, and are more likely to have higher mortality rates.

Many immigrants are confronted with considerable social and economic barriers to cancer treatment adherence. Such barriers include poor housing, limited opportunities for education and employment, limited access to health insurance, cost of treatment, lack of child care and transportation, and inadequate nutrition, language barriers, additional cultural factors, and other economic, personal, and family health priorities. There are also significant cost-related barriers to cancer treatment, medications, diagnostic tests, and hospitalizations – and immigrants are more likely to be charged out-of-pocket costs. Even logistical, practical barriers – such as transportation or concern over losing jobs – may prevent many immigrants from attending their appointments. Further affecting some immigrants are difficulties understanding the disease and its treatment because of language and literacy.

Quality of life, an important outcome for cancer patients, is also subject to disparate outcomes. Socioeconomic factors, as well as socioecologic context, life stress, comorbidity variables, and living situation, not ethnicity, have been shown to impact quality of life among minority breast cancer survivors. Economic stress, including employment status, health care cost concerns, and worries about income lost due to illness, was also shown to impact quality of life among mostly Hispanic, low-income women with breast or gynecological cancer undergoing active treatment or follow-up.

Patient navigation was designed as a broad-based approach to address these social and economic factors, particularly barriers faced by vulnerable populations such as financial obstacles (poor access to health insurance and ineligibility for Medicaid or Medicare, losing employment, lack of affordable cancer care), logistic barriers (transportation, lack of nearby cancer care facilities), language, and sociocultural barriers. Patient navigation typically assists patients through a distinct set of health services.

Communication is the cornerstone of effective, quality cancer care, from primary prevention to survivorship. Language becomes a medium for messages of survival, safety, and comfort. Fostering an environment that encourages clear communication and expression is imperative. In the USA, many locales have experienced tremendous growth of populations limited in English proficiency. In New York City, for example, about a quarter of the population has limited English proficiency. To promote equitable cancer care, it will be crucial to implement strategies to address this language barrier. Such strategies include trained medical interpreter services, professional translations, and professional transcreations, which involve accurate translation of concepts and ideas beyond simply literal translation.

By some estimates, approximately half of cancers could be eliminated if today's knowledge of cancer prevention, cancer control, and population sciences were widely implemented. The National Cancer Institute (NCI) notes in its 2007 Strategic Plan that overcoming cancer health disparities are one of the best opportunities we have for eliminating the suffering and death due to cancer. Addressing the needs of the medically underserved is a key component of the NCI's objectives. The NCI's Strategic Plan for Leading the Nation to Eliminate the Suffering and Death Due to Cancer highlights the need for interdisciplinary teams to work together to eliminate cancer disparities; inclusion of the community is key. The varied risk factors for cancer disparities and their complex interplay compel an integrated approach. Access to linguistically and culturally appropriate outreach, screening, treatment, and follow-up is a critical component in addressing cancer disparities.

Nervios

Bryan P. Bayles
Department of Family & Community Medicine,
University of Texas Health Science Center at San
Antonio, San Antonio, TX, USA

Nervios (Spanish for "nerves," "nervousness," or "anxiety") is one of several "culture-bound syndromes" included in an Appendix of the Diagnostic and Statistical Manual IV (DSM-IV-TR) of the American Psychiatric Association. Culture-bound syndromes are illness labels that express particular constellations of bodily, psychological, and/or social distress. These labels are meaningful and variably shared among different cultural populations, but do not correspond directly to diagnostic categories recognized by biomedicine. In contrast to its acute form, *Ataque de nervios* ("Nerve Attacks"), *nervios* refers to a chronic state of stress that gradually weakens an individual's physical, mental, and emotional health. While anthropologists and psychiatrists have examined the condition most thoroughly in Mexico, Central America, Puerto Rico, and their respective US mainland immigrant populations, *nervios* has also been studied in the Mediterranean and northern Europe.

Whether the term *nervios* means the same thing in these varying cultural contexts remains unclear. Anthropologist Roberta Baer and colleagues, however, found considerable agreement regarding a core group of causes and symptoms of *nervios* among samples of Puerto Ricans, Guatemalans, Mexicans, and Mexican Americans. Causes of *nervios* reported in the literature include strong emotions (e.g., anger or worry), family tension or conflicts, not eating well, and substance abuse. Frights or shocks (*susto*), such as witnessing a death or accident, are also widely believed to cause and/or exacerbate *nervios*. Symptoms of *nervios* can include hopelessness, excessive crying, trembling, irritability or increased anger, insomnia, weight loss, headaches, stomachaches, chest pain, a feeling of choking, high or low blood pressure, dizziness, as well as intense worry over a wide range of family, social, political, or economic concerns. In Mexico and Guatemala at least, *nervios* is also believed to play a causal role in diabetes. Individuals suffering from *nervios* may use a variety of approaches to treatment, including relaxation, prayer, herbal teas, and over-the-counter remedies (e.g., aspirin, Vicks, Alka Selzer) alone or in combination with prescription medications such as antibiotics. They may or may not seek help from conventional healthcare practitioners such as physicians, counselors, or psychiatrists.

While prevalence rates of *nervios* are largely unknown, familiarity with the condition (as well as other culture-bound syndromes) appears very high among both native and immigrant Hispanic populations. One study, for example, found that in a convenience sample of Mexican American primary care patients in South Texas 97% of respondents were familiar with the disorder and 73% reported that a friend, family member, or they themselves had suffered from it. Research to date indicates that women tend to suffer higher rates of *nervios* than males. Women of lower socioeconomic status, as well as those who are harassed, abused, and/or neglected are also generally believed to be at higher risk for the disorder.

While there does appear to be broad agreement cross-culturally about the nature of the syndrome, significant variability in causes, symptoms, and treatments of *nervios* remains, and its link to biomedical diagnostic categories is unclear. As Susan Weller and colleagues demonstrated in a sample of primary care patients in Guadalajara, Mexico, individuals reporting *nervios* showed significantly higher levels of current stress and depressive symptoms than those who did not report *nervios*. Nonetheless, the majority of individuals with *nervios* did *not* have a psychiatric disorder. In other words, there was an extremely high likelihood that someone who was depressed would report *nervios*; but the majority of individuals reporting *nervios* were not depressed. An individual who reports "Sufro de los nervios" ("I suffer from nerves"), therefore, may meet DSM-IV-TR diagnostic criteria for none, one, or several of the following psychiatric ailments: adjustment, anxiety, depressive, dissociative, somatoform, or psychotic disorders. Similarly, a study of Hispanic patients referred for cardiac testing at Baylor Medical College found that a positive history of chronic *nervios* was associated with elevated risk for somatoform disorders. On the other hand, patients reporting a history of *nervios* were more likely to have *normal* cardiac stress tests compared to those not reporting *nervios*, even after adjusting for several known cardiovascular risk factors.

Hispanics are the fastest growing minority in the USA. Individuals who work closely with Hispanic immigrant populations need to maintain an awareness of culture-bound syndromes as meaningful idioms of distress in the community. Healthcare providers, in particular, ought to consider discussing them in a nonjudgmental manner with patients who present with symptoms that are consistent with these syndromes. The suggestion that harassed or abused women may be at an elevated risk of *nervios* warrants further exploration and may suggest a need for improved screening and support for family violence or conflict. Individuals must also be sensitive, however, to the variation in how *nervios* may be understood by immigrants from different regions and that it may not be considered to be a "mental illness." Nonetheless, someone suffering from *nervios* may potentially be experiencing significant difficulty functioning in familial, social, or occupational roles and be in need of additional resources for support.

New York City

Moon Choi
Department of Epidemiology and Community Health, Virginia Commonwealth University School of Medicine, Richmond, VA, USA

New York City is located on the eastern Atlantic coast of the USA, at the mouth of the Hudson River. The city is divided into five districts called boroughs: Bronx, Brooklyn, Manhattan, Queens, and Staten Island. Manhattan and Staten Island are completely on their own land mass while Brooklyn and Queens occupy the western portion of Long Island. The Bronx, to the north, remains attached to the New York State mainland. The city is often called the “Big Apple” and is the largest city in the USA with over eight million residents including 2.9 million foreign-born residents.

New York City has for centuries served as a major point of entry for immigrants. More than 100 million Americans are estimated to be directly related to immigrants who passed through Ellis Island during its tenure as a federal immigration station. As of 2005, about 36% of its population was foreign-born in the city. Over 70% of the city’s foreign-born entered the USA in 1980 or later, similar for the overall US foreign-born population. The five nations constituting the largest sources of modern immigration to New York City were Dominican Republic, China, Jamaica, Guyana, and Mexico, based on the Census 2000 data.

A few neighborhoods have large numerical concentrations although immigrants are dispersed throughout the city. The largest immigrant neighborhood in the city was Washington Heights in Manhattan in 2000, but the next nine largest immigrant neighborhoods were either in Queens or Brooklyn. Each borough has a unique mix with respect of immigrants’ area of origin. For example, in the Bronx, Latin Americans accounted for over one-half the foreign-born while Europeans and Asians comprised 36% and 28%, respectively, in Staten Island. Queens is the most diverse borough – nearly half of its residents were foreign-born in 2000, representing over 100 countries and collectively speaking almost 170 languages. Reflecting this cultural diversity, the no. 7 train, which runs through Queens, is called “International Express.” The train passes one ethnic neighborhood after another such as from Peruvian to Colombian. Manhattan also has many neighborhoods with the rich ethnic heritages of the resident’s original homelands such as Chinatown, Koreatown, Little Italy, and Spanish Harlem.

Immigrants play a crucial role in the city’s labor market, comprising 43% of all city residents in the labor force in 2000. With respect to industry, immigrants comprised a majority of employed workers in manufacturing, construction, and many service industries. The largest employer in New York City’s economy is educational, health, and social services, and immigrants accounted for 41% of this service sector, in fields such as hospitals, elementary and secondary schools, home health care, nursing facilities, and colleges and universities.

Nigeria

Stefani Parrisbalogun
Department of Psychiatry, University Hospitals Case Medical Center, Cleveland, OH, USA

Nigeria is one of the largest developing yet impoverished countries in Africa. It is considered to be the most populated country with approximately 150 million people. Although the population growth rate is about 3%, there is still an extremely high maternal and infant/child death rate. Men slightly outnumber women and make up 50% of the population. The country is rich in multiethnic traditions and customs with more than 350 ethnic/linguistic groups. Adolescents constitute nearly 20% of the overall population with individuals younger than 15 years old constituting approximately 45% of the population. Those 15–64 years old make up 51% of the population and are considered to be Nigeria's economic workforce. Life expectancy has increased over the years to 46–53 years of age depending on gender; it is estimated that individuals older than 65 years of age may total 3–7% of the population and those 80 years of age or older could make up as much as 2% of Nigerian's population.

Nigeria, as a nation, is undergoing cultural as well as a demographic shifts. These shifts are due to an increasing number of older citizens secondary to increased life expectancy and the introduction of modern medicine. Similarly, Nigerian families are experiencing a cultural movement away from localized extended intergenerational families to smaller nuclear units largely due to socioeconomic, geographic, religious, and health-related factors.

In efforts to keep up with its dynamic population, Nigeria's system of health care delivery is also evolving. Nigeria's health care is largely managed by federal, state, and local governments. State and local government are responsible for all financial aspects of primary and secondary health care. Federal government develops policies, coordinates activities, and ensures quality management. Together, these different levels of administrative health care agencies comprise a comprehensive system consisting of specialized, federally managed tertiary referral university or teaching hospitals, state-run secondary referral general hospitals, and local governmental primary health centers, health clinics, or health posts. Private providers with *out-of-pocket* fees, donations, and community financing also have significant visible roles in maintaining Nigeria's health care delivery system.

Additionally, socioeconomic and political factors impact both the quality as well as accessibility of various health care facilities. Inadequate health care facilities impede effective delivery of appropriate health care to various health care centers in Nigeria such that standard care of common illnesses cannot be provided. Moreover, highly populated impoverished rural areas with little political influence can have limited access to medical facilities poorly equipped to manage medical needs as opposed to more affluent but less populated urban areas.

Over the last 50 years, the level of state and local government involvement in health care as well as investment in health care programs and education has helped to transform Nigeria's health care system to begin to appropriately meet the needs of all of its citizens. Historically, Nigeria's health care was only accessible to a select few in more urbanized areas. Likewise, more traditional health care delivery systems consisted of largely herbal remedies and faith healing. However, with the advent of more modern medicine, there has been an increase in the use of modern health care delivery systems all be it in tandem with more traditional treatments.

In addition, since 1988, a national health policy was adopted with the goal of providing a comprehensive health care system with a primary health care focus. Included in this goal was patient education, primary and secondary prevention, promotion of food supply and adequate nutrition, family planning, maternal/women's health, immunization/vaccination and reducing disease burden to due malaria, tuberculosis, and the HIV/AIDS pandemic. In fact, the economic cost and loss of productivity associated with both malaria and especially HIV/AIDS in Nigeria highlight the need for affordable access to appropriate essential medications, immunizations, and the need for extensive patient education particularly in more rural areas. Promotion of public–private partnerships, medication quality regulation, and augmentation of mental health services especially depression and cognitive disorders are supplementary areas of interest.

In 1999, the government created the National Health Insurance Scheme to provide health care insurance coverage and broaden access to medical care. This scheme included coverage for children under 5 years of age, permanently disabled persons, and prison inmates. In 2004, additional legislative power was incorporated into the original 1999 act in hopes of balancing out state and local budgetary constraints with the health care needs of all Nigerian citizens.

Retention of Nigeria's workforce is a significant concern especially in relation to health care. Not only do more urbanized areas within Nigeria receive an influx of workers but also countries bordering Nigeria employ a large percentage of the Nigerian trained workforce. However, in-migration of workers trained in other countries into Nigeria is limited severely due to the overall poor healthcare delivery system. For instance, health care workers such as physicians, specialists, nurses, and community and mental health workers face many challenges such as inadequate compensation, lack of appropriate general/emergency medical facilities, and lack of opportunities for professional development/research. As a result, many educated, trained Nigerian nurses and doctors practice medicine in other countries, further taxing Nigeria's already frail healthcare system. This combination of prominent out-migration and limited in-migration of Nigeria's overall workforce ultimately affects every aspect of Nigerian life compromising the delivery of primary care, maternal health, and high-risk obstetric care.

In summary, despite many positive and well-meaning legislative policies, overall patient dissatisfaction is high, job satisfaction is low, and the essential basic medical needs of Nigerian citizens are disproportionably met if at all.

Non-Governmental Organization

Beth E. Quill
Children's Defense Fund - Texas, Bellaire, TX, USA

Non-governmental organizations can be traced to the early 1900s. In 1910, the League of Nations referred to these unions, institutes, and organizations as its "liaison with private organizations." Formal recognition occurred in 1945 when the United Nations (UN) differentiated participation between international intergovernmental organizations and international private organizations in Article 70 and 71 of the United Nations Charter. These private organizations, designated as NGOs were required to be: (a) independent from governmental control; (b) not seeking to challenge governments either as a political party or by a focus on human rights; (c) nonprofit making; and (d) noncriminal and nonviolent. The significance of the UN action was to allow specialized agencies and NGOs to participate without vote in the UN deliberations and engage in consultation arrangements with the UN. The consultation role was further strengthened in Chapter 27 where the role of NGOs in sustainable development generated intense consultation with the

UN. A plea for global social responsibility by the World Economic Forum in 1999 engaged NGOs in the global advancement of social, economic, and human causes of the twentieth century.

There is no generally accepted legal definition of NGOs and multiple definitions have been articulated to address the diverse functions of NGOs. More than 40,000 international NGOs are often referred to as private voluntary organizations, civic societal organizations, grassroots organizations, social movement organizations, or self-help organizations. Those working in NGOs state they are "the voice of the people." NGOs are distinguished by important differences between themselves, political parties, interest groups, and government. They may also be described by membership associations, humanitarian NGOs, human rights NGOs, educational NGOs, environmental NGOs, women's NGOs, children's NGO, youth NGOs, and peace and conflict NGOs. The World Bank classifies them by orientation and level of cooperation. Others distinguish NGOs by their location (local, provincial, regional, national, or international). The World Bank notes these challenges. "The diversity of NGOs strains any simple definition. They include many groups and institutions that are entirely or largely independent of government and that have primarily humanitarian or cooperative rather than commercial objectives. They are private agencies in industrial countries that support international development; indigenous groups organized regionally or nationally; and member-groups in villages. NGOs include charitable and religious associations that mobilize private funds for development, distribute food and family planning services and promote community organization. They also include independent cooperatives, community associations, water-use societies, women's groups and pastoral associations. Citizen Groups that raise awareness and influence policy are also NGOs."

The diversity of NGOs can be noted by the following: OXFAM, CARE, International Red Cross, and American Civil Liberties Union. *OXFAM International* is 14 organizations with 300 partners in 100 countries dedicated to making lasting solutions in poverty, hunger, and injustice. *International Red Cross and Red Crescent Movement* is the largest humanitarian network with 97 million volunteers, supporters in 186 countries. The intent of their work is to provide protection and assistance to people affected by natural and man-made disasters and conflicts. *CARE* tackles poverty and encourages self-sufficiency emphasizing work with women in communities to make lasting social change. Programs in agriculture, water, nutrition health, and education support these efforts. *American Civil Liberties Union* primarily focuses on guarding liberty and working in the courts, legislatures, and communities to defend and preserve individual rights and liberties that the Constitution and laws of the United States guarantees to everyone in the country. Focus areas include human rights, immigrant rights, free speech, reproductive freedom, voting rights, and capital punishment.

NGOs play a critical role in proving information, services, protection, legal representation, and advocacy for immigrant groups internationally. In addition, numerous groups specialize in addressing the needs of immigrants and refugees. American Immigration Law Foundation, Central American Refugee Center, Citizen and Immigrants for Social Justice, Canadian Council for Refugees, Immigration and Refugee Service of America, and the National Immigration Forum represent some of the many organizations worldwide that may serve immigrant populations. Despite the challenges that NGOs face remaining free of governmental influence and gaining adequate resources to provide services, NGOs offer services to immigrants to support health, social and economic security, and safety in difficult and compromising circumstances. The UN endorsement of NGOs role underscores their influence, capacity, and status to make changes that benefit immigrant populations.

Nuclear Trauma

Shannon Moore
The Institute for Palliative Medicine at San Diego Hospice, San Diego, CA, USA

Definition

Trauma is variously defined, but whether physical or psychological, it is usually an unexpected and uncontrollable event, and often, outside the scope of ordinary human experience. Exposure to a potentially traumatic event may not necessarily result in maladaptive or harmful bio-psycho-social responses in a given individual or community, but in the right context, recognizing the potential of such a response is critical. Posttraumatic distress manifests in myriad ways, and may be crippling in the short and long term.

After any disaster or traumatic experience, the impact on psychological, social, spiritual, and physical health can be enormous. When that disaster is a nuclear event, added is the uniquely troubling aspect of the poorly understood and invisible nature of the "contagion." With several hundred nuclear reactors worldwide and increasing use of radioactive constituents for medical, military, and research purposes, nuclear "disasters" are not rare.

The Chernobyl Example

To date and from all accounts, the 1986 Chernobyl disaster has been considered to be the worst nuclear disaster in history (The post-tsunami nuclear event in Japan 2011 has not yet been fully studied, nor are the longer term sequelae known). When the nuclear reactor in the former Soviet Union (now Ukraine) exploded, the blast and fire, equal to about 100 of the bombs dropped on Hiroshima and Nagasaki, released a plume of radiation into the atmosphere. Though there was some intense contamination around the power plant, the bulk of the radioactive material was carried by the wind across northern Ukraine and toward southern Belarus and Russia. It is estimated that 60% of the fallout "settled" in Belarus, but increased radioactivity was picked up as far away as Western Europe (e.g., radioactive rain in Ireland). The "The Human Consequences of the Chernobyl Nuclear Accident" reported the health, socioeconomic and environmental effects on the people and communities 15 years after the accident. In response to the catastrophe in the region, hundreds of billions of dollars have been spent to address the potential economic and health-related losses, and to rehabilitate people and the land. A group of experts convened by the World Health Organization and the International Atomic Energy earlier predicted many deaths amongst the millions exposed to the radioactive cloud, but the most current number is "only"' 4000 radiation-related cancer deaths.

A reality is that the long-term mental health effects are perhaps the most costly in human terms. Beyond those who were in the contamination zone, there is a much larger group, totaling several million in Ukraine, Belarus, and Russia who, even though not exposed to dangerous levels of radiation, are affected by the actual or *potential* impact of the accident; they self-identify as "victims" of Chernobyl.

Some of the most difficult legacies of Chernobyl are the psychological effects in the population related to the lack of information and government's poor coordination in the immediate post-disaster time frame. Secrecy and poor management fostered a lack of trust in the science around the radiation risks and potential effects. The additional stress and potential trauma possibly intensified preexisting social, economic, spiritual, psychological, and medical problems. There is no doubt that the traditional list of exacerbating risk factors for distress may apply. Some of these will include:

- Perceived life-threatening danger or physical harm (especially to children)
- Extreme environmental destruction or human violence
- Loss of family, home, neighborhood, or community
- Extended exposure to danger, loss, emotional/physical strain
- Exposure to toxic contamination (such as gas, fumes, chemicals, radioactivity, or biological agents)
- History of chronic medical illness or psychological problems
- Chronic poverty, homelessness, unemployment, or discrimination
- Recent or earlier major life stressors or emotional strain

Immigration

There have been more than 500,000 immigrants to the USA from the former Soviet Union since the Chernobyl disaster. Several studies of the mental health of these immigrants document that those who were closest to the disaster site and had greater exposure to it have higher levels of anxiety and posttraumatic reactions than those who lived further away. Fear of medical illness, symptoms of depression, and cancer-related anxiety is more commonly expressed by this group than others. Similar concerns are heard from Russian immigrants to Israel. Amongst those exposed, there remain misconceptions and myths about radiation that have resulted in a paralyzing fatalism.

Conclusion

Any traumatic event or accident can increase stress symptoms, depression, anxiety, and unexplainable physical symptoms. Nuclear trauma is much more likely to be a public health catastrophe, affecting multiple people, entire communities or countries, and may require a broad multidisciplinary response. The insidious nature of radiation exposure, the general lack of understanding about nuclear energy, its uses, misuses, and unknown effects allows for fear to predominate in a way that is different from more visible and understandable disasters (earthquake, car accident, etc.).

Truthful and accurate information about the nuclear exposure, based on dependable scientific research and coupled to good quality counseling and health care if needed, will be a priority for anyone who is experiencing distressing symptoms. Addressing expressed needs and fostering a process of healing may alleviate longer-term posttraumatic stress disorder and its attendant suffering.

Nuremberg Code

Ecaterina Mariana Enache
Department of Microbiology, University of Medicine and Pharmacy "Gr. T. Popa", Iasi, Romania

The Nuremberg Code is a set of ten principles with relevance in the field of human experimentation. It was issued in 1947, being one of the outcomes of the Nuremberg Trials at the end of the Second World War.

The Nuremberg Code was the first international document that regulated from an ethical perspective the field of human experimentation.

The provisions of the Nuremberg Code emphasize mainly respect for research participants and their protection. From this perspective, the Nuremberg Code is the first official statement that empowers research subjects emphasizing the necessity of their informed consent, the lack of coercion against them, and the obligation of the investigator to protect them from any type of injuries.

According to the Nuremberg Code, informed consent of research subjects for participation is essential in all types of human experimentation. Research subjects have to exercise their power of choice, without any form of constraint or coercion. At the same time, they need to demonstrate comprehension of the study protocol (type, duration, and objectives of the experiment), its benefits and risks. Also, human subjects should feel free to end the experiment whenever they want if the continuation of experiment seems impossible for them.

The researcher has to avoid any physical and mental suffering and injury of human subjects. Moreover, when there is a reason to believe that death or a severe injury may occur, the experiment should not be done except the cases when the investigators are also the subjects.

Humanitarian importance of the investigated problem has to dictate the risks assumed by human subjects. In each experiment all tests and work conditions have to be well prepared in order to protect human subjects and all experiments have to be conducted only by scientifically qualified persons. The investigators have to be prepared to terminate the experiment at any stage if there is any possibility to produce injuries to the human subjects.

Any type of study has to be useful for society; at the same time, the expected results of the study cannot be obtained through other methods. The experiment has to be based on both previous knowledge regarding the natural history of the diseases and on results from animal experimentation.

Over time, several weak aspects of the Nuremberg Code have been pointed out. The Code refers only to human experimentation and ignores other types of scientific research. Also, it makes no difference between therapeutic and nontherapeutic human experimentation. Moreover, it implies that research subjects have to be competent to make decisions and so, it excludes children and incompetent persons from research hindering the possibility to achieve information that could improve their lives. Furthermore, the Nuremberg Code makes no statement regarding ways to supervise the investigators and to management of research results.

These problems have been solved by further international documents such as the Declaration of Helsinki or CIOMS Guidelines.

Even if the Nuremberg Code empowers research subjects, specific case is the one of immigrants. Mainly when a particular disease is investigated, it is mandatory to have study participants who have that disease; at times, they may be immigrants (for instance, African people involved in studies regarding onchocerciasis, filariasis, leishmaniasis). In the case of immigrants, informed consent is an important issue due to language barriers or different levels of education. In addition to this, the lack of coercion is another problem. If we consider immigration based on poverty in the origin country, any form of benefit, even minimal may represent a form of coercion which is difficult to be controlled.

Nurse/Nurse Practitioner

Connie H. Carr
The Institute for Palliative Medicine at San Diego
Hospice, San Diego, CA, USA

Although the word nurse is used to describe a variety of people, a nurse is actually a "licensed healthcare professional who practices independently or is supervised by a physician, surgeon, or dentist and who is skilled in promoting and maintaining health." According to the American Nurses Association, "Nursing is the protection, promotion, and optimization of health and abilities, prevention of illness and injury, alleviation of suffering through the diagnosis and treatment of human response, and advocacy in the care of individuals, families, communities, and populations." Registered nurses not only treat patients but educate patients, families, and the community about medical conditions. They also give advice, promote preventive health screening, and provide emotional support. Nurses assist patients to attain and maintain their highest level of health.

Registered nurses represent the largest healthcare occupation with over 2.6 million jobs in the USA. Approximately 60% of nurses are employed in hospitals. However, nurses also work in clinics, physicians' offices, patients' homes, public health agencies, skilled nursing facilities, and schools. Nurses provide a wide variety of services in these areas. They work independently and/or in collaboration with physicians to provide immunizations in local community clinics and public health agencies. Nurses also work in schools screening children for health-related issues. Skilled nursing facilities employ nurses to care for the elderly population requiring full-time nursing care. Nurses assist physicians in their offices to administer medications and therapies. However, in all areas of employment, nurses are responsible for educating patients, families, and communities on health-related issues.

Classification and Specialization of Nurses

The classification of nurses varies from nation to nation. In the USA, nurses are classified as licensed practical nurses (LPNs), registered nurses (RNs), and advanced practice nurses (APN/NPs). LPNs have 1–2 years of training and must pass a state or national certification board. They can perform some medical functions but are required to practice under the supervision of a registered nurse or physician. A registered nurse must graduate from an approved nursing program with a diploma, associate's or bachelor's degree in nursing and pass a national licensing examination. Registered nurses are able to assess, plan, implement, and evaluate care independently of physicians, and they provide support from basic triage to emergency surgery.

Registered nurses, like many other healthcare professionals, often specialize in a particular area of practice. Specialization is done in one of four ways: by work setting, disease or condition, body organ system, or population served. For example, specialization by work setting includes ambulatory care nurses who treat patients outside the hospital, and intensive care nurses who treat patients in the hospital unit. Specialization by disease may include diabetes nurses who educate patients on their disease process. Specialization of nurses by body organ includes cardiology nurses and oncology nurses who focus on a particular part of the body. The specialization by population includes pediatrics and geriatrics. Nurse Practitioners (NPs), according to the American College of Nurse Practitioners, are advanced practice "professional nurses who are prepared, through advanced graduate education and clinical training, to provide a wide range of health care services, including the diagnosis and management of common, as well as complex, medical conditions to individuals of all ages." NPs are licensed registered nurses with either a master's or doctoral degree. They are nationally board certified in a specific area such as pediatric, family, adult, women's health, psychiatric, or acute care.

NPs provide comprehensive care within their area of specialty. NPs are able to evaluate patients' health, diagnose medical conditions, manage health problems, promote optimal health through education, and collaborate with other healthcare professionals to provide coordination and management of patient care in a variety of settings. Each state has its own regulations for the practice of nurse practitioners. NPs can serve as a patient's primary healthcare provider in many states. They are legally authorized to provide comprehensive care management, including the ability to prescribe medications. In some states, NPs practice in their own offices and may admit patients to the hospital.

Nurses and Immigration

In 2005, the Center for Immigration Studies in Washington, DC reported that a rapidly growing immigrant population has made small private pay clinics their medical home. Many of these new immigrants and refugees lack health insurance and are ineligible for publicly funded clinics due to their immigration status. They have limited access to mainstream healthcare and look to these small private clinics for their health needs. These clinics vary in the services they provide. Some specialize in acute care illnesses while others provide basic healthcare screening for cancer or women's health. Many of these clinics are staffed by nurses and nurse practitioners.

Because of the influx of immigrants to the USA, the demand for bilingual and bicultural nurses has skyrocketed. Hispanics currently represent approximately 15% of the population of the USA; however, only 2% of registered nurses are Hispanic. This discrepancy highlights a major problem within the US health system. The lack of bicultural and bilingual nurses has created high demand for nurses with these skills.

Nursing Shortage

There is an ongoing shortage of registered nurses. The *2000 Sample Survey of Registered Nurses* reported by the US Department of Health and Human Services found too few young people are choosing careers in nursing, and the average age of registered nurses has increased substantially. In 1980, 52.9% of RNs were younger than age 40 and 26% of RNs were under the age of 30. By the year 2000, only 31.7% of nurses were younger than age 40 and less than 10% were under age 30.

As a result of the nursing shortage and aging nursing population, healthcare facilities in the USA are actively recruiting foreign nurses. In fact, nurses have regularly been imported from other countries for the last 50 years. In 2003, 14% of registered nurses were trained in foreign countries. While Filipino nurses represented more than half of the foreign graduates taking the US licensure exam in 2001, foreign nurses also immigrated from Canada, the United Kingdom, India, Korea, and Nigeria. As demand for nurses increases, the number of foreign nurses is likely to rise in response to this need.

As the USA continues their recruitment of foreign nurses throughout the world, the sending countries are increasingly questioning the impact on their own healthcare systems. A 2001 article in the *Wall Street Journal* discussed a domestic shortage of nurses in the Philippines as their nurses migrate to the USA creating a strain on their own system. The loss of qualified nurses from some of the nations in Africa is having a significant economic impact as well. The United Nations Conference for Trade and Development in 1998 estimated an economic loss of $184,000 annually for every professional between 25 and 35 years of age who migrated from South Africa. In Ghana, the government is actively urging recruiters to stop taking its nurses. In addition, the South African Nursing Council has considered a tariff on nurses wishing to practice abroad. In light of the global nursing shortage, the ethics of recruiting foreign nurses from developing nations to the USA continues to be debated internationally.

Nursing Relief Act of 1989 (U.S.)

Laura Fitzpatrick
Louis Stokes Cleveland VA Medical Center, Brecksville, OH, USA

The Immigration Nursing Relief Act of 1989 (INRA), Public Law No. 101–238 altered the United States' immigration laws to admit more nonimmigrant registered nurses (RNs) to enter the United States, and to allow the nonimmigrant RNs already in the United States to remain for longer periods of time. RNs had to be employed in that capacity for at least 3 years. In addition, their continued nursing employment had to meet certain labor requirements, through a process known as labor certification. Congress enacted the H-1A nonimmigrant visa category in order to address and compensate for the ongoing shortage of qualified RNs in the United States at the time. The INRA was allowed to sunset (expire) in 1995; however, the goals of the INRA were carried on by other forms of federal legislation, albeit with much stricter requirements for visas and for the employers wishing to hire the immigrating nurses. An understanding of nurses' ability to immigrate to practice their profession requires a brief review of immigration-related legislation and the structure of the US immigration system.

In the past, RNs initially came to the United States to work temporarily under the nonimmigrant H-1 classification. (In general, a "nonimmigrant" is someone who is going to remain in the country only temporarily and is coming for a specific purpose, to be fulfilled within a specific time period. In most cases, nonimmigrants must intend to leave the country once that specified period of time is over.) As originally written in the Immigration and Nationality Act of 1952 (INA), the H-1 described a person "of distinguished merit and ability," with a residence abroad that he/she had no intention of abandoning, who was coming to the United States for temporary employment. At the time there was no limit on the number of H-1 visas that could be issued annually.

The INA gave nonimmigrants an avenue to permanent residence and, eventually, citizenship status. Certain persons, who for family reasons, child welfare reasons, asylum, persecution or political retribution, were permitted to remain in the United States. Also included were any immigrants possessing much needed labor skills, such as physicians, attorneys, teachers, and other professional occupations. In 1967, RNs were added to the list of "professions" allowed temporary visas. The administration of immigration matters was assigned to the United States Citizenship and Immigration Service (USCIS), formerly part of the Immigration and Naturalization Service (INS), presently folded into the Department of Homeland Security (DHS).

Traditionally, RNs have been considered "professionals" under US immigration laws. From 1952 to 1989, US employers could hire foreign-born nurses using H-1 temporary visas. In 1989, the Immigration Nursing Relief Act (INRA) was enacted for a period of 5 years. INRA provided that only health care facilities with publicly filed attestations approved by the Labor Department could obtain H-1A status to employ nurses on a temporary basis in the United States. The Immigration Nursing Relief Act of 1989 was enacted in an effort to curtail the nursing shortage in the United States by giving health care facilities the permission to employ qualified nonimmigrant aliens as RNs. The passage of the INRA allowed nonimmigrant nurses who had been working in the United States for the preceding 5 years or more to stay in the United States, provided their respective qualified employers provided the INS with documentation regarding the nonimmigrant nurse, the qualifications of the nurse, the qualifications of the health care facility, and the assurances (attestations) that the facility had first taken adequate steps to recruit United States Citizens for the positions. The INRA enacted a new nonimmigrant category for temporary admission of qualified RNs denoted as the H1-A. Any RN seeking to remain in the United States would be required to show a passing score on either the NCLEX-RN or the Commission on Graduates of Foreign Nursing Schools (CGFNS) exam, or, alternatively, obtain a full and unrestricted license as an RN in their respective state. The INRA also required that employers of the nonimmigrant RNs provide specified documentation to the Department of Labor.

The INRA was allowed to expire in 1995. The nonimmigrant RNs who had arrived and stayed under the auspices of the INRA and an H1-A category were expected to leave by 1998.

On November 12, 1999, then President Bill Clinton signed into law the Nursing Relief for Disadvantaged Areas Act of 1999 (NDRAA). This was a limited extension of the INRA giving hiring precedence to disadvantaged urban and rural communities. The NRDAA officially expired in 2005; in 2006, Congress reauthorized the H-1C program for an additional 3 years. On April 5, 2010, the Department of Labor issued a Final Rule and allowed continued granting of H-1C visas, but still under the stringent guidelines of the 1999 NRDAA.

In 2010, a foreign RN may either enter the United States under an immigrant category or a nonimmigrant category. Currently, there are limited options for nonimmigrant RNs who wish to work in the United States. These include an H-1C visa and, for Canadian and Mexican RNs, a Trade NAFTA (TN) work permit, which is valid up to 3 years. Immigrant RNs (those seeking permission to remain in the United States on a permanent basis) may apply for a permanent residence (commonly called a "green card") through the visa petition process. To qualify, the RN must either have a CGFNS certificate or a full and unrestricted nursing license from the state of intended employment. Many nonimmigrant RNs find applying for the permanent residence/green card to be the most user friendly route to working as an RN in the United States.

Nursing Shortage

Beth E. Quill
Children's Defense Fund - Texas, Bellaire, TX, USA

A nursing shortage occurs when an increased demand for nurses outstrips the supply of practicing nurses in the workforce, as is experienced in the USA and other countries around the globe. In the USA, for example, the current nursing shortage is estimated at 150,000 and, by 2020, the deficit is expected to increased to 800,000, despite the creation of more than 650,000 new jobs in nursing over the next decade. The shortage is exacerbated by a loss of an estimated 450,000 nurses through retirement. Further, globally, the supply of an estimated 12 million nurses is insufficient to meet the global needs now and in the future and in 2002 the nursing shortage was termed a global crisis.

The global nursing shortage is of concern to immigrants who find themselves subject to local- and country-specific policies, practices, and financial disincentives that limit access to health care. This includes appropriate access to, and utilization of, nurses, who may find themselves confined by geography and specialization. These issues merit developing comprehensive, coordinated strategies among countries to address the ever-growing nursing shortage and, thus, the particular health needs of immigrants seeking care.

Nursing shortages can lead to increased patient loads, workplace errors, burnout, high turnover rates, and work injuries. Shortages may contribute to limited access to care, poorer quality of care, treatment errors, and dissolution of services that impact both individuals and health systems. In Botswana, for example, the government is unable to provide free antiretroviral therapy to address HIV/AIDS to its eligible citizens because of its nursing shortage.

Studies suggest several reasons for the shortage. First of all, nursing schools, confronted with reduced student enrollment and a shortage of school faculty cannot meet the projected increased demand. For example, the World Health Organization reported the number of people graduating has decreased by 70%, or 7,000 people, in the last 10 years. In Chile, out of 18,000 nurses in the country, only 8,000 are working in the field. Both the lack of new nurses entering the field as well as nurses qualified but not employed in the field contributes to the shortage. Secondly, a lack of minority nursing students and faculty creates a deficiency in providing culturally sensitive care for minority and culturally diverse populations and augments the lack of diversity in the profession. While enrollment has increased it is still disproportional to the minorities in the population. While 11% of US population is Hispanic, only 1.7% registered nurses are Hispanic, for example. Thirdly, nurses' demographics are changing. As of 2010, 40% of registered nurses in the USA are older than age 50 and planning for retirement. Further, the advancing age of the nursing workforce may increase the likelihood of illness or injury in this group. In addition to an aging nursing population, the population of nurses who are employed full time has declined as much as 35% below those working full time 20 years ago. Fourth, job dissatisfaction and burnout across employment settings have caused many nurses to leave the profession. Long hours, salaries, and stress have been cited as reasons for departure from the profession. Efforts to improve recruitment and retention have focused on enhanced benefits, salary increases, professional development, and flexible schedules.

The effects of the nursing shortages are magnified in developing countries, where the shortages are acute, the need is dramatic, and where nurses are often recruited to work in wealthier developed countries. This migration has generated accelerated debates regarding appropriate strategies to address global demand for nurses. For example, in the Philippines, the government sponsors a training program for nurses who want to work internationally. This may alleviate shortages in the host country but depletes the supply of qualified nurses in the local region.

Even though progress has been made regarding increased nurses' salaries, expanded work opportunities, and newly developed federal laws supporting nursing education, these strategies have not been uniformly employed globally. Thus, there is a disparity among certain countries and populations as a result of the nursing shortage. For example, in countries where nurses are not valued, governmental support and infrastructure may be inadequate to resolve a local shortage. These nurses may not be permitted to use their skills effectively to impact individual and population health due to system constraints.

To better address the growing global nursing shortage, 66 countries (2001) developed strategies in four key areas: (a) creating a policy agenda, (b) developing retention and recruitment efforts, (c) attracting returning nurses, and (d) importing nurses from other countries. This collaborative approach is expected to highlight the crisis and generate support for country-specific approaches in concert with the global agenda to address the nursing shortage.

Nutrient Intake

Jennifer D. Irwin
School of Health Studies, University of Western
Ontario, London, ON, Canada

As individuals from one country migrate to another, many changes occur, inclusive of their dietary habits and consequent nutrient intakes. For some, dietary changes may be forced upon them due to the lack of available traditional foods at the markets and grocery stores in their new country. It takes time to adjust to using and cooking with new foods, and during this time nutrient intakes may suffer. For others, immigration is parceled with a lower socioeconomic status, making healthy food choice and, concomitantly, adequate nutrient intake, difficult to obtain. In some countries, immigrants are more likely to experience food insecurity, and use public assistance food programs that may not always provide adequately for nutrient requirements. Regardless of the reasons, the limited research that has been conducted on immigrant nutrient intake has found that immigrants' nutrient intakes are poorer than native inhabitants of the country in which the research has been conducted. Furthermore, these deficiencies may eventually lead to nutrient-related chronic conditions.

Researchers have argued that individuals who are in particularly good health tend to be the ones who are able to immigrate to other countries and these individuals are often in better health than the average citizen in their adopted land. This phenomenon has been termed the "healthy migrant effect." Studies have also found that soon after arriving in their new country, immigrants adopt customs, practices, and even foods more typical of their new country, a process termed acculturation. Acculturation among immigrants has been associated with poorer dietary intake choices, including higher fats and refined sugars, and lower intakes of vegetables and fruits. Thus, immigrants often experience similar diseases and even have higher rates of nutrition-related disease and death than native inhabitants of their new country. To help facilitate healthier new citizens, health professionals need to work proactively with immigrant populations to ensure that adequate nutrient intakes are obtained.

Nutrition

Ming-Chin Yeh[1], Nancy Bruning[2]
[1]School of Public Health, Hunter College, City University of New York (CUNY), New York, NY, USA
[2]CUNY Immigration and Health Initiative, Queens College, City University of New York (CUNY), Flushing, NY, USA

Nutrition is the science of how food nourishes the body. More specifically, it is a study of foods (including beverages), their nutrients and other chemical constituents, and the effects of foods on health. Humans need enough food in their diet to provide energy (calories), nutrients, and other substances for proper growth and health. There is ample evidence to show that there is a strong connection between a person's diet and its effects on health. For example, several of the leading causes of death in the USA are diet-related, including heart disease, cancers, strokes, and diabetes.

This entry first provides an overview of fundamental nutrition information that covers topics such as what constitutes as essential nutrients, the understanding of the dietary reference intakes (DRIs), and the various dietary guidelines and objectives set forth by the US government. With the important background information established, it then proceeds to discuss individuals' difficulty in keeping a proper diet recommended by the government and, more importantly, the major factors that influence dietary intake among immigrants in the USA. Finally, the entry discusses two forms of malnutrition: undernutrition and overnutrition and concludes with a phenomenon called "nutrition transition" that could determine the nutritional well-being of people worldwide.

Essential Nutrients

There are six categories of essential nutrients the body needs: carbohydrate, protein, fat, vitamin, mineral, and water. They are called essential because the body cannot make these nutrients for itself and will develop deficiencies if one does not ingest them. Carbohydrate, due to its availability in an abundance of foods, is the least expensive and the primary source of energy worldwide. Carbohydrates such as starches and sugars are usually obtained from plant-based foods. Protein provides amino acids that are used to build and maintain body tissues such as muscle and connective tissue. In addition, protein is needed in the production of enzymes, hormones, and serum proteins such as albumin. Protein is available in meat, fish, poultry, eggs, nuts, legumes, and milk and milk products. Fat is an important source of energy as well and provides fatty acids for the synthesis of many compounds the body needs. Fatty acids are generally classified as saturated and unsaturated. Saturated fats are mainly found in animal products and unsaturated fats in plant foods. Unsaturated fatty acids can be further classified as monounsaturated (MUFA) and polyunsaturated (PUFA). A diet high in saturated fatty acids usually contains a high amount of low-density lipoprotein (LDL) that could lead to heart disease. On the contrary, certain unsaturated fatty acids (such as omega-3 fatty acid that is plentiful in fish oils) could help prevent heart disease. Carbohydrate, protein, and fat are also referred to as macronutrients.

As opposed to macronutrients, micronutrients include vitamins and minerals. Vitamins such as C, B1, B2, and B6 are water-soluble whereas vitamins A, D, E, and K are fat-soluble. Water-soluble vitamins can be readily excreted from the body; however, excessive intake of fat-soluble vitamins can lead to symptoms of toxicity. These organic substances are essential regulators of body metabolism. Minerals, on the other hand, are inorganic substances that are important for diverse functions in the body. For example, calcium helps build bones and teeth, and iron forms a major part of hemoglobin inside the blood cell. Finally, water is vital and functions as a solvent, a temperature regulator, and a medium for transporting nutrients to cells and waste products for excretion in the body.

Dietary Reference Intakes

So, how does an individual know that he/she is consuming enough nutrients each day? Taking into account of factors such as age, gender, growth, pregnancy, and lactation, the US government has developed a set of dietary standards for Americans: the Dietary Reference Intakes (DRIs). The DRIs, established by the Food and Nutrition Board and the Institute of Medicine, part of the National Academy of Sciences, are nutrient intake levels to be used as reference values for planning and assessing the diets of healthy individuals. It is a generic term that includes four types of reference intake values: Recommended Dietary Allowances (RDAs), Adequate Intakes (AIs), Estimated Average Requirements (EARs), and Tolerable Upper Intake Levels (ULs).

The RDAs are levels of essential nutrient intake judged to be adequate to meet the known nutrient needs of over 98% of healthy population whereas the AI values are similar to the RDAs but are based on less conclusive scientific evidence. The EARs are levels that are estimated to meet the requirements of 50% of the healthy individuals in a group while the ULs are upper limits of nutrient intake that are likely to pose no risk of adverse health effects. The risk of adverse effects increases when intake levels are above the ULs. It is recommended that individuals meet the RDA levels of nutrient intake to decrease the risk of certain chronic diseases and to promote health.

Dietary Guidelines and Objectives

In addition to the above dietary intake standards, the US government also publishes the Dietary Guidelines for Americans, sets public health dietary goals in documents such as Healthy People 2010, conducts nutritional surveillance and surveys such as the Behavioral Risk Factor Surveillance System to assess if the population is meeting these guidelines, and plans food and nutrition education programs following these recommendations. Dietary Guidelines for Americans is jointly published every 5 years by the Department of Health and Human Services (DHHS) and the Department of Agriculture (USDA). The US DHHS sets 10-year health objectives and goals for the nation in its publication Healthy People. The current version, Healthy People 2010, has an array of food and nutrition-related objectives. For example, objective 19–5 is to increase the proportion of persons aged 2 years and older who consume at least two daily servings of fruit, and objective 19–6 is to increase the proportion of persons aged 2 years and older who consume at least three daily servings of vegetables with at least one third being dark green or orange vegetables. These guidelines and objectives are to support national health promotion and disease prevention efforts.

Factors Associated with Dietary Intake Among US Immigrants

Even with the efforts put forth by the government, Americans do not seem to consume appropriate foods for adequate nutrition to stay in good health. Take fruit and vegetable consumption as an example. According to the most recent nutritional surveillance data from the 2005 Behavioral Risk Factor Surveillance System, only 32.6% of adults consumed fruit two or more times per day and only 27.2% ate vegetables three or more times per day. It is even more critical to assess how many people eat the recommended amounts of both fruit and vegetables. A study of the National Health and Nutrition Examination Survey (NHANES) data from 1988–2002 showed that only 11% of adults meet the combined fruit and vegetable recommendation of five servings a day.

Additional research reveals that fruit and vegetable consumption varies across other characteristics as well. Non-Hispanic Blacks are significantly less likely to meet these guidelines than Whites. Hispanics have reported higher intakes of fruit and vegetables than Whites and Blacks, but it has also been reported that Hispanics' consumption decreased when they became more acculturated. In fact, in addition to common barriers faced by the general population, such as a lack of time to prepare healthy foods, there are factors that uniquely impact immigrants' dietary intake and nutritional status. The following discusses two major factors that strongly influence immigrants' diet and nutrition: acculturation and food insecurity.

Acculturation

Despite having a seemingly healthy dietary habit before immigration, many immigrants, after arriving in the USA, adopt unhealthy dietary practices, such as drinking sugar-sweetened beverages and eating high-fat and high-calorie fast foods, as they become acculturated to the US lifestyle. Indeed, acculturation has been shown to be strongly associated with deterioration of dietary intake among immigrants in the USA. For example, according to a study conducted in Washington state among Hispanic immigrants from Mexico, results show that highly acculturated immigrants had a higher fat intake and ate fewer servings of fruit and vegetable per day compared with those not acculturated. Immigrants of other ethnicities also exhibit a similar trend. For example, a study conducted in Pennsylvania showed that Chinese immigrants increased consumption of Western-style foods and decreased consumption of traditional Chinese foods. In addition, the dietary patterns of the Chinese immigrants worsened and fat and sweets consumption increased significantly after immigrating to the USA.

Food Insecurity

Other than acculturation, food insecurity is also an important factor that affects immigrants' nutrient intake and health. Due to lack of financial resources or money, many low-income immigrant families worry about obtaining adequate food to feed the family. They often do not have a choice but to purchase calorie-dense, processed, and less healthful foods instead of fresh produce or other healthy food items that are usually more expensive than the unhealthy alternatives. As a result, food insecurity negatively impacts the nutritional status of members of immigrant households, especially among young children.

Prior literature has indicated that children in food insecure households were less likely to meet Food Guide Pyramid guidelines than other children. One study examining children of Mexican descent in the USA, for example, has shown that children experiencing food insecurity consumed more fat, sweets, and fried snacks than those not experiencing food insecurity. Thus, the consumption of calorie-dense and less healthy foods could contribute to unhealthy dietary habits and childhood obesity among low-income immigrant households.

For families experiencing more severe food access issues, such as adults and children skipping meals, and adults or children going without food for an entire day, their risks extend beyond food and nutrition inadequacy. For instance, immigrants who reported experiencing hunger, the most severe form of food insecurity, also reported more days of poor mental and physical health as well as poorer overall health compared with those not experiencing hunger.

Global Trend: Malnutrition and the "Nutrition Transition"

Nutritional problems often are not confined to one geographical area. Dietary deficiencies, especially, tend to be prevalent worldwide. For example, vitamin D and calcium insufficiencies present a nutritional crisis that has reached a global level. According to a research paper that examines 46 recent studies from Europe, North America, South-East Asia, and the South Pacific area, a low-vitamin D status and inadequate calcium nutrition are highly prevalent in the general population, with a range from 30% to 80%. The insufficiencies affect both genders, but are particularly high in people of low socioeconomic status and in ethnic minorities and immigrants.

However, it is important to note that malnutrition comes in two forms. It can be undernutrition that leads to nutrient insufficiencies such as the example shown above, or it can be overnutrition as exemplified by the global obesity epidemic seen in recent decades. Most of the data regarding obesity come from industrialized or developed nations. According to a recent World Health Organization (WHO) report, the levels of obesity have risen dramatically from 1977 to 2004 among Organization for Economic Cooperation and Development (OECD) countries. The 2004 Health Statistics Data of the OECD reported that the rates of people who were overweight and obese rose from less than 20% in 1976 to more than 50% by 2001.

The rates of obesity among developing countries, nevertheless, could also be of great concern as many of these countries become increasingly industrialized and adopt many of the same food production and eating patterns, which have led to the epidemic seen in OECD countries and other developed nations. This could lead to a period of time where overnutrition (e.g., obesity) and undernutrition (e.g., nutrient or calorie insufficiency) exist in juxtaposition to one another in developing countries. Many developing countries are in fact in a time of nutritional transition. The "nutrition transition" proposes that, if the trends continue, obesity rates among developing countries could parallel those of the developed countries. Thus, in order to stay healthy, consuming a balanced diet for proper nutrition is of paramount importance to all.

Nutrition Knowledge

► Nutrition programs

Nutrition Programs

Ledric D. Sherman
Department of Health and Kinesiology, Texas A&M University, College Station, TX, USA

As the number of Americans considered to be obese increases, a greater focus is being placed on healthy eating and nutrition. Obesity, defined as a body mass index (BMI) of 30 or greater, is a major risk factor for cardiovascular disease, type 2 diabetes, and some types of cancer. In the USA, only Colorado and the District of Columbia have less than 20% of their populations classified as obese (the obesity prevalence rate); 24 states have obesity rates between 25% and 30%; and nine states have an obesity prevalence of over 30%. According to the US Centers for Disease Control and Prevention (CDC), one in seven low-income children is obese. For immigrants, there are many risk factors to poor nutrition, which can lead to obesity and ill-health; factors may include poverty, limited access to fresh fruit and vegetables, cultural practices regarding food preparation, dietary changes to a diet higher in fat and sugar, and lack of culturally appropriate information regarding nutrition, among others. In addition, environmental factors also contribute to overweight and obesity, such as a lack of open green areas, sidewalks in poor repair and safety issues.

While attention has generally been paid to appropriate translation of nutrition information into different languages, there are few examples of the development of culturally appropriate nutrition programs for immigrants; most of these tend to focus on ethnic minorities or immigrants with type 2 diabetes. Two studies targeting different populations (Korean Americans with uncontrolled type 2 diabetes and Norwegian-Pakistani women without a history of type 2 diabetes) identified barriers to the adoption of a healthier diet: difficulty with the concept of a "serving size," difficulty measuring the amount of fat used while cooking, family members' dislike of food taste, and broader community expectations regarding food preparation. The authors of the studies highlight the need for community, rather than individual-based nutrition interventions for these immigrant communities.

Designing a Program for a Specific Immigrant Group: Latinos

Latinos in the USA are facing a serious health crisis as incidences of obesity, cancer, diabetes, and heart disease continue climbing. There has been a visible shift in how Latinos in the USA shop, cook and eat, resulting in these concerning trends. The encouraging news is that studies show eating a healthy and balanced diet lowers the risk of many of these diseases. Border states such as

Texas, California, Arizona, and New Mexico are well-known areas with concentrated Latino populations, but there has been significant growth in the Latino population in places such as Arkansas, Georgia, North Carolina, and Tennessee. This means that health professionals and retailers across the country can help inspire Latinos to reconnect with their flavorful and healthy food traditions in order to improve their health. To build awareness that making healthy food and lifestyle choices can reduce the rise of chronic diseases facing the Latino community, The Latino Nutrition Coalition (LNC) was developed and is dedicated to inspiring Latinos to improve and maintain their health through traditional foods and active lifestyles.

The Latino Nutrition Coalition (LNC) is an Oldways' educational program inspiring Latinos to improve and maintain their health through traditional foods and active lifestyles. Oldways is a nonprofit food issues think tank that creates and organizes a wide variety of programs and materials about healthy eating, drinking, lifestyle, and the traditional pleasures of the table. Its educational programs are for consumers, scientists, the food industry, health professionals, chefs, journalists, and policy makers. It is internationally respected and is changing the way people eat through practical and positive programs grounded in science, traditions, and delicious foods and drinks. Oldways is best known for developing consumer-friendly health promotion tools such as the Whole Grain Stamp. The Latino Nutrition Coalition (LNC), created in 2005, is one of Oldways' five core programs aimed at raising awareness and promoting broad-ranging nutrition education efforts for people of all ethnicities.

The LNC creates practical, culturally aware materials in English and Spanish that specifically help Latinos combine the best of their healthy food traditions with the realities of modern American life. The LNC is a multifaceted alliance of industry, scientists, chefs, policy makers, and other leaders who are united in their goal to address and transform the current dietary trends in Latinos living in the USA, thereby reducing the associated deleterious health effects among this population. It utilizes the support, expertise, and passion of its members to develop education and community outreach programs, to heighten public awareness of the need for Latino-focused public health, and establish culturally relevant nutrition tools.

LNC is charged to help carry out the goals of the Consensus Statement and to provide the Latino community with easy-to-understand nutrition information that can be easily applied to modern life. To build awareness that making healthy food and lifestyle choices can reduce the rise of chronic disease facing the Latino community, LNC has created numerous resources and materials to help educate consumers and health professionals alike. Examples of some of the educational materials are: a list of Latin American Super-Foods, Time Savers and Smart Swaps, Exercise Tips and Ideas for the Whole Family, a bilingual Latin American Diet Pyramid, and a 7-Day Healthy Latino Meal Plan with recipes that includes a grocery list. LNC also has information for health professionals and registered dietitians, such as statistics concerning obesity, nutrition, diabetes, cardiovascular diseases, and cancer rates in the Latin American population.

Obesity

Nancy Bruning[1], Ming-Chin Yeh[2]
[1]CUNY Immigration and Health Initiative, Queens College, City University of New York (CUNY), Flushing, NY, USA
[2]School of Public Health, Hunter College, City University of New York (CUNY), New York, NY, USA

Obesity has emerged as a worldwide health issue in recent years. The USA has led the way, with the prevalence of obesity more than doubling in the past three decades, from 15% to over 30%; overweight and obesity have a combined prevalence of over 60%. According to the World Health Organization (WHO) obesity has also risen dramatically in Organization for Economic Cooperation and Development (OECD) countries. A 2004 report found that the rate of overweight and obesity in 2001 was 50% – two and half times the rate in 1976.

Being either obese or overweight increases one's risk for many chronic diseases, including heart disease, high blood pressure, type 2 diabetes, certain cancers, and arthritis. Perhaps not surprisingly therefore, obesity is associated with increased health care costs, reduced quality of life, and increased risk for premature death.

Differences Among Populations

Overall in the USA one third of adults are obese, and another one-third are overweight, and approximately one-third of all children ages 2–19 are overweight or obese; however, certain racial/ethnic populations are affected disproportionately. There appears to be considerable variation among different population groups, and among various immigrant groups according to country of origin, race, length of time in the USA, generation, age, and gender. Most of the existing US data on obesity among immigrants represents immigrants of Hispanic origin since they comprise the largest and fastest-growing proportion of immigrants in the USA; within that, most data are collected about Mexican immigrants. In collecting obesity data, Black immigrants, who may include people from a variety of African, Caribbean, and South American cultures, are often not distinguished from American-born Blacks.

According to the Behavioral Risk Factor Surveillance System (BRFSS) surveys conducted from 2006 to 2008, the age-adjusted estimated prevalence of obesity overall was 25.6% among non-Hispanic Blacks, non-Hispanic Whites, and Hispanics. Non-Hispanic Blacks had the greatest prevalence of obesity (35.7%), followed by Hispanics (28.7%), and non-Hispanic Whites (23.7%). In other words, when compared with non-Hispanic Whites, non-Hispanic Blacks and Hispanics had a 51% and 21% higher prevalence respectively. Data from the 2003–2004 National Health and Nutrition Examination Survey (NHANES) found even higher prevalences: the prevalence of obesity was 45.0% among non-Hispanic Blacks, 36.8% among Mexican-Americans, and 30.6% among non-Hispanic Whites. However, the differences among the groups held to the BRFSS pattern: non-Hispanic Blacks had the greatest prevalence of obesity, followed by Hispanics and non-Hispanic Whites.

On the other hand, the percentage of Asian Americans classified as obese is very low, with considerable variation among geographic and gender subgroups. For example, only 9% of Vietnamese or Chinese women are overweight, but 25% of Asian Indian women are overweight. Furthermore, Vietnamese men have a low prevalence of overweight (17%) compared with Japanese (42%).

Obesity in Children and Adolescent Immigrants

Although obesity and overweight have been increasing among people of all ages, races, and ethnicities, the rate

Sana Loue & Martha Sajatovic (eds.), *Encyclopedia of Immigrant Health*, DOI 10.1007/978-1-4419-5659-0,

of increase among children in general and immigrant children in particular in the USA is particularly alarming. Overweight children are at higher risk for type 2 diabetes and other conditions that raise their risk for cardiovascular disease, and are more likely to become overweight as adults. According to NHANES 2005–2006, the prevalence for overweight among children overall was 15.5%. For Mexican-American male and female children, the prevalence was 23.2% and 18.5%, respectively. On the other hand, the children of Chinese, Vietnamese, Hmong, and Pacific Islander immigrants have the fastest growing rates of overweight and obesity. Adolescents fare just as badly: 30% of Hispanic adolescents are obese, as compared to 21% of Asian-Americans and 24% of White non-Hispanic adolescents.

Definition and Measurement Limitations

Obesity is defined as a body mass index (BMI) equal to or greater than 30. BMI is calculated by dividing a person’s body weight (kg) by his or her height in meters squared (m^2). Overweight is defined as a BMI equal to or greater than 25. In children, obesity is defined as at or above the 95% percentile of the sex-specific BMI for age-growth charts. The prevalence of obesity as defined by BMI varies considerably by gender, age, race, and ethnicity. However, these data should be approached with caution; although BMI has been useful for measuring trends in obesity, it is an imperfect measure for several reasons. For example, in the BRFSS, which is a national telephone survey and a mainstay in measuring the nation’s health, the weight and height are self-reported and thus are likely inaccurate. Another surveillance and monitoring mechanism, called NHANES (the National Health and Nutrition Examination Survey) for which the height and weight of adults are measured by survey staff members, is thought to be more accurate. As mentioned earlier, the NHANES figures are in fact higher than those from the BRFSS.

Another limitation of the BMI is that it relies on body weight and weight does not distinguish between body fat and lean tissue (muscle) nor does it accurately reflect the distribution of body fat – both of which influence obesity-related risk of disease. Recently, the amount of abdominal fat, as indicated by the waist circumference, has come to be considered a more accurate measure of risk of diabetes and heart disease. This is important in relation to racial and ethnic groups. For example, relative to White men and women, Black men and women of the same BMI tend to have more lean mass and less fat mass. On the other hand, Asians tend to have a higher percentage of body fat per body weight, and both Asians and Hispanics tend toward upper-body obesity. As a result, there is considerable discussion about how this might affect public health and policy issues regarding using different cutoff points for different ethnic and racial groups.

Factors Affecting Immigrant Obesity

Many factors have been associated with overweight and obesity. These include age, sex, marital status, socioeconomic status (education, income, employment status), health behaviors (diet, physical activity), and access to health care. Other factors such as gut bacteria and the role of genetics are also being studied. For immigrants, we must add another factor that intertwines with the others: acculturation.

Acculturation Effects

Interestingly, the majority of immigrants who have immigrated to developed countries usually arrive with a lower body weight than native-born residents. However, with time, immigrants and their children have tended to experience increased rates of obesity that meet and even surpass those of their native-born counterparts. Although this has been most evident in the USA, Canada, Britain, Austria, Germany, Sweden, Australia, and Israel have experienced the same pattern. Internal migration within developing countries has yielded this pattern as well, with poor rural immigrants gaining weight when they move to urban areas.

The overall obesity rate for immigrants who have been living in the USA less than a year averages about 8%. This rate rises slowly for the first 10 years after immigration, but by 15 years it jumps to 19%, except in foreign-born Blacks. Other data demonstrate a notable fourfold increase in the risk of obesity in longer-term immigrants (15 years or more) compared with immigrants of 5 years or less. The pattern intensifies with each generation, with a striking increase in overweight between first- and second-generation immigrants. For example, Asian-American and Hispanic adolescents born in the USA (second generation) are more than twice as likely to be obese as are first-generation adolescent immigrants. In addition, the younger the immigrant at the time of arrival, the more pronounced the effect. There is also evidence that Black immigrants tend to follow the pattern of lower rates of obesity upon arrival and increasing rates with duration of residence, as well as in subsequent generations. In a recent study focusing on low-income Blacks, foreign-born Blacks were 40% less likely to be obese than US-born Blacks, and those with foreign-born parents were significantly less likely to be obese than those whose parents were native to the USA.

Food and Physical Activity

Acculturation implies that immigrants are exchanging their active lifestyles and traditional whole foods – which are generally low in fat and sugar – for a sedentary lifestyle and high-fat, highly processed foods.

Indeed, researchers have found that acculturation generally worsens immigrant diets as they adopt the eating patterns and menus of their new country. While there are many possible reasons for eating obesigenic foods, a new concept that applies to immigrants, "nostalgic foods" may add to our understanding of this shift in eating. A subset of "comfort foods," nostalgic foods refers to the phenomenon of dropping the healthier traditional foods while emphasizing the less healthy traditional foods; at the same time, immigrants are adopting the fatty, sugary "comfort" foods plentiful and affordable in the new culture. It is thought that the stresses of immigration contribute to the need for comfort through food.

On the other hand, acculturation appears to have a rather mixed effect on physical activity. In one study, Hispanic women who were less acculturated had a 58% rate of inactivity compared with 28% for those who were more acculturated, and studies show that Asian females, too, become more active with acculturation. Yet, the physical environment in the USA, which depends on cars for transport, does not encourage the walking and bicycling that is common in immigrants' countries of origin. For example, rural immigrants routinely walked to an open market every day in their birthplace, but in the USA, they make weekly trips to a supermarket.

Living Conditions and Socioeconomic Status

The impact of changing living conditions inherent in immigration, and interactions with socioeconomic status (SES) must also be considered.

Many immigrants are of low SES which may create unique conditions relating to access issues, with many immigrants lacking access to healthy foods and places to be physically active. For example, low-income neighborhoods generally have few or no stores that sell healthy foods such as fresh vegetables; on the other hand, they may have plenty of fast-food restaurants. In addition, people living in low-income and high-minority neighborhoods have reduced access to physical activity facilities due to lack of transportation, lack of facilities or programs, personal or neighborhood safety concerns, and cost. Interestingly, rural minority women are more likely to be completely sedentary than their urban counterparts, perhaps as a result of poor access to exercise programs and facilities.

Other factors affecting immigrants' diets include lack of familiar foods in their new country; lack of familiarity with the community; language barriers; memories of hunger, deprivation, and malnutrition before migration; high-caloric foods equated with status; and traditional plant-based diet equated with poverty. Recent research suggests that the cultural acceptance of curvier body types in some immigrant cultures could help encourage women's overweight and obesity trends. At the same time, the mainstream ideal of thinness could be setting impossible standards and thus actually be countereffective in helping women to keep a normal weight.

Prevention and Treatment

Since immigrants face more barriers to quality health care and are less likely to receive preventive care than are native-born Americans, preventing obesity in the first place is urgent. An overarching goal of *Healthy People 2010* is to eliminate health disparities among racial/ethnic populations. However, as of 2007, no state had met the objective to reduce to 15% the prevalence of obesity among US adults. Interventions will need to be culturally specific if they are to be effective, and encourage immigrants to maintain the healthy aspects of their cultural traditions while adopting healthy aspects of western life.

In 2009, the Centers for Disease Control and Prevention released a set of strategies to prevent obesity in the USA, as well as ways to measure them. The 24 strategies are divided into six categories: (1) strategies to promote the availability of affordable healthy food and beverages, (2) strategies to support healthy food and beverage choices, (3) a strategy to encourage breast-feeding, (4) strategies to encourage physical activity or limit sedentary activity among children and youth, (5) strategies to create safe communities that support physical activity, and (6) a strategy to encourage communities to organize for change.

Understanding Immigrant Work and Health

Immigrants form a significant part of the US population. Patterns and trends in immigration in the USA have changed widely over time. Much of the migration to the USA today is from the developing countries of Mexico, Central America, the Caribbean and increasingly from Asian countries since the 1980s. The pressures to migrate in these countries are high. Schenker notes that developing countries have 342 candidates for every 100 jobs. According to the International Labour Organization (ILO), many developing countries face serious social dislocation due to economic insecurities such as persistent poverty, growing unemployment, and loss of traditional trading patterns.

The American Community Survey estimates that in 2009 there were 38.5 million foreign-born in the USA, comprising 12.5% of the total US population and 16% or about 20 million of the total US civilian labor force. Undocumented immigrants are also a significant part of the US economy; Migration Policy Institute (MPI) notes that they make up 30% of the foreign born population with about 44% of them having arrived since 2000. Approximately, 11.9 million workers in the US labor force were undocumented in 2008 and these undocumented immigrants contributed $50 billion in federal taxes between 1996 and 2003. The US economic recession of 2008–2010 resulted in official unemployment as high as 10% which may have impacted the labor opportunities - of the immigrants even more. Bureau of Labor Statistics (BLS) data show that while unemployment for Whites is 8.8%, unemployment for Blacks was twice as high (16.5%), and unemployment for Hispanics was 12.6%. MPI estimates that the number of undocumented immigrants fell by about one million between 2007 and 2009 due to the recession.

Although the majority of the migrant workers are men, more women and children are becoming international labor migrants. McCauley in her article on immigrant workers in the USA notes that 95% of these working immigrants live in metropolitan areas. Another report by Benach and colleagues notes that in some cases people are forced to migrate from rural to urban areas as some of them are evicted from their territories due to changing economic practices or due to corporate economic pressures. While a small portion of the new immigrants hold white collar jobs, most move into situations of vulnerability – they are young, poor, lack higher education, language skills, and they work in low-wage sectors performing labor-intensive, high-risk jobs. Murray notes that longstanding social divisions in the USA have led to the disproportionate concentration of Black, Hispanic, and other minorities in low-paying dangerous jobs. The Urban Institute in their profile of a low-wage immigrant workforce notes that in the USA one in five of all low-wage workers is an immigrant. On the positive side, Benach and colleagues note that immigrant workers are an asset, they contribute to economic growth of the high-income countries and create new demands for housing, products, and services. The countries of origin also benefit from their large remittances. On the negative side, migration presents a brain drain and loss of healthy workers in low and middle income jobs, leaving behind many children and wives.

Depending on the country of destination, migrant workers are present in industry sectors such as construction, manufacturing, food service, health care, domestic service, agriculture, and mining. With the shift in the structure of work from heavy manufacturing to service industries partially due to outsourcing and movement offshore, immigrant workers that concentrate in urban areas comprise the bulk of the service industry. Having a defined and consistent workplace is also becoming relative in some of these jobs. An increasing number of immigrant workers are in unstable work situations such as temporary work, part time work, day work, and contract work where workers are hired by outsourcing consultants. A report by Barten and colleagues showed that many businesses throughout the world and in the USA are using temporary workers and contractor-supplied services instead of hiring employees directly in order to retain more competitive position in the marketplace.

The growth of this “informal” economy is often unregulated, small-scale, and home-based, offering services such as food and beverage commerce, cleaning and domestic service and auto and electronic repair. Employers view contract labor or informal jobs as a favorable solution to fluctuating product demand, providing a supplement for staff absences, as a means of reducing labor costs, as a means to avoid unions and the resulting demand for higher wages and to avoid compliance with regulatory and immigration issues. Research by McCauley reported that nationally, one fourth of all hired crop workers are employed by a contractor rather than working directly for a grower or farm operator. While contractors can provide steady employment to workers who might otherwise float between day jobs and temporary positions, they can also transfer external costs to these marginal workers and derive revenue by charging workers fees for work transportation, tools and equipment, cashing checks, and providing assistance to workers with immigration problems. Undocumented workers have also been occupied in harmful illegal employment conditions such as servitude, bonded labor, trafficking, or slavery. These informal jobs are low wage and have little job or legal security, social work–related benefits, or access to occupational or health services.

Some migrants arrive at their new destination with many risks to their health. The WHO reports that migration itself can cause health risks from distress arising from displacement, insertion into a new environment, neighborhood segregation, social exclusion, and marginal access to social benefits and services. Ahonen and her colleagues reviewed the immigrant occupational health literature and found that an immigrant's health and quality of life may also suffer from the precarious occupational choices available to them upon arrival due to their immigrant status, deficient language skills, nontransferability of their education and training and economic need, but also marginalization of the job market, institutional and legal discrimination, and xenophobia. Lipscomb and colleagues note that social inequities in occupational settings remain a large problem which includes social issues and labor management relations in the workplace from autocratic management styles, exploitation of cheap labor, discriminatory employment practices, and the absence of mechanisms for promoting worker involvement in health and safety efforts.

According to the ILO, more than two million people die from occupational accidents or work-related diseases every year. Conservative global estimates quote 270 million occupational accidents and 160 million cases of occupational diseases with half of these possibly caused by hazardous chemical exposures. Information on immigrants' occupational fatality and morbidity rates is scarce. Few countries disaggregate data that permits analysis on occupational health issues. In the USA alone, BLS reported 3.7 million cases of occupational injury and illnesses in 2008, of which 2.5 million injuries (71%) occurred in service-providing industries and the remaining in goods-producing industries. Few migrants benefit from social security compensation or rehabilitation schemes for occupational disease or injury. Many immigrants do not have access to work and social support systems, health benefits, and access to health services.

Barten and colleagues note that occupational injuries and diseases are of greater consequence in the developing countries as 70% of the working population of the world live in areas where occupational safety and health is poorly regulated and is considered a low priority. By affecting the health of the working population, occupational injuries and diseases have profound effects on work productivity and on the economic and social well-being of workers, their families, and dependents. According to ILO, the cost of work-related health losses and associated productivity losses may amount to several percent of the total Gross National Product (GNP) of the countries of the world.

The reasons for establishing sound occupational health and safety standards are moral, economic, and legal. Work safety and health policies vary enormously from country to country depending on their economic factors and sociopolitical conditions. In the USA, the Occupational Health and Safety Act was passed in 1970. The Act established for the first time a nationwide federal program to protect the workforce from work-related death, injury, and illness. McCauley notes that many of the OSHA laws are applicable to all workers including immigrants. Immigrants are covered under the National Labor Relations Act and are entitled to organize a union to improve wages and working conditions. They are covered under the federal minimum wage and overtime law and by an array of state laws. They are protected from workplace discrimination and can bring legal action. In most states, undocumented workers are entitled to a broad range of constitutional and civil rights protections. Undocumented workers who are injured on the job are entitled to the protections of state workers' compensation laws. Additionally, OSHA and other national legislation movements have developed labor-management health and safety committees and such concepts as “Right to Know,” and at the community level, “COSH” (Community Occupational Safety and Health) groups in many cities to advocate for better worker health protection.

While some of the basic laws are in place to ensure equal protection of immigrant worker health and safety, Lipscomb and colleagues note that there has been a reluctance historically to dedicate appropriate resources to identifying hazards in the workplace and propose remedies due to its potential to adversely affect the profit margins of business. In recent years federal OSHA has emphasized a shift to voluntary industry standards and industrial consultation as opposed to the regulatory role it was established to serve. The lack of enforcement on the part of state and federal agencies can leave it to immigrant workers to take action on their own behalf, which may not occur given the vulnerable position of these workers. Exploitation of immigrant workers is made easier because they are desperate for work. Manipulation of this core factor results in a range of unethical labor practices which are known to increase health hazards and safety problems. The status of temporary workers, their lack of familiarity with union politics, their segregation from other native workers on the job and in the neighborhoods, fear of losing their job and income, employer retaliation, and deportation all combine to make immigrants unusually dependent on their employers and difficult to recruit into working class struggles. Sassen-Koob notes that it is this powerlessness that makes them exploitable. This leaves the worker in a vulnerable state with respect to work abuse ranging from violation of minimum wage for normal work hours and overtime work, discrimination, and lack of knowledge and access to work place benefits and workers compensation laws.

Eamranond and Hu in their article in "Environmental and Occupational Exposures in Immigrant Health" note that disparities in immigrant health are exacerbated by lack of adequate health care access and culturally appropriate health care. The Personal Responsibility and Work Opportunity and Reconciliation Act (PRWORA) of 1996 made legal immigrants ineligible for nonemergency Medicaid services and barred most future immigrants from applying for federal public benefits for the first 5 years in the USA. Even after 5 years, access to publically funded medical care is severely restricted to qualified aliens. And illegal immigrants are ineligible for federal, state, and local public benefits according to the 1996 Illegal Immigration Reform and Immigrant Responsibility Act (IIRAIRA). With a large majority of immigrants and illegal immigrants uninsured and without access to primary care follow-up, medicines or equipment, and long-term care facilities they largely rely on acute care facilities. This lack of appropriate health infrastructure has created an unnecessary health disparity for the immigrant populations.

The political will to correct these labor and basic human right injustices has been further weakened since 9/11 and the worldwide economic recession that followed. Deep ethnic boundaries have erupted in many places with immigrants increasingly exposed to xenophobic sentiments. There has not only been an increase in opposition to immigrants but also an increase in the US Immigration and Customs Enforcement (ICE) raids and deportations. Xenophobic rhetoric is also common in popular mass media outlets such as FOX-TV which deepens the process of "othering" toward immigrants. The dynamics of ethnic boundaries are a larger social process where social distances are created, that may be institutionalized and sustained through the practices of classifying and ranking – a stratification system that employs ethnic markers to determine differential access to opportunity. Social distance is also an underlying component of segregation that impedes assimilation. Assimilation is often seen as a one-way process on the part of the immigrant whereas it should be considered a two-way process on the part of both the hosts and the new comers.

A new code of ethics that inspires and strengthens efforts to democratize the work environment is needed. Dembe notes that a larger sociopolitical process is required to reduce the increasing xenophobic reactions toward immigrants, the elimination of job discrimination, and job ghettos. These efforts may widely range from legislative actions to broad-ranging social activities.

Effective policies and initiatives are vital catalysts in obtaining action. As the power of the immigrant employee is limited, they require the protection of the state to correct the unreasonable demands which the capitalistic system has exacted of labor. First, it is necessary to address the new demands posed by the changing face of labor. Labor legislation is needed to launch effective strategies that enforce a dynamic dialogue between hierarchical divisions in the workforce and to provide better understanding of the work organization and the social contexts within which workplace deaths, disability, violence, and discrimination occurs. Second, workers employed in the informal economy face a labor market that is largely unregulated. There are no personnel departments, formal training, skill certificates, centralized sites of employment, employer databases, labor laws, or workers' organizations to coordinate employment practices. The growing sectors of informal (contract jobs, temporary jobs, and day laborer jobs) and small-scale industries need better job and regulatory protection with a better enforcement of work and safety standards. Third, better understanding of risks is essential in high-risk trades to reduce work exposures, work-related injury and illness and to enforce effective regulatory policies. Fourth, nationwide effective health policies need to be extended equally to immigrants as well as the natives. The workplace could be used as an effective entry point for health services delivery and to convey public health messages to migrant workers and their families. Lastly, an effective immigration law is needed to improve employment conditions.

Earmond and Hu note that given the nature of the informal economy, an integrated rights-based approach and a more people-centered empowerment perspective is needed. Informal workers' representation, organization, and participation are important for ensuring the right to health of workers in the informal economy. Social mobilization may prove critical as it did in the past. Lipscomb notes that unionizing is the best way to guarantee safer workplaces. Unionized construction workers have been shown to have better health insurance coverage than nonunionized construction workers. However, unions are less common in low income work settings. Perhaps establishing community-based worker cooperatives would be a means to bring these disenfranchised workers together and provide opportunities to develop a political voice, increase workplace safety and determine rules and conditions of work, wage rates, and benefits.

In addition to policy measures, and broader community interventions, educational initiatives are essential to build precautionary measures and practices to prevent occupational illness and injuries. Linguistically and culturally sensitive health and safety training conducted at workplaces but also at community settings and in the popular media is needed. Surveillance of immigrant occupational fatality injury and disease is impaired by the lack of reliable data. Further research could also include more sophisticated techniques such as community-based participatory research, and more qualitative and ethnographic methods to gather comprehensive data. The single most important thing that could improve occupational surveillance would be to collect appropriate ethnicity data. Such data should be collected along with socioeconomic and educational background. Benach noted that there is also a need for studies to link immigrant worker health to employment using occupational titles, place of work, shifts, number of jobs, industry and site-specific details, and distinctive exposure-related attributes to work hazards and health risks. Enhancement of occupational health surveillance systems also requires improving the knowledge of occupational illness among physicians and other health care workers. More specific diagnosis of occupational conditions should include better reporting of exposures. Studies that evaluate the effectiveness of immigrant occupational health interventions are also needed.

Work is an essential activity and central to well-being. Lipscomb notes that work, if decent, can pave the way for broader social and economic advancement, strengthening individuals, their families, and communities.

Occupational Injury

Kerry Souza
Division of Surveillance, Hazard Evaluations and Field Studies (DSHEFS), National Institute for Occupational Safety and Health (NIOSH), Washington, DC, USA

Work figures prominently in the experiences of immigrants to the USA – most who relocate to the USA do so seeking employment opportunities, many seeking relief from economies that offer few opportunities to make a living. Immigration to the USA for employment takes many forms, including the recruitment of sought-after skilled professionals such as health care workers and scientists, the granting of temporary entry for seasonal work such as harvesting crops, and, in response to an increasing demand for cheap labor, the movement of undocumented workers into largely low-wage, labor-intensive jobs.

Immigrant Workers

Not all those who come to the USA for work should be called “immigrants,” technically a term reserved for those who travel to the USA with the intention to resettle here. Migrant workers and other nonimmigrants may move in and out of the USA while maintaining a home in their country of origin. However, occupational health studies and surveys do not always contain information on the circumstances of a worker’s employment, visa status, or residence in the USA. For that reason, immigrant and migrant and other foreign-born workers will, for the most part, be discussed together under the umbrella of “immigrant.”

Immigrants Hold Different Jobs

The occupational injury experience of immigrant workers in the USA is driven primarily by the occupations that they hold, but is also influenced by workers’ education and work history, language skills, and other important social factors that may increase or decrease their risk for injury on the job, compared with native workers. The employment profile of immigrants in the USA looks different than that of native workers. Immigrants are underrepresented in professional, management, and technical occupations, but are more likely than native-born workers to work in manual labor-intensive occupations. Typical work for immigrants includes construction, cleaning homes and offices, planting and harvesting crops, slaughtering animals and packing meat, operating machinery, and assembling consumer goods. In such occupations, the tasks performed, the tools and machinery used, the pace of work, and the workplace environment all present substantial risk for sustaining an injury.

In addition, the structure of jobs that are offered to immigrants, particularly undocumented immigrants, can affect their risk of occupational injury. Immigrants are often employed in contingent work such as day labor, securing daily work through temporary agencies. Day laborers are often unaware of who their actual employer is, what type of work they will be performing on any given day, and are often not given appropriate safety information or protective equipment. The lack of oversight over the employment and training of day laborers compounds the vulnerability of these workers to injury on the job.

Agriculture is an example of a hazardous industry with a large proportion of immigrants (note that many agricultural workers are *migrants* or *seasonal workers*) in its workforce. Immigrants account for a substantial proportion of the agriculture workforce across the USA with their highest representation in California, where approximately 95% of farmworkers are immigrants. Farmwork exposes these workers to extreme weather conditions (heat, cold, rain, sun), risk for falls from working on ladders, heavy burdensome work such as carrying crops, and ergonomic hazards such as stooping and extremely repetitive tasks, among other hazards. Farmworkers sustain injuries and illnesses from frequent exposure to pesticides and other chemicals. These same workers also experience poor general health and little access to quality health care, reflected in an average life expectancy among migrant and seasonal farmworkers of only 49 years, compared to a national average of 75 years.

The food manufacturing sector also relies heavily on immigrant labor. Recently, the experience of immigrant workers within processing plants, such as meatpacking and poultry facilities, have come to the attention of the general public through press coverage and popular books and films about the food industry (e.g., Fast Food Nation). In 2008, the *Charlotte Observer* ran a six-part investigative series, “The Cruelest Cuts,” focusing on the working conditions of immigrants in North Carolina’s poultry plants; poultry processing is among the industries with the highest rates of (nonfatal) injuries. The newspaper series reported the stories of workers with debilitating injuries, exposed the rate of safety violations within the plants, and found evidence of repeated underreporting of work-related injuries.

Immigrants are also overrepresented in occupations that involve extensive contact with the public, some linked to a high incidence of violence. In recent years, the leading cause of workplace fatality among immigrants has been workplace homicide. The disproportionate employment of immigrants, particularly Asian immigrants, in occupations characterized by unsafe conditions, is likely the main driver behind this statistic. Immigrants are more likely than US-born workers to work as convenience store and gas station clerks and taxi drivers – the occupations in which workers are most likely to be murdered on the job. These workers and their workplaces are often the targets of criminal activity, namely, armed robbery.

The federal Occupational Safety and Health Administration (OSHA) has released recommendations for protecting workers in these occupations, e.g., the use of bulletproof glass and other barriers, alarm systems, and drop safes. However, safety precautions have not been widely adopted. Immigrants working in non-secured work settings such as convenience stores continue to be murdered on the job. Surveys and studies also provide evidence that immigrants face a high incidence of violence, harassment including sexual harassment, and intimidation in many other work settings.

Not all foreign-born workers in the USA experience the same work-related injury rates; unskilled workers and workers with low education levels fill many of the most hazardous jobs. Among immigrants, undocumented immigrants fill many of the most hazardous jobs, while simultaneously facing economic pressures, language barriers, and other factors that inhibit them from seeking and obtaining safe work and from exercising their rights to a safe workplace. In 2008, an estimated eight million undocumented immigrants worked in the USA, comprising an estimated 5% of the total workforce.

Focus on Hispanic Workers

Recently, there has been a renewed focus on the occupational health and safety of Hispanic workers. In 2010, the National Action Summit for Latino Health and Safety (sponsored by OSHA and the National Institute for Occupational Safety and Health, in partnership with the National Institute for Environmental Health Sciences) was held to “develop a working agenda to prevent injury and death among Latino workers.” At this gathering of workers, trainers, unions, employers, researchers, and government officials, US Department of Labor Secretary Hilda Solis emphasized the rights of all workers to OSHA protections under the OSH Act of 1970, to include immigrant and undocumented workers.

In efforts to reduce injuries to immigrant workers, a focus on Hispanics is appropriate. Hispanics account for about half of the foreign-born working in the USA and also represent the largest proportion of low-wage immigrant workers. In addition, more than half of all undocumented immigrants in the USA are Hispanic, which implies that these workers will hold many of the most dangerous jobs. During the last decade, during a period when fatal workplace injuries among all workers declined, the rate of fatalities among Hispanic workers increased significantly. Although the data to describe the burden of *nonfatal* occupational injuries to immigrant workers are poor, foreign-born workers do appear to sustain more injuries in the workplace than native-born workers. Recent analyses also affirm that Hispanic construction workers are more likely to sustain a work-related injury than their non-Hispanic counterparts.

Risk Factors

It is clear that immigrants are more likely than native-born workers to hold jobs that present higher-than-average risk for occupational injury. In addition to riskier employment, occupational health researchers want to identify other root causes of injuries to immigrant workers. Identifying causes of disparities can point to policies and practices to reduce injuries among these workers.

Potentially important factors that may put a worker at risk of injury include language barriers and literacy (in the language of the destination country and/or native language), education level, skill and experience in the current occupation, perceptions of safety and willingness to take risks, and a worker's immigration status. Some of these risk factors can be recast as social, structural, or workplace factors. For example, many researchers suggest that that the fear of both losing income and being deported increase injury risk for undocumented immigrants, as workers are less likely to refuse unsafe work. Therefore, workplace health and safety practices and policies should also be examined. Likewise, while language barriers may be important, appropriate training and health and safety practices may allow immigrant workers to work safely alongside their English-speaking counterparts. More research is needed to distinguish contributing social risk factors from "cultural" or behavioral factors.

While the preceding paragraphs present a picture of increased risks and increased injuries to immigrant workers, it must be noted that we do not know enough about how work affects their health. The primary system that tracks work-related injuries and illnesses in the USA, the US Department of Labor's Annual Survey of Occupational Injuries and Illnesses, does not collect information on workers' birthplace. Therefore, injury rates for foreign-born workers cannot be obtained from this important source of data. Information on the occupational health of immigrant populations is often obtained from administrative datasets or special surveys and studies of immigrant populations.

The data that *are* available, however, do not tell the entire story. The reality of underreporting into injury and illness surveillance systems and of injuries going undocumented has become increasingly well appreciated. A 2008 report by the House Committee on Education and Labor entitled "Hidden Tragedy: Underreporting of Workplace Injuries and Illnesses" and a 2009 report from the US Government Accountability Office entitled "Workplace Health and Safety: Enhancing OSHA's Records Audit Process Could Improve the Accuracy of Worker Injury and Illness Data" detailed problems with injury reporting systems and the resulting data. Research suggests that the occupational injury experience of immigrants may be particularly poorly documented. Immigrants, both documented and undocumented, may be reluctant to report injuries, and may be discouraged by their employers from doing so. The House report concluded that immigrants are less likely to report injuries than native-born workers. Statistics on injuries to immigrants may also be biased because immigrant workers access health care and workers' compensation more seldom than native-born populations – two additional sources of data used to generate occupational injury statistics.

Workers' Rights

In any workplace covered by the Occupational Safety and Health Act of 1970 (almost all private sector workplaces), immigrants, regardless of their immigration status or documentation, are afforded the same rights as native-born workers. OSHA offices in each state can give workers information about their rights to a safe workplace and also offer technical assistance to employers. In many states, immigrant workers, with or without documentation, are eligible for workers' compensation benefits when injured or made ill on the job. Workers' compensation provides medical care, wage replacement, and death benefits for injuries that are deemed to be work-related, according to the state workers' compensation statute. Nonprofit organizations, workers' centers, and labor unions also assist workers faced with dangerous conditions in their workplaces.

Occupational Integration

Hannah Hyun Ah Kim
Mental Health Services, Waitemata District Health Board, Takapuna, North Shore City, Auckland, New Zealand

Occupational integration is a process by which immigrants enter and participate in the workforce of their new country. It is a key part of immigrants' adaptation process and it has a wide range of implications for the psychological social and economic dimensions of their lives. In addition to merely money, work provides many advantages, such as defining one's identity and purpose. For immigrants in particular, work allows for the building of relationships with others having similar interests in the new homeland. Not finding work may hence cause difficulty assimilating and decrease self-concept.

Occupational integration is often a long process and one of the most difficult problems that immigrants experience. In many countries, immigrants disproportionally represent unfavorable outcomes regarding unemployment, occupational status, and level of income. Barriers to successful occupational integration are numerous. Lack of competency in the local language and difficulty in getting their qualifications and work experiences from their original country recognized are common barriers. Lack of local work experience, local network, and knowledge in local work culture also make it difficult for immigrants to find a job or become an entrepreneur. In addition, prejudice and ignorance that employers, agencies, or corporations may have against immigrants severely impede integration.

Recent research has shown that unemployment increases risk of depression and the likelihood of poor adjustment. This is because unemployment deprives immigrants the benefits of work mentioned above. Results of unemployment are not only loss of income and financial strain, but loss of status and self-esteem, as well as constrained social contacts and network. Furthermore, the unemployed may be significantly stigmatized and have feeling of shame and guilt where full employment is a norm in the society. For refugees, stress, shame, and guilt may be even greater because some may feel a duty to provide not only for themselves and the family in the country of resettlement, but also for all those other family members and relatives left behind in the original country.

Underemployment is also a risk to poorer mental health. Skilled immigrants are underemployed when their job does not fully utilize their qualifications and skills gained in their original country. As a result, they find themselves in an occupation of lower socioeconomic status compared with the one in the original country. This drop in socioeconomic status and limited status mobility creates stress and is associated with poorer mental health. Underemployment is also an issue for the host country, as underutilization of skilled immigrants is a loss of a valuable resource.

Occupational integration requires a capacity for adaptation from both the immigrants and the host society. The host society and its members at different levels have a role to embrace diversity and eliminate discrimination. Individual immigrants have a responsibility to acquire competency in the language and in job skills. The host society also has a role to assist with this by improving access to language education and job training for immigrants. Pre-immigration training can provide information on the resources, work, and training opportunities in the host society and better equip immigrants to enter occupational integration process. Public education and support for cultural diversity and zero tolerance toward racism should be promoted in school, corporations, organizations, and media. Improvement in immigrants' occupational status will lead to an improvement in their mental health outcomes and will benefit the host society by ultimately saving health costs and by contributing to job creation and a diverse workforce.

Oral Health

Raul I. Garcia
Department of Health Policy & Health Services Research, Boston University, School of Dental Medicine, Boston, MA, USA

The dental health status of immigrants is typically worse than that of native-born populations, and dental health care is often a major unmet health care need. Documented disparities exist in regards to dental caries ("cavities") in children, adolescents, and adults, and also in regards to periodontitis ("gum disease"). The major predictor of dental caries in immigrants, after taking into account socioeconomic status indicators, is time since immigration, with the more recent arrivals having worse disease. This association has been consistently noted in studies in the USA, Canada, Europe, and elsewhere in the world. The dental health of immigrant children is also typically better than of that of their adult caregivers.

In addition to recency of immigration, other predictors of dental health have been identified. In a cross-sectional study of dental health in adult immigrants from diverse geographic and cultural origins, Cruz et al. (2009) found that acculturation and certain immigration attributes play an independent, and perhaps more important, role than differences in socioeconomic characteristics such as education and income levels. Length of stay in the host country was inversely associated with need for treatment of dental caries, but not with any other indicator of dental disease. Factors such as country of birth and age at immigration were associated with variations in dental disease prevalence and need for dental health care, while language preference was not.

Immigrant dental health has generally been shown to be positively associated with acculturation, with greater acculturation associated with measures of fewer decayed teeth, less periodontal disease, and fewer missing teeth. While the process of acculturation may lead to adoption of habits deleterious to good dental health, such as a diet with a high content of refined carbohydrates, it may also lead to adoption of better preventive practices and enhanced access to professional dental health care services. In this regard, "acculturation" may serve as a proxy for cultural norms and behaviors that affect care-seeking and self-care behaviors and, ultimately, dental health outcomes.

In regards to children's dental health, it has been found that the dental health knowledge, opinions, and practices of their caregivers are significant predictors of the child's dental health. In particular, the "dental health literacy" of caregivers may be a critically important factor, independent of mother's education and family income. Culture plays an important role in determining dental health status, primarily through the effects on self-care dental hygiene practices, dietary patterns, and access to and utilization of professional dental health care services. Despite their disproportionate greater burden of dental disease, immigrants have lower utilization of dental services.

A major access barrier to dental care, for immigrants as well as for other population groups with dental health disparities, is the lack of dental insurance. Affordable dental care is typically beyond the reach of most uninsured persons. Work in Hispanic migrant farm worker families in the USA suggests that children's dental health and use of dental care is positively associated with being born in the USA. Children are also more likely to receive regular dental care and have better dental health than immigrant adults, who usually receive no care or only emergency care. The differences noted among family members suggest that access to services, and not lack of education, is the primary dental health care barrier facing farm worker families.

An important determinant of good dental health is access to affordable professional dental services, and a key prerequisite for such access is having dental insurance coverage. In the USA, over one-third of the population lacks dental insurance, which is approximately three times as many as those lacking medical insurance. Major effort has been devoted in US health care reform to extend access to dental services, and the Affordable Care Act of 2010 guarantees dental insurance for all children, to age 21. Efforts continue to extend dental insurance coverage to all adults.

Oral Hygiene

Esther A. Hullah[1], Maud E. Nauta[2], Wai Yoong[3]
[1]Department of Oral Medicine, Guy's and St Thomas' NHS Foundation Trust, London, UK
[2]General Practitioner, Tottenham, London, UK
[3]Department of Obstetrics and Gynaecology, North Middlesex University Hospital, London, UK

Dental health affects eating, speech, social function, and self-esteem and periodontal disease has been associated with diabetes, cardiovascular disease, chronic respiratory illness and obstetric problems such as preterm deliveries. Immigrants and refugees have particularly high rates of dental disease and unmet dental needs and should be regarded as at risk for oral health problems. Even individuals with optimal oral health can experience dramatic decline when under stressful conditions. Sadly, the high prevalence of neglected oral hygiene can be the result of low priority of oral health compared to the more immediate problems for example of resettlement.

The Need for Oral Hygiene in Immigrant Populations

Good oral hygiene is essential to keep the teeth and gums healthy and prevent tooth decay (caries) and periodontal (gum) disease. There is much evidence that certain immigrant groups demonstrate poorer oral hygiene compared to nonimmigrant groups and the reasons for this are likely to be multifactorial. Cohen studied an immigrant Ethiopian Jewish population in Israel and found that this population was in need of oral hygiene instruction, with almost 80% needing scaling. Angelillo and colleagues investigated the caries (cavity) prevalence, oral hygiene status, periodontal health, and treatment needs in immigrants and refugees in Catanzaro and Crotone, Italy and revealed poor oral hygiene and periodontal health as well as unmet needs for dental treatment in certain immigrant and refugee groups, in particular Moroccans and Yugoslavs. In a study of 298 children in Sweden, Wendt noted that immigrant children brushed their teeth less frequently, used less fluoride toothpaste, and had a higher prevalence of visible plaque at 1 year of age than native-born children.

Immigrant groups are often those who suffer the worst oral health and therefore optimal oral hygiene is highly desirable. Efforts to improve the uptake of dental care and improve oral hygiene should be directed toward all immigrant groups in order to improve oral health and decrease the need for extensive and often costly dental treatment. In children, early establishment of good oral hygiene habits and regular use of fluoride toothpaste are important for achieving good oral health.

Current Oral Hygiene Recommendations

Throughout history, many different measures have been used for teeth cleaning from chewing sticks to rubbing teeth with ash or wood charcoal. Dentists currently recommend careful tooth brushing with fluoride toothpaste and the use of dental floss or interdental cleaning aids to prevent the accumulation of plaque on the teeth. It is also advised to visit a dentist regularly, as professional cleaning including tooth scaling or debridement and tooth polishing may be required.

Teeth should be brushed at least twice a day for at least 2 minutes using a soft-tufted brush small enough to cover all areas of the mouth. It is important to pay particular attention to where the teeth meet the gums (gingival margin). The head of the toothbrush should be placed against the tooth and the bristles should be tilted to a 45° angle against the gum line and moved in circular movements several times on all the surfaces of every tooth. It is usual to brush the outer surfaces of each tooth, upper and lower, keeping the bristles angled against the gum line. This is repeated on the inside surfaces of the teeth and finally on the biting surfaces of the teeth. To clean the inside surfaces of the front teeth, the brush is tilted vertically and several small circular strokes are performed with the front part of the brush. Manual toothbrushes should be replaced every 3–4 months or sooner if the filaments become worn. Electric toothbrushes are sometimes used and may be more effective.

Interdental cleaning (cleaning between the teeth) is also important to remove the plaque and the decaying food remaining stuck between the teeth. Retained food debris and plaque cause irritation to the gums which can lead to periodontal disease and acid formation, which can cause demineralization, eventually causing cavities. Interdental cleaning commonly involves using dental floss at least once a day after brushing and preferably twice a day. The dental floss should be passed against either side of each tooth, going beneath the gum line by curving the floss around each tooth from the gum upward. A fresh piece of dental floss or tape should be used each time to clean the narrow spaces between the teeth which the toothbrush cannot access. The gums may bleed when flossing for the first time but this usually settles within a few days.

Many periodontologists often prefer the use of interdental brushes to dental floss; these are thought to be gentler to the gums and carry less risk for hard dental tissue damage.

Other Oral Hygiene Measures

Regular tooth brushing and interdental cleaning, along with regular dental checks, is usually sufficient although additional oral hygiene measures may be beneficial. An antiseptic mouthwash can help control plaque and reduce gingivitis, especially in people who are unable to use a toothbrush. As fluoride protects against dental cavities by making the surface of teeth more resistant to acids during the process of remineralization, fluoride mouthwash or topical fluoride applications can help prevent tooth decay. Some people also clean their tongues using a toothbrush or a special plastic tongue scraper after cleaning their teeth.

A well-balanced healthy diet is important, in particular, limiting the amount of sugary foods and drinks, which contribute to tooth decay. Interestingly, it is how often sugars are consumed (and not the amount) that is most important. It takes 40 minutes for the saliva in the mouth to neutralize acids caused by ingesting sugars or acidic drinks (such as colas) and it is therefore important to limit sugary foods and drinks to mealtimes. It is relevant to inquire into the dietary habits of immigrants as many may not be aware of the relatively high sugar content of prepared meals from supermarkets and fast food chains. Sugar-free chewing gum increases the flow of saliva, and its use after meals helps to “flush” the mouth and clear any remaining debris. Saliva contains buffer chemicals which help to stabilize the pH near to 7 (neutral) in the mouth and prevent acid attacks. Smoking is a major risk factor for developing gum disease and smoking cessation has many benefits for oral health.

Plaque and Calculus

Plaque is a sticky film of bacteria which forms on teeth and gums. Following eating food, bacteria in plaque release acids that attack tooth enamel: repeated attacks can weaken the enamel, eventually causing tooth decay. The bacteria are more active if frequent sugary and starchy snacks are ingested although plaque can easily be removed by a good oral hygiene regime.

If plaque accumulates through absence of daily brushing and cleaning between teeth, it can eventually harden into calculus or tartar which firmly stick to teeth and generally can only be removed with difficulty by a dentist or dental hygienist with special instruments.

Periodontal Disease in Immigrants

Plaque also produces substances that cause gum inflammation. These substances can make the gums red, tender, or bleed easily and may lead to periodontal (gum) disease. The gums may lose their attachment to the teeth and their supporting structures. Pockets may form which fill with more bacteria and in some cases pus. If left untreated, the bone around the teeth can be destroyed and the teeth may become loose. Periodontal disease is the main cause of tooth loss in adults.

Periodontal disease is a chronic infection or inflammation that affects the gingival, bone, and other tissues that surround the teeth. It is also a cause of bad breath (halitosis). Infection in these tissues can initiate inflammatory and immunologic changes commencing with gingivitis, which is inflammation of the gums and, in most cases, caused by plaque. If gingivitis progresses and worsens to involve the supporting tissues of the teeth (the periodontal membrane), it is called periodontitis, which may cause destruction of connective tissue and bone, leading to loss of teeth.

Immigrants are at risk of developing periodontal disease due to their interrupted lifestyles, lack of resources, and impaired access to dental care. In a study assessing dental health in adult refugees in Boston, 88% had some degree of gingival inflammation while 9% presented with acute periodontal infection requiring emergency dental referral. Gum diseases such as acute necrotizing ulcerative gingivitis (ANUG) and noma (or cancrum oris, an acute bacterial infection of the gingival and face) can still be prevalent among children in African countries and may be seen in immigrants.

Oral Health Assessment

This should include examination of the tissues of the head and neck; dentition; and soft tissues of the oral cavity, lips, and upper throat. It is important to detect and document signs of infection, oral cancer, manifestations of HIV/AIDS, injury or trauma and torture, as well as nutritional deficiencies such as scurvy (a nutritional deficiency caused by lack of Vitamin C). Pertaining to HIV, approximately 40–50% of seropositive individuals have evidence of oral fungal or bacterial infections in the early course of the illness and oral health providers can therefore contribute to diagnosis, prevention, and treatment of the condition. Kaposi’s sarcoma (a type of cancer), oral thrush, oral hairy leukoplakia (white patches caused by Epstein-Barr virus), herpes simplex infections, and oral ulceration are other common manifestations of HIV/AIDS that one should be vigilant for.

Particular care should be given to immigrants or refugees from countries with a high level of violence exposure and torture. Inadvertently, the healthcare practitioner can invoke “flashbacks” of previous violence or torture by examining the mouth, if for instance, oral rape or dental torture has occurred in the past. A simple question such as “Is there any reason why this examination could be difficult for you?” or “Did anything bad happen to your mouth in country X?” might be an opening sentence to explore this possibility.

Access to Dental Services

Most publicly funded national health services in the USA and UK do not provide any special or fast-track access to dental service for refugees. Hullah and colleagues, in a questionnaire-based study of 206 postnatal mothers in an inner city London hospital (of whom 74.2% were non-British born) noted that only a third visited their dentist during pregnancy (despite having free care) and at least half of these women required treatment. Interestingly, 26% of the women questioned did not know about the availability of free dental care during pregnancy and for 12 months afterward. Immigrants face many barriers when trying to access dental care such as language and low literacy rates. Many are unfamiliar with the health care system and are not able to navigate through the process of receiving dental care in their host country. Efforts must be made by advocates and community leaders to improve the uptake of dental care as periodontal disease has been shown to represent a significant risk factor for systemic diseases.

Cultural Beliefs and Oral Health Practices

Traditional oral hygiene practices vary widely throughout the world. Chewing sticks, which is quite effective in removing plaque, is a common practice in parts of Africa, the Middle East, and Asia, and many refugees prefer this as part of their daily oral hygiene regimen rather than using a toothbrush. Somalians use sticks from the "roomay" or "muswaki" trees and ashes and wood charcoal are often rubbed on the teeth to whiten them.

Members of the Dinka and Nuer tribes of Sudan often remove the lower anterior canine teeth of both male and female adolescents as a rite of passage to adulthood while uvulectomies (which leave a variety of anatomical soft palate changes) are often done traditionally on East African infants to prevent throat and tonsillar infections.

Conclusion

Accessing oral healthcare is challenging for immigrants due to financial constraints and issues of language, literacy, culture, and different care-seeking behavior. Maintenance of oral hygiene is important as periodontal disease has strong associations with systemic conditions such as diabetes, cardiovascular disease, and chronic respiratory illness. Medical and oral healthcare practitioners have to be culturally aware, and community leaders from immigrant societies can help encourage uptake of dental care within this group of individuals.

Paan

Sajay P. Nair
Beachwood, OH, USA

Paan is a chewing mixture popular in India and Southeast Asia. The mixture has different varieties (from bitter to sweet) and varies dependent on location. It is deep rooted in the culture of Asia as a social practice, but research is now arising about its addictiveness and negative effects to the human body.

Ancient Greek, Sanskrit, and Chinese texts dated back to 5000 B.C. have made references to this chewing mixture. Initially used by royalty, paan is now generally used in social gatherings, particularly after meals. Paan consists of a betel leaf smeared with lime paste (aqueous calcium hydroxide) then packed with boiled areca nut (see ► Betel nut) and spices, rolled into a quid or package and then chewed. Tobacco or sweet spices (e.g., cloves, cardamom, and peppermint) have also been used in its preparations. The package is chewed and sucked on for several hours while excess saliva is spit out. Paan chewers have a distinctive red discoloration to their lips and mouth.

The effects of paan are mainly due to the areca nut. Effects are described as those resembling a mild stimulant (increased heart rate, increased attention). The addictiveness of the chew is further increased with the addition of tobacco. Studies have now shown the direct link to paan chewing with cancer, even without the use of tobacco. Oral submucous fibrosis, a condition that leads to limited movements of the mouth, and precancerous and cancerous lesions of the mouth (in particular, squamous cell carcinoma) have a direct link to regular paan chewing.

Pacific Islanders

James Cavney
Regional Forensic Services, Waitemata District Health Board, Auckland, New Zealand

Pacific Islanders

For thousands of years Pacific Islanders have explored the outer reaches of the Pacific Ocean due to population pressures, the need for resources, and in the pursuit of new opportunities. In recent history, Pacific Island migration has also been influenced by colonial expansion and ambition. Contemporary migration patterns continue to reflect traditional political alignments with larger colonial powers.

The migration history of Pacific Islanders is reflected in their distribution across many island nations and Western colonial territories. Pacific Islanders have become a heterogeneous mix of people with differences and similarities in cultural, social, and political structures. The effects of migration have thus often been beneficial and many Pacific Islanders

Sana Loue & Martha Sajatovic (eds.), *Encyclopedia of Immigrant Health*, DOI 10.1007/978-1-4419-5659-0,

continue to gain employment and academic opportunities abroad.

However, the process of migration can also result in acculturation stress and adversely affect an individual's health and well being. The following discussion therefore seeks to contextualize Pacific Island migration within an historical and contemporary framework in order to explore some of the specific health effects of immigration in these groups.

Geography

The Pacific Islands comprise some 10,000 islands in the Pacific Ocean south of the tropic of Cancer. They can be organized by archipelago or political unit but are commonly divided into Melanesia, Micronesia, and Polynesia.

Melanesia means *black islands* and is a reference to the dark skin pigmentation of their inhabitants. Comprised of mainly high volcanic islands with fertile soil, it is the most populous of the three regions. Melanesia includes New Guinea (which is divided into Papua New Guinea and the Indonesian provinces of Maluku, Papua, and West Papua), New Caledonia, Torres Strait Islands, Vanuatu, Fiji, and the Solomon Islands.

Micronesia means *small islands*. These include the Marianas, Guam, Wake Island, Palau, the Marshall Islands, Kiribati, Nauru, and the Federated States of Micronesia. Polynesia means *many islands* and is the largest of the three zones. It includes New Zealand, the Hawaiian Islands, Rotuma, the Midway Islands, Samoa, American Samoa, Tonga, Tuvalu, the Cook Islands, French Polynesia, and Easter Island. Micronesia and Polynesia are comprised of low islands formed by reefs or atolls which are relatively small and infertile.

Early Pacific Island Migration

The people of the Pacific Islands have a history of migration dating back some 50,000 years to the Pleistocene era. The first inhabitants of the greater Australian continent moved to settle the Bismarck Archipelago through a "voyaging corridor" that extended to the Solomon Islands. Beyond there, land masses were smaller and further apart and migrating settlement stopped until around 3500 BC.

The archeological record indicates that deep sea colonization began after 3500 and was probably associated with the Lapita culture. Evidence of this archeologically distinct group has been found on islands of Melanesia, Fiji, and West Polynesia dating to 1000 BC. Settlement moved across to Eastern Polynesia around A.D. 0. Cooler weather and more difficult sailing conditions likely delayed the migration south by the Maori to New Zealand until 1000 AD.

Colonization and Migration

The past three centuries have seen increasing contact between Pacific nations and colonial powers seeking to expand into the Pacific. The Dutch, French, Germans, English, Japanese, and Americans have all had an influence in the region over time. Although historical colonial contact and allegiances with the Pacific Islands continues to influence modern migration patterns, the legacy of these colonial histories is somewhat checkered.

The opportunity offered by these early colonial contacts was no doubt as tempting then as it is today. Many young Pacific Island men took the opportunity to work, see the world, or avoid the tyranny of their chiefs by signing to crew trade and whaling ships. However, with the demise of slavery, indentured labor became a new source of recruitment. Colonial contracts were primarily with China and India; however, initiatives were also explored in relation to Pacific Islanders.

The Polynesian Labourer's Act of 1868 and the Queensland Labor Trade were introduced in Australia during the same period that indentured Indian laborers were being brought to Fiji to work on sugar plantations. Tens of thousands of so-called kanakas were brought to Australia as migrant workers from Melanesia. In 1901 the Pacific Island Labourer's Act saw the end of the trade and indentured laborers were required to leave. Some, however, gained dispensation to stay and their descendents continue to seek compensation from the Australian Government for their mistreatment.

At best these initiatives acted as types of early labor exchange schemes; however, in reality it was little more than a civilized form of slavery. Nevertheless, more brutal forms of forced labor were to come under the occupation of Japanese Imperial forces during World War II. The role of the USA in defeating Japan and liberating occupied Pacific Islands has led to enduring and sanctioned opportunities for migration among Micronesian territories.

Later migrant labor schemes have continued to attract Pacific Island workers in both New Zealand and Australia. However these too have at times had negative consequences. In New Zealand, the 1970s saw the emergence of the so-called Dawn Raids, where so-called illegal overstayers were aggressively and sometimes traumatically deported leaving lasting memories in subsequent generations. Ironically, the late 1980s saw significant growth in migration from the Eastern Pacific due to more liberal immigration policies and visa-free experiments. The introduction of a new Immigration Act in 1987 and a swell of Indo-Fijian migrants in response to a series of coups in 1987 also contributed to growth.

Modern Pacific Island Populations

Population data from 2003 to 2004 estimated there were nearly nine million people living throughout the Pacific Islands. Of these 7.4 million were of Micronesian descent including over five million from Papua New Guinea and about 800,000 from Fiji. These totals eclipse the rest of the region where Micronesian people number just over half a million and Polynesians around 740,000 people. Often omitted from Pacific Island data are Maori who comprise the second largest ethnic group in New Zealand at around 565,000 people.

The indigenous population of Papua New Guinea is one of the most heterogeneous in the world and yet foreign residents account for just over 1% of the population. Papua New Guinea has several thousand separate communities, most with only a few hundred people, although a considerable urban drift has occurred in recent years.

In Fiji, indigenous Fijians account for 57.25% of the population with Indo-Fijians accounting for 37.64%. Europeans, other Pacific Islanders, and Chinese account for just over 5%. With the exception of Indo-Fijians, Polynesians and Micronesians tend to live outside their place of origin more often than Melanesians and are represented in higher numbers in migrant statistics.

Contemporary Immigration Patterns

Contemporary Pacific Island migration has tended to follow patterns of historical and political affiliations. Indigenous Melanesian people thus tend to move to Australia or Papua New Guinea rather than North America. Polynesians frequently migrate to New Zealand, America, and to a lesser degree Australia. Micronesians and Hawaiians tend to migrate primarily to the USA. Indo-Fijian people tend to disperse more widely to commonwealth countries and North America.

Of the destination countries, New Zealand provides the most comprehensive census data. In 2006, Pacific Island ethnic groups totaled 265,974 people representing 6.9% of the total New Zealand population. The Pacific Island population grew by over 30,000 (14.7%) from 2001until 2006, which reflected increases in immigration as well as the highest birth rate of all of the major ethnic groups, at 37.7%. Samoan, Cook Islands, Tongan, and Tokelau and Niuean people comprised the overwhelming majority. Although relatively smaller in numbers, Fijians migrants also grew by 40% to 9,864.

The 2001 Australian census found just over 2% of the population identified as Aboriginal or Torres Strait Islander, although the indigenous population has since increased by 11% (45,000 persons) to 455,031. Eighty-six per cent of the 2001 population were Australian citizens with England (4.3%) and New Zealand (2%) being the next highest groups. The largest Polynesian group that lives in Australia is the New Zealand Maori. Although other Polynesian communities do exist, particularly in New South Wales, they are relatively small.

In 2000 the US Census Bureau recorded over 800,000 Pacific Islanders living there. Most identified as Native Hawaiian. The rest were referred to as other Pacific Islanders and included Samoans, Tongans, Chamorros, and Guamanians.

Migration therefore continues to be prevalent throughout the Pacific exemplified by Samoa where the majority of ethnic Samoans now reside in other countries. In 2006 there were estimated to be 188,000 Samoans living in Samoa, in 115,000 New Zealand in New Zealand, 70,000 in the USA and some 40,000 in Australia.

Politics and Finance

Sovereign Pacific nation states include Australia, the Federated States of Micronesia, Fiji, Indonesia, Kiribati, Marshall Islands, Nauru, New Zealand, Palau, Papua New Guinea, Samoa, Solomon Islands, Tonga, Tuvalu, and Vanuatu.

Dependencies and other territories are administered by Australia (Christmas Island, Cocos Islands, Norfolk Island), Chile (Easter Island), Fiji (Rotuma), France (French Polynesia, New Caledonia, Wallis and Futuna), New Zealand (Cook Islands, Niue, Tokelau), the United Kingdom (Pitcairn Islands), and the USA (American Samoa, Guam, Hawaii, Northern Mariana Islands, US Minor Islands).

Smaller Pacific nations rely heavily for aid and development money from the larger states. Educational systems, currency, and health exchange schemes are often shared reflecting these relationships. In addition to foreign aid, remittances provide an indispensible source of foreign currency for small Pacific Island economies. Money and goods earned by family members in other countries are sent back to the Islands and can lead to increased development funding and better qualities of life for Island inhabitants.

Recent decades have seen the establishment of a number of regional trade, health and migration forums to collectively face the needs of the Pacific peoples. At a national level, New Zealand established a separate Ministry of Pacific Island Affairs in the 1980s. Australia has had an Ethnic Affairs Commission since 1977; however, it has no specific policies for different ethnic groups. These have served as initiative to improve communication between these countries and their Pacific neighbors.

Health and Welfare

There have been sporadic implementations of health programs through the Pacific Islands including immunization and sanitation. However, as different colonial powers have withdrawn their interests, these health systems have failed to be sustained. As a result, there are relatively impoverished health services in many of the Pacific Islands.

The major health problems among Pacific Islanders living in other countries are diseases of modernization and relate primarily to obesity. These include cardiovascular disease, diabetes mellitus (type II), and high cholesterol. This in large part relates to changes in diet, food production, and food distribution. Processed foods have for example now replaced tradition food gathering sources.

Pacific Island immigrants are also overrepresented in certain socioeconomic indices and mental health statistics. They have high rates of alcohol and drug problems and problem gambling is also increasing. They often experience poor housing conditions, unemployment, and domestic violence. Access to health and social resources can also be a barrier to receiving appropriate care and support. New Zealand in particular has made significant efforts to develop parallel cultural health and mental health services to meet this need.

It is thus encouraging that statistics suggest the children of Pacific Island migrants born and raised in their new culture do better in terms of qualifications and skilled jobs than their parents and grandparents.

Discussion

Migration has always played a key role in the development and formation of the social and cultural organization in the Pacific region. It has occurred for thousands of years in response to limited resources and population pressures. Strong kinship ties have, however, resulted in robust trading and political relationships between the Islands and provided a means of cultural cross-pollination.

Contemporary migration continues to be driven by the promise of better educational and employment opportunities abroad. To the extent that these promises are fulfilled, financial and cultural remittances continue to return to the extended family members who remain behind.

Looking to the future, one can only see rates of Pacific Island migration increasing. In a world moving toward globalization, there will be greater demand for the wealth and trappings of the Western lifestyle. Environmental change is also emerging as a new threat that could displace large numbers of Pacific Island people and dramatically change migration patterns. As birthrates of Pacific Islanders continue to increase nationally and internationally, it behooves the larger and more powerful Pacific partners to be responsive to the needs of these migrant groups.

The history of the Pacific Islands and its diverse peoples is nevertheless a common history and regional kinship and political ties remain strong. The future of the smaller and more vulnerable nations and the health of its people will therefore depend on the collective and coordinated responses and interventions of the wider Pacific region to ensure that current and future generations have access to international standards of education to compete on the global stage.

Padrino

Paul Allatson
University of Technology Sydney, Broadway,
NSW, Australia

Padrino, or compadre, are the Spanish terms for godfather; madrina, comadre, and padrina refer to a godmother. Compadrazgo, and the related comadrismo, designate Latin American kinship arrangements, duties, and expectations of godparents in a ritualized communal relationship that preserves and bolsters gender and familial structures, while also providing a socioeconomic mode of support beyond the extended family. Conventionally across the Americas, children baptized in the Catholic Church are given a madrina and padrino, the roles coming with mutual obligations and responsibilities to assist parents in raising the godchild, contributing funds to pay for baptisms, quinceañeras (15th birthday parties for girls), graduations, and weddings and, in the event of death of the parents, raising the children. Moreover, in Latin America, a padrino (or compe or compadre) may be an address of familiarity, like buck, pal, or mate. At times, a padrino can be the main force in fraternal relationships in a system that binds men in neighborhoods, communities, gangs, or enterprises in fictive kinship arrangements.

Given its place in a cultural system based on notions of mutual respect (respeto) and strong family values (familismo), the padrino role has many implications for health and medical policy, work, treatment, and support involving Latin Americans, and Latinos and Latin American immigrants in countries such as the USA and Canada, particularly when families are distanced from their home communities. Throughout Latin America, relations with medical authorities are often a collective or communal affair involving direct and extended family members, padrinos and comadres, and other family associates. Many children may have more than one padrino and comadre, with different roles. Health practitioners in the Spanish-speaking Americas may be aware of, and thus account for, these arrangements due to cultural familiarity.

The padrino is a particularly crucial support role when parents are away from direct family. He may take a leading role both supporting and liaising with absent parents, and in making or being involved in key family decisions about the medical care given to godchildren, including their access to health services, their general treatment and welfare, prognoses of survival in instances of serious illness or accidents, and procedures with regards to dying or deceased patients. As with the traditional father, the padrino figure also plays a role in upholding family honor, a duty that may involve being a provider for the family, for instance, if the family male head is ill or incapacitated. Circumstances such as these ones, often oblige the padrino to make considerable sacrifices of money and offer additional support to godchildren and their parents, including paying for medical treatments and other costs. Even when physically absent, the padrino may be involved in medical discussions via technologies such as the Internet and cellular phones.

Godparenting among Latinos and Latin American migrants may not be understood by medical practitioners in the USA, or in Canada. Such practitioners may need to adjust their conventional thinking that only closely related family members are entitled to be involved in discussions about medical issues involving non-related people. Medical practitioners also need to be aware that in many countries, including the USA, the issue of undocumented immigration can present numerous obstacles to medical systems attempting to deal with patients who may be classified as “illegal” by legal authorities. Godparents, rather than direct family, may in such instances be more willing to liaise with medical authorities and deal with health care systems as a means of protecting the parents or children involved if designated “illegal” and thus potentially subject to deportation.

Pain

Laura Janine Mintz
Department of Epidemiology and Biostatistics, Case Western Reserve University School of Medicine, Cleveland, OH, USA

Pain is a symptom that has wide ranging causes, origins, and widely differing experiences in all populations, including immigrant populations. The causes, diagnosis, treatment, and management of pain in immigrant populations have some special characteristics for practitioners to consider.

Causes of Pain

Pain can be caused by physical and psychological experiences, and is often a mix of both. Immigrant populations frequently experience enormous stress as a result of the reasons underlying their departure from their country of origin, the stress of living in a new culture where they may or may not be fluent in the language and customs, and the limited employment opportunities immigrants often have, which are often jobs that involve a lot of physical and emotional stress, and little leisure. Undocumented immigrants experience all of these stressors more acutely as their concern over state interference in their lives can have even more dire consequences. Leaving a country of origin because of oppressive circumstances can lead to extraordinary pain not only in the form of headache, but also in the form of physical pain, including conditions like fibromyalgia, chronic back pain, and other forms of muscle and skeletal pain. In addition, the stress of living in a new culture – negotiating systems of health care, state registrations, and the immigration system in general can be an additional stress, leading to conditions such as high blood pressure, headache and migraine, and physical pain. In addition, immigrants may perceive state authority as suspicious, and be reluctant to reach out for assistance with pain. Additionally, if immigrant populations are not from countries where chronic pain is regularly treated, they may not seek out treatment for chronic pain, potentially leading to worse pain by the time they access a health care provider. Immigrants that do not speak the language of their new country of residence may be limited to employment that is taxing to the body – such as day labor, nail salon work, garment work, or other forms of physically taxing and potentially physically dangerous work that can lead to muscle strain, broken bones, burns, and other forms of injury. These risks are greater in undocumented immigrant populations, who may not have a choice in their work, and who may not feel that violations of their rights will be taken seriously by reporting authorities. Additionally, undocumented immigrants may be suspicious of the interaction between health care systems and immigration authorities, so may be unwilling to seek care except for in the most extreme circumstances – this can lead to problems with pain becoming worse for lack of treatment. In addition, living with chronic pain or injury is psychologically taxing, and thus immigrant patients with chronic pain may have their conditioned worsened by the toll that chronic pain can take on a person.

Diagnosis of Pain

The International Association for the Study of Pain (IASP) established a committee in the 1980s to attempt the arduous task of a chronic pain classification. They defined pain as “an unpleasant sensory and emotional experience,” and devised a scheme that codes pain disorders along the following six categories: region involved, systems involved, temporal characteristics, degree of intensity, time since onset, and etiology (origin).

Pain is diagnosed by patient reports, physical exam, and by diagnostic testing, including x-ray, MRI, and CT scan. Pain is often classified as acute or chronic pain. Acute pain is often from injury, accidents, movement, or rupture. Chronic pain can happen in many conditions, including cancer, neurological conditions, rheumatic conditions, and from unknown sources. Patient reports are often inaccurate in immigrant populations as nonnative speakers of a language may be unfamiliar with the typical terms used to describe pain states, and thus interviews can lead to miscommunication. In addition, people from different cultures can have different explanations for the causes and experiences of pain, so immigrants may have difficulty expressing themselves in ways that health care providers in their country of residence understand, and this may lead to mismanagement of pain. If health care provider and immigrant do not speak the same language, this leads to further difficulty, and often under-treatment of the pain the patient is experiencing. Physical exams are also used to diagnose pain – in these, the health care provider attempts to move the patient’s body (or have the patient move their body) in ways that can convey the nature of an injury. If a physical exam is inconclusive, or the patient is having difficulty expressing the impact of the physical exam on his or her body, the physician may decide that the patient is “drug seeking” or not really in pain. This is another reason why the pain of immigrants may go untreated. Various forms of imaging (x-ray, magnetic resonance imaging, and computerized tomography) are used to diagnose the exact origins of pain, but these examinations are often expensive, so depending on the resources of the health care system and the country in which the patient is located, it may or may not be done. In addition, the source of chronic pain is often not seen on any of these kinds of scans, and thus patients may have a difficult time being treated for pain that they are experiencing.

Treatment and Management of Pain

Immigrants may wish to manage their pain with traditional medicine from their cultures of origin and may not disclose to hospitals and other parts of the health care system that they are utilizing these strategies. Additionally, health care providers in the host country may be unfamiliar with the traditional practices in the culture of origin of their patients, so they may not ask questions that would lead a patient to answer about traditional medical practices. This can cause problems as all medicines can have both side effects and interactions, and so this miscommunication can lead to poor health outcomes in patients.

Many medications are used to treat pain, including nonsteroidal anti-inflammatory drugs (NSAIDs) such as aspirin, ibuprofen, and acetaminophen. Additionally, opiate drugs like codeine, morphine, fentanyl, and hydromorphone are used to treat more severe pain. There are also "non-opiate" painkillers such as tramadol, which have similar strength to opiate drugs, but have fewer of the side effects of opiate drugs. Each of these drugs has side effects – the most notable from NSAIDs being bleeding in the digestive tract, and the most notable for opiates being drug addiction. The issue of drug addiction to pain medication is believed to be one of the reasons for so-called "pain disparities," which are the differences in pain treatment based on race, class, or sex of individuals suffering from pain conditions. These pain disparities also affect immigrants, who face cultural and language differences in pain treatment, and thus may receive inappropriate or incomplete care from practitioners.

Though the prevalence of pain and pain disorders is high in immigrant populations due to work conditions, psychological factors, and lack of access to health care, its diagnosis and treatment do not adequately address this need. Persons working with immigrants should ask regular and culturally appropriate questions regarding pain, and help immigrant persons advocate for effective treatments for their pain conditions.

Pakistan

Assadulla Khan Khaishgi
Ohio Department of Mental Health, Northcoast Behavioral Healthcare, Northfield, OH, USA

Background Information

Pakistan is located in southern Asia. Its immediate neighbors are India to the East, Iran and Afghanistan to the West, and a small common border with China in the Northeast. In the south, it is bordered by the Arabian Sea. It covers 307,374 mi^2. Though there has not been an official census since 1998, the estimated population in 2010 is 169,000,000. Pakistan is divided into four provinces – Sindh, Punjab, Balochistan, and Khyber-Pukhtoonkhwa (formerly called the North West Frontier Province). Also, it controls what is called Pakistan-Administered Kashmir of the disputed region of Kashmir. There are Federally Administered Tribal Areas (FATA) as well as Provinicially Administered Tribal areas (PATA) also, where, traditionally, the government exercises little control, and the local tribes run themselves fairly autonomously.

Nation's History

Pakistan achieved its formal independence on the August 14, 1947, when Britain divided the Indian subcontinent into Hindu-majority India and Muslim-majority Pakistan. Referred to as Partition, this has been considered the greatest exchange of populations in history, as many Muslims left the territory that was to become India; and, similarly, many Hindus left the territory that was to be Pakistan. Over 1,000,000 people are presumed to have lost their lives in this process as mobs attacked the vacating populations. Pakistan was initially composed of two wings, West Pakistan and East Pakistan – however, following a civil war in December 1971, East Pakistan became Bangladesh and West Pakistan was known simply as Pakistan.

Culture and Language

Ninety-five percent of Pakistan's population are practicing Muslims; after Indonesia, Pakistan is the second most populous Muslim-majority country in the world.

The remaining 5% of the populace are mainly Hindu and Christian, with smaller numbers of other religions such as Sikhs and Parsees. The majority of Pakistanis are Sunni Muslims. The capital of Pakistan is Islamabad, and the largest city and major port is the city of Karachi in the south – in the province of Sindh. Karachi's population is estimated to be 20 million. The city of Lahore in the Punjab is acknowledged generally as the cultural center of Pakistan.

The national language of Pakistan is Urdu, which is written in Arabic script. Urdu and Hindi, used in India, are very similar spoken languages, except that the latter is written in Sanskrit script and that there are differences in formal vocabulary. An Urdu speaker and a Hindi speaker, however, should be able to communicate without too much difficulty. English remains the major language of government and business. In addition, each province has its own regional language with numerous regional dialects.

Political History

Pakistan's history has remained tumultuous and violent. It includes several wars with India, a civil war in 1971, being a frontline state against the Soviet Union and its Afghan proxies in the cold war, and three bloodless military coups. It is formally a parliamentary democracy, with the President as Head of State and the Prime Minister as the Head of Government. However, there have been many times when the Prime Minister was more ceremonial, with the President wielding the true powers of government.

At this time, Pakistan is fighting several groups of militants led by Islamic extremists in the tribal regions; this has led to large numbers of internally displaced refugees fleeing the fighting. Pakistan continues to host close to 2,000,000 refugees from Afghanistan who fled the Soviet invasion in the 1980s. At one time, this number peaked at nearly 5,000,000 refugees.

Economy

Historically, Pakistan's economy has been agriculture based with its major exports being textiles and leather products and agricultural produce; however, official statistics suggest that the service sector, which includes transportation, retail trade, communications, and financial services, made up 53% of the economy.

Emigration

Pakistanis have migrated to many parts of the world. In the 2005 US Census, it was estimated that there were 210,000 Pakistanis in the USA. In 2009, the Institute of Developing Economies reported that there were around 4,000,000 overseas Pakistanis – about one half were in the Middle East, with 800,000 in the UK; 600,000 in the USA; and 250,000 in Canada. Pakistani emigration was mainly to the UK until the 1960s, after which the USA became a preferred destination. The majority of immigrants to the Middle East and the UK were of lower socioeconomic status; this is true especially of immigrants to the Middle East who settled and found manual labor jobs. Conversely, initial emigration to the USA was mainly of professionals such as doctors and engineers, although a wave of blue-collar workers followed in the 1980s and 1990s. The majority of Pakistani immigrants to the USA are based in the New York – New Jersey metropolitan area. The numbers of immigrants from Pakistan to the USA has dropped markedly after the September 11, 2001 attacks.

Emigrants and the Pakistani Economy

Pakistani expatriates have played an important role in Pakistan's development, thanks to remittances they have sent back. Undoubtedly a significant source of motivation for the laborers who immigrated to the Middle East and were met frequently with deplorable working conditions, the money sent back to Pakistan allowed many families to improve their economic standing. Many Pakistani expatriates used the informal banking sector to send money back. However, due to crackdowns after the attack on the World Trade Centers on September 11, 2001, more people have begun using authorized banking routes, which has further benefited the general economy.

Health Statistics

Pakistan's major burden of disease remains communicable illnesses. The most common cause of death is lower respiratory infections, pneumonias, followed by ischemic heart disease and diarrheal-related illness. Life expectancy is 62 years for men and 63 years for women, while the mortality rate for those under 5 is 89 per 1,000 live births. Chiefly contributing to the mortality rate in those under 5 is neonatal causes, of which, neonatal infection is the highest subgroup. Although polio has not been eradicated from Pakistan, the reported number of cases has dropped from 1,100 in 1997 to 118 in 2008.

It remains difficult to properly assess burdens of disease in Pakistan as much research is lacking or out of date. An estimate of the prevalence of diabetes done in the 1990s suggested that 12% of the population older than 25 had diabetes and another 10% had impaired glucose tolerance, while central obesity was the most common risk factor, with Type 1 diabetes being relatively rare. The World Health Organization (WHO) lists Pakistan in the top-ten countries with diabetes.

Further information on the health statistics of Pakistanis yields information on cigarette smoking, HIV, and the use of alternative medicine. The prevalence of cigarette smoking is estimated at 19.4% in adults over the age of 15. HIV is concentrated among IV drug users and male sex workers. Actual surveillance data suggests that there may be 40,000–45,000 HIV cases in Pakistan, though other estimates have gone as high as 80,000.

There is a notably high use of alternative medicine as 70–80% of Pakistanis use it to some degree. Often these healers are the first to be sought in cases of sexual dysfunction, epilepsy, psychiatric issues, chest and stomach disorders. There is a prevalent use of medicinal plants in what is referred to as the "Unani" (Grecian) tradition. Due to a combination of affordability, accessibility, and societal preferences, traditional healers often are the major source of medical care in the rural community. Faith healers are also often sought, especially as a treatment for mental illness. They provide prayers and talismans against possession and magical practices such as the "evil eye." Despite the generally religiously conservative beliefs of people, shrines of saints are also popular places where people go to pray for relief from medical problems, as well as for other issues.

Cultural Issues

In terms of culture, Pakistanis tend to be conservative, and many first- or second-generation immigrants will try to maintain the cultural mores to which they were accustomed. Concerning health care, female patients may be reluctant to be examined by male physicians, and, in some cases, they may be forbidden by their male family members to be seen by a male doctor. Similarly, male patients may be reluctant to be evaluated by a female doctor.

Religion is very important for most Pakistanis. Often they feel a deep affinity for Islam and Muslims around the world. Consequently, frequently they will have strong feelings toward perceived injustices against Muslims.

Panel Physician

Yecai Liu
Division of Global Migration and Quarantine, Centers for Disease Control and Prevention, Atlanta, GA, USA

The US Immigration and Nationality Act (INA) mandates that all immigrants and refugees migrating to the USA undergo an overseas medical screening examination. A panel physician is a medically trained, licensed, and experienced physician practicing overseas, who is appointed by the local visa-issuing US Embassy or Consulate to conduct these examinations. Worldwide, over 675 panel physicians perform the overseas medical examinations required for US-bound immigrants and refugees. The US Centers for Disease Control and Prevention (CDC) is responsible for providing the medical screening guidelines (referred to as technical instructions) to the panel physicians in performing the overseas medical screening examination. Through its Quality Assessment Program, CDC also monitors the quality of the overseas medical examination process.

The mandated medical examination focuses primarily on determining any inadmissible condition for the purposes of visa eligibility and of preventing the importation of a "communicable disease of public health importance." These medical conditions include infectious diseases such as tuberculosis (TB), syphilis, chancroid, gonorrhea, granuloma inguinale, lymphogranuloma venereum, and Hansen's disease (leprosy); mental disorders associated with harmful behavior; and substance abuse or addiction. On October 6, 2008, CDC amended the regulations that govern the required overseas medical examination for immigrants and refugees to include the following additional disease categories: (1) diseases subject to federal quarantine authority, as designated by Presidential Executive Order and (2) diseases that meet the criteria of a public health emergency of international concern, which requires notification to the World Health Organization under the revised International Health Regulations of 2005. CDC also amended the provisions that describe the scope of the medical examination by incorporating a more flexible, risk-based approach based on medical and epidemiologic factors. This approach will determine which diseases are included in the medical screening and testing of immigrants and refugees in areas of the world that are experiencing outbreaks of specific diseases.

Panel physicians must follow specific identification procedures to ensure that the person appearing for the medical examination is the person who is actually applying for the visa. The panel physician makes local arrangements for any radiologic and laboratory examinations required as part of the medical examination. The panel physician is responsible for the entire examination and also for reporting the results of all required tests and consultations on the US Department of State forms and for ensuring that the completed medical report forms are sent directly to the consular officer. The US Department of State sponsors refugees, but immigrants pay for their own medical examinations.

For the purposes of determining the inadmissibility of an applicant, medical conditions are categorized as Class A or B. Class A conditions are defined as those that preclude an immigrant or refugee from entering the USA. Class B conditions are defined as physical or mental abnormalities, diseases, or disabilities serious enough or permanent in nature, as to amount to a substantial departure from normal well-being. If an immigrant or refugee is found to have a Class A condition, a visa may still be issued after the illness has been adequately treated or after a waiver of the visa ineligibility has been approved by the US Citizenship and Immigration Service. Immigrants and refugees found to have a class B condition are not precluded from entering the USA.

Through the web-based Electronic Disease Notification (EDN) system, CDC electronically notifies the receiving health departments of all arriving refugees and of immigrants with Class A conditions (with waiver) or Class B TB conditions who are resettling in their jurisdiction and need follow-up evaluation and possible treatment. Health department physicians are asked to conduct post-arrival follow-up evaluation of newly arrived immigrants and refugees with Class A TB conditions (with waiver) or Class B TB conditions and report the results to CDC.

Canada, the United Kingdom, Australia, and many other countries also require immigrants and refugees to undergo medical examinations before their arrival. Like the USA, many of these countries appoint local licensed physicians to perform the examinations.

Pap Test

Josie E. Burnley[1], Crista E. Johnson-Agbakwu[2]
[1]College of Nursing and Health Care Innovation, Southwest Interdisciplinary Research Center, Arizona State University, Phoenix, AZ, USA
[2]Southwest Interdisciplinary Research Center, Arizona State University, Phoenix, AZ, USA

Cervical cancer is defined by the National Cancer Institute (NCI) as a disease in which cancer cells develop slowly over time in the cervix, becoming more abnormal by a process called dysplasia. The degree of cellular abnormality determines the need for treatment. In the absence of appropriate treatment, dysplasia will progress to cervical cancer over several years. The most common cause of cervical cancer is infection of the cervix with the human papillomavirus (HPV). There are more than 80 types of HPV, with 30 types that can infect the cervix, half of which have been linked to cervical cancer, and are mostly spread through sexual contact. The Pap test has been shown to detect human papillomavirus, abnormal or precancerous cells, as well as cervical cancer lesions.

Among the risk factors for cervical cancer are: HPV infection, smoking, high number of full-term pregnancies, and long-term use of oral contraceptives. Women who are sexually active at a young age or have many sexual partners are at a higher risk of developing HPV, which can progress to cervical cancer. In women who are infected with HPV, dysplasia and invasive cancer occurs two or three times more often in current and former smokers than nonsmokers. Women who have had seven or more full-term pregnancies may have an increased risk of cervical cancer. Finally, women who have used oral contraceptives for 5 years or more have a higher risk of developing cervical cancer compared to women who have never used oral contraceptives with the risk increasing after 10 years of use.

According to the NCI's recent guidelines, cervical cancer screening is not beneficial for women younger than 21 years of age, women who do not have a cervix as a result of a hysterectomy for a benign condition, and for women who are older than 60 years of age with a history of recent negative tests. As cervical cancer is slow growing, women with a consistently negative screen, require testing once every 3 years. Yearly screenings are still the recommendation for women with a history of positive Pap tests.

Epidemiology

The US age-adjusted death rate between 2002 and 2006 was 2.5 per 100,000 women. Approximately 1 in 145 women will be diagnosed with cervical cancer in their lifetime. The greatest burden of cervical cancer is found among underserved, resource-poor populations as 80% of all new diagnoses and related mortality occur in this population. The National Institutes of Health (NIH) estimates that half of the women who receive a cervical cancer diagnosis have never been screened for cervical cancer. An additional 10% had not been screened in the previous 5 years.

More than half of cervical cancer deaths in the USA have been reported to occur in foreign-born women. These groups represent vastly diverse national, linguistic, racial, cultural, and religious backgrounds, and are more likely to lack health insurance, have less timely contact with the health care system, and have a host of socio-demographic and health access barriers to healthcare. Based on the NCI's Surveillance Epidemiology and End Results (SEER) cancer statistics, the age-adjusted incidence rate for cervical cancer was 8.2 per 100,000 women per year between 2002 and 2006. The median age for diagnosis of cervical cancer in the same period was 48 years. Approximately, 0.2% of the cases were diagnosed in women under the age of 20, while 14.9% were diagnosed between the ages of 20 and 34. The highest cervical cancer incidence was 26.2% between the ages of 35 and 44, and 23.5% between 45 and 54. The incidence of cervical cancer during this period decreased with advancing age with the rate dropping to 15.8% between age 55 and 64; 10.4% between 65 and 74; 6.6% between 75 and 84; and 2.5% in women 85 years of age and older. The incidence rates by ethnicity in the same period demonstrated that Hispanic women had the highest incidence at 12.7 per 100,000 women, followed by Blacks at 10.4 per 100,000 women. The rate for White women was 8.1 per 100,000 women, while 7.6 per 100,000 women among Asian/Pacific Islanders. American Indian/Alaskan Native women had the lowest rate at 7.2 per 100,000 women.

Worldwide, cervical cancer accounts for approximately 10% of all cancers, and is one of the three main female cancers, accounting for over 370,000 new cases of cancer each year. In mainland China, invasive cervical cancer is the second leading cause of cancer death with Chinese immigrant women in the USA demonstrating a higher rate (12.3 per 100,000 cases) of cervical cancer compared with 7.2 per 100,000 for non-Hispanic White women.

Barriers to Cervical Cancer Screening

Regular pelvic exams and Pap tests can detect abnormal cells in the cervix before cancer can develop. However, among immigrants and ethnic minorities, there are barriers to screening that result in a higher incidence of cervical cancer morbidity and mortality in these populations.

Barriers to Pap Screening Among Hispanic Immigrants

Among Hispanic women, perceived barriers to Pap testing in the USA includes: threatened virginity, embarrassment, fatalism, distrust of health system, fear of pain, fear of diagnosis, lack of physician referral, presence of male health care provider, and difficulty finding qualified interpreters. Other barriers include: lack of general knowledge about cervical cancer and Pap testing; as well as the perception that Pap tests are unnecessary unless when one is ill.

Inadequate functional health literacy in Spanish is another barrier to screening among Hispanic women as nearly half of a study population would experience difficulty interpreting written materials even in Spanish. When compared with those with adequate and marginal literacy, Hispanic women with inadequate functional literacy in Spanish were significantly less likely to have ever had a Pap test even when controlled for other socio-demographic factors.

Barriers to Pap Screening Among Asian Immigrants

Among Asian immigrant women, similar barriers to cervical cancer screening were found as in other immigrant groups. Sociocultural beliefs, lack of knowledge about the disease process and Pap testing, language barriers, low acculturation levels, and lack of physician referrals were found to be barriers to screening. The stigma of cancer, lack of familiarity with Western medicine, and use of traditional health practices are also concerns. A study among Asian Canadian immigrant and nonimmigrant women demonstrated that Asian immigrant women had a significantly lower rate of Pap testing (52%) compared to the nonimmigrant population (72%). The barriers to screening were a lack of time and lack of necessity of testing.

Barriers to Pap Screening Among African and Caribbean Immigrants

There is a dearth of available literature on Pap testing and cervical cancer among African and Caribbean immigrant women. One reason for the lack of representation among these groups is the failure to distinguish the various ethnic groups that comprise the general umbrella of the term African-American. Administrative barriers to screening such as long wait times, scheduling delays, limited availability of physicians, as well as poor patient communication skills, perceptions of racism, and lack of family/community support, have been noted among African-American as well as Caribbean immigrant women.

Implications

Although there are general similarities in the challenges and barriers to Pap testing across immigrant and ethnic minorities, there also exist many unique factors within each group that prevent them from accessing appropriate cervical cancer screening. For any intervention to be effective in raising awareness and access to screening, it must first take into consideration the unique needs of each group. It is evident that the education and health promotion strategies common in Western constructs of care may not be adequate in these populations. Programs that have been shown to have the greatest effectiveness are those that incorporate the sociocultural context and other unique characteristics of each of these groups in their practice models.

Language barriers, lack of knowledge of the health care system, and lack of provider/physician recommendation are common across immigrant groups. Health care policy makers must formulate policies to improve cervical cancer screening that reflect an attention to reducing these barriers. Likewise, health care providers caring for immigrants and ethnic minorities should reinforce their recommendations for screening and Pap smear referrals among their patients as well as take a partnered approach in engaging directly with communities in further outreach and education.

Future Directions

Targeting immigrant and ethnic minority women with population-based programs has been shown to increase overall cervical cancer screening rates. Access to screening can be improved by eliminating or reducing out-of-pocket payments and removing geographical barriers. The best strategies to improve adherence in populations where it has previously been low are: to have organized programs where free tests are available, facilitate appointments, arrange transportation, and as much is feasible, tailor each program to the specific cultural/ethnic identity of the target population(s).

HPV vaccines have been shown to not only prevent infections with the virus, but it also reduces cervical malignancies. Policymakers should consider parental acceptability of HPV vaccines when strategizing improved vaccination campaigns. Parental acceptability and attitude toward HPV vaccination has more to do with parental beliefs and general discomfort about the vaccines rather than lack of knowledge about the vaccines. Another factor that affects parental acceptability is the age of the child, as the greater the proposed vaccination age, the greater the parental acceptability. Further research is needed to address barriers to screening in African and Caribbean immigrant communities as these communities continue to increase in the USA due to the recent influx of immigrants and refugees from war-torn regions of the world. In addition, interventional programs should utilize the available research among Hispanic and Asian communities to design programs that target the eradication of barriers to screening and increase access to Pap testing among these groups.

Patient Satisfaction

Jennifer Durand
School of Public Health, University of Texas
Health Science Center, Houston, TX, USA

Patients' perspectives regarding the quality of healthcare provided have been considered an important indicator for health service quality, including patient satisfaction.

Avedis Donabedian, a pioneer in public health and proponent of quality assessment, believed quality of care could be evaluated based on three criteria: structure, process, and outcomes. Namely, researchers should focus on environmental attributes (i.e., material and human resources), how and what things are done (i.e., diagnoses and treatments), and the effects on patient satisfaction and health status to determine quality (i.e., health status and patient satisfaction). Structure tends to be the major cause of quality of care, while a process provides judgments about the relationship between process and outcome. Finally, outcome is considered because, according to physicians, patients' health and well-being are the most desired outcome. However, outcome has the advantage of showing the quality of the patient's treatment as well as the skill with which the care was given. Also, patients are able to evaluate many outcomes, allowing them to evaluate the quality of care they have received.

He also noted that patient care has technical and interpersonal factors. In particular, quality services are the degree to which patient care increases the likelihood of desirable outcomes and reduces the likelihood of undesirable outcomes.

Patient satisfaction often is measured to improve service efforts, fulfill accreditation requirements of health plans, receive reimbursement from the government agencies, and calculate financial bonuses for doctors. For example, surveys may be used to identify areas of weakness and to make necessary changes, such as adjusting patient appointment patterns for more effective scheduling and developing new policies. Physicians also may use this information to help negotiate third-party contracts, measure specific initiatives, train staff, and increase employee morale. In a competitive healthcare environment, marketing surveys help provide insight into patient expectations and the demands for services. Organizations and providers, who utilize these results to improve care, maintain a competitive position in the marketplace. Differences in measurement tools, however, are a barrier in making patient satisfaction a reliable benchmark. Patient satisfaction data typically is collected by various organizations, for different purposes, and at different levels in the healthcare system. With the recent launch of the hospital report card initiative by the Department of Health and Human Services, efforts have begun to bring consistency to measuring patient satisfaction at healthcare centers.

Patient satisfaction also is an important index because patients use services continuously, recommend healthcare services to others, and comply much more readily with physicians' recommendations. Low patient satisfaction is associated with lower trust in caregivers and greater chance of a change of health providers, resulting in less continuity of care. Furthermore, low patient satisfaction also is associated with a greater number of patient complaints and malpractice lawsuits.

Satisfaction is related to the overall effectiveness of communication between physicians and patients. Studies have indicated that empathy and patient-centeredness during consultations, for example, increased patient satisfaction and better compliance with healthcare provider recommendations. Noncompliance toward healthcare services is attributed to a lack of intimate and effective communication between the patients and physicians. Therefore, teaching and assessing communication skills are critical components in health professionals education designed to improve the communication knowledge and skills of health providers. .

Complaints in healthcare settings are two times more likely to be related to communication problems than to medical techniques. Additionally, higher patient trust and satisfaction occurs when a healthcare receiver is more involved in his or her treatment.

Further, an increased focus on enhancing relationships with patients also can result in a reduction in medical errors because patients are more comfortable asking about their medications and treatment.

Immigrants have specific needs that influence their perception of a satisfactory experience. Availability of translators, providers who understand their culture and language, systems that account for their family members, food preferences and health beliefs may be central to them having a satisfactory experience. Immigrants may be reluctant to respond to efforts to assess their satisfaction if they perceive a language barrier or fear consequences (such as deportation or discrimination) to their responses. Therefore, determination of patient satisfaction in immigrant populations must include culturally sensitive queries and appropriate quality benchmarks.

Pediatrics

Amy R. Grube
Department of Pediatrics, Rainbow Babies and
Children's Hospital, Cleveland, OH, USA

Children of all ages migrate across the globe. Exact numbers are unknown, but there are estimated to be at least 20 million migrant children worldwide. The United States is the top destination country for all immigrants. This encyclopedic entry will address the issues pertaining to child migrants around the world and focus specifically on those children entering the United States. It will include children migrating with their families, refugees, international adoptees, and children and adolescents traveling alone. In this entry, migrant children in the United State will include U.S.-born children living in families with immigrant and undocumented parents. These children face many of the same issues as non-US-born children.

Demographics

Seventy million children live in the United States today; 2.3 million were born outside of the United States to foreign-born parents, and 13.9 million were born in the United States to foreign-born parents. One in five children in the United States lives in a family in which at least one parent is an immigrant. Today, the majority of immigrants to the United States come from Latin America and Asia. In addition, each year, US families adopt more than 20,000 children internationally. Very few statistics regarding child immigration in countries outside the United States are available. However, one study conducted by UNICEF in the UK reports 4,285 unaccompanied children entered that country in the year 2008 alone.

Children migrate both with their families and independently. Children under the age of 18 years migrate without their parents for a variety of reasons, including fleeing their own families, fleeing war or political upheaval, natural disasters, extreme poverty, and escape from forced labor. Many are victims of human trafficking. Still others are sent by their families to initiate networks for other arrivals, to be cared for by other families, or to receive education. Several thousand adolescents immigrate to the United States unaccompanied each year. In 2008, over 8,000 unaccompanied immigrant children were taken into custody by United States immigration authorities.

Although not technically immigrants, over three million children come to the United States each year as temporary visitors, usually accompanying their parents who may be temporary workers, diplomats, or students. A portion of these children are exchange students traveling alone. A small segment of US immigrant families with children are educated, financially stable, and coming from a market economy. This group of children typically has very few health problems on arrival to their new country. However, some of these children may have medical issues similar to those of immigrants. Several thousand children travel each year to the United States through various humanitarian organizations in order to receive medical care for various congenital defects, cancer treatment, and rehabilitation. Some stay with foster families for several years while receiving care.

Civil Rights

Migrant children around the world are at a high risk of being abused and being denied basic rights. They are forced into child labor and early marriage. They may become victims of violence, neglect, and exploitation. While the United States grants automatic citizenship to anyone born on its soil, this is not the case around the world. Depending on the country's laws and particular circumstances of the parents' citizenship and nationality, it is possible for a child to be born and there be no official registration of birth and the child to be without citizenship anywhere. These children are essentially "stateless" and cannot claim the rights or protections that come with citizenship.

The number of unaccompanied minors immigrating to Europe rose 40% from 2007 to 2008. In 2008, unaccompanied minors in 22 European states filed 11,000 requests for asylum. European Union law allows for the detention of "irregular migrants" and asylum seekers for up to 18 months. Depending on the laws of the country they have entered, children may be detained in harsh conditions for extended periods of time. Often times, children are housed with adults which increases their risk of abuse. Research in Europe has found that the immigration detention centers are poorly equipped for children. Children in these centers experience violence, abuse, overcrowding, and do not receive schooling. They often are kept from family members and access to service providers for long periods of time. Additionally, staff members of the centers are not trained in the needs of children and reports of suicide have been noted.

Human Trafficking

Every year, thousands of foreign-born children arrive in the United States unaccompanied. Among those taken into federal custody to undergo immigration processing, many have been trafficked, persecuted in their home countries, or subjected to domestic violence, abuse, and neglect. On December 23, 2008, the William Wilberforce Trafficking Victims was passed in the United States. Among other things, it provides a 90-day interim of assistance to child victims of trafficking, it determines the eligibility for long-term assistance, and provides a program to protect and repatriate alien children and ensures that they receive critical services.

Health Screening

Health-screening strategies for newly arrived immigrants can be found in the U.S. government Centers for Disease Control and Prevention's (CDC) *History and Physical Guidelines* and The American Academy of Pediatrics' *Policy Statement on Providing Care for Immigrant, Homeless and Migrant Children.* Several points from their published guidelines are particularly salient.

- Children should be screened within 3 weeks of arrival to the United States or sooner if medically indicated. All internationally adopted children are required to have a medical exam performed by a physician designated by the US State Department in their country of origin (panel physician). It is not a comprehensive exam of the child's health but screens for certain communicable diseases and serious physical or mental defects that would prevent the issue of a permanent residency visa.
- Child refugees may have been residing in refugee processing camps and will have had access to basic medical care and treatment but not a comprehensive assessment. Growth and development measures should be plotted on standardized growth charts. Children who were previously in refugee camps may have growth charts from the camp.
- Children born outside the United States often suffer from malnourishment, which can lead to growth stunting and poor weight gain or even weight loss. Immigrant children frequently do not meet established height for weight, weight for age, or head circumference standards. Many will experience catch-up growth over the first year of their arrival but should be monitored.
- Internationally adopted children have high rates of developmental delays, and screening for developmental delay should be included in their initial well-child assessment.
- Although in the United States there are standardized newborn screens performed at birth, this is often not the case for foreign-born children and diseases such as congenital syphilis, hemoglobinopathies, and inborn errors of metabolism must be considered. Congenital cardiac disease is often undiagnosed in immigrant children and should also be considered.
- A thorough dental assessment of children is very important. Dental problems and disease are among the most common complaints of children entering the United States. In elementary school, immigrant children have been found to have twice the number of cavities in primary teeth as compared to their US-born counterparts.
- Hearing and vision assessments should also be performed.
- A medication history should be taken, and caregivers should ask about traditional and herbal medicines, home remedies, and traditional therapies unique to their culture. Many of these substances can have potentially serious interactions as well as contain contaminates if purchased outside the United States (e.g., lead and other toxins).

Vaccines and Disease

A review of an immigrant child's vaccination status is important but often impossible to obtain. Frequently, records do not exist, are incomplete, or get lost during migration.

The *American Academy of Pediatrics Redbook* provides detailed vaccine guidance. People immigrating to the United States after 1996 must show proof of at least the first doses of all the recommended vaccines in the current immunization series. This applies to almost all children entering the United States. There are several exceptions: (1) A vaccine is not required if it is not available in their country of origin. (2) Children under the age of 10 years who are being internationally adopted by US parents are exempt from the requirement as long as the adoptive parents sign a waiver that states they intend to comply with the ACIP immunization requirements after the child arrives in the United States. (3) Refugees are not required to comply at the time of entry but must show proof of immunization when they apply for permanent residency.

Children who were living in refugee camps prior to entering the United States may have received some immunizations in the camp but rarely have documentation demonstrating completion of the required immunizations. Either a new record may be established or measurement of antibody concentrations may be performed. Vaccines for Children (VFC) is a US governmental program that provides free vaccines for providers that can be administered to children without insurance. Immigrants are not excluded.

Antibody concentrations to the following may be tested if deemed necessary to determine whether a child needs additional immunizations: diphtheria, tetanus, measles, mumps, rubella, varicella, poliovirus (each serotype), and anti-HBs. If the child is from a Hepatitis B endemic area, then HBsAg and anti-HBc are also required.

Although wild-type polio has been eradicated from the Western Hemisphere, it is still found in at least six countries: Afghanistan, India, Pakistan, Nigeria, Niger, and Egypt. Importation of measles is a significant source of measles cases in the United States. Measles antibody can be measured, but it is often not necessary because many children will need a dose of mumps and rubella vaccines since these are not routinely given in developing countries, and measles, mumps, and rubella are combined in one vaccine, the MMR.

Clinical histories of rubella and varicella are not considered acceptable evidence of immunity, and the children should have antibody testing performed.

Immigrant children often have diseases that are infrequent in the United States, including malaria, amoebiasis, and schistosomiasis. Immigrant children are considered to be 100 times or more at risk of contracting tuberculosis than US-born children. In comparison to adults, children who have been infected with mycobacterium tuberculosis are at an increased risk of going on to develop active disease. Infants are up to 40 times more likely to develop active disease if untreated. More information regarding vaccination and screening for specific diseases is available both in the *Redbook* and through the Centers for Disease Control and Prevention.

Migrant Workers

It is currently estimated that between three and five million migrant farm workers and their dependents live in the United States. Most are Spanish speaking.

Children of migrant workers experience unmet medical needs at a proportion 24 times that of US children overall. One study found that 80% of migrant workers' children had never had a dental exam. Preschool age migrant children were at a significantly higher risk of having unmet medical needs. Reasons for the lack of care included lack of transportation, lack of knowledge of where to go for care, and an inability to leave work for a child's medical care for fear of losing their job.

Children of migrant farm workers of all ages are at increased risk of respiratory and ear infections, bacterial and viral gastroenteritis, intestinal parasites, and dental problems.

Furthermore, migrant children are at risk of lead and pesticide exposure, unintentional and intentional injuries, occupational injuries, and substance abuse. In addition to screening all immigrant children for lead after arrival, consideration should be given to screening the children again in the future because immigrants are more likely to live in poor housing on arrival to the United States and are at a new risk for lead exposure.

Parents and older children should be asked regarding their work history in order to determine possible environmental and chemical exposures.

Adolescents

Childhood and adolescence are the time when activities that promote health and prevent illness produce maximum results. Interventions can significantly affect risk-taking behavior, such as smoking, substance abuse, and high-risk sexual activity.

In addition to questions regarding alcohol and tobacco use, questions should be asked regarding the use of other substances that are common in the immigrant's country. Important examples include: betel nut, "khat" or "qat, "and "hookah." Hookah, also known as sheesha or argileh, is a form of tobacco smoking using a water pipe that many erroneously think is safer than cigarette smoking, when in fact smoking an argileh for a typical session of 40–60 min is comparable to smoking 100–200 cigarettes in terms of the amount of smoke and nicotine that is inhaled. Argileh smoke contains tar, nicotine, and heavy metals. Children exposed to secondhand smoke are at risk for SIDS (sudden infant death syndrome), asthma, ear and throat infections, and permanent loss of lung function. Hookah is popular throughout the Middle East, Asia, Philippines, Southeast Asia, and South Africa.

Psychological Impact

Immigrant children are at risk for psychological distress and may go on to develop mental illnesses resulting from their exposure to traumatic events, war-related violence, and the upheaval and displacement of the migration process itself. Immigrant children may display symptoms of depression, grief, anxiety, posttraumatic stress disorder (PTSD), and conduct disorders. Psychological symptoms in children exposed to violent conflicts include regression, withdrawal, nightmares, and anxiety.

Some studies have shown that children who witness traumatic events, including mass murders, bombings, and abuses frequently develop PTSD, anxiety, and depression. Moreover, if the experience affects their nuclear family or they experience personal loss or harm (e.g., the loss of a parent or witnessing a family member's murder), they are particularly at risk for psychological trauma.

Other studies have shown that a child's culture and region of origin affects their symptoms and expression of emotional distress. For instance, in 1996, a report by McCloskey and Southwick stated that Latin American refugee children present with many of the same problems as children from Southeast Asia; however, the Latin American children have more prevalent academic and conduct problems, while the Southeast Asian youth were more likely to display withdrawal.

US-born citizen children whose parents have been deported have been reported to have an array of changes in their behavior, including increased crying, withdrawal, aggression, and changes in their sleeping and eating habits. Children who witnessed their parents' arrest seemed to be the most affected.

Undocumented Immigrants

According to the Urban Institute, there are 5.5 million children currently living in the United States with one or more undocumented parents. It is estimated that two-thirds of these children are US-born citizens themselves. Approximately 37% of these children are 5 years old and under.

While the majority of their U.S.-born children are under 10 years of age, immigrant parents' adolescent children are most often foreign-born and not citizens. This has wide implications. The Urban Institute has published studies regarding the affects of parental deportation on the children left behind. When parents are arrested or detained, young children are often left stranded without care. Many times, parents do not report to authorities that they have children for fear of losing them to child welfare services. Long-term detention without access to telephones or in remote facilities is particularly hard on families with small children. Frequently, other family members and friends go into hiding quickly after a workplace raid or when family and friends have been detained and do not want to be discovered for fear of deportation. It then becomes very difficult for attorneys and social workers to make contact with them or to arrange care for the children left behind. This further disrupts the children's already unstable lives. Sometimes, other immigrant family or friends will take the children into their homes, which often forces the children into more crowded and poorer living conditions, putting them at risk of food insecurity and general hardship. While the parents are in detainment (detention) centers, they are unable to work and earn money and when parents are released, they are often not permitted to work for several months while their cases are pending worsening their economic position.

Government Assistance

It is difficult for both immigrant and U.S.-born children of immigrant parents to obtain public benefits and medical assistance, including health insurance. Children of immigrants live in lower income families than children of natives. One study found in 2003 that 54% of children of immigrants versus 36% of children of native-born parents had family incomes below twice the federal poverty level. Lower incomes are associated with food insecurity, crowded housing, poorer health, and lower rates of health insurance coverage in immigrant families. Yet young, low-income children of immigrants are significantly less likely to receive federal assistance than low-income children in nonimmigrant families.

In the United States, both the federal and individual state governments have medical assistance programs for immigrants. There are differences in eligibility requirements between the federal and state programs, as well as differences between individual. The terminology and requirements are complex and can be difficult for an English-speaking U.S. native and much less for an immigrant parent to understand. Until very recently, federally funded Medicaid and CHIP (Children's Health Insurance Program) were available only to "qualified" immigrants who have held the "qualified status" for at least 5 years. The definition of a "qualified" immigrant is available at the National Immigration Law Center. Certain refugees and other "humanitarian" immigrants were able to get Medicaid or CHIP without a 5-year waiting period. Some states denied federal Medicaid to most "qualified" immigrants who entered the United Sates on or after August 22, 1996, even after they completed the federal 5-year bar. In 2009, Congress passed the Children's Health Insurance Program Reauthorization Act (CHIPRA), giving states an opportunity to provide health coverage through Medicaid and CHIP for "lawful" immigrants without having to wait 5 years. Undocumented immigrants remain ineligible for nonemergency Medicaid and CHIP. States have the opportunity to choose whether to adopt the new CHIPRA option, which may mean there will continue to be a wide variation in health coverage for children across the United States.

Many of the current U.S. child and family government assistance policies to aid low-income families were enacted in the 1960s. However, the characteristics of "low income families" today are very different compared to when the programs were first designed. The number of U.S. immigrants has tripled in the last 35 years, and a large and growing share of low-income children in the United States live in immigrant families. The vast majority of U.S. immigrant families are Latino. Today, 22% of all U.S. children are Latino, and the number of school age children who speak Spanish number over seven million. This shift in demographics affects the governmental programs and institutions that assist children, including schools, health providers, and social service agencies. Additionally, the number of children of immigrants who are considered low-income and in need of government assistance is continually increasing due to the rising numbers of immigrant parents with little education, limited English, and worsening poverty.

According to the Pew Hispanic Center, the number of US-born children with an unauthorized parent has increased 48% since 2003. Although the majority of children in immigrant families are US citizens and fully eligible for public assistance and social service programs, their immigrant parents may be ineligible for these programs if they are undocumented or not legal permanent residents.

Many parents do not participate in or even apply for public benefit programs such as TANF (Temporary Assistance for Needy Families), food stamps, public housing, EITC (Earned Income Tax Credit), or Medicaid. A number of factors contribute to their lack of obtaining services. Some avoid any contact with governmental agencies. Parents fear discovery or deportation either for themselves or for other relatives or friends.

Some parents worry that accepting government assistance or public funds could impede their path toward citizenship or legalization. Further, parents do not understand that if their children were born in the United States, those children are eligible for SCHIP and Medicaid. Lastly, immigrant children's access to care can be significantly hindered if their parents have limited English skills, cannot read English, and do not understand the applications required to obtain aid. Not many states have the resources such as bilingual teachers or health interpreters to help immigrant families or their children. Immigrants need literacy skills in order to obtain and understand basic health information and services needed. In addition, they need literacy skills to interact with other social systems such as schools, social welfare, and the legal system that affect their children's well being.

There are estimated to be millions of child immigrants across the globe. Yet data regarding their numbers are lacking. More research is needed to quantify their numbers and circumstances in order to address their unique health and social needs as well as protect their basic rights.

Peer Education

Katherine Crow
WebMD Health Foundation, Rancho Santa Fe,
CA, USA

Peer education is an approach to health promotion. It is a tool or strategy used by people who share similar ages, backgrounds, or interests to communicate messages, raise awareness, and provide accurate information. Peers are traditional providers of information and talk to each other about sensitive issues they may not feel comfortable discussing with an authority figure. Peer education is provided in a multitude of venues including health clinics, churches, parks, recreational centers, homes, schools, and places where youth congregate.

Peer education is one of the most widely used strategies to address the HIV/AIDS pandemic; it has also been commonly used with other issues such as tobacco, alcohol, and other drug use; STI (sexually transmitted infections) and pregnancy prevention; and reproductive health. The purpose of peer education is to effect change at the individual level with the goal of modifying a person's knowledge, attitudes, beliefs, and behaviors.

Peer education has been viewed as a relatively inexpensive program strategy; however, there is an ongoing need for funds in order to adequately train, support, and supervise peer educators. Compensation of some kind is also critical for peer educators. This can come in several forms, for example, items that identify the program including bicycles, key rings, tee shirts, baseball caps, pens, and backpacks. Other incentives can include stipends, gift certificates, transportation support, community service credit, and the opportunity for personal and professional development.

Peer educators convey health promotion messages and information by leading group discussions and participating in individual conversations with peers; role playing; offering counseling, support, and referral services; and linking participants to health care services in the community. Peer educators are also able to access hard-to-reach populations, such as homeless youth and immigrant communities with language barriers, who otherwise may not seek out services or information.

Percent Body Fat

Ming-Chin Yeh[1], Anahí Viladrich[2]
[1]School of Public Health, Hunter College, City University of New York (CUNY), New York, NY, USA
[2]Department of Sociology, Queens College, City University of New York (CUNY), Flushing, NY, USA

Percent body fat is a measure of body fat in relation to body weight and is calculated as the total weight of a person's body fat divided by the person's body weight. There are several techniques of measuring body fat, including anthropometry (e.g., skinfolds and waist circumferences), density (e.g., underwater weighing), and conductivity (e.g., bioelectrical impedance). Sophisticated radiographic (X-ray) techniques such as the duel energy X-ray absorptiometry (DEXA) also exist and are used mostly in clinical and research settings. DEXA employs two beams of X-rays that pass through body harmlessly and could differentiate muscle tissue, fat tissue, and bone tissue. It provides high-quality assessments of total body fatness and fat distribution.

Due to its direct measure of body composition, percent body fatness obtained through techniques such as DEXA is considered a more precise measurement of an individual's fatness level compared with the body mass index (BMI), a widely used measure that estimates body fatness through a formula using a person's weight and height (BMI=weight in [kg]/height in [m^2]).

Ideal percent body fat varies depending primarily on gender and age. It has been recommended that a healthy range for men is between 12% and 20%, and for women it is between 20% and 30%. As for indications of excessive body fat, data have suggested the following cutoffs: a body fat percentage at or above 22% for men and 32% for women age 40 and younger, whereas a body fat percentage at or above 25% for men and 35% for women over age 40. However, these cutoffs are not the same for all individuals. Other factors such as lifestyle or stage of life may also influence the required fatness. For example, elite marathon runners often have a lower body fat level compared with the general population. On the contrary, pregnant women may need additional fat to ensure proper fetal growth. It has been estimated that the increase in the percentage of body fat during pregnancy ranges from 2.6% to 8%.

A high level of body fat is often associated with a greater risk of diseases and consequent mortalities. For example, using BMI as a proxy for body fatness, prior research has shown that people with a higher BMI level (presumably a higher level of body fatness) have higher risks for developing cardiovascular disease, diabetes, hypertension, and certain types of cancer. Certain immigrant and/or minority populations, including Hispanics and African Americans, have higher BMIs compared with White Americans. Asians, on the other hand, generally have a lower BMI compared with other race/ethnic groups.

However, recent research seems to question the validity of using BMI as a proxy for body fatness. The discrepancy between BMI and percent body fat is especially profound among Asians. That is, for a given BMI, Asians have higher percent body fat than Whites. According to a recent literature review, Asians (Indonesians, Singaporean Chinese, Malays and Indians, and Hong Kong Chinese) had a higher percent body fat at a lower BMI compared to Whites. The research findings show that for the same BMI Asians' percent body fat was 3–5% points higher compared to Whites. For the same percent body fat, their BMI was 3–4 units lower compared to Whites.

These findings also apply to children. Using a sample of multiethnic children from New York City as well as children from China, researchers have found that, for the same BMI, Asian children have significantly higher percent body fat compared with African American and White children. In addition, girls are found to have higher percent body fat than boys.

The above findings seem to indicate that the relationship between percent body fat and BMI is ethnic specific and that the BMI threshold for defining obesity in Asians should be lower than the threshold for other ethnic groups. With obesity and its associated comorbidities on the rise rapidly, caution is warranted when applying universal BMI cutoffs across sex and ethnic groups. Percent body fat that measures body fatness directly should be an important measurement in assessing the risk of obesity and chronic diseases, especially among immigrant and/or minority populations.

Personality

Kristin L. Hicks
Department of Psychiatry, Mount Carmel Health Providers, Columbus, OH, USA

Personality, a term derived from *persona*, the Latin word for mask, refers to the organization of behavioral and emotional attributes that characterize a unique individual. A broad definition of personality typically includes dimensions of stability, determinism, and uniqueness; that is, personality changes little over time, is determined by both internal processes and external factors, and reflects an individual's distinctive qualities. Conceptualizations of personality date back at least 2,000 years to the work of Hippocrates, who described four basic human temperaments. Hippocrates thought temperament was related to a person's prominent bodily fluids, or *humors*: blood (*sanguine*), yellow bile (*choleric*), black bile (*melancholic*), and phlegm (*phlegmatic*). For example, a person with a kind, cheerful temperament would be described as sanguine, meaning his or her prominent bodily fluid was blood.

The nineteenth century marked several important advances in the understanding of personality. Franz Gall wrote about *phrenology*, the idea that a person's skull shape can reveal personality traits. The link between brain and personality was established when Phineas Gage experienced personality changes after an iron rod accidentally pierced his skull. Sigmund Freud began his career in psychiatry and neuroscience, and Auguste Comte described *la morale*, a science dedicated to the examination of the individual person as both "a cause and consequence of society."

In the early twentieth century, personality became a popular concept in the United States as Americans feared depersonalization, while they experienced rapid societal changes associated with industrialization, immigration, and urbanization. By the 1930s, personality psychology emerged as a scientific discipline, marked by the publication of Gordon Allport's monograph. Allport defined personality as "…the dynamic organization within the individual of those psychophysical systems that determine his unique adjustments to his environment".

There are several theoretical perspectives on personality and its development. Most can be grouped into one of the following classes: behavioral-genetic, social-cognitive, cultural, psychoanalytic, and humanistic. Trait theory, a behavioral-genetic approach that attempts to identify basic personality traits and their organizational structure, is probably the most fundamental perspective in personality psychology. As defined by the American Psychiatric Association's *Diagnostic and Statistical Manual* (DSM), personality traits are "prominent aspects of personality that are exhibited in a wide range of important social and personal contexts." Thus, according to trait theorists, a friendly person is likely to act friendly in any situation because of relatively stable personality traits. The *Five-Factor Model*, which organizes 30 common traits into five broad dimensions, is the most widely used structural model in personality psychology. The five dimensions are neuroticism, extroversion, openness, agreeableness, and conscientiousness. Neuroticism refers to a person's tendency to experience negative feelings, extroversion is measured by one's level of engagement with the external world, openness refers to imagination and curiosity, agreeableness reflects one's tendency to cooperate, and conscientiousness concerns impulse control.

While trait theory implies that personality and behavior are relatively stable in a given individual, it is evident that situational influences also affect the way a person thinks, acts, and feels. There has been considerable debate among psychologists regarding behavioral consistency, and from this emerged the "person–situation debate" of personality. Most contemporary behavioral-genetic perspectives acknowledge the fact that behavior results from an interaction between personality and situational forces and are thus "interactionist" in nature. Behavioral-genetic data from twin and adoption studies show that the heritability of many adult personality traits is between 0.40 to 0.60, with the remaining variability accounted for by a person's unique environment and experiences. In the late twentieth century, neuroscience advanced the study of personality psychology by introducing more objective tools for brain analysis such as positron emission tomography (PET) and functional magnetic resonance imaging (fMRI).

Social-cognitive theories emphasize the complex relationship between a person's environment, cognitions (thoughts), and behavior. The term "reciprocal determinism" is used to describe how this complex relationship shapes one's distinctive personality. An important concept in social-cognitive theory is "locus of control," which is the degree to which people believe they have control over their lives. People with an "internal" locus of control believe they are responsible for what happens in their lives while those with an "external" locus attribute life circumstances to fate, luck, or influential others. Locus of control is one example of a cognition that is likely to influence behavior.

Cultural theory holds that many qualities treated like personality traits are actually influenced by one's culture. Cultural psychologists view culture and personality as interdependent, since the very concept of the person is seen as socially constructed and variable across cultures. Proponents of this perspective prefer "constructionist" assessment methods, which emphasize the construction of meaning by cultural groups, rather than researchers. In constructionist assessment, an individual's dimensions or narratives of self and others are generated in his or her own terms. Many of the personality inventories developed around the world do not appear culture-specific, despite their local origins, because they are based on constructs imported from Western psychology.

Psychoanalytic theories, based on the work of Freud, explain human behavior in terms of interaction between the various components of personality. According to Freud, personality is shaped by the interaction of three components: the ego, superego, and id. Psychoanalysis emphasizes unconscious motivations and the conflicts between primal urges (id) and learned social mores (superego), stressing the importance of early childhood experiences in determining mature personality.

Humanistic theories emphasize that people have free will and play an active role in behavior. This approach places less emphasis on genes, past learning, and psychological conflicts, and instead explores the strengths and inner potential of each human being. Both psychoanalytic and humanistic perspectives regard the objective measurement of traits as too fragmented to fully capture personality development.

Several personality tests have emerged from the various theories of personality. These tests, commonly administered by psychologists, aim to assess aspects of a person's character that remain stable across a variety of situations. Some involve self-assessment questionnaires in which subjects rate themselves on a series of attitudes. The widely used Minnesota Multiphasic Personality Inventory (MMPI) uses a true–false questionnaire to delineate normal personality types from variants. Others, called projective tests, involve the evaluation of a person's responses to ambiguous pictures. The Rorschach inkblot test and the Thematic Apperception Test are examples of projective tests.

When personality traits are maladaptive and cause significant functional impairment or subjective distress, they may result in a personality disorder, as defined by the DSM. The DSM describes ten personality disorders: paranoid, schizoid, schizotypal, antisocial, borderline, histrionic, narcissistic, avoidant, dependent, and obsessive-compulsive. Many of these correspond to extreme variants of the "five factors" of personality. For example, paranoid personality disorder may be related to extremely low agreeableness, reflecting a wariness and mistrust of others.

In summary, personality is a complex and evolving area of study. Each individual has a unique combination of inherent abilities and preferences as well as learned responses. As a single model of personality is unlikely to account for all of its complexities, it may be most useful to integrate diverse perspectives, in recognition that personality is truly multidimensional.

Pesticides

Rhona P. Julien
US EPA Region 1, Boston, MA, USA
Harvard Extension School, Cambridge, MA, USA

Introduction

Pesticides are widely used in agricultural and residential settings and public places. According to the US Environmental Protection Agency (EPA), 213 million pounds of active ingredient (a.i.) are used in the nonagricultural sector compared to 675 million pounds a.i. in the agricultural sector. In an effort to safeguard the safe use and handling of pesticides, the US EPA is mandated under the federal insecticide, fungicide and Rodenticicide Act (FIFRA) to ensure the safe use and management of pesticides, and defines pesticides as "any substance or mixture of substances developed to prevent, destroy, repel or mitigate insects (i.e., insecticides), rodents (rodenticides), fungi (fungicides), or weeds (herbicides)."

Under FIFRA, EPA evaluates the risks posed by these substances prior to registration, and also reevaluates older pesticides already on the market. There are currently more than 1055 active ingredients registered as pesticides which are formulated into thousands of pesticide products that are sold in the USA.

Chemical pesticides compared to other forms of pest control, for example, biopesticides, antimicrobials, and other pest control devices, have traditionally been the pest control of choice in many households. They consist of several classes of pesticides, which generally exert their toxic effect on the nervous system (neurotoxins). Some examples are organophosphate pesticides, which exert toxicological health effects through the disruption of the enzyme, acetycholine esterase, an enzyme that is responsible for regulating the neurotransmitter, acetycholine at the cholinergic junctions of the nervous system; carbamate pesticides also inhibit the actions of acetylcholinesterase, however, the hydrolysis of carbamates occurs more rapidly than organophosphate and the toxic effect is reversible; organochlorines exert their toxic effect through the disturbance of the neuronal membrane which results in hyperexcitability of the nervous system. The pyrethroids are synthesized from the naturally occurring pesticide, pyrethrin found in the chrysanthemum plant. Pyrethroids exert their toxic effect by inhibiting ion movements across the nerve cell membrane.

Exposure to chemical pesticides occurs via three major pathways of exposure, that is, inhalation, ingestion (dietary and non-dietary), and dermal. Health response varies among individuals and is largely dependent on the health condition, age, and characteristics of exposed individuals, typically with more deleterious effects in individuals with compromised health, small children, and the elderly. These sensitive populations are especially vulnerable when frequency and duration of exposures to pesticides are extensive.

Below are some examples of studies of the workplace or the home, and information examining the relationship between adverse health effects and pesticide exposures, often in immigrant populations.

Examples of Research Conducted During the Period of 2000 and 2010 in Various Settings

Residential Setting

It is reported that in the USA, individuals spend more than 90% of their time indoors, and approximately 74% of households use pesticides. It is therefore logical to assume that indoor residential exposures can potentially be a significant exposure pathway for many individuals, especially occupants of urban multiunit dwellings with severe pest infestation, which may result in high prevalence of pesticide. This situation is especially true in older, poorly maintained housing stock where pesticide usage oftentimes includes the use of prohibited or restricted-use pesticides that are sometimes influenced by social networks.

A study conducted by Whyatt et al. with a cohort of African American and immigrant women of Dominican descent between the ages of 18–35 years found that there was a statistically significant association between birth weight and length and cord plasma chlorpyrifos and diazinon. Whyatt et al. concluded that the deficit in fetal growth among this cohort was associated with the prenatal exposure to diazinon and chlorpyrifos. However, these two pesticides were phasing out several years later due to the potential to cause adverse health effects to occupants, especially children. Whyatt and colleagues were able to also demonstrate that this association was no longer significant for babies born subsequent to the phase out.

In another study known as the Healthy Public Housing Initiative (HPHI), Julien and colleagues investigated the magnitude and distribution of pyrethroid and organophosphate pesticide loadings within public housing dwellings in Boston, Massachusetts. They collected dust samples from 42 households of which more than two-thirds were immigrants with Hispanic heritage. The dust samples were tested for 11 pyrethoids (e.g., permethrin and cyfluthrin) and two organophosphates (chlorpyrifos and diazinon) in house dust. Permethrin and chlorpyrifos were detected in kitchen floor wipes in all homes, followed in frequency of detects by diazinon (98%), cypermethrin (90%), and cyfluthrin (71%). The majority of homes had at least six pesticides and in some homes, banned or restricted use pesticides were also detected, which underscored the need for alternative pest management strategies that embrace the safe and judicious use of pest control products.

Other Settings

Agricultural

Studies have shown that children living in an agricultural community may experience higher levels of pesticides compared to children from nonagricultural community. Sources of exposures contributing to the elevated levels in children in agricultural communities are multifaceted and include exposures from pesticides being tracked into the home due to living in close proximity to a farm and from breast milk during lactation.

One of the many studies conducted under the auspices of the Center for the Health Assessment of Mothers and Children of Salinas (CHAMACOS) looked at the relationship between exposures to pesticides in utero and early post natal exposures to organophosphates and neonatal neurobehavior in humans. Study participants were largely Mexican immigrants who worked in the Salina Valley, an agricultural region in California. Cluster measurements were taken for "habituation, orientation, motor performance, range of state, regulation of state, autonomic stability, and reflex," were conducted using the Brazelton Neonatal Behavioral Assessment Scale (BNBAS). Young and colleagues examined this relationship in a cohort of 381 infants, 2 months old who were born to women attending the CHAMACOS center. The results from this longitudinal, birth cohort study found a significant association between OP exposure and an increase in the number of abnormal reflexes.

Another study that was conducted by Arcury and colleagues analyzed biological samples from 60 farmworker children, ages 1–6 years of age. These children were from an immigrant population of Hispanic heritage. Study results which showed metabolites of organophosphate pesticides, for example, parathion/methyl parathion detected in 90% of the children including the range of pesticide metabolites detected (0–7) were all indicative of an environment where multiple exposures to pesticides occurs. Because some of these pesticides are known to be persistent in the indoor environment, Arcury et al. concluded that more needs to be done to quantify and address these exposures.

Daycare

Wilson et al. conducted a study which monitored pesticide concentration in 10 day care centers. They focused on young children because of their rapidly developing bodies and immature immune systems and activity patterns that collectively increased their exposures to pesticides indoors. Wilson and colleagues monitored for select pesticides and other persistent pollutants, for example, organophosphate pesticides (diazinon, chlorpyrifos), organochlorine (DDT, chlordane), and lawn herbicide 2,4-dichlorophenoxyaceti because of their persistence in the indoor environment. Using the monitoring results, the researchers selected the centers with the lowest and highest levels of pesticide residues and obtained environmental and biological data from nine preschool children (including

Hispanic children from immigrant households) ages 2 to 5 years. Target pesticides, including persistent organic pesticides, were collected in several media (e.g., indoor floor dust, outdoor soil, solid and liquid food, hand wipes, and urine). Researchers found that the children's diet did contribute to their exposures to target substances but found no difference between their exposures at home when compared to the daycare.

Conclusion

These examples are studies that were conducted to expand on the body of literature around pesticide exposure and human health effects. It is by no means representative of all the studies and investigations that have been conducted to date in these settings. However, it is the hope that they provide some measure of insight into the type of research that has been conducted in order to shed some light on pesticides, pesticide prevalence, and the possible associations between pesticides and human health effects.

Peyote

Peter N. Jones
Bauu Institute, Boulder, CO, USA

Peyote (*Lophophora williamsii*) is a small, spineless cactus native to southwestern Texas and northern and central Mexico. In Mexico, peyote grows in the states of Chihuahua, Coahuila, Nuevo León, Tamaulipas, San Luis Potosi, and Zacatecas, while it is only found in a few counties in Texas bordering the Rio Grande River. Growing on or near desert scrub limestone hills, the cactus flowers sporadically, producing small edible pink fruit. The largest part of the cactus is located underground in a long, carrot-like root, while the aboveground portion of the cactus is the crown, which develops disc-shaped buttons no larger than 12 cm diameter that are cut, dried, and consumed.

History

Consumption and use of peyote by humans has been documented as far back as the middle Archaic period (8000–1000 BCE). The first, historically documented reports of peyote use by indigenous peoples of North America come from early Spanish missionary records, dating to the 1600s and early 1700s, and indicate that its use was sporadic but widespread across much of northern Mexico. In the 1800s, the use of peyote is believed to have increased among indigenous peoples, especially those living in the southern Plains of North America as a response to colonial and missionary pressures. Indigenous peoples in the southern Plains and northeastern Mexico began to incorporate certain indigenous peyote rituals into the newly imposed and supported Christian teachings, resulting in the formation of a syncretic set of practices and beliefs. Today, the use of peyote continues in the United States by Native Americans under the auspices of the Native American Church. In Mexico, indigenous and Mexican communities continue to use peyote for spiritual and medicinal purposes. Outside of these two population groups, consumption and use of peyote is very limited; however, development and traffic from immigrants crossing through Chihuahua and Coahuila into the United States has caused the cactus to become scarcer.

Consumption

The peyote cactus contains more than 55 alkaloids and related compounds, many of which have direct affects on human physiology and brain neurochemistry, but only lophophorine, anhalodine, anhalonidine, hordenine, pellotine, and mescaline have been studied. Although each peyote cactus contains all of these alkaloids, no two plants contain the exact same ratio of alkaloids and, therefore, there is no standard effective dose size. Anecdotal evidence suggests that four or more buttons, the dried tops of the peyote cactus, are required for any psychological effects to take place on a human individual.

Mescaline is considered by many pharmacologists to be the main psychologically active alkaloid in peyote, and it has been extensively studied compared to the other alkaloids. Mescaline is believed to affect the action of serotonin, one of the main neurotransmitters within the central nervous system. This hypothesis accommodates the wide array of physiological effects that mescaline has been reported to produce, including an increase in blood pressure, pulse rate, perspiration, breathing, motor activities, and body temperature.

The direct psychological actions of mescaline, unlike the physiological effects, have only recently begun to be understood. For example, research indicates that mescaline inhibits cholinergic neuromuscular transmission by blocking the release of the neurotransmitter acetylcholine at the neuron sites, affecting the storage of memories and the binding of information in the brain.

Likewise, mescaline has neurophysiological affects on the release and reuptake of the neurotransmitter serotonin and dopamine. It also appears to have access mediating effects on the flow of information to the cerebral cortex. Finally, mescaline has hemispheric-specific activation in the brain. That is, mescaline has activation-specific effects on the right hemisphere that may account for the reported effects of increased creativity, understanding, and visualization during ingestion.

Legal Status

Peyote is currently classified as a Schedule-I controlled substance under the Comprehensive Drug Abuse Prevention and Control Act of 1970. It is illegal for anyone to grow, import, possess, use, or distribute peyote. However, use of peyote by Native Americans is legal under 21 CFR 1307.31. Furthermore, the American Indian Religious Freedom Act of 1978 (AIRFA), which was subsequently reenacted by Congress in 1991, supports the use of peyote by members of the Native American Church (NAC). As such, AIRFA preserves the sacramental use of peyote, while 21 CFR preserves the legal use by Native American Church practitioners.

In Mexico, peyote is classified as a Schedule-I controlled substance, and it is illegal for anyone to grow, import, possess, use, or distribute peyote.

Philippines

Amy N. Sharpton
Department of Veterans Affairs, Louis Stokes DVA
Medical Center Cleveland, Brecksville, OH, USA

Introduction

Officially known as the *Republic of the Philippines*, the Philippines is an island nation located in the Malay Archipelago in Southeast Asia, a subregion of the continent of Asia. The country was named *Las Islas Filipinas*, The Philippine Islands, by Ruy López de Villalobos after King Philip II of Spain. Philippine culture has many resemblances with that of the West; for example, it is one of only two Roman Catholic countries in Asia, and English is one of the official languages.

History

The ancestors of the majority of the Filipino people settled in northern Luzon around 2500 BC, spreading through the Philippines and later colonizing most of maritime Southeast Asia and the Western Pacific Islands. The basic unit of settlement was the *barangay,* which was headed by a chief who was a leader over nobles, freemen, and dependents – including landless agricultural workers and slaves. Throughout the next 1,000 years, Muslim, Chinese, and Indian traders made contact with the Philippines. Traders and proselytizers from the Indonesian islands brought Islam, which by the sixteenth century, was established and reached the Manila area by 1565. Although in some areas Muslim immigrants set up territorial states ruled by rajas who exercised sovereignty over the barangay chief, animism, the belief that *everything is conscious*, or that *everything has a soul*, remained the religion of the majority of the Philippine islands.

Ferdinand Magellan and his crew were the first Europeans to arrive in the archipelago in 1521; thereafter, Magellan was killed at the hands of indigenous warriors. Miguel López de Legazpi arrived in 1565, forming the first Spanish settlements and paving the way for colonization. Roman Catholic missionaries converted most of the inhabitants.

Over the following 333 years, the Spanish military fought off indigenous revolts and external challenges. The most significant loss for Spain was the temporary occupation of the capital, Manila, by the British during the Seven Years' War. Before it was administered directly from Spain, from 1565 to 1821, the Philippines was governed from Mexico. The *Manila Galleon* traveled once or twice a year to Acapulco, Mexico, beginning in the late sixteenth century. The Philippines opened itself to world trade in 1834.

Demands for greater representation in Spain grew into a revolution in 1896, led by Andrés Bonifacio. Emilio Aguinaldo established a revolutionary government; however, revolutionary leader José Rizal was executed for treason on December 30, 1896. The Spanish–American War began in Cuba in 1898. The war soon reached the Philippines, as Commodore George Dewey defeated the Spanish squadron at Manila Bay. Aguinaldo declared the independence of the Philippines on June 12, 1898, and was proclaimed head of state. Together with Cuba, Guam, Puerto Rico, and Spain then ceded the Philippines to the USA; although by 1899, the USA was at war with Philippine revolutionaries. Though the struggle continued until 1913, Aguinaldo was captured by American troops in early 1901, at which time the USA proclaimed the war's end.

The country's status as a colony changed when it became the Commonwealth of the Philippines in 1935, which provided for more self-governance. On December 8, 1941, just 10 h after the attack on Pearl Harbor, Japan launched a surprise attack on the Philippines. The Philippine defense continued until the final surrender of US-Philippine forces on the Bataan Peninsula in April 1942 and on Corregidor in May. The majority of the 80,000 prisoners of war captured by the Japanese were forced on the infamous Bataan Death March to a prison camp 105 km to the north. Approximately 10,000 Filipinos and 1,200 Americans died before reaching the camp.

US General Douglas MacArthur's Allied forces landed on Leyte on October 20, 1944, while additional landings followed in other parts of the country. The Allies pushed toward Manila, and fighting continued until Japan's formal surrender on September 2, 1945. An estimated one million Filipinos had been killed, and Manila was extensively damaged.

Although the war had left the Philippines severely damaged, elections were held in April 1946, resulting in Manuel Roxas election as the first president. The Philippines achieved independence from the USA on July 4, 1946. After a series of presidents, Ferdinand Marcos was elected president in 1965. He initiated ambitious public works projects, intensified tax collection, and led the nation to unprecedented prosperity throughout the 1970s. With massive loans and economic aid from the USA, his administration built more roads than all his predecessors combined, and more schools than any previous administration. Although barred from seeking a third term, Marcos declared martial law on September 21, 1972, and ruled the country by decree. However, his authoritarian rule became marred by pervasive corruption.

Pressure against the Marcos regime crested when opposition leader Benigno Aquino, Jr., returned from exile and was assassinated on August 21, 1983. Following pressure from the USA and intense mass protests in the Philippines, on February 7, 1986, Marcos allowed a presidential election. The election was believed to be fraudulent, however, resulting in a heavily disputed outcome and a subsequent stand-off between military rebels and military loyalists, with protesters supporting the rebels. Soon, prominent cabinet officials resigned.

On February 22, 1986, a radio call for mass protest inspired the *People Power Revolution of 1986* (EDSA Revolution), 4 days of peaceful action by millions of Filipinos in Manila. The outcome of the action was the downfall of the Marcos regime and the inauguration of Corazon Aquino, widow of Benigno, as president. Government reforms and the return of democracy have been hindered, however, by substantial national debt, government corruption, coup attempts, a communist insurgency, and a Muslim separatist movement. Although the economy improved during the administration of Fidel V. Ramos, elected in 1992, the economic improvements were offset in 1997 by the East Asian financial crisis. The current administration, since June 30, 2010, includes President Benigno Aquino and Vice President Jejomar Binay.

Geography

The Philippines is an archipelago, a chain or cluster of islands, consisting more than 7,000 islands, with a total land area, including inland bodies of water, of approximately 300,000 km^2. It has the fifth longest coastline worldwide, with 36,000 km^2; it borders the Philippine Sea on the east, the South China Sea on the west, and the Celebes Sea on the south. The island of Borneo is located southwest and Taiwan is located directly to the north, while the Moluccas and Sulawesi are located to the south-southwest and Palau is located to the east of the islands.

The Philippines has a tropical maritime climate, usually characterized as hot and humid. There are three seasons: *tag-init* or *tag-araw*, the hot dry season or summer (March to May); *tag-ulan*, the rainy season (June to November); and *tag-lamig*, the cool dry season (December to February). Temperatures usually range from 21°C to 32°C, although it can vary depending on the season. The coolest month is January; the warmest is May.

Government

The Philippines is a constitutional republic with a presidential system of government, in which exists an executive branch that operates separately from the legislature – to which the executive branch is not responsible and by which the executive branch cannot be dismissed. It is governed as a sovereign state in which the central government is supreme and any administrative divisions, or subnational units, exercise only powers that the central government chooses to delegate. Frequently, countries are divided into subnational units, whereby simplifying the managing of the land and the affairs of the people. Subnational units are each granted a certain degree of autonomy and are required to manage themselves through their own local governments. The Autonomous Region in Muslim Mindanao, which is largely free from the national government, represents the sole exception to the country's inclusive sovereignty.

The Philippine President functions as the nation's head of state, head of government, and commander-in-chief of the armed forces. The president is elected by popular vote for a single 6-year term, during which he or she appoints and presides over the cabinet that represents the executive branch.

The Congress of the Philippines is its national legislature; it is bicameral, hence it has two chambers. The bicameral Congress is composed of the Senate that serves as the upper house, with members elected to a 6-year term, and the House of Representatives that serves as the lower house, with members elected to a 3-year term. The Senate is composed of 24 senators half of which are elected every 3 years. The senators do not represent a geographical district and are elected by the whole electorate, while the representatives are elected from both legislative districts and through sectoral representation.

The judicial power is vested in the Supreme Court, composed of a Chief Justice as its presiding officer and 14 associate justices who are appointed by the President. Since the Ramos administration, there have been attempts to change the government to a federal, unicameral, or parliamentary government.

Culture

Philippine culture is a combination of Eastern and Western cultures, with prominent facets that are noted in countries sharing a Malay heritage; nevertheless, its culture exhibits also significant Spanish and American influences. Common in the culture are traditional festivities known as *barrio fiestas* (district festivals) that are held to commemorate the feast days of patron saints; the Moriones Festival and Sinulog Festival are two of the most well known. These celebrations provide the community opportunities for feasting, music, and dancing.

However, due to modernization and the influence of other cultures, gradually, some traditions are being forgotten. The Bayanihan Philippine National Folk Dance Company has been extolled for its efforts to preserve the nation's traditional folk dances; in particular, dances such as the *tinikling* and *singkil* that feature the use of clashing bamboo poles. The tinikling, the National Dance of the Philippines, is an indigenous dance that involves two people beating, tapping, and sliding bamboo poles on the ground and against each other in coordination with one or more dancers who step over and in between the poles in a dance. The singkil, a popular dance performed during festive entertainment, is performed only by females and acts as an advertisement to would-be suitors. While manipulating fans, scarves, or their bare hands, the dancers step graciously in and out of clashing bamboo poles arranged in a parallel, rectangular, or crisscross fashion.

In terms of culture, one of the most obvious Spanish legacies is the Spanish architecture that has shaped the way many Philippine towns were designed around a central square or *plaza mayor*. Although many of the buildings reflecting Spain's influence were demolished during World War II, some examples remain, including churches, government buildings, and universities. Four Philippine baroque churches are included in the list of UNESCO World Heritage Sites.

An example of the American influence on Philippine society is the common use of the English language; this use has contributed to the influence of American pop cultural trends. Filipinos are regular consumers of contemporary American music and film.

Economy

With an estimated 2010 GDP of $189 billion, the national economy of the Philippines is the 45th largest worldwide. Primary exports include semiconductors and electronic products; transport equipment; garments; copper and petroleum products; and coconut oil and fruits. Major trading partners include China, Japan, the USA, Singapore, Hong Kong, and Saudi Arabia.

The Philippines is a newly industrialized country, with an economy that has been transitioning from one based on agriculture to one based more on services and manufacturing. Of the country's total labor force of approximately 38.1 million, the agricultural sector employs nearly 32%; however, it contributes to less than 14% of GDP. Conversely, the industrial sector employs approximately 13.7% of the workforce and accounts for 30% of GDP, and the 46.5% of the workforce involved in the services sector accounts for 56.2% of GDP.

Education

The Philippine Republic Act 9155 provides the framework for basic education in the Philippines; it provides for compulsory elementary education and free high-school education.

The National Statistics Office reports a simple literacy rate, the proportion of the population over age 15 that can read and write, of 93.4%, and a functional literacy rate of 84.1% for 2003. Literacy is about equal for males and females.

Filipino children may enter public school beginning at age four, although officially children enter elementary school at age 7 and attend for 6–7 years. Elementary school is followed for 4 years by secondary school, after which students may then sit for the College Entrance Examinations (CEE). Students who score well enough on the CEE may enter a tertiary institution for 3–5 years.

Though elementary schooling is compulsory, it is reported that 24% of Filipinos of the relevant age group do not attend. Reasons cited for lack of attendance include the absence of a school in the area, education being offered in a language that is foreign to the student, or financial distress. The school year in the Philippines is from June to March, with a 2-month break during April and May, a 1 week semester break during the last week of October, and a week or two of Christmas break.

Health Care

The majority of the health care burden is borne by private health providers. For example, in 2006, total expenditures on health care represented 3.8% of GDP; 67.1% from private expenditures, 32.9% was from government expenditures, and external resources accounted for 2.9%. Health expenditures represented about 6.1% of total government spending for 2006. The 2010 national health budget proposed $7 US per person. Retention of skilled practitioners is low, with approximately 70% of nursing graduates leaving the country to find employment. In 2001, there were about 1,700 hospitals, of which about 40% were government run and 60% private.

Migration

Since the 1970s, the Philippines has supplied thousands of skilled and low-skilled workers to the world's more developed regions. As of December 2004, an estimated 8.1 million Filipinos – nearly 10% of the country's 85 million people – were working and/or residing in close to 200 countries and territories. In the last 30 years, a "culture of migration" has emerged, with millions of Filipinos eager to work abroad. A nationwide survey of 1,200 adult respondents in 2002 found one in five Filipinos expressing a desire to migrate. Although the Philippines is largely a country of emigration, it does attract some immigrants. Traditionally, the foreign population in the Philippines consists of people of Chinese origin. Presently, there are roughly 36,000 foreign nationals working and residing in the Philippines.

Photonarrative

Ken Crane
Department of History, Politics, Society, La Sierra University, Riverside, CA, USA

Photonarrative is the use of photographic images to tell a story about an event or chronicle, or some aspect of a person's life. Some claim that the practice originated with the French artist Nadar who published a series of photographs of the chemist Chevruel, each with a caption of the spoken words at the time the photo was taken. Sometimes known as a Photo Essay, photonarrative is essentially is a visual means of telling a story about an event, a social problem, a segment of society. The practice may go by other monikers, but the process is similar whether utilized by journalists, photographers, or researchers.

In the history of photography, there have been notable examples of the power of photographs to tell stories. The photographs of Dorothea Lange and Paul Evans, who were commissioned by the federal government to document rural life during the Great Depression of the 1930s, put a face on the suffering of the Great Depression. Lange's photographs of labor camp families have become iconic, enduring representations of the suffering and desperation of migrant farm workers.

Some photo essayists try to capture the cultural and social life of subcultures and communities. They work more like ethnographers – anthropologists and sociologists who use images to give in-depth representations of people's culture and various social phenomena – taking time to immerse themselves into the life routines of their subjects and communities. Their photos attempt to tell the story of what life is like, not as posed for the camera, but as if the photographer were a "fly on the wall" simply observing people as they naturally behave. Some examples of this are Paul Fusco's essay of coal miners in West Virginia or Laura Wilson's portrayal of a Hutterite colony in Montana. Of course, the photographer never becomes entirely invisible, and there is always an element of intrusion.

This type of photonarrative is also used in combination with text that explains or elaborates on the subjects, provides an interpretation of the image, or the reasoning behind the choice of certain images over others. An example is James Agee's commentary on his collaborator Walker Evan's carefully structured photographs of poor rural families in the Southeast, or Hart Crane's poem "The Bridge," accompanied by Walker Evan's photo of the Brooklyn Bridge. However, Dorothea Lange and Paul Taylor, in their book *An American Exodus*, attempted to move beyond "explanation" and "illustration" to a "third effect" in the way photographs and text work in combination to provide a new means of expression that evokes an emotional experience in the viewer.

Photonarrative uses photographs of individuals to tell a story of problems faced by others in similar circumstances. The sociologist Morrie Schwartz allowed himself to be photographed while his debilitating disease left him slowly losing use of all his muscles. While an interesting individual in his own right who would later be featured in the book "Tuesdays with Morrie," his story illustrates the challenges of aging, and of how not only the elderly, but also how people with health issues maintain human dignity in the face of losing control of bodily functions.

Photonarration is used to document events as they unfold, such as Paul Fusco's photographs of the farm-worker strike led by César Chávez. These images capture something of the atmosphere of the event. Journalist Tom Stanton vividly captured the feeling of despair during the siege of Sarajevo, particularly the fear in people's faces as they ran through "sniper alley." Likewise, Sebastião Salgado's large format black and white depictions of displacement, refugees, and laborers show the hardship of their experience etched in faces and bodies.

In the emerging fields of visual anthropology and sociology, there is a long history of using photographs to show various sides of the human experience, from portrayals of culture to documenting social problems. While the photographs are often used to supplement a scholarly text, they nevertheless stand on their own as a powerful and compelling narrative. Sociologist-ethnographer Steve Gold's photographs of Vietnamese and Russian immigrants in Los Angeles are a fine example.

Photographs have been used in the social sciences as interview tools. This is known as photo-elicitation, and carefully chosen photographs are utilized as the main prompts in open-ended interviewing. More recently, a new kind of methodology using photonarrative has been developed to facilitate conversations about a concern or issue in the community, and further to involve people significantly in research by having them use photographs to tell stories. Pioneered by public health scholar Caroline Wang, this technique is known as "photovoice." Photovoice puts simple cameras in the hands of ordinary people and trains them to take photographs of their lives and issues in the community that concern them. In similar fashion, filmmakers Briski and Kauffman used this technique with children of prostitutes in Mumbai's red light district. These photos are collected and used to generate discussion of community concerns from multiple perspectives. Caroline Wang used the photovoice method in China's Yunnan Province. Women in rural communities used cameras to chronicle their daily lives and to express their concerns and aspirations, and ultimately to bring these messages into policy decisions that affect their quality of life. In this type of photonarrative, the images are not the carefully constructed aesthetic of a Walker Evans, but rather the attempts to capture the common events of daily life and communal activity.

Physical Activity

Raymond R. Hyatt
Public Health and Community Medicine, Tufts University School of Medicine, Boston, MA, USA

Immigration is often motivated out of a desire to improve the quality of one's life and the lives of one's offspring. Immigrants throughout the world may expect to find employment, better roads, clean water, public sanitation, and more, and perhaps higher-quality, educational opportunities for themselves and their children through access to public and private schools. Whether improvements are measured in terms of direct instrumental support or in terms of perceived opportunities, the scale of the effort to relocate one's self and family as well is weighed against these perceived benefits. People who migrate to a new country, particularly those who migrate from developing countries to the developed world, may also expect to find higher quality health care along with greater access, and a lifestyle where the risk of injury and accident are reduced and where healthy lifestyles are reinforced and supported. With respect to education and economic opportunity, these expectations are often met. However, there is overwhelming evidence that the pot of healthy lifestyle gold may not be waiting at the end of the migration rainbow.

Immigrants from developing countries, for example, often find many of these benefits when they arrive in the more developed world and continue to experience even greater benefits as their residence extends. At the same time, though, they also find themselves at much greater risk for weight gain, obesity, and the associated risks for chronic disease as they adapt to their new society. In this time of unprecedented international mobility and migration, the implications for the health of immigrants and the impact on provision of health care are staggering.

The underlying mechanism of weight gain and obesity is energy balance – calories consumed versus calories expended, or simply diet and physical activity. In particular, this discussion will focus on the relationship between immigration and opportunities for, and changes in, levels of physical activity. I will begin with a brief overview of the issues linking immigration and changes in physical activity, then turn to specific barriers to physical activity facing immigrants in more developed countries, and conclude with some suggestions for improving opportunities for physical activity for new immigrants.

The aspect of immigration that seems most often studied, either directly to assess a hypothesis within the research design, or as a control or adjustment when examining characteristics of immigration, is acculturation. Despite the difficulties in defining and measuring the concept of acculturation, researchers often look to this concept when trying to understand the consequences of migration. In very broad terms, we can define acculturation as a process of acquiring cultural capital in a destination country, a process embedded in migration. This process often requires the acquisition of some level of skill in the dominant language in the host country to facilitate exchange enabling employment, education, and access to services, including health care. Even a cursory review of the literature on immigration demonstrates the reliance of researchers on language skills as a measure of acculturation. The other dominant approach has been to use the length of time in the destination country as a proxy for acculturation. Both measures are used to represent the socialization that an immigrant will experience in their new social context.

Of course, acculturation is much more than language or time in a new country. Acculturation implies an understanding and adoption of social norms and values, local customs and expectations, and knowledge of one's context. Importantly though, in whatever manner we measure the concept of acculturation, we see that acculturation is associated with lower levels of physical activity among immigrants, regardless of their country of origin. In terms of overweight and obesity, immigrants are often likely to have had a healthier diet and more a physically activity lifestyle prior to their migration to a more developed country. While increased access to food and a more regulated, and perhaps safer, work environment are factors that can benefit immigrants in developed countries, immigrants also experience weight gain, obesity, and increased risk for chronic disease.

The reasons for this are many, and they are complex. They include the structure of transportation in the developed world which is decidedly in favor of the automobile as opposed to walking or use of public transportation. While the physical environment and norms in an immigrant's country of origin may be in favor of walking as a mode of transportation, where the expectation is to walk to and from school, work, or the local market, in the United States as in many developed countries, walking is not seen as transportation but as exercise. Walking is something additional, often at either the beginning or the end of a busy day on a stationary treadmill and not an integrated part of working, shopping, and commuting.

This limitation to physical activity is exacerbated by changes immigrants will find in both workplace activity and economic pressures. While immigrants often have more than one job to make ends meet and accept jobs that community workers are unwilling to accept, they also frequently find themselves in more sedentary occupations than they held in their country of origin. In the destination country, immigrants may find themselves in occupations such as store clerk, shop keeper, taxi driver, and computer programmer compared with the more active occupations like construction worker, painter, janitor, etc. When listening to immigrants talk about changes in their lifestyle within their new host country, one often hears how walking was a valued part of premigration life. They talk of people walking to and from their jobs, schools, markets, and social engagements, and about the culture of being out of doors in their country of origin. Many immigrants speak of sitting outside in the evening on the front steps to their home or in the front yard while neighbors, friends, and relatives would walk by and stop to chat from time-to-time only to then take they own turn on the evening neighborhood promenade stopping to visit and socialize with local families.

By contrast, developed societies depend more heavily on motorized transportation for many activities, including commuting to work or school, routine shopping for food and other necessary goods, and even for recreation. Pass by a school playground used for soccer on a Saturday morning and you will observe the resulting traffic jam and parking problems. The implicit message to those coming to developed societies may well be that walking is a sign of poverty and low social status and that if you are to belong in the new society, you will learn to drive yourself and your children to and from such destinations.

The built environment in developed countries adds another layer of barriers to physical activity for immigrants which are nonetheless barriers for the local population as well. The absence of sidewalks and poor street lighting has been shown to discourage physical activity and walking as transportation in neighborhoods throughout the world. The presence of trash, vacant lots, unrepaired buildings, bars, liquor stores, and even all-night convenience stores has been linked to lowered physical activity in residents within a self-described catchment area. Uneven walkways, streets busy with fast moving cars, and the noise and pollution from high-density traffic areas, all lead us to find ways to reduce exposure by limiting our time in outdoor activities. Further, as immigrants in the Western world have, on average, lower income jobs, they find themselves living in urban areas with high poverty, low resources, and high crime. In these types of urban, and rural areas as well, here is a perception that the environment is not safe, particularly for children. Add to this, the difficulties of language and the intense social stigma attached to immigrants in many developed countries and the idea of taking a walk becomes unacceptable.

Many studies note the need for safe walkways, green spaces, bike paths, and bike lanes on popular streets. Our market and shopping areas are congregated in the suburbs, where driving to work, shop, or play is required. Urban areas, where many immigrants live, are left to be serviced by convenience stores with limited choices and very little fresh or perishable food. Fresh food is frequently only available in supermarkets that are often located in areas where large, if not enormous, parking lots can be constructed once again reinforcing the need for powered-vehicle transport in order to buy fresh food.

Physical activity can also be limited by the lack of knowledge of one’s surroundings, a lack of equipment and clothing, and a lack of necessary skills or training. In a study of Somali youth who migrated to Maine with their families, barriers to physical activity included no knowledge of, or skill in, winter sports, a lack of winter “gear,” and, most importantly, cultural issues around appropriate winter attire, in particular the wearing of pants for adolescent Somali females. When these issues of appropriate winter clothing where addressed in a culturally appropriate manner, winter physical activity became an option for the Somali girls. In the absence of such solutions, though, immigrant children, and adults, experience barriers to physical activity simply due to their personal and social values and beliefs. A challenge in this regard is to ascertain the steps necessary to find balance for both the immigrant and existing populations.

Immigrants themselves are aware of the differences in lifestyle pre- to postmigration. Within the context of both completed and ongoing work in the area of nutrition and physical activity, this author has facilitated and attended several meetings with members of three immigrant communities (Brazilians, Haitians, and Latinos) in Somerville, MA, to discuss opportunities and barriers to physical activity and healthy lifestyle. Themes that have emerged throughout these conversations are:

- Work-related time constraints are fundamental obstacles to physical activity, healthy eating, and family meals. Immigrants often have more than one low-income job, most often, both parents work.
- The rigidity of parents’ work schedules makes it difficult to enforce children’s behavior.
- The built environment is not supportive of physical activity and many immigrants experience difficulty

adjusting to a colder climate and find temperature to be a barrier to exercise.

- Junk food is seen as a luxury in many developing countries. It is expensive and used as a special treat for events like a birthday celebration. In much of the developed world, junk food is available, appealing, affordable, and consumed regularly, every day.
- Younger generations favor assimilation more than their parents. This shift is noted in preferences of language, style of dress, and food selections putting immigrant youth at even higher risk for long-term health issues related to nutrition and physical activity.
- There is little support for immigrant physical activity in the community, particularly within the existing population. Institutions and governments could do much more to facilitate opportunities for physical activity in immigrant communities.
- Common foods that were readily available in the country of origin are often in short supply or not available in the new host country, and the supermarket may be too far away from where they live. Ways to enable higher-quality food access in low-income and immigrant neighborhoods should be addressed.

Conclusion

More work needs to be done to better understand the barriers and opportunities to increased physical activity for immigrants. Each of the themes above could be used to generate one or more hypotheses and/or public health interventions to address a specific facet of immigrant physical activity. Looking downstream from an immigrant's point of entry, host countries may want to look at employment practices that inhibit physical activity for both immigrant adults and their children. Minimum wage policies and work schedules combined with school schedules may make time for physical activity unattainable for both children and adults. As developed societies, we need to consider the type of society we are creating and cost of poverty to both individuals and to our societies in terms of poor health outcomes, functional limitation, and hospitalization.

Developed societies which are most often the destinations for immigrants should consider how healthy lifestyles and active living are supported. This is important for the existing populations and well as for immigrants. Walkable areas, bike paths, street lighting, traffic control, sidewalks, and integrated communities, where office, shopping, and living are within walking distance as opposed to urban/suburban development, are being designed to help address the sedentary lifestyle of the developed world. The framework of supports and barriers to physical activity constructed and maintained by our institutions, including government, as well as our norms and values must also be examined further. Representatives of one large immigrant population in Massachusetts suggested that universities that study immigrant populations do not do much to support healthy lifestyles in those communities. They cited the scale of athletic facilities, gyms, pools, health centers, etc., and asked why none of these were open to community members. Even in places where institutions do make buildings available, the open time itself is likely not enough to create an effective result. Immigrant populations may need instruction on how, why, and when to use certain facilities and equipment. In every meeting, where immigrant community members spoke, knowledge and education were among the first solutions they would suggest. "We need to know where we can go for physical exercise in the winter?" "We would like to exercise but who will take care of our children?" "How do we walk in our neighborhood when we are worried if it is safe?"

Established communities need to understand why it is important to make some of these changes. Many such changes will benefit those already in the community at least as much they do new immigrants. While socialization of new immigrants and expectations of acculturation are important, developed societies can benefit greatly from understanding the unhealthy effects of migration on new immigrants, particularly in the areas of physical activity and nutrition. Research shows clearly that the benefits of healthy communities extend beyond political and social boundaries and thus have a positive impact the health outcomes of nations.

Physician–Patient Communication

M. Barton Laws
Department of Health Services Policy and Practice,
Brown University, Providence, RI, USA

Communicating with patients may well be the most important element of clinical practice. It is also among the most complex and least well understood. Physician–patient communication is problematic for everyone. International migrants may face additional difficulties, but these are best understood as exacerbations of the standard problem.

Medicine is a professional service so physician–patient communication is generally thought of first in functional terms. The physician must collect information to understand the patient's health history and condition and make diagnoses and treatment recommendations; provide information and explanations to the patient; and promote adherence to medical advice, whether it be taking prescribed medications properly, diet, smoking cessation, or other health-related behaviors. Patients must be able to convey their complaints and wishes accurately; solicit information they desire; convey obstacles that may prevent them from following medical advice – such as drug allergies, occupational or family demands, and lack of financial resources; and understand their situation, prognosis, and options.

These instrumental functions depend on interpersonal factors to be successful. The patient must trust the physician's good intentions and competence, and be willing to confide intimate information. The physician must be able to trust information provided by the patient and accurately gauge the patient's informational needs and motivations, among other elements of rapport. Furthermore, the function of a medical encounter is not only to treat disease, relieve symptoms, and promote future health, but also to provide reassurance and comfort. This also interacts with the instrumental functions because the patient must have a satisfactory experience that will promote returning for subsequent visits and following medical advice.

Until the mid-twentieth century, the generally accepted physician–patient relationship in the West was of a nature now characterized as "benevolent paternalism." The expertise and wisdom to choose the appropriate treatment of disease resided entirely with the physician. The patient's role was to trust and to follow "doctor's orders." During the 1970s, and with increasing prominence in the 1980s, a movement grew in medicine to promote "patient-centered" care. Patient-centered interactions were defined by Lipkin et al. in 1984 as treating the patient "as a unique human being with his [sic] own story to tell." The various definitions of patient-centered care share consistency with the biopsychosocial model for health and health care, which sees health in more than just biological terms. For example, Epstein et al. propose that patient-centered communication must include: “(1) Eliciting and understanding the patient’s perspective – concerns, ideas, expectations, needs, feelings and functioning. (2) Understanding the patient within his or her unique psychosocial context. (3) Reaching a shared understanding of the problem and its treatment . . .. (4) Helping patients to share power and responsibility. . ..”

These ideals live uneasily with the reality that physician–patient encounters are asymmetrical in power, expertise, and usually in social status. After all, the reason for the encounter in the first place is that the physician has exceptional expertise. Physicians ultimately control what information they share with patients and what options they present. They monopolize the power to prescribe medications, authorize tests, and perform surgery. They have unique privileges to invade people’s bodily integrity and inquire into intimate matters that are never ordinarily discussed with strangers, or perhaps with anyone. They have immense cultural authority and prestige, and typically earn multiples of the income of their average patient.

Patients may not understand much of the vocabulary that physicians routinely use and may lack the background knowledge to accurately interpret what physicians tell them. They may be overawed by the physician’s elevated social status and reluctant or entirely unable to express doubt or objection, admit lack of understanding, or ask questions. It has been found consistently that people typically do not accurately remember or understand much of the information and instructions from physicians even immediately after a visit; and that people adhere to prescribed medication regimens only about half of the time.

The decision-making heuristics of physicians and patients may be quite different. Physicians base diagnostic conclusions and treatment recommendations on biomedical theories and statistical reasoning: the probability of a beneficial outcome of an intervention versus the probability of adverse effects, weighted by the physician’s judgment of the magnitude of possible benefits and harms. Patients may not understand these calculations or may simply use other criteria, such as prior experiences of people they know, social norms of their community, shorter time horizons, idiosyncratic aversions, cost and convenience, or alternative theories of health and illness, whether from formal systems or lay conceptions. They may or may not ever discuss these criteria with their physicians.

For international migrants, the most important additional difficulties may be classified as language discordance; cultural discordance – a category with many relevant components; lack of financial or other resources ordinarily available to natives; lack of knowledge typically possessed by natives; physicians’ attitudes which may include stereotyping and prejudice; and physicians’ lack of knowledge or inaccurate beliefs about their current circumstances. (Physicians’ lack of knowledge or inaccurate beliefs about possible exposures or other relevant history in the country of origin can be an important problem for clinical practice, but is less directly relevant to the subject of this entry.)

Language Barriers

While it is obvious that people who do not share fluency in a common language will have impaired communication, the problem of language barriers in medicine does have some less than obvious complexities. In fact, even when physicians and patients share the same native language, a language barrier exists in that physicians use specialized vocabulary and modes of expression which patients may not readily understand. When either the physician or the patient has some ability in a language in which the other is fluent, what degree of ability is sufficient to achieve acceptable communication, and how does this vary with the circumstances and nature of the encounter? How can the adequacy of second language ability be defined and practically assessed? How do the benefits and harms of communicating in a language in which one party has less than native fluency compare with the benefits and harms of communicating through interpreters? These questions remain open.

Language interpretation is a complex problem which has not been well studied. (Parlance in the field is that interpretation refers to speech and translation to written materials.) Patients are generally found to prefer language concordant physicians and to be more satisfied with their interactions when physicians speak their preferred language, but there is little direct evidence concerning differential outcomes, if any, in interpreted versus language concordant encounters.

Case reports have illustrated psychological and social harms that can result from having family members interpret. These include traumatization of children, disruption of family relationships, and deliberate manipulation or concealment of facts by the person serving as interpreter. Nevertheless, some people prefer to have family members, rather than a professional, interpret. Institutional policies in the USA increasingly discourage this, but it is more accepted elsewhere.

It is widely accepted that interpretation by trained, skilled professionals is much to be preferred, if not the only acceptable option in most circumstances. However, in most of the world, there are no legal or generally accepted standards for interpreter training, skills assessment, or accreditation. Only a few studies are based on direct observation of interpreted medical encounters, and these are generally based on small numbers of cases. (Observational research involving two or more languages is very laborious and the supply of bilingual investigators is limited.) It has been found that even professional interpreters frequently fail to interpret accurately or completely; may edit statements by physicians or patients according to their own judgment of what is relevant or appropriate; and may engage in behavior outside of the interpreter's professional role. Interpreted encounters have been found to be less patient-centered and to include less psychosocial content.

The extent to which these problems may have been reduced by increased professionalization of medical interpretation in recent years is unknown. Standards of practice and codes of ethics for medical interpreters have been developed and training programs have become more widely available in the USA in the past decade, but information about the proportion of language discordant encounters in which professional interpretation is provided is lacking. An alternative to having an interpreter physically present is the use of telephone interpreter services, but there is little evidence about which method, if either, is superior.

There is controversy about the appropriate role of the medical interpreter. The "interpreter as conduit" views the interpreter essentially as a "black box" who converts one language into another and is as invisible as possible. Although full equivalence of meaning across languages is often unattainable, achieving the closest possible equivalence while maintaining neutrality and nonintervention are still the goal. The "interpreter as manager" sees the interpreter as more active in facilitating communication by working to negotiate social and conceptual differences between the interlocutors (e.g., cultural barriers) while resisting being drawn into the interaction as a partisan. The "incremental intervention" model has the interpreter preferring what is essentially the "conduit" role, but expanding that role when it fails. Finally, the "interpreter as embedded in her cultural and linguistic community" model assumes that the interpreter shares the cultural background and community identity of the patient and functions as an advocate for the patient and the patient's cultural community.

Researchers from a variety of disciplines (e.g., anthropology, communication, and biomedicine) have also investigated the interpreter's role and have jointly argued that the conduit role is inadequate in cross-cultural medical encounters Rather, interpreters should seek to facilitate understanding and meaning between health care providers and patients. However, there is not yet full agreement on the ethical boundaries of interpreter behavior. A common consensus, however, is that interpreters are obliged to make any intervention transparent to all parties. Any exchange which the interpreter has with one individual must be interpreted in the other language, for the other party; it must be clear to all that the interpreter is actively intervening.

Even when a patient has skill in the physician's language which is sufficient to achieve success in work, school, and daily life, or even essentially the capabilities of a native speaker, are there still some respects in which clinical communication is less than optimal? There is evidence that people are less likely to reveal personal information or express affect when speaking a second language. Communication in the patient's first language seems to be especially desirable in psychiatry and psychotherapy. This also has been little studied.

Finally, language barriers can affect written communication, such as the ability to read drug labels or informational materials, or to find public health and medical information from sources other than the medical provider. The impact of such problems on physician–patient communication is indirect and little studied, but it may be hypothesized that people with limited literacy in the vernacular of a host country can have informational deficits that affect communication with their physicians.

Cultural Discordance

Interest in cross-cultural medicine first emerged in the 1970s, largely based in medical anthropology. The premise was that people, especially from outside of Europe and North America where the allopathic biomedicine had its principal development, might have explanatory models of health and illness that differed from those of allopathic physicians. These included formal, professionalized, and institutionalized systems – such as Indian Ayurveda and Chinese Medicine; less formal traditions, including shamanism, religious healing practices, and "folk" systems in which practitioners might be trained through apprenticeship; and lay explanatory models and healing practices followed within the family or close community. The essential problem of cross-cultural medicine was thought to be discordance of belief between physicians, and migrants or members of ethnic minorities who adhered to such "alternative" beliefs. "Cultural competence" was often promoted by teaching providers about "folk" illnesses and healing practices that might lead patients to discount or reject providers' advice and pursue their preferred remedies.

Today, it is generally understood that this emphasis was misplaced. Allopathic medicine (a term derived from early controversies in the development of scientific biomedicine in Europe and the USA which is used today as a non-invidious, if etymologically inappropriate label for medicine as taught in accredited medical schools and practiced by licensed medical doctors) is today accepted as authoritative in most of the world, even where it may exist beside other systems. What is more, many people who are native to the Western home turf of biomedicine adhere to non-allopathic beliefs and practices, including formal and informal systems, as witness extensive shelf space in corporate pharmacies filled with non-approved nutritional supplements and herbal remedies, and thriving practices of naturopaths, acupuncturists, faith healers, and so on. Yet physicians are not often enjoined to study these systems or routinely inquire about them of their native-born patients. The vast majority of individuals pursue them in addition to, rather than instead of, allopathic health care, and this is true in most of the world. In poor countries, many people may rely on non-allopathic healers because they do not have access to medical doctors – but they still prefer to see medical doctors when they get the chance. There are exceptions, to be sure, and there have been celebrated cases of individuals and families who have come into conflict with the medical institution in the USA and Europe over health beliefs. But this is not the most salient issue in cross-cultural medicine.

Of far more importance, culture shapes expectations about the physician and patient roles; interaction process; involvement of family; and other dimensions of communication and relationship. For example, physicians and patients may have differing understandings about relational boundaries, etiquette, or expression of affect. Physicians may not appreciate the importance some people place on involving family members in decisions. Gender role norms and boundaries may create discomfort over physical examination or interviewing. People may be offended by physician questions that are routine in one cultural context but suggest the patient may be transgressing strong cultural or religious proscriptions, such as alcohol use.

More broadly, theorists distinguish cultures along dimensions labeled Individualism-Collectivism (IC), Power Distance (PD) (also labeled "Group" and "Grid," in a roughly similar formulation), and Uncertainty Avoidance (UA). The dominant culture in the USA, and to a lesser extent much of Western Europe, is thought to be characterized by a high degree of individualism, which means that the needs and values of the individual supersede those of the group, defined as family, community, or a larger aggregation. High PD cultures are characterized by greater acceptance of differential social power. The USA and Western Europe tend to be low in PD. Cultures with high UA tend to value consensus, formal rules, and conformity. Again, the USA and Western Europe are characterized by a tendency toward low UA. However, all of these assertions refer only to general tendencies in comparison with some other regions of the world, and more collectivist, high PD and high UA people and groups are common within the USA and Western Europe.

These differences may influence people's expectations about the physician–patient relationship and interaction, symptom presentation, and decision-making processes.

For example, physicians from low PD contexts may expect patients to speak up if they are dissatisfied, do not understand something, or are reluctant to follow the physician's advice, but people from high PD cultures may not do so. People from more collectivist cultures may expect to involve family members in decision making, or even defer to others, whereas physicians from individualist cultures may expect the patient to be a more autonomous decision maker. While these ideas seem plausible and have anecdotal support, there is very little systematic research that applies them to cross-cultural medical communication.

It can be said that the norm of patient centeredness and shared decision making has advanced farther in the USA than it has in much of the world. Physicians who are US natives may erroneously expect people to speak up spontaneously if they have complaints or questions, do not understand instructions, or think the physician has failed to ask the right questions or lacks essential information, whether this is because of low PD or simply the evolving etiquette of the specific situation. (To be sure, US natives may also fail to do so.) There are only a few studies that compare interaction process in ethnically or culturally discordant medical encounters with concordant encounters based on direct observation and systematic coding. These have not entirely consistent results, but this is not surprising since they are not necessarily comparing the same cultural pairings. Generally, cross-cultural and cross-ethnic encounters tend to be shorter and have less psychosocial and interpersonal content.

Also important is the physician's limited understanding of the patient's life world. For example, the physician may give inappropriate dietary advice due to lack of knowledge about the patient's cuisine, child-rearing advice which is unlikely to be followed, or fail to appreciate the patient's lack of autonomy due to gender role or generational norms. Again, these problems are not confined to cross-cultural situations. Differences in social class, education, and financial circumstances can create similar failures in culturally concordant relationships. Cultural discordance merely adds additional complexity.

The Circumstances of Migrants

International migrants are frequently economically disadvantaged. They may face financial barriers to health care access and be less likely than natives to have regular contact with a physician who knows them personally. In the USA, undocumented immigrants and legal immigrants who have not yet met certain requirements for residency status and tenure are ineligible to receive publicly subsidized medical insurance. They are therefore likely to get medical care, if at all, in hospital emergency departments and safety net clinics where they receive only urgent care, from physicians who see them only once. Relationships of trust and confidence with physicians develop over time, and this cannot occur under such circumstances.

Migrants also may lack knowledge about the organization of the medical system in their host country, and have difficulty finding appropriate providers or getting to the right place at the right time, even if services are available to them. Jobs in the secondary or even illegal labor market tend not to provide paid time off, and family or other demands may make it impossible to keep appointments or mean they are kept at great sacrifice. Such problems might have indirect effects on physician–patient communication because of missed appointments, distress over having to wait a long time, or undisclosed anxiety about missing work or other obligations.

Stereotyping and Prejudice

While stereotyping and prejudice by physicians with respect to patients who are immigrants are often thought likely to occur, the problem has been little studied. In the USA, there have been studies of physician's responses to African American and White patients with similar presentations, and some differences have been found. There are differential outcomes and differential rates of some interventions, such as cardiac revascularization, for White, Black, and Latino patients in the USA, but it is not clear to what extent these should be traced to differential treatment by physicians, differential preferences or presentation by patients, or differences in the sites where people of varying ethnicity receive care. How such differences may apply to immigrants is unknown. (Latinos in the USA are not necessarily immigrants, whereas some Black people are.) It has also been found that Latino patients are less likely to be prescribed opioid analgesia when it is appropriate, perhaps because physicians presume they are more likely to be drug abusers.

One objection to the practice of teaching about "folk" health beliefs and practices in the name of cultural competence is that it can promote stereotyping. In a country where a particular belief or practice exists, not everyone will follow it. It may even be stigmatized among much of the population. In the current consensus view, it is best to inquire about people's health beliefs, rather than ascribe beliefs based on their national origin or ethnicity.

Summary

The most important problems in physician–patient communication for migrants center on language discordance, and cultural norms regarding relationships and interactions. Contextual factors also may be of some importance. It is important to keep in mind, however, that physicians and patients typically differ in social status, background, and expertise, and that problems specific to migrants are mostly extensions of problems that are pervasive. Our knowledge of physician–patient communication and international migration is quite thin. Above all, we must resist over generalization as every situation is unique.

Pibloktoq

Michelle Fulk
Department of Psychiatry, University Hospitals Case
Medical Center, Cleveland, OH, USA

Pibloktoq (Piblokto) also known as Arctic Hysteria, is an abrupt dissociative episode with four distinct phases. The first phase, or prodrome, may last hours to days and consists of irritability and social withdrawal. The second, or excitement phase, consists of the sudden onset of extreme and wild excitement. During this phase, the individual affected may be seen tearing off his or her clothing, shouting, throwing objects, and running out of doors with a noticed lack of sensitivity to the extreme cold. This phase typically lasts about 30 min. The third phase, convulsions and stupor, follows this excitement. The individual may have convulsive seizures followed by extreme somnolence or coma due to the fatigue produced by the excitement. This third phase may last up to 12 h. The fourth and final phase, or recovery, is notable by complete recovery. Complete amnesia for this event is typically reported.

Pibloktoq is noted to affect the Arctic and circumarctic populations, namely the Inuit Eskimos. Recent estimates report 150,000–200,000 Inuit Eskimos worldwide. They are mainly distributed throughout Greenland, Canada, Alaska, other parts of the USA, Denmark, and Russia. Females tend to be affected more often than males and adults more commonly affected than children. There have also been reports of similar behaviors observed in sled dogs, frequently resulting in death. Such reports note sled dogs having convulsive fits followed by exhaustion or death. Most cases have been reported to occur during the winter months. There is little information regarding Pibloktoq occurring in other cultures or geographic areas.

Pibloktoq is defined as a culture-bound syndrome. Culture-bound syndromes are patterns of aberrant behaviors and troubling experiences which are recurrent and specific to certain localities or populations. They generally fall outside of traditional Western psychiatric categories or definitions of illness. Such syndromes tend to be recognized by the culture but are not necessarily thought of as illnesses. Each culture will have its own distinct way of defining such a syndrome based on the relevance to the culture. In the *Diagnostic and Statistical Manual, Fourth Edition, Text Revision* (DSM-IV-TR), pibloktoq is listed under dissociative disorder not otherwise specified as a dissociative trance disorder. This is defined as “single or episodic disturbances in the state of consciousness, identity, or memory that are indigenous to particular locations and cultures.”

There are many theories as to the causative nature of pibloktoq. These theories can be divided into biological, psychological, and social categories. The most prevalent current biological theory as to cause of Pibloktoq is hypervitaminosis A. Vitamin A is a lipid (fat)-soluble compound, known as retinoic acid. It may be found as a provitamin in green leafy vegetables. In this form, it needs to be converted into active vitamin A, which is subject to a regulatory feedback mechanism and, therefore, unlikely to lead to toxicity. However, it may also be found in its preformed state in foods such as liver, kidneys, egg yolks, and butter. In this state, it is quickly and easily converted to its active state with no regulation, therefore, more likely to become toxic. About 50–85% of the body’s vitamin A is stored in the liver. The Inuit diet is high in organ meats, specifically liver. The amounts of vitamin A in polar bear liver and seal liver are known to be toxic. There are both acute and chronic forms of vitamin A toxicity. In the acute-form symptoms include nausea, vomiting, vertigo (dizziness), blurry vision, drowsiness, and malaise. In chronic states, it may cause ataxia (gait disturbance), alopecia (hair loss), hyperlipidemia (elevated cholesterol), hepatotoxicity (liver damage), visual impairment, bone and muscle pain, and headaches, as well as fatigue and irritability. Signs of vitamin A toxicity have been reported in the European explorers of the past. Despite these reports, none noted a progression to a full episode of pibloktoq. Other biological theories hypothesized in the past include low calcium and vitamin D, as well as interrupted circadian rhythms related to the long periods of darkness throughout the winters.

Other theories fall under the categories of the psychological and social factors. Psychologically, it is thought to be something of a “functional hysteria” serving the function of helping an individual with the resolution of some internal conflict. Others have hypothesized that it may be a reaction to traumas, which had been high in the past during the long winters due to hunting accidents and possibilities of starvation. Socially, or culturally, many characteristics of a pibloktoq episode are similar to the behaviors in the ritual “drum song.” This ritual may be initiated during times of distress in the area. Behaviors included in the ritual may include high-pitched singing, arms moving frantically about, uncontrollable sobbing, and hysterical laughter followed by exhaustion. As a population, this ritual is thought to be an outlet for feelings of anger or hostility. When translated by an individual into an episode of pibloktoq, it is thought to be a catharsis for personal stressors.

Pibloktoq appears to be self-limited, and little intervention is required. The local people may intervene only to protect the individual from harming either themselves or others during the excitement phase. Many are known to have only one attack, but others may have repeated attacks. Each attack is generally followed by complete recovery and return to normalcy.

Plague

Elie Saade
Department of Internal Medicine, University Hospitals
Case Medical Center, Cleveland, OH, USA

History of the Disease

Plague is a disease affecting animals primarily; however, it can affect humans also. It is caused by the bacterium *Yersinia pestis*, which was identified first toward the end of the nineteenth century. The disease itself dates to ancient times and is thought to have originated in Central Asia. The first plague epidemic on record was the outbreak among the Philistines in 1320 BC, described in the Bible. Worldwide occurrences, or pandemics, have claimed lives on the order of tens of millions. Global outbreaks have included: the Justinian Plague in the sixth century AD, the "Black Death" of the fourteenth century decimated Europe's population, and the "modern pandemic." The modern pandemic occurred in the 1860s in China and persisted through the early twentieth century, killing millions as it spread from Hong Kong to 77 ports on five continents in 10 years. In the first half of the twentieth century, India was affected most severely by plague epidemics; then in the 1960s and 1970s, war-torn Vietnam became the country affected most by plague. Recently, plague has resurged in the nations of sub-Saharan Africa and the adjacent island of Madagascar; currently these account for more than 95% of cases reported to the World Health Organization (WHO). Since the Los Angeles epidemic in the 1920s, the plague has occurred in the United States mostly as scattered cases in rural areas; approximately 10–15 cases are reported yearly. In the United States, most human cases occur in two regions: (a) northern New Mexico, northern Arizona, and southern Colorado; and (b) California, southern Oregon, and far western Nevada. To illustrate the frequency and distribution of the plague, note that between 1989 and 2003, 25 countries reported approximately 38,300 cases, including 2,850 deaths. Most cases were reported in Madagascar, Tanzania, Democratic Republic of the Congo, Vietnam, Mozambique, Namibia, and Peru.

Favorable Conditions

Yersinia pestis persists in natural foci in relatively dry areas without thick woody vegetation, including areas such as: deserts, semideserts, steppes, savannas, prairies, and similar environments. The bacterium is harbored by local rodent and flea populations. Natural foci include North and South America, Africa, Asia, and southeast Europe; affected regions include areas in the Caucasus Mountains, the northern Caspian Sea, the Eurasian Steppes, Siberia, Iran, Turkey, China, India, Madagascar, southeast Asia, most South American countries, the Arabian Peninsula, and the four corners of Africa. In North America, natural foci of plague occur mainly in the western states of the United States, in southwestern Canada along the US border, and in northern Mexico.

Animal-To-Human Transmission

Humans acquire the infection from flea and animal bites, handling infected animal carcasses, or through transmission via respiration during animal-to-person or person-to-person contact. The most common animals to transmit plague in the United States are squirrels, rabbits, and prairie dogs, while undetermined species account for about one-third of cases. Domestic cats are implicated in the transmission from animals to humans also, occurring through bites or human respiration. Both sexes and all ages of patients are susceptible to disease, with the plague thriving in the unsettled conditions of war, natural catastrophes, and the relocation of refugees who lack public-health services. In all countries with a high occurrence rate, human plague demonstrates seasonal variation. In the United States, the season of highest frequency is from February through August.

Medical and Public-Health Preparedness

Yersinia pestis is a potential agent of bioterrorism, classified as category A (the highest) by the Centers for Disease Control and Prevention (CDC). Historically, plague victims were reported to have been catapulted into besieged cities; examples include use by the Japanese against China during World War II and the development of *Y. pestis* as an aerosol weapon during the Cold War. Active terrorist groups who have employed biological agents pose an ongoing risk, and the potential development of biological warfare by organized armies is a subject of utmost secrecy. Misuse by terrorists is considered an important national security threat requiring special measures for medical and public-health preparedness.

Disease Presentations

Plague develops usually 1 day to 1 week after penetration of the microbe to the human body. There are three main presentations: bubonic, pneumonic, or septicemic. Bubonic plague is the most common form and presents as high fever, headache, and weakness – accompanied by the appearance of a bubo. A bubo is an inflamed, very painful, lymphatic ganglion, with inflamed red skin overlying. It occurs mainly in the groin, the axilla, or the neck; however, it can occur elsewhere, such as the elbow, in cases in which a cat is the source of the infection. In some cases, people may have this presentation without the appearance of a bubo; this is called septicemic plague. Pneumonic plague, highly lethal and contagious, is the involvement of the lungs with development of a respiratory infection; this can complicate the previous forms or be present initially, especially in the case of acquisition through respiration. Plague can affect the meninges, the digestive system, or the throat. Without treatment, fatality is high, claiming one-half of patients with bubonic plague and virtually all patients with the septicemic or the pneumonic form. Appropriate and timely treatment substantially lowers the risk of death; however, it remains high. When death occurs, it is rapid, striking within a few days of the onset of the disease.

Treatment

Doctors suspect the presence of plague when a patient was exposed recently to infected animals or their fleas in an area with a high rate of occurrence. The presence of a bubo is a helpful indicator, but it is not universal. Special imaging of the chest is necessary to detect lung infections. To confirm the diagnosis, blood or bubo samples, expectorated phlegm, or other body fluids are collected and examined in specialized laboratories. Doctors begin treatment usually without waiting for a final diagnosis as a delay puts at high risk the life of the patient. Treatment is by specific antibiotics; streptomycin is the preferred treatment, but other medications are used sometimes because of its limited availability. All patients suspected of having the plague should be placed under isolation for a period of time. All suspected plague cases should be reported immediately to state health department authorities. Family members, care providers, and others with direct contact should be isolated also for a period of time and may benefit from preemptive treatment.

Preventive Measures

Reducing exposure is the best preventive measure. Persons living in endemic areas should use protective measures against rodents and fleas, including living and working in rat-proofed dwellings, removing food and harborage for rodents, using repellents, applying insecticides on their pets, and should avoid handling dead rodent carcasses. A vaccine, with limited benefit and use, is produced currently in limited quantities, but research driven especially by concern for bioterrorism is under way to develop improved plague vaccines. In the United States, the CDC fields a team of specialists to investigate cases of plague; interventions include pest control, education, and early detection of disease.

Poland

Joy E. Stankowski
Northcoast Behavioral Healthcare System,
Northfield, OH, USA

Introduction

Poland is a nation of almost 40 million people, living on 121,000 square miles in north central Europe. Outside of the capital city of Warsaw, and other large cities such as Krakow, most of Poland's citizens live in rural areas, working in agriculture, mining, or heavy industry. Poland is strongly Roman Catholic.

The character and outlook of the Polish people have been shaped by various hardships. Geographically, the county is composed of plains with few natural boundaries, save the Carpathian Mountains to the south and the Oder and Neisse rivers to the west. As a result, Poland is vulnerable to occupation and invasion by neighboring lands. This geographic vulnerability fosters political unrest; over the last century alone, Poland struggled with both dictator and communist rule. With constant challenges to land and citizenry, Poland has had difficulty keeping economic pace with Western Europe. As a result of these struggles, Poland has long been a country of net emigration as citizens seek better economic or political circumstance. Poland's 2002 entrance into the European Union, however, may change this equation.

Political History

The last one hundred years illustrate how challenges to Polish land and politics have shaped the Polish people. In 1795, the constitutional monarchy ended, and Poland's lands were completely partitioned between Prussia, Austria, and Russia. For the next 100 years, until the end of the First World War, therefore, Poland was a country in name only. Its people were held together largely by a common Catholic faith, which may explain Poland's continued fealty to the modern Roman Catholic church.

From 1920 to 1939, Poland was a self-governing nation and enjoyed some economic and intellectual development. The effects of the Second World War, however, were devastating: Poland lost proportionally more citizens than any other country in Europe (6 of 35 million people, or roughly 1/6 of the population). The capital city of Warsaw was leveled, farmlands were burned, and factories and industries were in ruins. Adding insult to injury, Allied leaders at the end of the war answered the "Polish Question" by allowing it to become part of the Soviet Bloc. Poland's citizens therefore moved from restrictions under German occupation to different restrictions under communism. Again, a common faith held people together during these difficult times, as did trust in family and community.

Poland again became a self-governing nation with the fall of communism in 1989 but then was left to struggle with a lack of resources for technological and economic advances. In 2002, Poland became a member of the European Union, which improved its economic and political position in Europe.

Polish Immigration

Due to the difficulties described above, Poland has long been a nation of emigration, receiving immigrants from other nations infrequently. Although Polish natives have immigrated to many countries over the years, the largest number of Polish immigrants outside of Poland is in the United States. Indeed, the 2000 United States census reflected over 800,000 Polish known immigrants in Chicago, making it the second largest city of Polish nationals outside Warsaw. Polish immigration to the United States began in Texas in the 1850s but spread to the Northeastern and Midwestern United States, where the climate (short summers and long harsh winters) and economic opportunities (mining, factory work) were most familiar.

The first wave of Polish emigration occurred in the late 1800s and early 1900s when opportunities in the rapidly industrializing West prompted uneducated and poorly skilled workers to emigrate *za chlebem* ("for bread"). These immigrants were interested in making a new home and life in their new countries and worked to establish large communities in cities such as Chicago, New York, and Detroit (commonly called *Polonia*). This group sought assimilation and raised their children to be Americans.

The second wave of immigration came after the Second World War, which left Poland devastated economically, physically, and emotionally. This group included the *za chlebem* immigrants, but also held a large number of intellectual dissidents and political refugees. As a group, members of this 1939 to 1950 wave were more educated and skilled than their earlier counterparts but, nevertheless, shared the goal of assimilating into United States life and culture.

A third wave of emigration from Poland began in the late1980s. Poland was a member of the communist Soviet Bloc from 1945 to 1989, and emigration was largely restricted to those who won "visa lotteries" or falsely promised that their stays abroad would be temporary. After communist rule, the United States dollar was much stronger than the Polish *zloty*, and Polish immigrants were drawn to relatively high-paying jobs in the United States. This group of both skilled and unskilled laborers were focused less on finding a new home and community in the United States and more on working to send money home. As a result, many in this group have not spent money on health or dental care, and have not assimilated into US culture or communities.

The fall of communism expanded emigration possibilities for Polish citizens seeking better employment, asylum, or different living conditions. Although many still come to the United States, Polish nationals wishing to remain closer to their home culture and family ties go to Western Europe and the Netherlands.

Polish Health Care

The Polish health care system has been affected by the geographic, political, and economic struggles outlined above. Access to good health care has been most lacking. First, the rural location of many Polish people means that visiting a doctor or clinic is difficult at best. Missing a day's work to travel to a clinic is an added negative incentive. Second, political upheaval produced spotty and undependable health care. For example, under communism, Polish citizens had free national health care, but the system was poorly funded and maintained. After communism, the country focused on reorganizing the system but lacked resources to train and staff the necessary workforce. Political upheaval also spawned mistrust, and even when health care was available, many Polish citizens preferred to seek help from their trusted family or priest.

Other factors contribute to health care challenges for the Polish people. The Polish diet is traditionally heavy in meat and root vegetables, often preserved for winter consumption in sodium-heavy pickling solutions. Alcohol is ubiquitous in Polish social gatherings, and many start drinking in their mid-teens. The Polish economy revolves around agriculture, mining, and heavy industry. Governmental regulations have been overlooked at times in the latter categories, exposing Polish workers to chemicals and inhalants that predispose to respiratory conditions, and cancers such as leukemia. Finally, lack of education has been a problem under both communism, and Catholic Church influence. For example, under communism Polish citizens were not widely informed about AIDs/HIV or transmission risk factors. Public education efforts in this area remained hampered after communism due, in part, to the opposition of the Catholic Church regarding safe-sex education.

Polish Immigrant Health

Predictably, Polish immigrants bring their dietary and health habits, along with predisposing conditions, to receiving countries. As described above, these include cardiovascular problems from poor diet, respiratory disease and cancers from unregulated work, alcoholism, and chronic pain that the stoic Polish immigrant may be reluctant to report. Dental problems are common in both Polish citizens and immigrants, owing to low numbers of dentists in Poland. Smoking is also common in Poland, adding to respiratory risk factors.

Although the widespread and social use of alcohol raises the risk of alcohol abuse and dependence in the general population, rates of thought and mood disorders are lower or equal to other immigrant populations. Studies show that immigrant mental health is related less to country of origin than to success of acculturation. Although more recent immigrants remain external to US culture, Polish immigrants traditionally acclimate well to the communities and cultures of their host countries. Such acculturation is related to higher subjective quality of life.

Emigration to Poland

Due to repeated hardships, Poland has been a net emigration country for years. Census information from Poland in 2002 reported that only 0.2% of the population was foreign-born. The Polish government has therefore adopted a fluid policy toward migration that has been especially successful since the opening of Eastern European borders in 2006–2009 (e.g., Bulgaria and Romania entered the European Union in 2007, expanding the local labor market). In a circular pattern of migration, temporary or seasonal workers come to Poland (largely from the Ukraine) for a limited work engagement, then return home. This introduces a beneficial labor force to Poland, but one that is unpredictable.

Portugal

Amy N. Sharpton
Department of Veterans Affairs, Louis Stokes DVA Medical Center Cleveland, Brecksville, OH, USA

Introduction

Located on the Iberian Peninsula in the southwest of Europe, Portugal is Europe's westernmost country. It is bordered by the Atlantic Ocean to the west and south and by Spain to the north and east; the Atlantic archipelagos of the Azores and Madeira are part of the state also. The country's official name is the Portuguese Republic, but the shorter designation is used more often. The land of today's Portuguese Republic has a long and varied history dating to prehistoric times.

Roman settlers had a profound influence on the Portuguese culture, particularly the language. In 29 BC, the territory was integrated into the Roman Empire as the provinces of Lusitania and a portion of Gallaecia. After the fall of the Roman Empire, the land was occupied in the fifth century by several Germanic peoples – the Suevi and the Visigoths. Subsequently, Muslim Moors conquered those Christian kingdoms in the eighth century and occupied most of the Iberian Peninsula. During the Christian Reconquista, or Reconquering, northern Portugal was settled as part of the Kingdom of Galicia. The Kingdom was recognized in 1143, and with the stabilization of its borders by 1249, Portugal claims to be the oldest European nation-state.

Portugal became the world's major economic, political, and military power when in the fifteenth and sixteenth centuries, it established a global empire that included possessions in Africa, Asia, Oceania, and South America. After a political crisis over succession to the throne, in 1590 Portugal was united with Spain for a time; however, in 1640 it reestablished full independence. As the monarchy was overthrown in 1910, democracy was established. However, it was unstable and replaced subsequently by the *Estado Novo* dictatorship. Following the Portuguese Colonial War and the Carnation Revolution in 1974, democracy was restored and the country relinquished its last overseas provinces, notably, Angola and Mozambique. In 1999, the last overseas territory, Macau, was handed over to China.

Geography and Climate

The geography of Portugal's mainland is divided by the river, Tagus, which flows from Spain, empties into the Tagus Estuary, and further into the Atlantic Ocean. Northern Portugal is mountainous toward the interior with several plateaus. Southern Portugal, however, includes the Algarve and the Alentejo regions. The Algarve is the southernmost part of the mainland; it is known for its hills, rich valleys, and coastline. The landscape of the Alentejo includes rolling hills and plains that are dotted by cork oaks and olive trees.

Portugal, defined as a Mediterranean climate, is one of the warmest European countries. The annual average temperature on the mainland varies from 13°C in the mountains of the north to over 18°C in the south. In areas such as the Guadiana Basin, annual average temperatures can reach 20°C, with summer temperatures over 45°C. In the high mountains, a maritime climate exists. The record high, 47.4°C, was recorded in Amareleja. The country has roughly 2,500–3,200 h of sunshine a year, averaging 4–6 h in the winter and 10–12 h in the summer.

Economy

Since the 1990s, business services have overtaken more traditional industries as the basis of Portugal's economic development model has shifted from public consumption toward a focus on exports, private investment, and the high-tech sector. Portugal scored 19th highest worldwide on *The Economist*'s 2005 quality of life index. It is a member of the United Nations and the European Union, and as of 2007 was the eighth most globalized country in the world according to the Swiss Federal Institute of Technology's globalization index. Portugal has a strong tradition in the fishing sector, and it has one of the highest rates of fish consumption per capita. With Portugal's transition toward tertiary sector growth, travel and tourism will continue to be critically important to the economy. Portugal has niche attractions such as health, nature, and rural tourism.

Politics

Since the ratification of the Constitution of 1976, Portugal has been a democratic republic; Lisbon, the nation's largest city, is the capital. The constitution grants the separation of powers among legislative, executive, and judicial branches. The four main institutions detailed in the constitution are the President of the Republic, the Parliament, the Government (headed by a Prime Minister), and the courts.

The President is elected to a 4-year term and has a supervisory nonexecutive role. Parliament is comprised of 230 deputies who are elected for a 4-year term. The government, headed by the Prime Minister, chooses a Council of Ministers, which comprises the

Ministers and State Secretaries. The courts are organized into several levels: judicial, administrative, and fiscal branches.

Healthcare

The Portuguese health system is formed by three coexisting systems: the National Health Service (NHS), special social health insurance schemes for certain professions (health subsystems), and voluntary private health insurance. The NHS provides universal coverage. In addition, about 25% of the population is covered by the health subsystems, 10% by private insurance schemes, and another 7% by mutual funds.

The Ministry of Health develops health policy and manages the NHS. There are five regional health administrations that implement the national health policy objectives, develop guidelines and protocols, and supervise health care delivery. Decentralization efforts have aimed at shifting financial and management responsibility to the regional level. The NHS is funded largely through general taxation. Employer (including the state) and employee contributions are the main funding sources of the health subsystems. Direct payments by the patient and voluntary health insurance premiums account for a large proportion of funding as well.

Immigration and Emigration

Historically, Portugal was a country characterized by emigration. In recent years, however, Portugal has experienced immigration such that no simple characterization adequately describes the country's emigration and immigration trends – although emigration still greatly outnumbers immigration. While net migration in the 1990s was positive, the meaning of migration is complex for Portugal and cannot be understood by the binary nature of net migration alone.

Portugal and its authorities have developed an expansive view of migration supported by links with the longstanding Portuguese diaspora. It is reported that worldwide, there are more than 100 million persons with recognizable Portuguese ancestors – owing to immigration and the Portuguese Colonial Empire – the first global empire in history. From the sixteenth century, inhabitants of Portugal immigrated in large numbers to destinations such as India, the Americas, Macau and East-Timor, Malaysia, Indonesia, and Africa. With the exception of Ireland, between 1886 and 1966, Portugal lost residents to emigration more than any West European country. From the middle of the nineteenth century to the late 1950s, nearly two million Portuguese left Europe to live in Brazil and the USA. Due to massive immigration in the late nineteenth and early twentieth centuries, approximately 40 million Brazilians have relatively recent Portuguese background, and about 1.2 million Brazilian citizens are native Portuguese. Significant numbers of Portuguese minorities exist in Israel (Portuguese Sephardic Jews), the Netherlands, the USA, France, Venezuela, Brazil, and Turkey. In the USA, there are Portuguese communities in New Jersey, the New England states, and California. In the Pacific, Hawaii has a sizable Portuguese population that dates back to 150 years. Since 1940, Canada – particularly Ontario, Quebec, and British Columbia – have had significant Portuguese communities.

Portugal's Ministry of Foreign Affairs has registered and attempts to maintain ties with those who have emigrated. Notably, the number of emigrants from Portugal outnumbers by 10 to 1 the number of foreigners and those with foreign ancestry who have immigrated to Portugal. Members of Portugal's diaspora community have maintained close relations with their homeland. This relationship is manifest in frequent visits to Portugal, regular sending of remittances (approximately 3% of GDP in 2000), faithful viewing of Portuguese television programs, significant participation in civil society associations and parliamentary elections, and consumption of "ethnic" goods.

In addition to this rich heritage, Portugal has always had a special relationship with its former colonies. Brazil, along with the association of Portuguese-Speaking African Countries (PALOP) that includes Angola, Mozambique, Guinea-Bissau, São Tomé and Principe, has played a prominent role in Portugal's migration history. Immigrants from PALOP states have recently been joined, however, by arrivals from nontraditional source countries.

Portugal continues to balance these two forces: an enormous diaspora that maintains close social, economic, and cultural ties with Portugal – and immigrant flows from former colonies that continue to benefit from some legal preferences, such as the demand for a shorter period of continuous residence in Portugal in order to request Portuguese citizenship.

Posttraumatic Stress Disorder

James Spilsbury
Division of General Medical Sciences, Case Western Reserve University School of Medicine, Cleveland, OH, USA

People of any age who experience or witness distressing, life- or injury-threatening events may be psychologically affected by them and experience a range of symptoms that includes nightmares, insomnia, flashbacks of the event, psychological numbing, or avoidance of reminders of the event. For many individuals, these symptoms fade over time. However, for some individuals, such symptoms persist and form the basis for a psychological disorder referred to as posttraumatic stress disorder (PTSD). PTSD is classified as a clinical anxiety disorder that results from experiencing a traumatic event. According to the *Diagnostic and Statistical Manual of Mental Disorders (DSM-IV-TR)*, the event may involve: (1) direct experience of actual or threatened death, serious injury, or other threat of harm either to a person's physical integrity; (2) witnessing such events; or (3) learning about the unexpected or violent death, serious injury, or threat of death or harm experienced by a family member or close associate. The person's response to the event must involve intense fear, helplessness, or horror. Responses in children may also include agitated or disorganized behavior.

PTSD is characterized by the development and persistence of three clusters of symptoms in response to the traumatic event(s): increased arousal (e.g., hypervigilance, insomnia, irritability), re-experience of the traumatic event(s) (e.g., nightmares, intrusive thoughts, flashbacks), and avoidance of stimuli associated with the event and numbing of general responsiveness (e.g., efforts to avoid thoughts, feelings, places, activities associated with the event; detachment; diminished interest in important activities; restricted range of affect; and sense of foreshortened life or future). In children, symptoms are expressed differently. For instance, younger children may experience nonspecific frightening dreams instead of flashbacks or trauma-specific nightmares, and daytime recall may involve repetitive play, drawing, or reenactment of the event or trauma-related themes. Children's responses to the event may also include somatic complaints (stomachache or headache), as well as regressive, antisocial, aggressive, or destructive behavior. Although most persons recover over time, a sizable minority of individuals' symptoms will persist. A diagnosis of PTSD requires that at least 1 month has transpired since the experienced traumatic event. PTSD is considered chronic if symptoms persist beyond 3 months, and in some individuals the disorder may continue for years.

PTSD is not without controversy. Of particular significance is the fact that the construction of PTSD as a disorder links psychological distress to the experience of specific events. Thus, its diagnosis can serve social and political purposes by standing as medically backed, hard evidence of a person's (or group's) suffering and may thereby be used both to identify legitimate victims and justify governmental and nongovernmental responses to those victims. In the context of immigrants, such responses could include humanitarian assistance or determination of asylum or refugee status. Another controversial aspect is that although PTSD as a diagnosable disorder was originally developed with war-related experiences as the triggering event(s), the type of triggering event has expanded over time to include a much wider range of events: for example, vehicular accidents and childbirth. Whether the PTSD construct codifying reactions to war experiences is equally valid or applicable to the complex distress experienced by persons in other circumstances (e.g., child maltreatment, torture, and refugees) is debated. In a related vein, the current PTSD diagnostic criteria may not adequately capture the poorer physical, affective, behavioral, cognitive, or social functioning displayed by children with the disorder. Whether the constellation of adverse symptoms and functioning reflects PTSD with comorbid conditions or the proposed alternative "complex PTSD" condition is unclear. Furthermore, the appropriateness of the disorder across cultures has been questioned because cultural groups may have specific idioms of traumatic reaction or distress not encompassed by the DSM-IV classification. However, collectively, the presence of the three symptom clusters in traumatized persons throughout the world has lent credence to the validity of PTSD as a diagnosable disorder.

PTSD can be devastating to persons' health and well-being, affecting individuals in numerous ways: for example, lower self-esteem, increased behavior problems, impaired interpersonal skills and social functioning, poor school or work performance, increased risk of self-harm, and poorer general health and greater somatic complaints. Moreover, although the precise causative pathways are unclear, PTSD may increase the risk for other co-occurring disorders, including depression, dissociation, and substance abuse. Longitudinal studies of PTSD's course are rare, but available evidence suggests that worrisome proportions of individuals with PTSD show no significant remission over time.

Both psychologic and pharmacologic approaches are used to treat PTSD. In general, psychological treatments consist of activities such as therapist-led, imaginal exposure to the traumatic event(s) via oral, drawn, or written recollections in order to gradually confront and overcome memories and "triggers" of the event; training in relaxation skills; restructuring inaccurate or unhelpful thoughts and feelings about the event; uncovering and processing of previously unconscious thoughts and emotions (this latter approach being more psychodynamic in nature). In a recently developed therapy, eye movement desensitization and reprocessing, the client recalls the traumatic event while visually following the rapid, back-and-forth movement of the therapist's finger or hand. Pharmacologic treatment is used to decrease PTSD symptoms. Selective serotonin reuptake inhibitors (SSRIs) are approved for use in adults with PTSD. Current evidence suggests that SSRIs may also be effective in pediatric PTSD, but there is not yet sufficient evidence to support their use alone with children.

Exposure, cognitive behavioral, and stress management approaches, as well as pharmacologic treatment, have shown effectiveness in treating PTSD. However, it is important to note that the systematic, meta-analytic research providing such evidence has relied largely on nonimmigrant North Americans and Europeans; the evidence for the efficacy of narrative exposure or cognitive behavioral techniques specifically among refugees or asylum seekers is present but is more limited.

PTSD is a special concern among immigrants, particularly for the nearly 16 million refugees and asylum seekers around the world. Recent meta-analytic reviews of psychiatric conditions among refugee populations have reported PTSD prevalence rates ranging from 9% to 31% for adults and 11% for children. Thus, even conservative estimates suggest substantial numbers of immigrants with clinical PTSD. Moreover, the striking heterogeneity in prevalence rates observed across individual investigations (e.g., from 10% to 90%) reflects not only differences in sampling and assessment methods but also differences in the complex configuration of etiological, protective, and risk factors that shapes the actual experience of an immigrant: for example, type, severity, and timing of threatening events encountered; presence of family or other supportive individuals; and presence of other stressors experienced by an immigrant (explained below) that may increase the likelihood of developing PTSD or increase its severity.

Studies of PTSD among immigrants reveal that the potential for experiencing PTSD-inducing events occurs throughout any of the phases of immigration: premigration, migration, and postmigration. For example, potentially traumatic premigration stressors might include events such as war, torture, persecution, famine, or natural disasters, and may have been primary factors in individuals' decision to leave their countries of origin. The migration or transit experience itself may be psychologically and physically traumatic. Travel circumstances may be perilous, as immigrants move through war zones or other areas of social unrest or upheaval. Transport may involve crossing large bodies of water in small, unseaworthy vessels, being smuggled in ill-equipped, hidden compartments of trucks or ships, swimming across dangerous rivers, or crossing deserts on foot. The transit experience may also involve high risk of sexual violence, forced labor, or confinement/imprisonment. Also, persons in refugee camps and detention centers, whether these locations are situated "in transit" or within the host country, may be at risk of physical and sexual violence from other refugees, staff, or both. Once in the host country, immigrants, particularly refugees or undocumented migrants, may have limited economic resources and therefore live in disadvantaged areas, with elevated rates of violence and crime. The stress of life in a new sociocultural environment, particularly with diminished material and social resources, can be traumatic and may heighten risk of family violence. One important conclusion to be drawn from the literature on traumatic stress and immigration is that an immigrant need not be a refugee or asylum seeker to have traumatic stress symptoms: even for those individuals who migrate voluntarily to a new country for economic reasons and the hope of a more prosperous life, the travel or resettlement period may be traumatic.

Increased frequency and severity of exposure to violent or otherwise disturbing, life-threatening events throughout the migration experience are recognized risk factors for the development of PTSD among immigrants. Research on posttraumatic stress has also identified other factors that act to increase the risk, or conversely, decrease the likelihood of posttraumatic symptomatology. These factors may also operate throughout the immigrant experience. Individual characteristics such as preexisting chronic physical illness or psychological and behavioral problems may increase risk, while positive self-esteem, the ability to adapt to new situations, a good temperament, and "positive beliefs" (e.g., ideological commitment to one's side in a political struggle or finding personal meaning in adverse events) may act as protective factors. Social support has been consistently identified as a factor either reducing the risk of posttraumatic stress or mitigating its effects. Thus, the presence or absence of family members, friends, or other members of one's social network influence the degree to which disturbing events become psychologically traumatic. Child refugees unaccompanied by other family members may be especially vulnerable. Along these lines, it is important to recognize that even if physically present, normally supportive individuals may be incapable of providing support to others because of the distress they experience in response to traumatic events. Thus, for example, parental distress may increase risk of PTSD among the children.

Upon arrival in the new host country, the immigration or asylum-seeking process itself may be stressful. As described above, detention centers or refugee camps may be dangerous. Immigrants may endure economic hardship, unemployment or underemployment, including well-educated professionals who are unable to practice their profession in the host country because of licensing or other legal issues. Reduced economic resources may force immigrants to live in inadequate housing in disadvantaged neighborhoods, with poorer resources and increased violence and crime. Immigrants may experience acculturative stress as they try to adapt to new (often disadvantaged) living circumstances, a new language, and a new sociocultural milieu. Immigrants may also experience discrimination from host-country nationals, other immigrant groups, or both. Moreover, because immigrant children frequently attend school and therefore learn the host-country language faster than older family members, both immigrant parents and children may need to adapt to their children's role as the family's interpreter or "cultural broker." Of course, some immigrants may also experience the threat of denied asylum or discovery of one's undocumented status and subsequent deportation. Collectively, such compounding stressors – immigration-related legal processes, fear of denial of asylum status, economic hardship, discrimination, and acculturation – may facilitate the development of posttraumatic stress symptoms or exacerbate existing symptoms. Moreover, services for immigrants, including refugees or asylum seekers, may be economically or socially inaccessible, fragmented, or lack the adequate expertise to recognize and treat mental health issues, including PTSD. Even if the expertise is present, treatment of PTSD among some immigrants may be complicated by numerous factors, such as the lack of culturally validated diagnostic or assessment measures, differences in therapist's and client's cultural understandings of trauma, the need for assistance from the client's family or community to get or keep the client in treatment, the need for interpreters, the possibility that in some instances continuation or exacerbation of PTSD symptoms may be seen as advantageous to an immigrant seeking refugee status or asylum.

Despite these formidable circumstances, services have made notable strides over the years in treating immigrants with PTSD and collectively have learned important lessons to increase their effectiveness. First, it is critically important to recognize that any single immigrant group is not homogeneous. Psychological, social, political, and economic differences among immigrants exist in the home country before migration, and, especially given the complex experiences of immigrants during the actual migration process, differences likely exist among individuals of the same immigrant group after their arrival. Services for PTSD cannot rely on a "one-size-fits-all" approach to be effective. Also, individual and group resilience should be recognized and used in therapy. Indeed, the narrow view of immigrants with PTSD solely as *victims* of trauma should be avoided.

Second, services for immigrants with PTSD need to be as comprehensive as possible (e.g., mental health services integrated in broader services), addressing ongoing basic needs, assisting with legal procedures, and mitigating stress related to change in family economic circumstances (often for the worse) and social roles (children as cultural brokers), language barriers, and discrimination. These stressors may actually be a greater source of immediate distress to immigrants in the host country than traumatic stress.

Third, the need for cultural sensitivity and understanding in treating immigrants with PTSD cannot be overemphasized because sociocultural barriers may preclude treatment even in settings where services are affordable and easily accessible. Ideally, pairing an immigrant with PTSD with a practitioner of the same cultural or ethnic group could foster more effective communication. However, such cultural matching is not always possible. In this regard, it is important for clinicians to recognize that the broader immigrant community to which an immigrant belongs may constitute an important source of learning, understanding, and support to both clinician and client. For example, an immigrant's religious institution may serve as a critical resource for information and even a preferred meeting place, where private matters can be discussed without the stigma of seeking help in a mental health facility.

Concerning culturally sensitive treatment, although current therapeutic techniques may rest on imaginal reexposure to and discussion of the traumatic event(s), not all cultural groups may find such "retelling" therapeutic. In fact, these approaches may be counterproductive or even harmful among persons coming from locations where information-gathering procedures were used for nefarious purposes. In the case of children, the school may be an important site for both recognizing and treating PTSD. Such services may be more accessible to children if offered at a school than in a clinical setting. Also, school-based services may provide an opportunity to address broader issues related to acculturation that immigrant children face, and may offer an avenue through which immigrant children's parents and other family members may be engaged and assisted.

In conclusion, PTSD is a substantial problem among immigrants, particularly among populations of refugees and asylum seekers. While important strides have been taken to improve its recognition and treatment, more work is clearly needed to develop more effective, culturally valid ways to assess and treat this disorder.

Poverty

Amy N. Sharpton
Department of Veterans Affairs, Louis Stokes DVA Medical Center Cleveland, Brecksville, OH, USA

Economists assess wealth and poverty using a variety of measures; the three most common include income, assets, and socioeconomic indicators. Socioeconomic metrics account for health, nutrition, infant mortality, sanitation, and other indices of well-being. Considering the lived experience, poverty can be defined as lacking the resources to satisfy basic human needs – such as clean water, nutrition, health care, education, clothing, and shelter. When persons are impoverished to the degree that basic human needs cannot be met, they are existing in a state of absolute poverty.

Relative Poverty

Relative poverty is defined as having fewer resources or a lower income as compared to others within a society or as compared to those in other societies. It is estimated that at this time approximately 1.7 billion people are living in absolute poverty. Notably, before the opportunities secured by the Industrial Revolution, poverty was commonplace for the vast majority of the world's population. The Industrial Revolution affected nearly every aspect of daily life, as average income and population began to exhibit unprecedented sustained growth. From 1800 to the year 2000, the world's average per capita income increased more than tenfold, while the world's population increased more than sixfold.

Causes of Poverty

There are scores of theories on the origin of poverty and why it persists. The divergent theories are organized around a variety of epistemological themes. However, researchers agree that the causes of poverty at the macro level are complex and interrelated, and that there are many occurrences that can intensify poverty's effects. Once a community or society has reached an impoverished state, they are predisposed to crises. For example, natural disasters frequently cause famine, hunger, and poverty in areas of the world in which persons are barely surviving already. In regions where food production and availability are only marginally sufficient to provide a sustainable food supply, this predicament intensifies when droughts or other natural disasters obliterate crops and critical infrastructure. Once a region's food production and supply have been severely diminished, it becomes necessary to import food. However, many of these countries do not possess sufficient funds and an infrastructure to enable them to import the life-sustaining food, thereby magnifying the pervasiveness of poverty.

Effects of Poverty

One of the most concerning outcomes of poverty is its impact on the health of individuals, communities, and societies. Approximately 18 million people a year die from causes related to poverty. Those living in poverty have a much shorter life expectancy. According to the World Health Organization, hunger and malnutrition are the single greatest threats to the world's public health, while malnutrition is by far the greatest contributor to child mortality. Malnutrition is present in one-half of all cases of child mortality; annually, approximately 11 million children living in poverty die before their fifth birthday. Frequently, women in poverty bear children into poverty – children who likely cannot be nourished sufficiently. Malnutrition leads to a weakened immune system and frequently hastens the onset of disease. Considering the population worldwide, the three most common diseases related to poverty include AIDS, malaria, and tuberculosis, while other common ailments include measles, pneumonia, and diseases affecting the gastrointestinal tract.

Social Determinants of Health

The social determinants of health are the conditions in which individuals are born and live their lives. These conditions are shaped by the distribution of resources, including money, at all levels. In large part, social determinants are associated with the disparities in health across and within countries. The range in average life expectancy worldwide is from 34 years in Sierra Leone to 81.9 years in Japan. Social determinants help to explain why the poor, as compared to their wealthier counterparts, suffer disproportionately from disease and premature death. Examples include Indonesia, where the under-five mortality is nearly four times higher in the poorest fifth of the population than in the richest fifth, and England and Wales, where the latest data reflect a 7.4-year gap in life expectancy between men in professional occupations and men in manual labor occupations.

Education

It has been documented extensively over the last century that in terms of educational outcomes, children from poorer backgrounds do worse than students who are more privileged financially. If children are impoverished greatly, they may lack access to any opportunities for a formal education. Disparities in educational attainment between children from rich and poor families continue. A recent study entitled "Higher Standards, Better Schools for All" detailed that one's educational achievements are strongly linked to the parents' social and economic backgrounds. Poor children have reduced access to health care and, in general, a reduction in the quality of the care. Frequently the effects manifest as poor cognitive development, frequent illness, hunger, fatigue, and other illnesses that impede students' educational attainment.

Housing

Each year, more than 3 million persons in the United States alone experience homelessness, including 1.3 million children. According to recent national studies, many more Americans are at risk of homelessness. Millions of US households spend greater than 50% of their income on rent. It is estimated that no more than 30% of a household's disposable income, total income less total taxes, should go toward housing. For these millions, the thinnest of margins stands between them and homelessness – a layoff from work, a health emergency, or one of a variety of other potential crises. Beginning in the early 1980s, the number of homeless Americans grew dramatically, and the homeless population grew increasingly diverse – including mothers and fathers, sons and daughters, and all manner of racial and ethnic backgrounds. A full one-third of the current US homeless population is comprised of families, while almost one-half works but does not earn enough to pay for housing.

Poverty Reduction

Worldwide, there are countless initiatives to eradicate poverty – from local grassroots endeavors to broad movements aimed at shaping federal policy. Historically, poverty reduction has occurred as the result of economic growth. Modern technology leads to increased production, providing opportunities for increased wealth generation. Many consider the core of the global antipoverty movement to be the modernization of agriculture and increasing yields. Notably, three-quarters of the world's poor are rural farmers.

Additional efforts aimed at addressing poverty include extending rights to land ownership; making financial services accessible, especially savings; ridding institutions of corruption; creating stable infrastructures; addressing inequities in access to technology; and, perhaps most critically, providing access to quality health care – including public health and health education initiatives aimed specifically at empowering women and other marginalized groups within the global population.

Pregnancy

Margaret D. Larkins-Pettigrew
University Hospitals MacDonald Women's Hospital,
Cleveland, OH, USA

Pregnancy is a normal physiologic process in all cultures but presents various challenges to immigrant women who have limited support systems.

The complaints of various aches and pains cross all ethnic and socioeconomic groups. The management of pregnancies and the multitude of discomforts that accompany may vary. In many ethnic groups, techniques and homemade remedies may be contraindicated in pregnancy but have been sanctioned as essential practices for generations. The health care provider must possess a level of cultural competency that respects traditional techniques and practices but protects the expectant mother and neonate from associated documented or theoretical harm.

Prenatal counseling is necessary for discovery and avoidance of genetic disorders. Among immigrant women, this is a service which is not affordable or sought after.

Early prenatal care has been associated with the most positive outcomes when caring for both low- and high-risk obstetrical patients. Although most immigrant women who do not receive traditional prenatal care deliver viable healthy neonates without maternal complications, many women suffer from unsuspected poor outcomes. It is recommended that women seek prenatal care as soon as they discover they are pregnant.

Immigrant women who are obese or undernourished remain a challenge during pregnancy. Nutritional balance that includes all needed food groups is difficult because cultural norms and traditional eating habits dictate selected diets. A provider or nutritionist who is well informed is essential but not always available. Clear weight-gain goals should be communicated to the pregnant women by a health provider that has an understanding of cultural practice and which will enhance a providers' goal to manage maternal weight and fetal growth.

Education of women that include expected changes in body image, discomfort, and significant changes in emotional status is the cornerstone to detect preventable pregnancy complications. Conditions such as urinary tract infections resulting in pylonephritis, hypertensive disease, and preeclampsia carry warning signs easily recognized and reported by expectant mothers. Use of kick counts during the second trimester for surveillance of fetal well-being is easily taught and accepted by immigrant women.

Women who have had previous operative deliveries are at risk for uterine rupture and should be counseled appropriately. Many women have had multiple operative deliveries and should be offered elective deliveries prior to onset of labor.

Contractions that warrant attention during the prenatal period (preterm) or immediately prior to parturition should be recognized and reported. Preventing preterm delivery and preparing for a safe and supportive experience depends on the expectant mothers understanding of how critical this symptom is to preventive care.

Breastfeeding and sexual activity are two major topics that are discussed among immigrant women. Breastfeeding is a desirable and expected behavior in most immigrant communities. Historically this has been a practice that most women respect as a part of motherhood. Recently, there has been a slow rising trend toward bottle feeding that stems advertisements and promotions that offer free formulas as well as other needed newborn supplies. The World Health Organization (WHO) recommends exclusive breastfeeding for women with human immunodeficiency with studies supporting benefits versus risks of combining breast milk with bottle feeding.

Sexual activity is a subject rarely discussed by pregnant women but is safe unless there is evidence of abnormal placental location or preterm labor.

The three deadly delays have been extensively discussed and used as the focus for many innovative programs that target maternal and neonatal mortality. Delay in recognition of a potential life-threatening condition, transport to a specialized medical facility, and delay in prompt medical intervention are the most challenging areas in delivering optimal care.

Limited health care workers and local facilities in rural areas prevent close monitoring of pregnancy which would detect warning signs of complications such as preeclampsia, infection, bleeding, and protracted labor. Once these common complications are recognized, transport to a medical facility equipped to handle such emergencies may be by foot, mule, or public transport resulting in loss of valuable time for intervention. Those women who do present in a timely manner often receive delayed or ill-advised care resulting in death. Immigrant women who find language as an additional barrier to access to care are more vulnerable to these poor outcomes. Every effort should be made to develop a system that addresses these challenges starting with the immigrant community. Identification of community outreach workers who can be taught to recognize warning signs is desirable.

Many immigrant women find themselves in communities that lack essential equipment and supplies as well as clean water. This lack of infrastructure adds an additional burden to health care providers when attempting to deliver safe health care.

Pregnancy is a normal physiologic process that subjects all women to both physical and psychological changes. Most women handle these dynamic changes without significant and chronic complications. Other women have significant physiologic changes that warrant close observation and early intervention. Immigrant women may be part of this later group.

Pregnancy Outcomes

Margaret D. Larkins-Pettigrew
University Hospitals MacDonald Women's Hospital,
Cleveland, OH, USA

Pregnancy outcomes are as diverse as the many immigrant groups that are displaced or relocated but remain as a primary focus as we attempt to meet the millennium development goals developed by the World Health Organization in 2002. These goals target developing countries and outline goals, objectives, and interventions to decrease the morbidity and mortality in women and children by 2015. The factors that must be considered when attempting to improve pregnancy outcomes are numerous and may directly or indirectly influence pregnancy outcomes of a given group. The overall concerns target the recognition and management of common disease entities that remain the most common causes of maternal morbidity and mortality.

Comparative studies have looked at maternal characteristics and the availability of resources, health care workers, and medical facilities. The overall conclusion is that prenatal care with community involvement may pressure a community to implement policy change that decreases the loss of life for mothers and infants. This community type of pressure brings about a minimal decrease in maternal morbidity in populations where maternal mortality has remained high. Most causes of maternal death are from preventable causes.

Death related to pregnancy is defined as death that occurs while pregnant or within 42 days of the termination of pregnancy. The causes of death are irrespective of the duration or the site of the pregnancy, and may be from any cause related to or aggravated by the pregnancy or pregnancy management; accidental or incidental causes are not encompassed in this definition. The major causes of maternal death are preeclampsia, hemorrhage, and infection.

Preeclampsia is one of the most feared obstetric emergencies. This may result in the death of the mother or the fetus from an unexplained pathologic process. The preeclampsia continuum of hypertensive disease, altered multisystem dysfunction, loss of clotting mechanisms, and seizures still remains an unrecognized entity that warrants early intervention and delivery. In many communities the resources such as antihypertensives, antiseizure medications, and the ability to deliver a neonate operatively are scarce.

Postpartum hemorrhage is another leading cause of death. Lack of uterine tone, cervical and vaginal tears, and placenta previa and abruption require emergent recognition and intervention. Minimal interventions by trained laypersons could prevent loss of life from the most common cause of bleeding which is uterine atony.

Infection, the third threat to maternal health and survival, continues to be a major challenge in all settings. Within the immigrant populations, lack of simple hand washing in overcrowded living quarters with inadequate water sources may result in an outbreak of infectious disease that claims many lives.

Fetal and neonatal deaths are attributed to both maternal and fetal factors. One recognized contribution to neonatal death is preterm birth. Immigrant and refugee women have a high burden of premature births resulting in neonatal deaths. This can be attributed largely to the overall stress to which these women are subjected.

Stress may also be one cause of premature birth and it may involve the production of corticotrophin-releasing hormone originally found in the hypothalamus of the brain, but it also produced by the placenta. Levels rise substantially several weeks before birth, which stimulates the production of prostaglandins, which in turn induce labor. Early production can lead to premature birth. Stress can increase the production of corticotrophin-releasing hormone by the placenta, which would initiate labor and cause premature birth. Stress has become frequent in developed countries, as terrorist threats, actions, and their aftermaths are experienced in otherwise stable populations. Offspring whose mothers were stressed during pregnancy show strong evidence, from experimental biology with animals, that intrauterine stress affects neurodevelopment and alters behaviors in ways that are thought relevant to models of cognition, aggression, anxiety, and depression. Prenatal stress changes the way that glucocorticoids and sex hormones regulate neurogenesis in the developing brain, e.g., in the hippocampus by modifying the fetal hypothalamic-adrenal axis (HPA) and other systems. Stress in pregnancy perturbs endocrine function in animal models of diabetes, cardiovascular disease, and metabolic syndrome. Recent work shows sex differences in fetal responses to maternal stress that may be specific to the gestational age at which the stress is applied experimentally.

In addition to the common challenges of pregnancy, immigrant women who are challenged with a new environment, language barriers, and limited health care options may be at risk for poor pregnancy outcomes.

Prejudice

Brittany Daugherty
Department of Psychology, John Carroll University,
Cleveland, OH, USA

Being prejudiced involves negative feelings toward members of a specific social group. Prejudice is a bias, a preconceived notion which is not based on reason or an actual experience; hostility toward a race, sex, or other class of people. The terms "prejudice," "stereotypes," and "discrimination" are often used interchangeably; however, there are distinct differences between the three. Feelings of prejudice involve a biased judgment that is based on faulty claims and is expressed toward the targeted group as a whole. Close attention is paid to information in support of the prejudice and used to confirm the negative belief. Prejudice, which involves attitudes, is much different from discrimination, which is a negative behavior expressed toward a specific group. Discrimination is behavioral and can be demonstrated in an overt or covert manner. Stereotypes are the beliefs held about a group's behavior, character, and/or intellect. Despite the differences between the three terms, they tend to heavily influence one another. Stereotypes, a cognitive factor, fuel prejudice, an attitude or emotion, which results in discrimination, a behavioral element. This interrelated process is central to its social influence.

Expressions of Prejudice

There are two ways to express prejudice – blatant and subtle. Blatant prejudice is a pronounced and direct way of displaying prejudice and involves two main components. The first component involves a sense of threat from the "out-group" (the group toward which prejudice is being expressed), which invokes a negative response from the in-group (the dominant or mainstream group). For example, this can include the out-group being identified as genetically inferior, thus denying there is discrimination against the group. The second component opposes close contact with the two groups, including marriage and any sort of sexual contact. Essentially, blatant prejudice is a straightforward ousting of the out-group from the broader society, exemplifying their distinctiveness from the dominant group. Subtle prejudice is a vague and indirect way of displaying prejudice. Subtle prejudice has three main components: defense of traditional values, the exaggeration of cultural differences, and the denial of positive emotions. The defense of traditional values suggests that the out-group is estranged because their behavior is inconsistent with standard norms of the dominant or mainstream society. The out-group is used as a scapegoat, which threatens conventional morals. All too often, this component of subtle prejudice is correlated with the "authoritarian personality," which supports a more conservative ideology. The exaggeration of cultural differences blames the out-group's disenfranchisement to cultural distinctions. It is believed that out-groups and in-groups differ in beliefs, and these different beliefs, values, customs, and attitudes provoke intergroup fear, distrust, ignorance, and disapproval, which may eventually lead to violence. Lastly, the denial of positive emotions encompasses the in-group's lack of positive emotions toward the out-group as well as the failure to admit its negative feelings. These emotions are not directly displayed; however, they are subtle biases which covertly indicate prejudice feelings. Often, these concealed feelings may be implicit prejudices which can affect overt behavior.

Sources of Prejudice

Prejudice has been known to originate from a source of threat. When a group's interests are threatened, they are most often experiencing fear. The effect of fear usually motivates prejudice and causes opposition between different groups. Prejudice usually plays a major role in protecting or enhancing perception of group value. When a group's interests are at stake, they retaliate by attacking the opposing group in order to retain the in-group's positive image and display group membership pride. Criticizing another group boosts the dominant groups' confidence, allowing them to feel superior and uphold their value.

Four distinct types of threat have been identified as realistic threat, cultural or symbolic threat, intergroup anxiety, and negative stereotypes. *Realistic threat,* derived from the realistic conflict theory, is simply when the in-group's economic power and well-being is allegedly threatened by the out-group. Threats can arise due to competition between groups over scarce resources such as land, employment, and money. This major cause of prejudice can allow opposing groups to view each other as enemies, increasing intergroup negative views. *Cultural threat,* also known as symbolic threat, is when the out-group's values, lifestyle, and attitudes threaten the worldview of the in-group. Threats arise not only because the opposing worldviews are different, but also due to the "moral rightness" of the in-group. The in-group believes their values are being weakened and thus feel threatened and as a result prejudice is heightened. This particular threat can be explained by the social identity theory, which suggests that individuals perceive themselves positively as an in-group member and express favoritism toward their own social group. The need to enhance one's own self-worth allows the out-group to be viewed as inferior. Our own cultural identity allows us to value our own group's distinctiveness over another group's identity. *Intergroup anxiety,* the lack of contact between groups and the anxiousness that results from this group segregation, is very important in explaining its relation to prejudice. Intergroup interaction is often due to fear of rejection and embarrassment. The groups tend to have no prior experience or contact with each other, perceive themselves as being dissimilar, and have strong views about their own group values. *Negative stereotypes* serve as a negative expectation on the part of the in-group, of the out-group's behavior. Stereotypes are beliefs about a social group that its members are believed to share. However, when portrayed negatively they can carry a prejudiced undertone. These four distinct forms of threat are related to theories explaining why prejudice persists.

Prejudice is known to be prevalent in race, sexual orientation, gender, ethnicity, and religion. Given its strong and perverse history, prejudice against racial groups is the most commonly studied focus. Racial prejudice is an antipathy based on a negative prejudgment against another race. It is most often a collective process where four main feelings are present: (1) superiority, (2) subordinate race is viewed as distinctively different, (3) entitlement to privilege, and (4) fear that subordinate race will threaten the position of the dominant race. Race prejudice is used as a protective factor for the dominant group, such that their advantaged group position and self-esteem can be maintained. The need for a positive group identity drives these prejudiced beliefs. Race prejudice shall only see a decline when and if racial harmony is sought out and when group position no longer holds its strong relevance.

Prejudice and Immigrants

The emerging importance of immigrants and immigration policy has reached the forefront in prejudice research and literature. Prejudice against immigrants is causing an exceptionally troubling dilemma. The theoretical framework suggests that immigrants are often seen as a threat to native culture. As immigrants assimilate into society, they may be faced with negative attitudes from members of the receiving society. Research tends to suggest that immigrants are evaluated more negatively when they pose a threat to those of a host country via cultural threat and/or realistic threat. These perceived threats lead to xenophobic fears which may lead to harsh immigration policies. This cycle of prejudice can grow in intensity and focus. In order to diminish the negative perception of immigrants across society, a number of issues, such as group similarities, links between groups, and common goals, need to be addressed. The support of intergroup interaction is needed to emphasize group similarities which in time may transmit more favorable attitudes toward immigrants. The increase in contact and familiarity with immigrants can work to eradicate prejudice by highlighting the link between immigrants and natives. Finally, recognizing common goals for social and economic progression could reclassify immigrants and natives as having a common identity, which could improve the immigrant native relationship.

Summary

Most often prejudice is learned through a process called social learning. Social learning theory states that prejudiced views can be adopted by direct experiences with significant others and peers. Direct contact with outgroups can also create negative views about particular groups. Just as bigotry is learned, it can be unlearned. However, unlearning can be more difficult and more time consuming. Despite the many efforts to reverse the damaging effects of prejudice, it persists for many reasons. It can continue due to the need for a dominant group to feel authoritative and to increase their sense of worth. However, prejudiced views are not inevitable; there are ways to mitigate the effect of prejudices. Ways to combat prejudice include intergroup contact, reclassifying or recategorizing social groups, and cognitively rebutting stereotypes.

The intergroup contact hypothesis predicts that increased contact between in-group and out-group members could prove to eradicate prejudice. This contact could give opposing social groups an opportunity to learn about each other and possibly create new social groups. By simply obtaining knowledge about another group, tension and stereotypes can be broken and friendships and bonds could be formed. Recategorization involves shifting the boundaries between the in-group and out-group. The common in-group identity model suggests that recategorization can indeed limit the negative effects of prejudice. This model implies that when opposing groups view themselves as a part of a single social entity, the in-group/out-group barriers are eliminated, and as a result antagonism and prejudice are tremendously reduced. Inclusivity can be a beneficial method to learning to foster positive views about opposing groups. Lastly, breaking the habit of relating stereotypic traits to certain social groups can be difficult. However, research has shown that it can be beneficial in negating prejudice. Since stereotypes are cognitively essential to adopting prejudiced beliefs, the weakening of stereotypes can directly affect its implicit link with prejudice, resulting in reduced stereotypes and prejudiced beliefs. Even though this process takes effort and time, it can prove to be valuable in the long-term learning process.

Prenatal Care

- ► Pregnancy
- ► Prenatal health promotion

Prenatal Health Promotion

Margaret D. Larkins-Pettigrew
University Hospitals MacDonald Women's Hospital,
Cleveland, OH, USA

Prenatal health promotion is the cornerstone for delivering information and directing prenatal as well as preconceptual care. Existing programs have invested in extensive outreach programs to advocate early care to promote positive maternal and neonatal outcomes. Many of these outreach programs are careful to address language barriers, cultural competence, and accessibility. Programs that include comprehensive gynecologic screening are essential for women who range in age from menarche through menopause.

Health care beliefs and traditional practices remain the primary challenge when attempting to engage women in accepting preventive care options. Immigrant women who clearly see pregnancy as a normal life process may not see the need to present for costly preventive evaluations. Statistically, most Latino women who have no documented prenatal care remain healthy throughout their pregnancies and delivery healthy normal-weight neonates. In contrast, African-American women who have little prenatal care fall victim to preterm labor, preterm delivery, very low-birth-weight births, and neonatal deaths.

Multiple studies suggest that some immigrants may not believe that preventive care is of value especially when the health care of women has not been a priority in their home countries. Small group sessions within the community that allow women to socialize while they receive needed information are valuable vehicles to promote wellness. Understanding basic female anatomy, physiology, the menstrual cycle, pregnancy, and sexually transmitted disease prevention in lay terms has been a successful strategy establishing trust and limited unwarranted concerns. These outreach sessions have been effective in establishing networks of support that also address the psychological trauma that often accompanies both intra- and intercountry displacements. These sessions allow pooling of limited resources and offer affordable referral services.

Empowering women to take control of their health through education is the hallmark of wellness, including prenatal and preconception health care. Exercise, nutrition, self breast exams, and weight management remain the gold standards for all age levels. Careful assessment of pertinent health challenges may warrant more extensive health surveillance. Family history of reproductive cancers such as breast cancer requires greater patient knowledge and understanding for early recognition. Recognition of the importance of wellness of all women despite immigrant status can contribute to the overall health of a community and society in general.

Prescription Drug Use

Laura Janine Mintz
Department of Epidemiology and Biostatistics, Case Western Reserve University School of Medicine, Cleveland, OH, USA

A United Nations panel has reported that abuse of prescription drugs worldwide will soon exceed illicit drug use. The International Narcotics Control Board (INCB), based in Vienna, Austria, noted in its 2006 report that medications containing narcotic or psychotropic drugs are becoming the drugs of choice for many abusers, and that drug traffickers are responding by increasing diversion and the production of counterfeit drugs. The problem is particularly severe in the United States; according to the INCB, cannabis is the only illicit drug that is more widely abused than prescription drugs – even more so than analgesics, stimulants, sedatives, and tranquilizers. Between 1992 and 2003, the number of individuals in the USA abusing prescription drugs increased from 7.8 million to 15.1 million.

Fueling the production of counterfeits is the increased demand for prescription drugs. In North America, such demand has led to the distribution of counterfeit oxycodone that contained illegally produced fentanyl. According to the World Health Organization, in developing countries where poverty and lack of access to health care influence many to seek medications on the black market, 25–50% of all medicines consumed may be counterfeit.

Persons use prescription drugs to (a) treat illnesses that they have, (b) treat illnesses that they believe they have, (c) to become intoxicated, or (d) a combination of one or more of these. Immigrant use of prescription drugs is complicated for many reasons. First, to acquire prescription drugs, many immigrants travel back and forth from their country of residence to their country of origin – where prescription drugs may be more readily available or less expensive.

Immigrants not fluent in the language of the country of residence may not receive adequate instruction concerning how to take prescription drugs. Therefore, it is likely that they will not have as good an outcome when taking them as people fluent in the language. Access to multilingual pharmacy instruction helps more people take medications in the way they were prescribed. In their country of residence, immigrants may have different ideas than health care providers about how to take drugs. They may come from cultures where people regularly self-prescribe medications; however in the new culture, this may not be advisable. This leads to people bringing drugs from one country into the other and to health care providers not being entirely aware of the medications their patients are taking.

In addition, in countries with and without universal health care, the cost of prescription drugs for immigrants may add a significant financial burden to the health care system. Experts are concerned about the growing cost. The exact amount of the cost seems to vary based on the immigrant population, the drug in question, and the costs associated with the country's health care system.

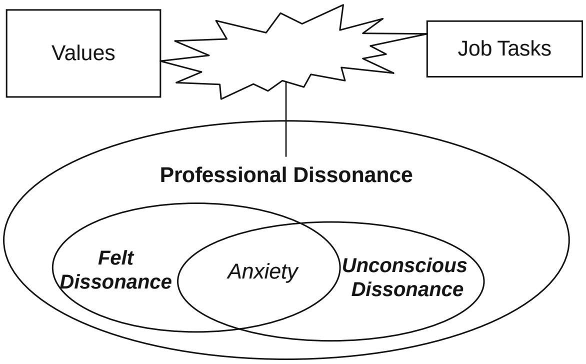
Professional Dissonance

Melissa R. Floyd
Department of Social Work, University of North Carolina Greensboro, Greensboro, NC, USA

Professional dissonance is defined as *a feeling of discomfort arising from the conflict between professional values and job tasks*. It has been developed through the application of cognitive dissonance theory and existential theory to the study of values and ethics and the realities of practice climate in the mental health social work arena. It is easily applicable to working with immigrants and may yield information regarding helping professionals' reactions to difficult scenarios in work with immigrants such as the aftermath of discrimination and deportation, negotiating institutional bias, and managing personal biases related to this population. The figure below uses a visual schematic to illustrate dissonance (Fig. 1).

The concept of professional dissonance seeks to add a new element to the discussion around burnout and job longevity by exploring the ways helpers feel torn or ambivalent about the ways their values and job interventions coexist. In this way, the professional dissonance concept relates to the burnout literature in that it attempts to understand the inner lives of helpers and *how* their inner thoughts and outer actions may contribute to burnout. This is especially true if the helper's ways of resolving their dissonance lead to negative feelings about consumers individually and as a group. An example is provided by the long-term social worker who has become so frustrated with his or her inability to help immigrant children who are also involved in child welfare programs that the social worker begins to associate abusiveness with a particular demographic "Well XXX group just doesn't value children the way we do."

Importantly, an individual helper's insight into his or her own dissonance reduction processes may wax and wane, in much the same way that a person unconsciously uses a defense to manage anxiety but is not aware of what he or she is doing. Even if a person is aware, once experienced dissonance has been reduced or resolved, the person is comfortable again and has a stake in remaining comfortable rather than rehashing the reasons for the initial dissonance. This is important in understanding professional dissonance as a supervision issue because the role of the helper's supervisor may be to stimulate dissonant discussions that raise



Professional Dissonance. Fig. 1

anxiety in an effort to illuminate constructive dissonance reduction; in the context of the helping agency, these discussions may help raise awareness of potentially problematic practices.

Program Management

BETH E. QUILL
Children's Defense Fund - Texas, Bellaire, TX, USA

Program management is a mechanism through which organizations create projects and realize their goals and objectives. Multiple projects may support a particular program with each project having specific purposes, tasks, and deadlines. Program management and project management are often distinguished by the following characteristics: (1) Projects deliver discrete products or outputs with achieving deadlines a predominant feature. (2) Programs create outcomes and focus on the long-term benefits to the organization. A central feature of program management is the importance of doing it right and attaining the maximum benefits. The benefits occur based on the capacity of the programs to change and respond to different external influences. These influences may include technology, or economic and social circumstances.

Program management provides oversight of projects and includes several key aspects. *Governance* includes defining roles and responsibilities for the program. *Management* of the program focuses on the essential planning and administration of program activities and specific projects. *Financial management* includes the implementation of specific practices and controls to ensure fiscal stability. *Structure* refers to the establishment of physical space, technology, staff, and creation of a work environment to support the program. Finally, *planning* is central to the program achieving objectives of the organization. The planning occurs at multiple levels in the organization with multiple goals, all consistent with the mission of the organization.

Successful program management requires executing several tasks. These tasks include: (1) problem identification; (2) needs assessment; (3) planning goals; (4) program design; (5) information management; (6) fiscal procedures; (7) project monitoring; and (8) program evaluation. Collectively, these tasks create the successful operation of the program. Periodic evaluations of the program ensure that the program continues to serve the intent of the program and respond to changes in the environment.

Immigrants seeking services often experience programs at multiple organizations and programs that have program eligibility and service requirements. Depending on the organization, the program effectiveness in meeting the need of immigrants may be variable. Organizations like the World Health Organization (WHO), United States Agency for International Development (USAID), and local nongovernmental organizations (NGOs) offer examples of programs specific to the needs of immigrants.

Promotora

Hector G. Balcazar
Health Science Center Houston, School of Public Health, University of Texas, EL Paso, TX, USA

The word *promotor de salud* in the Hispanic/Latino community is synonymous to an individual who is from the community and works for the health and well-being of the community. The male version in Spanish is called *promotor*, the female is called *promotora*. *Promotores de salud* is the plural term. Many Hispanic/Latino immigrants have been served and helped by *la promotora de salud*. In many instances, the female description is the one used since the majority of *promotores* are female. *Promotoras de salud* may be the most commonly used term.

There are an infinite number of descriptions (close to 35 terms) that have been associated with *promotores*. The term commonly used is that of Community Health Worker (CHW). *Promotores* are those who serve Hispanic/Latino communities. Recently, and in part of the great recognition of the role of community health workers in the community, there is a standard occupational classification (21–1094 code) from the Bureau of Labor Statistics for CHWs. The CHW Section of the American Public Health Association has adopted the following definition of the CHW:

- "A CHW is a frontline public health worker who is a trusted member of and/or has an unusually close understanding of the community served. This trusting relationship enables the CHW to serve as a liaison/link/intermediary between health/social services and the community to facilitate access to services and improve the quality and cultural competence of service delivery. A CHW also builds individual and community capacity by increasing health knowledge and self-sufficiency through a range of activities such as outreach, community education, informal counseling, social support and advocacy."

Documentation on the uses of CHWs can be found in the USA as early as 1950. Some programs that initially involved CHWs include county health departments, migrant health programs, university departments of public health, and Indian Health Services. The proliferation of CHWs to work on the expansion of health services to underserved communities (including immigrant communities) became a reality as a result of legislation enacted in 1962 with the Federal Migrant Health Act of 1962 and the Economic Opportunity Act of 1964.

Promotores de salud working in the Hispanic/Latino community have for many years addressed the health-related needs of immigrant communities. *Promotores* help individuals not only to address health needs but, also, they play many other functional roles. Examples of the health and non-health roles include: (1) providing a variety of "informal" but "direct" involvement to enhance actions that relate to the delivery of health services; (2) promoting advocacy and actions to solve problems at the individual, family, and community levels; (3) serving as a bridge to encourage individuals (many of which are immigrants) to understand how to navigate systems (including the health system); (4) promoting the support of people by giving advice, guidance, pertinent information to reach a service in the community, bridging cultural, linguistic, and literacy differences, facilitate social support; (5) providing community education, access, and adherence to preventive care and monitoring of risk, treatment, and promotion of self-care and follow-up care.

For many immigrants, *promotores* de salud are the synergy and hope that are required to live "in community" at times when there are many financial, social, family, and individual constraints and challenges. Immigrant families may be exposed to great sources of stress as they strive for a better life in the USA. There are many transformative processes that immigrants undergo as they immigrate. These include changes in the family and in the social system. Immigrants must cope with new realities as the new environment brings new challenges and opportunities. *Promotores de salud* provide much support to the immigrant individual and family member (including emotional support) serving a variety of roles. The *promotora* tries to solve problems at various levels in the lives of the immigrant by seeking support from different agencies and institutions.

Given the amount of evidence that currently exists in the research literature, the work of *promotores de salud* is becoming legitimate. Soon *promotores* will be officially part of the health team for many agencies, institutions, hospitals, and other health-related services. That means, employment for *promotores* will improve as the concept of prevention in the health care reform becomes a reality. How would this employment work for *promotores de salud*? There are several options. One is the opportunity of getting reimbursements from Medicaid as a result of the work *promotores de salud* do with individuals for improving their health conditions, including control and management of diseases like diabetes, and with providing prevention for reducing risk factors such as high blood pressure, high cholesterol, obesity, and many more. Another option is that employers in clinics, community-based organizations see the value of *promotoras* and invest in them, by creating a financial infrastructure in their agencies. Bringing *promotoras* to be an integral part of the systems of health care, health promotion, and disease prevention is the future.

In providing services to many immigrants communities, *promotores de salud* work as volunteers and are not being remunerated financially. Thus, a mixed model of *promotores* exists, those who are paid and those who are not. There is a heated debate as to whether *promotores* should always be paid for their services. Some groups believe that the "volunteer nature" of *promotores* will always exist because *promotores* love to help people in their community. Thus, there is an element of altruism present in the *promotora* who works for the community where she is from. *Promotores de salud* are always connected to the needs of communities. In addition, they respond to those needs (particularly health needs) by always receiving the best training possible. Training is an important prerequisite for success of the *promotora*. Training and adequate supervision of *promotores de salud* is becoming a prerequisite for the practice of *promotores de salud* in communities. Currently, two states, Texas and Ohio, offer credentialing of CHWs. This practice is also somewhat controversial.

Prostitution

Vanessa A. Forro
Case Western Reserve University, Cleveland, OH, USA

According to the Universal Declaration of Human Rights, everyone has the right to freedom of movement and residence within each state, to leave any country – including his or her own – and to return to his or her country of residence. The lack of social and economic opportunities for prostitutes in economically deprived countries remains a chief cause of migration. Often this phenomenon among female prostitutes is referred to as the "feminization of migration." It has been documented well by Kamala Kempadoo, who argues that migration is a result of oppressive globalization for many poor countries. In terms of the legality of their trade and the systems of support within the trade, prostitutes may be better off in another country. Conversely, being a migrant and a prostitute can present a double illegality – with little to no access to health and legal and social support services. The following offers a brief examination of historical aspects of migrant prostitution, a short overview of legal challenges that migrant prostitutes face, and a discussion of the health implications for migrant prostitutes.

The Page Law of 1875 was the first legislative statute in the USA to restrict immigration federally. Named after California Republican Horace F. Page, the law banned the immigration of women from entering the USA for purposes of prostitution and other immoral acts. Page testified that many Chinese women who came to the USA and settled in San Francisco were not the wives of Chinese immigrants, but they were polygamous concubines or prostitutes. Furthermore, he contended they were no more than slaves, contrary to the American system of free labor. Prior to the introduction of the Page Law of 1875, several statutes were implemented in California in an attempt to prevent the entry of Chinese women, claiming they jeopardized the health, morals, and lives of its citizens. This was the first passage of repressive migratory laws specifically aimed at preventing prostitutes from entering the USA. In more recent years, laws such as the Trafficking Victims Protection Act (TVPA) have served as smoke screens for the protection of victims. The TVPA, enacted in 2000, has continued to sanction the arrest, detainment, and deportation of migrants working as prostitutes in the United States.

Accurate numbers of international migrant prostitutes are hard to determine, largely because in most countries it is an underground activity. A report by TAMPEP estimated that there was an average of 65% of migrant sex workers within the European Union (EU), with the majority of these migrant sex workers being third-country nationals – non-EU citizens. An extremely restrictive legal framework consisting of residency status, access to the labor market, and legal regulations on prostitution reinforces the vulnerable status of migrant prostitutes. Prostitution is discussed frequently within the context of discrimination, violence, and trafficking, but rarely in terms of autonomy, human rights, or self-regulation. Often migrant prostitutes who experience violence, harassment, and poor working conditions are unable to report this to authorities for fear of deportation, expulsion, or other undesired legal ramifications. Language and cultural barriers, social isolation, fear, and dependence on brothels or pimps contribute to the vulnerability of migrant prostitutes.

The health implications for migrant prostitutes are connected primarily to HIV/AIDS and other sexually transmitted diseases. Migrant and mobile prostitutes, especially those who are undocumented, have very limited to no basic health education and healthcare. Many migrant prostitutes do not establish medical care, and if they do, treatment is rarely continued to resolution of the condition. This scenario presents for migrant prostitutes a high degree of risk for contracting a disease, a condition not being treated properly and unwanted pregnancies due to poor contraceptive knowledge. In countries where prostitution holds some level of legality, often there are labor-related regulations in place that one must follow in order to work as a prostitute; the most common regulation is mandatory health checks. However, because migrant prostitutes are residing in the country illegally, their illegal status poses a barrier for them to adhere to the mandate. Therefore, access to care for undocumented prostitutes is dependent on a variety of factors including: ability to pay, interpretation availability, provider cooperation, and confidentiality regarding occupational status. UNAIDS recommends that to make sex work safer, occupational health and safety standards should be adopted and that health service providers should be trained in addressing stigma, discrimination, and violence.

Psychological Acculturation

Kenneth Fung
Department of Psychiatry, Toronto Western Hospital,
Toronto, ON, Canada

Acculturation describes changes, cultural or psychological, that occur as a result of prolonged firsthand contact between two different cultures. *Psychological acculturation* describes changes that occur at the individual psychological level. This construct helps us to study and understand changes, adaptation, and other psychosocial processes that occur when immigrants and refugees settle in a host country with a different culture – which in most cases is the dominant and majority culture with the most social power.

Historically, it was assumed that acculturation proceeds along a linear direction, as newcomers and minority groups gradually relinquish their traditional cultural identities, values, customs, and other characteristics, and become absorbed or assimilated into the mainstream culture of the dominant host group. At the midpoint along this trajectory, individuals may be described as bicultural, straddling between two cultures.

It has since been recognized that a bidimensional model more aptly captures the varieties of acculturative strategies that newcomers may employ. From this perspective, newcomers and minority groups may identify with their heritage culture and the host dominant culture to varying degrees. Some may maintain aspects of their heritage culture as well as adopting elements from the host culture, using a strategy of *integration.* Alternatively, some may disengage from their heritage culture and completely adopt the host culture through *assimilation.* Some may not take up the host culture, but maintain their traditional heritage culture using the strategy of *separation.* This may be a viable option especially when there is a critical mass to maintain a cultural community, such as an ethnic enclave. Finally, with *marginalization*, they may find themselves disengaged from both traditional and host culture. It is believed that integration may be associated with better mental health, while marginalization may lead to increased vulnerability and adverse effects on health. The other two strategies may occupy an intermediate position.

Acculturation may not neatly fall into these four strategies uniformly across all domains of an individual. For example, individuals may adopt mainstream dietary practices or clothing out of necessity, while retaining traditional cultural values in other areas. Further, acculturation is not a static state. Individuals may vary their acculturative strategies with time due to personal and contextual psychosocial events or factors. For example, some developmental models describe changes in ethnocultural identities over time that may be applicable to certain individuals from minority groups and immigrants. While the details vary, such models often describe an initial wish, attempt, or actual identification with the dominant sociocultural group. The individuals may then come to realize that the fit might not be perfect or possible, arising from cultural differences, power inequity, or experiences of outright discrimination and rejection. The individuals may then re-identify with their own cultural or ethnic identity, rejecting the dominant culture. For some individuals, they may eventually attain internal reconciliation and integration of the different cultural values and identities.

Thus, many factors affect the process of acculturation, including both individual internal factors, such as personality, preferences, and personal history, and external factors, such as the host culture and other societal forces. The Interactive Acculturation Model proposes that the attitudes of the host cultural group can be described in an analogous bidimensional model: *integration*, the attitude that immigrants should ideally retain their heritage culture and adopt host culture; *assimilation*, immigrants should relinquish the heritage culture and be assimilated into the host culture; *segregation*, immigrants should retain their own culture, and be segregated into their own communities; and *exclusion*, immigrants should neither try to adopt the host culture nor retain their traditional culture. In addition, it has been proposed that some immigrants and host group members may actually subscribe to an *individualist* ideology – that culture is not an important identifying variable and each person should be treated as an individual. This may especially be found in more individualistic and less collectivistic cultures.

The host cultural group and the immigrant groups may prefer different acculturative strategies, and one group's preference may affect the other. The dominant group with more social power may make it difficult for the non-dominant group to actualize their preferred acculturative strategies. This can result in problematic and conflictual intercultural relationships. Among the dominant cultural group, integrationists, assimilationists, and individualists are open to the idea that immigrants can become full members of the host society, while segregationist and especially exclusionists tend to have rejecting attitudes toward immigrants.

From a larger societal or national perspective, policies may affect acculturation. A *pluralistic multicultural policy* values the nation's culture as well as the immigrants' heritage culture, providing resources and funding to support the maintenance of both. A *civic policy* similarly is permissive of both cultures, but does not actively support immigrants' heritage cultures with funding or resources. An *assimilation* ideology, or "melting pot," supports the national culture and the relinquishment of other competing cultures. An *ethnist* perspective is the least tolerant, and may never grant full status to immigrants or other ethnic groups in their own society.

The process of acculturation may potentially lead to the positive adaptation of immigrants and the enrichment of the host society. Conversely, certain acculturative strategies at the societal, host group, or individual level and the resulting interaction among these levels may give rise to increased tension, conflict, discrimination, and inequity. This, along with other psychological, social, and cultural stressors, gives rise to *acculturative stress* for immigrants, which may lead to adverse health outcomes.

Psychopathic Personality

Susan Hatters Friedman
Departments of Psychiatry and Pediatrics, Case
Western Reserve University School of Medicine,
Cleveland, OH, USA

Psychopathic personality has two meanings, one meaning in psychiatry and another in the context of immigration to the USA. While the initial meaning for immigration may have sought to be similar to psychiatry's definition, it is actually an example of psychiatric terms being misused by both legislative and judicial arms of the government.

Mental Health Definitions of Psychopathy

Psychopathy describes a subgroup of persons with Antisocial Personality Disorder. Up to 1% of people may be categorized as psychopaths, though rates may be 7–20 times higher in prisons. The average criminal is not a psychopath.

Hervey Cleckley, in his seminal work, *The Mask of Sanity* (1941), described characteristics of psychopaths, who appear normal on the surface ("the mask") but are merely mimicking personality traits of others. A lack of empathy for others is the primary defect. Other characteristics of psychopaths, described by Cleckley, include superficial charm, insincerity, untruthfulness, lack of remorse, egocentricity, fantastical behaviors, lack of a life plan, inability to learn from experience, unreliability, and lack of irrational or delusional thinking or affective responses. Sexual experiences inevitably occur without a capacity for love or relationship. They say what they have seen others say in apparently similar situations.

More recently, researcher Robert Hare developed the Psychopathy Checklist-Revised, which is used by mental health professionals to assess psychopathy. Building on Cleckley's description, deficits are rated in areas such as interpersonal relationships, emotions, and self-control. Scores on the PCL-R are predictive of violence and recidivism as well as response to treatment.

In sum, persons with psychopathic personality have a fundamental defect in their ability to have empathy for others. They are superficially charming and can be charismatic manipulators who do not have consciences. This description is quite different from all that was previously included in US immigration policy.

"Psychopathic Personality" and Immigration to the USA

A long history of exclusion of sexual minorities from the US is the backdrop for the intersection of immigration policy with "psychopathic personality." The 1917 Immigration Act excluded immigrants who were "mentally defective" or who had "constitutional psychopathic inferiority" from the USA. The Public Health Service's definitions of homosexuality reinforced the characterization and the effect was to ban homosexual immigrants. The Immigration and Naturalization Act (INA) of 1952 passed by the Senate and House excluded those with "psychopathic personality, epilepsy, or a mental defect" from immigrating to the USA. These terms were considered to include both homosexuals and "sex perverts." "Sexual deviation" was added to the exclusion list by a 1965 amendment. By the Immigration Act of 1990, Congress abandoned the exclusion of homosexuals, and did not reference the "psychopathic personality" or "mental defect." (However, Congress did not make provisions for same-sex couples to immigrate).

Deportation proceedings occurred in 1959 against George Fleuti, a Swiss national admitted into the USA in 1952. Because he was gay, he fell under the "psychopathic personality" category under the INA. Later, the 1967 case of *Boutilier v. INS* was decided by the Supreme Court. Mr. Clive Boutilier was admitted to the US in 1955, made a brief trip to Canada in 1959, and applied for US citizenship in 1963. His partner, his siblings, his mother, and stepfather lived in the USA as well. He had been arrested for sodomy in 1959, a charge which was later dismissed. He was asked to submit an affidavit about his sexual history and based on that, was diagnosed as "afflicted with a class A condition, namely psychopathic personality sexual deviate" by the Public Health Service. Two psychiatrists submitted reports noting that he was gay, but that he did not have a psychopathic personality. The Court needed to decide whether "psychopathic personality" included homosexuals. His deportation was upheld.

Psychotherapy

Kenneth Fung
Department of Psychiatry, Toronto Western Hospital,
Toronto, ON, Canada

Psychotherapy is a form of psychological intervention. Most commonly, it involves a form of therapeutic dialog between a therapist and a client, or "talk-therapy." It may be used to treat mental illness, such as depression and anxiety disorders; help overcome situational emotional difficulties, such as grief and coping with other stressors; make long-term personal changes, such as aspects of personality; or enhance various aspects of life, such as improving interpersonal relationships and living a more fulfilling life. Psychotherapy is often conducted in individual sessions between a therapist and a client. It may also be conducted with couples, families, or in small groups.

Currently, there are many types of psychotherapy in practice, based on different models and theories of psychological health and psychopathology. One of the earliest forms of modern psychotherapy is psychoanalysis pioneered by Sigmund Freud. This continues to be practiced, and has a great influence on the field, as many other therapeutic models incorporate its ideas and assumptions, such as: the mind unconsciously influencing one's behaviors; past trauma, loss, developmental deficits, or other formative experiences shaping present predisposition and behaviors; problems being caused by psychological conflicts or deficits and the use of compensatory defense mechanisms; and the notion of transference and countertransference reactions, i.e., the client's and therapist's respective unique psychological and emotional reactions to one another in therapy related to therapeutic issues, personal issues, or past experiences. Different types of therapy may widely differ in their relative emphasis on the importance of the relationship between the therapist and the client; the importance of cognitive insight (knowing) versus emotional experience (feeling) versus behavioral changes (doing); the level of activity of the therapist, from empathic listening to actively interpreting or teaching; the focus on the past versus the present; and the focus on the client's life outside of therapy versus moments transpiring in therapy between the therapist and the client. The duration of psychotherapy varies. Time-limited short-term therapies may consist of 12–16 weekly 1-hour sessions, while open-ended therapies may last months to years.

Several types of psychotherapies are commonly practiced. Psychodynamic psychotherapy derives most directly from psychoanalysis. Depending on the therapist, it may be subdivided into various schools, including ego-psychology, object-relations, or self-psychology, and may locate variably on an expressive-supportive continuum. Cognitive-behavioral therapy (CBT), which is relatively amenable to be manualized for research, has a large body of empirical support for a variety of specific disorders. In CBT, the therapist tends to be more active and directive, and collaborates with the client to explore the connections between thoughts, emotions, and behaviors. It aims to correct *cognitive* errors, such as negative automatic thoughts and core beliefs about the self, others/world, and the future, and use *behavioral* strategies to facilitate change, such as planning activities to increase motivation or setting up a hierarchical list for systematic exposure to desensitize feared situations. Other evidence-based therapies include behavior therapy (BT), dialectical behavior therapy (DBT), manual-based family therapy, interpersonal psychotherapy (IPT), multisystemic therapy (MST), and parent training. Although there are many different types of therapies, "common factors," such as the *therapeutic alliance* between the therapist and the client, have been found to account for a significant part of psychotherapy's beneficial effects.

From a cross-cultural perspective, in addition to common Western psychotherapies, *cultural-embedded healing practices*, such as shamanism, may share some common healing elements with Western psychotherapy. *Culture-influenced psychotherapies*, such as Morita or Naikan psychotherapy, are unique psychotherapies that are generally not practiced in Western countries, and are developed and practiced in Asian countries. In recent development, many Western developed psychotherapies implicitly or explicitly share elements of traditional Eastern philosophies or practices. For instance, some therapists have incorporated Buddhism explicitly into traditional psychoanalysis. The newer developed "third-wave behavioral therapies," such as Dialectical Behavioral Therapy (DBT), Mindfulness-based Cognitive Therapy (MBCT), and Acceptance and Commitment Therapy (ACT), all include elements of *acceptance* and *mindfulness* from Zen Buddhism.

In applying psychotherapy in cross-cultural situations, cultural competence becomes especially important. Practitioners may need to make philosophical, theoretical, or technical adjustments. Culturally competent elements, including requisite attitudes, knowledge, and skills, can be identified longitudinally in all phases in therapy, including preengagement, engagement, assessment, therapy, and termination phases. For example, self-reflection and awareness of potential sociocultural transferences and countertransference may become an important consideration in therapy. In understanding the client and applying the therapeutic model, culture needs to be taken into account, and an Outline for Cultural Formulation may be used to enhance this understanding. With Outline for Cultural Formulation, five domains are explicitly considered: (i) the client's cultural identity (including acculturation); (ii) explanatory model of illness; (iii) sociocultural factors (including stressors and supports) and levels of functioning; (iv) cultural factors in the relationship between the therapist and the client; and (v) a summary of cultural factors in assessment, diagnosis, and treatment.

Using culture as a reference point, practitioners can consider whether their psychotherapeutic interventions, including the formulated goals and the chosen therapeutic content and process, are culturally reinforcing, culturally congruent, culturally neutral, or counter-cultural. None of these orientations are inherently superior, and each may be therapeutic to the client in different circumstances at different points in time in therapy.

Thus, psychotherapy can be an important therapeutic intervention for immigrants of diverse cultures if sociocultural issues are taken into consideration. In addition, it is important to note that practical issues such as transportation, childcare, cost, and language barriers may result in inequitable access to treatment or premature dropout from psychosocial interventions.

Public Health

Margaret A. Potter
Graduate School of Public Health, University of Pittsburgh, Pittsburgh, PA, USA

Introduction

Public health is concerned with optimizing the health of populations by preventing diseases and promoting healthy behaviors, environments, and policies through efforts of both government and private-sector organizations and individuals. Its scope includes but goes beyond assuring that people have access to health care and services: public health encompasses the health of individuals in the contexts of family, community, workplace, environment, and society both nationally and internationally.

The functions of public health include: prevention of epidemics and disease spread, protection against environmental hazards, prevention of injuries, promotion of healthy behaviors, response to disasters, and assurance of the quality and accessibility – though not necessarily the direct provision – of health care services.

Challenges to Promoting and Protecting the Health of Immigrants

Immigrant populations present unique challenges to national and international systems of public health. As of 2007, there were 34.2 million US residents of foreign birth, over half of whom originated in Latin American countries and over a quarter of whom originated in Asian countries. Whether they are naturalized citizens, noncitizen residents, or undocumented residents, these immigrants may face threats to health and well-being that are different from those confronting the native-born population. These special challenges arise from migration status itself, from personal circumstances, or from the environments where individuals and families work and live.

First, immigrants may have diseases acquired in their countries of origin that are otherwise well-controlled in the USA. For example, some enter the USA with tuberculosis needing ongoing and aggressive treatment. Immigrants in the USA may have difficulty in finding customary foods and therefore lack adequate nutrition. They may not have important information about vaccinations against preventable infections for themselves and their children. They may be exposed to dangerous environments and social conditions that compromise their health.

Language barriers may isolate them from health-relevant information or impair the quality of their interactions with health care providers. Fear of detention, whether or not justified, may deter immigrants from seeking governmental assistance, advice, and health-related services. Immigrants in the USA use social services at rates well below those of the native-born population.

Noncitizen immigrants often work in agriculture. Census data show that over three times the percentage of noncitizen immigrants (2.2%) work in farming, fishing, and forestry occupations as do percentages of citizens both native-born (0.5%) and naturalized (0.6%). In farm labor, where undocumented workers may comprise half or more of all workers, the migratory nature and seasonality of employment put workers at risk of inadequate housing, unfair labor practices, injuries, and exposure to toxic pesticides.

Immigrant populations in the USA disproportionately lack health insurance, due in part to their overrepresentation in industries where employer-provided health plans are less common and in part to their limited eligibility for public health care programs.

Public Health Law and Policies for Immigrant Populations

Public health depends on contributions from private sector organizations and individuals, but its core functions depend on governmental organization, delegation, and oversight. Public health has international, national, and – in the United States – state- and local-level components. The World Health Organization promulgates policies and calls upon individual nations to support and implement them. Federal agencies in the USA regulate food and working conditions, contribute to national health policy making, support health services, conduct and fund research for health and health care, support health professional education and development, and provide expert advice and consultation to agencies, institutions, and individuals. Each individual US state fulfills its responsibilities for health of the public separately both from other states and from the federal agencies. States also contain public health systems at the level of counties and cities. This wide distribution of governmental authority and responsibility for public health means that numerous public health systems can influence the health of immigrant populations.

International

In 2005, the World Health Organization (WHO) revised the International Health Regulations (IHR) and created a system of infectious disease reporting. The IHR is intended to inhibit the spread of disease and to protect national populations from imported diseases. Unlike its earlier version that limited regulation to a few specified diseases, the IHR of 2005 includes any and all disease posing significant harm to humans. It requires each nation to have a core public health capacity that is capable of monitoring disease outbreaks and, when they threaten to spread beyond national borders, providing notification to WHO authorities. The IHR specifies protections for travelers, including immigrants.

The WHO adopted a “Global Strategy for Health for All by the Year 2000.” Its purpose is to assure that resources for health become more evenly distributed, emphasizing both governmental and personal responsibilities in preventing illness and relieving the effects of disease and disability. Pursuing the goal of health for all persons at a level sufficient to permit socially and economically productive lives, WHO sets health standards, monitors health status, and maintains health statistics. Among the nations that have opted into Health for All strategies, the United States has taken a minor part.

Domestic

The USA has numerous separate agencies at the federal, state, and local levels and many organizations both voluntary and for-profit with authority to make policies affecting public health. Among all of these entities, there is overlapping scope of authority and no clear or consistent hierarchy.

At the federal level, the United States distributes responsibility for various aspects of public health among a number of agencies. The Centers for Disease Control and Prevention (CDC) contributes expertise, information, and tools needed to protect the health of people and communities. The Food and Drug Administration (FDA) monitors the safety and effectiveness of drugs and vaccines as well as the safety of the food supply, cosmetics, dietary supplements, and other products. The Department of Agriculture (USDA) works to enhance food safety and to provide food assistance and nutrition education. The Health Resources and Services Administration (HRSA) helps to improve access to health care services for people who are uninsured, isolated, or medically vulnerable by training health professionals and improving systems of care in rural communities. The Department of Labor (DOL) enforces fair labor and housing standards under laws specifically intended to protect migrant and seasonal farm workers.

State and local public health agencies screen for, vaccinate against, and/or treat infectious diseases such as HIV/AIDS, seasonal influenza, and infectious diseases of childhood. School attendance laws in every state require that children be vaccinated against measles, mumps, rubella, pertussis (whooping cough), hepatitis B, and other infectious diseases. Since tuberculosis outbreaks in US port cities have been traced to immigrant populations, the federal government mandates a program to test and treat all immigrants to the USA for tuberculosis under guidelines established by the CDC. In addition, state laws mandate tuberculosis reporting; and many state and local public health agencies also identify and treat cases regardless of the person’s ability to pay.

The Safety Net

While access to health care services represents only one of many public health concerns, it deserves particular attention because immigrants in the USA may suffer systematic exclusion from the nation's health care systems. Exclusion may result from lack of health insurance, low incomes, language barriers, and living in rural areas where availability of health professionals and services is sparse. A patchwork of safety-net programs – including health insurance, direct services, and emergency services – helps to support the needs of immigrant populations.

Health Insurance

Medicaid is a program that each state funds jointly with the federal government within federal guidelines. Rules for eligibility and duration of Medicaid coverage are complex and vary state by state. Generally, those eligible include low-income pregnant women and children, parents, disabled adults, and the elderly; typically ineligible are those persons who are childless non-elderly adults. Children and some adults whose incomes are slightly above the Medicaid-eligibility limit may qualify for the Children's Health Insurance Program (CHIP; formerly called SCHIP), which is also jointly sponsored by states and the federal government. Only immigrants with permanent resident status are eligible for Medicaid and CHIP, usually subject to a 5-year residency requirement. Undocumented immigrants are generally not eligible, but a few states do provide CHIP coverage for pregnant women without regard to immigration status.

Low-Cost Direct Services

Community and migrant health centers provide health services at low cost or no cost, with fee scales adjusted to the patient's ability to pay. There are over 7,000 such community centers in all states; there are 147 centers focused on migrant farm workers' needs in 39 states and Puerto Rico. The services available include wellness check-ups, treatment for illness and injury, prenatal care, immunizations, dental care, prescriptions, and mental health and substance abuse care.

Emergency Care

Hospitals in all states are subject to federal law requiring that they provide treatment, stabilization and, if necessary, referrals to anyone who needs either emergency health care or childbirth services – regardless of ability to pay. Anyone needing such care may go to a hospital emergency department and receive treatment within the particular hospital's available expertise. The demand for these services may be heavy at times and in certain locations because emergency departments have become the provider of last resort for populations lacking health insurance or access to regular physicians and clinics.

Conclusions

Public health systems and policies encompass immigrant populations but fall short of meeting their particular needs and vulnerabilities. International regulations are designed to prevent disease spread among nations rather than to assist or protect individuals. Immigrants in the USA face health threats often greater than do native-born citizens but lack access to services due to restrictions from public insurance, lack of employment-based coverage, and apparent reluctance to seek care. The newly enacted health insurance reform legislation (March of 2010) does little to improve access to health insurance and health care for noncitizen US immigrants regardless of legal status.

Public Health Insurance

Karen Love, Jennifer Mineo
Harris County Healthcare Alliance, Houston, TX, USA

Public health insurance in the United States refers to the use of public funds for medical care of individuals. The Veterans Affairs and Indian Health Service use public funds and provide medical care for their respective populations, for example. By far the most familiar public insurance programs are the Medicare and Medicaid programs. Enacted as Title XVIII of the Social Security Act in 1965, Medicare was created as a comprehensive health insurance program for older Americans. The program was expanded in 1972 to provide coverage for persons with disabilities. Eligibility for the Medicare program is not based on financial need; but rather is a federally funded entitlement program. Financing for Medicare Part A's Hospital Insurance benefits, for example, derives from a FICA (Federal Insurance Contributions Act) withholding tax applied to wages. Medicare Part B for physician, outpatient hospital, home health, and medical equipment and supplies is optional and funded in general by beneficiaries directly. An estimated 46 million individuals are covered under the Medicare program in 2010. The Medicaid program was also established in 1965 as a federal–state partnership under Title XIX of the Social Security Act to provide health insurance for low-income Americans, including many older Americans (referred to as dual eligibles). Depending on a state's per capita income level, the federal government pays from 50% to 76% of a State's Medicaid program costs, with the remainder being funded by each state. The Children's Health Insurance Program (CHIP) was established in 1997 and can either be a separate state program or a component of a State's Medicaid program and is available to cover children up to 300% of the federal poverty level. Fifty-eight million individuals are estimated to be covered under Medicaid and CHIP programs in 2010.

In addition, some states and local governments have established publicly funded health insurance or health coverage programs for certain portions of the safety net population (for example, county indigent health programs, and family planning programs).

Private health insurance in the United States is primarily operated through the many large and some small employers who offer health insurance to their employees as a fringe benefit. Additionally, individuals may purchase private health insurance for themselves and/or their families in the individual market. Private health insurance is generally regulated at the state level.

The gap between public programs and private insurance accounts for the uninsured in the USA, which according to the most recent estimates exceed

46 million individuals. Individuals without insurance in the United States are less likely to have a usual source of care, seek early prevention and intervention services, and both report being in poorer health and have measurably worse health outcomes than their insured counterparts. They are more likely to postpone care and therefore require more acute and expensive treatment at later stages in many disease processes. The uninsured account for substantial proportions of the unnecessary and preventable hospitalizations and inappropriate utilization of emergency departments for primary care related conditions.

When large numbers of individuals are uninsured, the costs of providing generally uncompensated care falls upon healthcare providers, particularly safety net providers such as publicly funded hospitals, and local governments. Additionally, providers seek to cover their losses from uninsured care by charging higher fees to their insured consumers. These higher healthcare fees are in turn passed on from insurers to the insured individuals who pay for the insurance premiums. As insurance premiums rise, some employers raise the cost-sharing rates for their employees or drop coverage altogether, and/or individuals drop coverage due to its unaffordability. This, in turn, creates more uninsured, and the cycle of cost-shifting and fewer insured individuals continues.

The majority of the uninsured nationally are citizens (80%). That figure is estimated at 76.3% for Texas. The Pew Hispanic Center estimates there were about 6.8 million uninsured undocumented immigrants in 2007 who accounted for 15% of the uninsured (Kaiser Family Foundation, December 2009). Estimates suggest that 7 of 10 immigrants are either naturalized citizens or lawfully residing noncitizens who together account for 9% of the US population. Approximately 11.9 million undocumented immigrants make up 4% of the population and 5.4% of the workforce. Some 40% of noncitizens (lawfully residing and undocumented) have private insurance, but they are significantly more likely to be uninsured than citizens, with 46% of noncitizens lacking coverage. This higher uninsured rate reflects more limited access to private and public coverage, because while noncitizens are as likely to work as citizens, they often do so in jobs and industries that do not typically offer employer-sponsored health coverage.

Passage of the Affordable Care Act of 2010 has only minimally impacted access to public or employer-sponsored insurance for immigrants in the United States. Immigrants are generally defined as foreign-born individuals residing in countries other than their country of origin. In the USA, this includes naturalized citizens and noncitizens (both lawfully residing and undocumented). Undocumented immigrants, for example, remain ineligible for the expanded Medicaid program. Lawfully residing immigrants without access to employer-sponsored coverage would be eligible for federal subsidies for coverage obtained through state health insurance exchanges upon verification of their citizenship status and income. Additionally, states have the option of allowing enrollment into Medicaid by those lawfully residing immigrants during their first 5 years in the USA. The consequence of not addressing expanded immigrant access to coverage in federal health reform places the full costs of healthcare delivered to these individuals squarely on state and local governments, business owners, and residents who therefore have a continued incentive to provide healthcare to this population in the most cost-effective manner possible.

Public–Private Partnerships

Because the costs of providing care to the uninsured fall mainly upon local and state public and private stakeholders, there are significant incentives for these stakeholders to find ways to effectively partner to minimize these costs. CHIP buy-in programs for above-income eligible children, publicly funded reinsurance programs, and 3-Share programs are a few of the innovative public–private partnerships that have been created in recent years to address subpopulations of the uninsured. Three-Share (or multi-share) programs are public–private local or state collaborations to provide low-cost health benefit coverage for small businesses and their employees. They are public in the sense that local, state, and/or federal sources of funding often comprise a portion of the premium subsidy and that local publicly funded safety net providers are often found within the programs' provider networks. They are private in the sense that private funding may also be available for the subsidy pool and often private safety net providers are in their provider networks and benefit from reductions in the uninsured resulting from these programs in their community. Three-Share Plans are particularly effective programs in that they leverage each dollar contributed by the public–private subsidy fund with two additional dollars from the small business employer and his/her employee. Without that subsidy dollar, much of the other contributions are not harnessed to cover the costs of uncompensated care for the uninsured.

The concept of multi-share or 3-Share programs originated in Michigan. The first 3-Share program – Access Health – began in Muskegon, Michigan. Existing 3-Share Plans are located in Pueblo, CO; Duluth, MN; Wayne County, MI; Muskegon, MI; Texas; and Arkansas. Common characteristics among local access to care programs have been noted by Blewett and colleagues. These common characteristics are: (1) they are community-based initiatives, (2) run by nonprofit organizations, (3) have eligibility requirements for participation, (4) are generally for low-income individuals, and (5) the program usually has a limited benefits package as well as a closed provider network. Each of the 3-Share programs mentioned above meets all of the defining 3-Share criteria. Most plans promote prevention and wellness through primary care and offer such services as physical examinations, immunizations, mammography’s, and health education. As a way of promoting wellness, Wayne County 3-Share and the AR HealthNetworks program in Arkansas, for example, do not exclude participants for preexisting conditions. By doing this, members are encouraged to seek care for their conditions.

The Employee Benefit Research Institute suggests there are certain features of a 3-Share program that must be tailored to the specific community where it is implemented in order for it to be successful. Additionally, research on local access programs to determine what factors beyond a subsidy influence enrollment reveals that having a subsidized, affordable program available to members in the community is not enough to attract participation if the community members do not like the plan features. Awareness of the program as well as clear information on how to apply and enroll in the program is important to attract members. Specifically, among programs where both the employer and employee were subsidized, program features important to subscribers were having a large provider network, covering preexisting conditions, and offering at least some first dollar coverage for preventive services or office visits.

3-Share Programs: Texas

Approximately 24% of uninsured Texans are noncitizens. In Texas, approximately 20% of native US citizens are uninsured. Nearly 29% of naturalized citizens in Texas are uninsured. More than half (54.5%) of noncitizens in Texas are uninsured. Federal rules require state Medicaid programs to provide certain mandatory benefits for certain mandatory populations, and allow states to cover other optional benefits and populations. Texas remains one of the few states that have not exercised such Medicaid expansion options. Because of this, a significantly lower percentage of low-income individuals are covered by the Texas Medicaid program than are covered by Medicaid programs in other States. This makes 3-Share Plans particularly useful for reaching low-income working adults in Texas.

Texas Department of Insurance State Planning Grant (SPG) research shows that the majority (76.6%) of the uninsured in Texas are working age adults. While the majority of working-age adults obtain their health care coverage through an employer-sponsored plan, the percentage of employers who offer coverage to their employees has been declining – particularly among small business owners. In 2008, Austin-based economic analysis and public policy consulting firm TXP reported that while the percentage of businesses offering employer-sponsored health insurance among large (200+ employees) businesses remained fairly constant at 99% during the period 2000–2007, the percentage of small (3–9 employees) businesses dropped precipitously from 57% in 2000 to 45% in 2008. In 2007, only 53% of Texans had health coverage through their jobs, compared to the national average of 61%. Programs aimed at low-income employees of small businesses are critical to reducing their numbers among the ranks of the uninsured in both Texas and nationally.

A 2004 SPG survey of Texas small employers revealed that while 81% of employers believe that they should provide insurance if they can afford to do so, the number one obstacle to small employers offering coverage is cost. Due to their size, location and health status of their employees, small businesses face healthcare premiums significantly higher than their large employer counterparts. An additional barrier to offering coverage for their employees is the complexity of the insurance market and the need for simpler enrollment materials and processes. Small businesses do not have the typical employee benefits staff found in large firms so their owners handle these matters themselves and often lack the time to adequately assess programs, meet with insurance brokers multiple times to determine the best program, and to complete application paperwork. In order to address this barrier, 3-Share programs strive for transparency in their business and employee eligibility criteria, premium rates, and covered benefits.

TexHealth Harris County 3-Share Plan began offering coverage in December 2009. Businesses eligible for the TexHealth Harris County 3-Share Plan are those employing between 2 and 50 employees, who have been in business for at least 1 year, who have not offered group health insurance to their employers in the past 12 months, and who have at least 30% of their employees eligible for subsidy assistance. All employees of an eligible small employer are allowed to enroll in the plan, but only those whose pretax income is below $16.00 per hour (roughly 300% of the federal poverty limit) are eligible to have up to one third of their monthly premium cost covered by the public–private subsidy pool. Subsidy funding for the TexHealth Harris County 3-Share Plan comes from contributions or grants from the City of Houston, the State of Texas, and the federal State Health Access Program grant awarded to Texas by the US Health Resources and Services Administration.

Many 3-Share programs, including the Galveston and Central Texas 3-Share Plans, offer a single benefit plan at the same cost for all enrollees. The TexHealth Harris County 3-Share Plan offers two benefit plans and varies the premium costs based on the age and sex of the employees as a means to further encourage the enrollment of younger employees. Thirty percent of the uninsured are of relatively young (19–29 year-old) individuals who do not purchase insurance because they are healthy and do not see insurance as a necessary investment, or because they earn relatively lower wages and thus do not consider insurance a necessity. Immigrants are highly represented among these young, low-income uninsured persons.

Using an average premium of $240 per member per month (PMPM), the employer is required to pay at least 50% of the monthly cost (or ~ $120 PMPM), the subsidy can cover one third or about $80 PMPM, and the subsidy eligible employee pays about $40 PMPM. For higher income employees, the cost is shared only between the employer and employee. A premium in the range of $40 PMPM can represent a much more affordable percentage of a low-income worker's earnings than the typical 50+ % share he or she might be required to pay for a traditional insurance product offered by his/her small employer.

In a unique twist on the public–private partnership model, TexHealth Harris County 3-Share Plan utilizes two third party administrators through which to operate its two benefit plans – United HealthCare for Plan A and Community Health Choice for Plan B. UnitedHealthcare is one of the largest commercial insurance companies in both the large and small group markets in the United States and Texas. Community Health Choice is a Medicaid and CHIP health maintenance organization owned by the Harris County Hospital District. This unique partnership between an insurer with expertise in small commercial group coverage and a health plan with expertise in managing the care of low-income populations provides an ideal solution for the Houston marketplace. Enrollees have the choice of plans, along with the provider networks and premiums associated with those plans.

In its first 6 months of operation, the TexHealth Harris County 3-Share Plan enrolled 31 businesses with 178 employees. The average hourly wage of enrolled employees is just below $14 per hour, with 80% of total enrollees eligible for subsidy assistance. Forty-three percent of enrollees are between 18 and 35 years of age, and 61% represent traditional racial minorities. Early results show that the program is reaching those groups most represented among the low-income uninsured population. Businesses that have enrolled to date include a wide variety of business types, including construction and food service, among which immigrants are highly represented among the workforce.

An economic impact analysis of 3-Share programs in Texas conducted in 2008 by TXP, for the TexHealth Coalition found that fully implementing 3-Share programs statewide could:

- Provide almost 400,000 more Texas employees and their dependents with coverage within 3 years and as many as 700,000 Texans in the next 10 years if Texas has the same experience as some of the established, older 3-Share programs
- Generate over $700 million in additional healthcare spending in Texas
- Boost annual economic activity by just over $1.7 billion
- Create about 16,000 permanent new jobs
- Generate nearly $30 million in new tax revenues from newly created jobs and healthcare spending

The ability to leverage a subsidy dollar to secure an additional 2 dollars from employers and employees makes for an effective public–private partnership to addressing access to coverage for low-income employees of small businesses.

Conclusion

Although the major public insurance programs (Medicare, Medicaid and CHIP) in the United States cover an estimated 80+ million people, or roughly 27% of the population, and private health insurance is purchased by employers and individuals to cover 170+ million people, roughly 46 million remain uninsured and in need of safety net providers and programs. Large numbers of uninsured create large uncompensated care burdens for healthcare providers, higher insurance premiums for the insured, and poorer health outcomes in our communities. As the number of uninsured individuals has climbed since public programs were instituted in 1965, there has been an increasing need for state and local public–private partnerships to develop creative mechanisms through which to offer and finance care for these individuals. Programs like 3-Share Plans, in which public dollars are leveraged to bring in private dollars, represent cost-effective and efficient means to finance coverage for the low-income working component of the uninsured population, just as CHIP buy-in programs have addressed coverage for children in low-income families who earn more than program income limitations. As immigrants comprise a significant proportion of uninsured individuals in the United States, they stand to benefit from such local public–private partnerships.

Puerto Rico

Eloy Franco, Isabel N. Schuermeyer
Department of Psychiatry & Psychology, The Cleveland Clinic Foundation, Cleveland, OH, USA

The Commonwealth of Puerto Rico is a United States territory situated in the northeastern Caribbean Sea basin, where the Caribbean Sea and Atlantic Ocean waters meet. The archipelago includes Puerto Rico mainland and its islands: Vieques, Culebra, and Mona.

Immigration to Puerto Rico Prior to the Twentieth Century

Puerto Rico received its first European immigrants in 1493 after the second voyage of Christopher Columbus. Around 1,500 Castilian Spaniards settled first in the Guaynabo area. American Indians called *Tainos* inhabited the land with an estimated population of 50,000 that almost perished entirely due to slavery, diseases, suicide, escape, and unsuccessful fight against the conquerors. Thousands of African slaves from what are today Ghana, Nigeria, the Republic of Benin, the Guineas, and Togo replaced the Tainos in the gold industry. More Spaniards arrived and founded new towns along the Caribbean coast and later in the mountain regions, where they may have mixed with the remaining Tainos.

In 1815 Spain signed the “Royal Decree of Graces” that permitted free immigration of non-Hispanic European Catholics to Puerto Rico. Most were Spaniards, but thousands of farmers arrived from other countries such as France, Portugal, Malta, Ireland, Germany, Lebanon, Scotland, and Italy. The population grew from 150,000 to almost a million, Spaniards being only 55% of the foreign-born.

African runaway slaves from other Caribbean territories also arrived to the island, after Spain signed the “Decree of Graces of 1789” that permitted slaves to buy or earn their freedom. From 1795–1844, the first and smallest Dominican immigration to Puerto Rico occurred after Santo Domingo suffered the Haitian invasion. Despite so much diverse immigration, it was during the nineteenth century that Puerto Rico developed its strong national identity.

Immigration to Puerto Rico in the Twentieth Century

In the twentieth Century, Puerto Rico became a United States (US) territory, making it an attractive destination for immigrants escaping from dictatorial governments. In the 1930s Jewish refugees moved from Hitler’s Germany and in the 1940s and 1950s, hundreds of Galicians left Franco’s dictatorship in Spain. In the 1960s Cuban, Chinese and Jewish businessmen left Cuba after Castro’s government nationalized their businesses, while a few Dominicans ran away from Trujillo’s dictatorship. After Trujillo’s regime (1961), thousands of lower class Dominicans moved to Puerto Rico due to extreme poverty. Around 60,000 Dominicans live today in Puerto Rico, which is 56% of the foreign-born population. Dominicans have concentrated in the San Juan metropolitan area working as unskilled workers for lower pays than Puerto Ricans. Many arrive to Puerto Rico illegally, risking their lives by crossing the wild waters that divide both countries. Their illegal status (estimated to be 30%), their high intermarriage rates with Puerto Ricans, and their disadvantaged socioeconomic background have been a controversial issue for Puerto Ricans and the local government.

Other recent immigrants to Puerto Rico are Southern Americans from different social segments. Almost 5% of Puerto Ricans on the island are US-mainland born, reflecting the constant migration back and forth to the mainland US. Non-Puerto Rican US citizens have also moved to the island to work as professionals in the pharmaceutical and manufacturing companies, mainly in the northern and eastern areas.

Puerto Rican Emigration prior to the Twentieth Century: The Spanish Colonial Era

There is little known about Puerto Rican emigration prior to the twentieth century. It is likely that the first to leave the island were thousands of *Tainos* who escaped to the Lesser Antilles and South America, after the Spanish colonization. During the sixteenth to nineteenth centuries there may have been minimal movement to Spain, South America, and other Caribbean territories. By the late nineteenth century, earthquakes and hurricanes destroyed the island’s economy bringing unemployment, malnutrition, and extreme poverty. As a consequence, a small wave of Puerto Rican skilled workers immigrated to the Dominican Republic to work in the sugar industry.

Puerto Rican Emigration in the First Half of the Twentieth Century: The US Territory Era

In 1898, the USA won the Spanish-American War against Spain and Puerto Rico became a US territory. During the first decade, only 2,000 Puerto Ricans immigrated to the US mainland, settling mainly in New York City. Another 5,000 jobless laborers were recruited by the renowned *Big Five* sugarcane corporations in Hawaii, due to a workers shortage there. Today there are about 30,000 Puerto Ricans in Hawaii.

On March 2, 1917, the Jones-Shafroth Act granted US citizenship to Puerto Ricans. A month later the US declared war on Germany and 18,000 now US citizen Puerto Rican men emigrated to military bases around the world to serve in World War I. Thousands of Puerto Rican men moved to US industrial complexes to keep up with war artillery and other markets demands. Over the next 30 years, tens of thousands continued to move to Brooklyn and northeastern Manhattan forming Puerto Rican communities in East Harlem (a.k.a "*El Barrio*"). During 1945–1965, Puerto Rico experienced the *Great Migration* in which Puerto Ricans arrived to the US mainland at rates of 45,000 people per year. The federal, state and island governments coordinated active massive recruitment of semi-skilled workers who were needed by major US industrial cities to sustain their market expansions. The most common destinations were: New York City, Newark, Hartford, Chicago, and Philadelphia.

After settling in the US, many immigrants faced discrimination at work, in school, and in the neighborhoods. Salaries were much lower than their non-Hispanic White counterparts. Puerto Ricans were unable to find proper housing, nutrition, and education. Most had to move into poor neighborhoods that had high crime rates and had rampant drug use. Reliance on welfare, food stamps, and other government programs became an option to bring food home and pay rent. Other workers began to portray Puerto Ricans as delinquents, drug addicts, and welfare leeches. Despite all this, emigration to the US mainland continued until 1953 when it reached a peak, with about 200,000 Puerto Ricans living across the nation. Then it began to decline until the mid 1960s for several politico-economical factors.

Puerto Rican Emigration in the Second Half of the Twentieth Century: The Commonwealth Era

In 1952, the US Congress approved the development by Puerto Rico of its own constitution and a Commonwealth status began. Luis Muñoz Marin (first governor elected by popular vote) began a transition of Puerto Rico's economy from an agricultural to an industrial one. In the 1950s rapid industrialization occurred under the name of *Operation Bootstrap* that promoted bringing US industries to Puerto Rico in exchange for cheap labor and federal tax exemption. One hundred US companies became interested, and as a result Puerto Rico became a large pharmaceutical manufacturing center.

Industrialization required development of an infrastructure, and therefore Puerto Rico improved in many areas including better roads, schools, illumination, potable water, and sewage systems. Subsequently, emigration to the US mainland began to decline since jobs were in surplus and quality of life had improved substantially. In the 1970s Puerto Rico had negative emigration for the first time since the nineteenth century. However, in the 1980s and 1990s Puerto Ricans had achieved higher salaries and with financial prosperity, population growth was dramatic. The college graduate rates increased substantially leading to a surplus of professionals. Also, other markets around the world were offering cheaper labor and Puerto Rico's tax exemption laws expired. All these factors prompted US industries to leave and a new cycle of emigration began, but this time mainly to Florida.

Health Issues of Puerto Ricans in the US and Puerto Rico: General Health and Demographics

Puerto Ricans are the second largest Hispanic group in the US after Mexicans (9.6% of all US Hispanics). Of the eight million Puerto Ricans, half live on the island and the other half live on the US mainland. Two-thirds of mainland Puerto Ricans are second generation migrants and one-third is first generation migrants. This first generation moved to the US mainland prior to 1990 (60%) and a second group migrated during the period 1990–2000 (25%). Mainland Puerto Ricans are 10 years younger, with a median age of 28 years and 75% are less than 45 years old. They make twice the salary ($34,000/year) of their island counterparts. Mainland Puerto Ricans are less likely to fall below the poverty line (24% versus 45% of island Puerto Ricans). However, Puerto Ricans residing in the USA are two times less likely to be homeowners and three times less likely to have a college degree compared to island Puerto Ricans. Mainland Puerto Ricans also have the highest unmarried and the second highest single-woman household rates among all US Latinos.

Life expectancy in Puerto Rico is 74 years for men and 82 years for women, ranking 27th and 9th worldwide, respectively, similar to US rates. Clinical research suggests that place of birth, acculturation, and sex play a role in discrepancies when comparing health outcomes. For example, Puerto Rican women have the lowest death rate of all Latinas in the USA, but Puerto Rican men have the highest death rate among all Latino men. Higher acculturation of Puerto Ricans and being US born increases health risk behaviors (e.g., smoking, lack of exercise) and consequently mortality.

Puerto Ricans moved to urban areas in New York, New Jersey, Illinois, Florida, and Pennsylvania, and in smaller numbers to California, Connecticut, Massachusetts, and Ohio. After 1990, Florida has become the most common destination with almost a million Puerto Ricans residing in the Orlando area. Puerto Ricans came mainly from the uneducated poor lower class and were predominantly dark-skinned with a more mixed or African heritage.

These demographics along with moving to colder climates and poor English proficiency may explain the outcome differences between Puerto Ricans and other Hispanics in the US. For example, Cubans came from the educated, more English proficient, light-skinned middle and upper classes and moved to a similar tropical climate (Miami), making them less of a target of racism than Puerto Ricans. In the last 2 decades, middle class Puerto Rican professionals have moved to the US due to a professional surplus in the island and unemployment. This has contributed to intellectual fugue or polarization and a reduction of the middle class.

Characteristics of the Puerto Rican Patient

Despite having the highest health insurance rates among all US Latinos, Puerto Ricans have worse health status compared to other Hispanics with low insurance rates. They also tend to use health care less, especially for preventive measures.

Like other Hispanics, Puerto Ricans have a high degree of *familismo* which is a strong orientation toward both the nuclear and extended family. A good example of this is that most of the people in a doctor's waiting room might be family members rather than patients. Most of the time Puerto Ricans prefer to have a family member present when seeing a doctor and delegate the responsibility of narrating the history and of asking questions to their family members (especially elderly patients). Family members feel that they must help the patient with less English proficiency and less educational attainment. Furthermore, family members may have the responsibility of transporting the patient and administering medications.

The relationship with the physician tends to be a patriarchal one. Family involvement in a patient's treatment may improve patient outcomes. Some patients may also prefer to use Spanish when seeking health care. They may be also at higher risk of medication side effects and may prefer nontraditional treatments and may present more frequently with atypical symptoms of diseases.

Risk Behaviors

Many times individual behaviors may increase the risk for medical illnesses. These behaviors can include such things as failure to use seat belts while in a car, nonuse of condoms during sexual activity, as well as use of tobacco, alcohol, and drugs. Studies have shown that needle sharing, intravenous drug use, polydrug abuse, and heterosexual multiple partners are clear risks for progression of HIV. When a person has a higher number of risk behaviors, they more likely are to be unemployed, single, and have a lower educational level.

Puerto Ricans have lower rates of tobacco use compared to the general US population; however, Puerto Rican men have higher rates of alcohol dependence than most other Hispanic subgroups and their US cohorts. Hispanics have a lower rate of substance abuse than non-Hispanic Whites.

Top Five Reasons for Death

Puerto Ricans who live in Puerto Rico have heart disease as the leading cause of death. This is followed by cancer, which is the second leading cause of death. In third place is diabetes, fourth is hypertensive disease, and accidents are the fifth leading cause of death.

For Hispanics, including Puerto Ricans, living on the US mainland, the top five causes of death are heart disease, cancer, accidents, stroke, and diabetes, in that order. Unfortunately the data for the causes of death are not more specific for Hispanic subgroups. In comparison though, accidents as a cause of death are higher for those living on the US mainland perhaps because of the types of employment that Hispanics take once in this country. This may be more applicable to the other Hispanic subgroups, especially those without citizenship.

Infant Mortality

Stateside Puerto Ricans have the highest infant mortality rate (8.3 per 1,000) of all US Hispanics, as well as the highest unmarried rates and the second highest single female householder rates. Fertility rates of both mainland Puerto Ricans and island Puerto Ricans are also among the highest. Studies have shown increased rates of late or no prenatal care in Puerto Rican mothers, increasing probability of infant mortality, and overall worse health status later in life.

Asthma

Hispanics as a group have a lower percentage of asthma (5.0%) when compared to non-Hispanic Whites (7.4%) and non-Hispanic Blacks (7.8%). However, Puerto Rican asthma rates are twice as high (13.4%). About 18% of adult women and 9% of adult men are reported to have asthma currently. Also the lower the income, the higher the amount of asthmatics found.

HIV

Although HIV/AIDS is ranked as the 16th cause of death for Hispanics, when individual subgroups of Hispanics are analyzed, Puerto Ricans living on the island have twice the rate of new infections (45%) compared to the rate in the mainland US population (23%) and US mainland Hispanics (29%). Males account for 65% of new HIV infections in Puerto Rico, injection-drug use (39%) and heterosexual contact (37%) being the most common transmission routes. This is different from the US mainland, where unprotected male-male sexual relations is the primary mode of HIV transmission.

Transmission is highest between the ages of 30–49, correlating with rates of injection drug use. As a result, Puerto Rico has implemented efforts to target drug use infection, such as: needle exchange programs, selling of syringes without medical prescription, and drug rehabilitation program promotion.

Puerto Ricans seem more educated about HIV risk than Mexicans for instance, but this knowledge does not prevent risk behaviors. Also engagement in high sexual risk behaviors seems to increase with acculturation. Puerto Rican men have the highest injection drug use among Hispanics.

Homicide

Homicide rates have declined among all races and ethnicities, but continue to be the 7th leading cause of death for Hispanics. Puerto Rican men seemed to be the most affected group among Hispanics, having twice the risk of dying from homicide compared to Puerto Rican women. Puerto Rican men have the highest rates of death, compared to other Hispanic men. This particular segment of the population should benefit from strong substance use, HIV, and homicide prevention programs.

Psychiatric Diseases

When compared to other Hispanic subgroups, Puerto Ricans have higher rates of depression and anxiety. Second generation Puerto Ricans have an increased rate of substance abuse, while third generation Puerto Ricans have an increased rate of all psychiatric disorders. Puerto Rican immigrants have the same rate of mood and anxiety disorders as the mainland US-born population. This is in contrast to other Hispanic immigrants, which have lower rates of psychiatric illness compared to the US population in general.

Summary

Puerto Rico's history, geography, politics, and cultural background result in a very unique population which is clearly different from other Hispanics. This can help to explain why Puerto Ricans may have unique healthcare issues and should not be simply looked at as *another* Hispanic subgroup. Analysis of the Puerto Rican population is very important, as extrapolating information from other Hispanic subgroups and applying it to Puerto Ricans may be detrimental to their healthcare. Puerto Ricans' health issues should be viewed within their singular context.

- ► Narrative research

Quality of Life

Brittany Daugherty
Department of Psychology, John Carroll University,
Cleveland, OH, USA

Most often used interchangeably with terms such as life satisfaction, happiness, and subjective well-being, it is important to understand that quality of life (QOL) reflects both objective and subjective factors that affect personal growth and reflection of oneself. Objective factors such as income and education along with subjective factors such as one's satisfaction with one's education or income play a major role in effecting one another. Quality of life refers to a subjective evaluation of the fulfillment of a person's needs, goals, and wishes. It can include every aspect of one's life such as health, family, finances, and career. Quality of life is a multidimensional approach known to have three main components: subjective well-being or life satisfaction, functioning in social roles/self-care, and access to social and physical environmental resources. Its complex interaction between external conditions and internal perceptions is unique and essential to understanding its many impressions on human health. Quality of life serves as an umbrella term to many of its other related terms; it often lacks a succinct and consistent definition, which allows it to be used vaguely and leaves the interpretation up to its readers. Early research proclaims there to be three components to subjective well-being: life satisfaction, positive, and negative affect. The key component – life satisfaction – is considered to be mostly equated with quality of life. Happiness, on the other hand, is deemed a subcategory of positive affect; a short-term concept dependent on mood and situation.

The quality of life demonstrates the degree of satisfaction one has with their daily life. Life satisfaction is a term coined by Ed Diener, a distinguished psychologist whose research focuses on subjective well-being, life satisfaction, and positive psychology. Diener et al. (1985) created the Satisfaction with Life Scale (SWLS), a five-item scale which measures the cognitive judgments of satisfaction with one's life. It can be determined by your ability to make choices about the way you wish to live your everyday life. It is naïve to think that quality of life will be the same for everyone, for it is greatly subjective and is influenced by many different factors.

The term quality of life is a multi-approach measure used to explain micro- and macro-level factors and the effect they have on human life. Quality of life measures have often been used to predict economic progress and stability. The field of economy measures the quality of life by using the "quality of life index," which includes the following nine indicators to determine a country's quality of life: material well-being, health, political stability and security, family life, community life, climate and geography, job security, political freedom, and gender equality. Research shows that unemployment, a country's prosperity, and economic growth are highly correlated with quality of life. Economists have studied how economics can have a major impact on how the quality of life is perceived.

Quality of life measures have also been used in areas such as public health, health research, and medicine. The concept of health-related quality of life (HRQOL) refers specifically to the functional status, emotional

Sana Loue & Martha Sajatovic (eds.), *Encyclopedia of Immigrant Health*, DOI 10.1007/978-1-4419-5659-0,

state, and the impact of illness on patient health. The Center for Disease Control and Prevention (CDC) specifically uses this to track HRQOL in various populations and forms interventions to enrich public health. The CDC uses an assessment called the Health Days Measure to evaluate HRQOL; it consists of 14 items which are calculated by estimating the number of healthy and unhealthy days. The number of overall days when a responder felt that their physical/mental health was not good would constitute as unhealthy days. The number of overall days when a responder felt that their physical/mental health was good would constitute healthy days. Healthy and unhealthy days are then compared and if there are 14 or more unhealthy days recorded, this would indicate a significant stage of impairment. Health-related quality of life has shown to be an essential tool for identifying health concerns and encouraging the concept of healthy lives.

Positive psychology is often used to study and increase the quality of life. Positive psychology is a field of study which promotes a holistic view of human fulfillment. It is considered the study of mental health instead of mental illness. Positive psychology seeks to identify and uplift character strengths to improve life satisfaction. Its goals are to enhance one's well-being by strengthening their positive character and then by enhancement of positive communities and cultures. Positive personal traits such as courage, interpersonal skills, perseverance, and originality can be used to effect larger institutions and encourage responsibility, civility, tolerance, and work ethic. These traits have been known to act as buffers which protect against instability, lack of satisfaction, and even mental illness. The objective of positive psychology is to allow people and the communities in which they live to flourish by using the skills they already possess and focusing on the basics of enjoyment and livelihood at the upmost level. Positive psychology does not focus on the negative states of human mental health; instead of single-mindedly treating mental illness by restoring damage, it improves individual's outlook on life by providing encouragement and acknowledging strengths and virtues. This emerging field of scientific study serves as a foundation for improving the quality of life.

Still seeking to be valuably incorporated into the study of quality of life is the study of resilience. Resilience and quality of life are two psychological terms which are often explored independently. However, they should be addressed collectively due to their direct impact on well-being. Resilience is the ability to adapt to stressors in life such as trauma, death, and other sources of stress. This interdisciplinary element serves as a buffer to risks that can affect both your physical and mental ability. Traits often associated with resilience are decisiveness, self-care, responsibility, support, and optimism. Many researchers believe that genetics plays only a partial role in coping with stressful events; learning resiliency coping skills is also advantageous while facing stress. There are two main attributes that impact resilience: protective factors and protective mechanisms. Protective factors are considered inherent traits, a natural ability one can possess. Protective mechanisms are deemed to be coping skills adopted from successfully handling adversity. Therefore, these factors can be influenced by personality characteristics as well as learned skills. Resilience can produce a positive entity and moderate risk factors that may negatively affect the quality of life. Despite their detached disciplines they share a close relationship with each other; whereas resilience can prevent the quality of life from being damaged by life stressors. Resilience is the ability to adapt to adversity and the quality of life is the successful evaluation of adversity and how it affects well-being. Future collaborative research should address the interconnection of these two terms.

Immigrants are impacted heavily by migration and the quality of life. It is important to recognize that both are extremely fragile physical and emotional situations. The relationship between immigrants and the quality of life are twofold. Migration is usually caused by push and pulls factors; these factors are highlighted in four categories: political, economic, environmental, and demographic. Push factors are instances that cause for outmigration such as environmental disruption, crime, and high population pressures. Pull factors motivate migration and can be seen as incentives; this depends heavily on economic factors, for instance, decent wages, economic freedom, upward social mobility, urbanization, and the acquiring of new skills and opportunity to succeed. Since migration has been known to be a distressing event full of sacrifice, emotional turbulence, and lifestyle changes, it can have a varying effect on the quality of life of immigrants. A negative effect on the livelihood of immigrants by push/pull influences could result in a significant decrease in the quality of life, whereas acquiring their anticipated needs following migration could possibly result in an increase in the quality of life. However, once immigrants have settled into their aspired positions, the quality of life may change for natives as well. Some individuals may associate immigration with dangerous population growth, a depletion of resources, a strain on infrastructure, higher costs of living, and a decrease in economic gain. Therefore, natives may perceive a decrease in the quality of life due to immigration. It is important to take into consideration that the opposition that immigrants may face could diminish migrants' quality of life.

Quarantine

Nicholas K. Schiltz
Division of Health Services Research & Policy,
Department of Epidemiology & Biostatistics, Case
Western Reserve University, Cleveland, OH, USA

Introduction

The quarantine and isolation of immigrants has occurred many times throughout civilized history. Often quarantines are invoked before they enter a new country, although there have been instances during which certain immigrant populations were quarantined in response to an outbreak. Quarantines of immigrants may involve a medical inspection where only those displaying signs and symptoms of a communicable disease are isolated. Others involve detaining all immigrants for a specified period of time longer than the incubation period of the suspected disease. Immigrant quarantines are often compulsory for the individuals, and so most of this paper will focus on mandatory quarantines. Many social, legal, ethical, and epidemiological issues arise out of the practice of quarantine, including the relationship between individual civil rights and population health.

A note about terminology is appropriate as terms are often confused. *Isolation* is the practice of isolating an individual known to be contagious, commonly in a health facility, for the duration of the illness. *Quarantine* confines people who have been exposed to a communicable disease for the disease's presumed incubation period.

History of Quarantine

The idea of quarantine has been around since ancient times. The Bible describes the confinement of lepers away from society. The name quarantine derives from the Italian word *quarante*, which referred to a thirteenth century policy requiring the holding of merchant ships for a period of 40 days before entering the port. Communicable diseases such as bubonic plague, small pox, and tuberculosis have caused widespread death in the past and have often led to attempts at quarantine to control the spread of disease. Modern medicine has largely eradicated these diseases in developed countries. Therefore, the idea of quarantine is foreign to many persons today, whereas it would have been a commonplace part of society a century ago.

Perhaps the most famous example of immigrant quarantine occurred at Ellis Island during a wave of mass immigration into the USA in the late eighteenth and early nineteenth centuries. Inspection agents at the station gave each immigrant a brief health inspection. Those with visible signs of sickness were held for a period of several weeks, whereas healthy immigrants were processed in a few hours. Three thousand would-be immigrants died in quarantine, and about 2% of would-be immigrants were sent home due to having a contagious chronic disease or criminal background. One third of the American population today can trace their ancestors to immigrants who arrived through Ellis Island. Today, medical inspections are often done at the embassies or affiliated health center of the originating country before the immigrant arrives in the USA.

Epidemiological Issues

The purpose of quarantine is to halt the spread of infectious disease in the general population. Because most infectious diseases transfer by human to human contact, isolating infected individuals from society until they are no longer contagious can prevent the further spread of disease.

These factors affect the ability of quarantine to be successful: the duration of the incubation period, the attack rate of the disease (i.e., how contagious it is), the number of persons infected, and the ability to identify and isolate those infected. If the incubation period is long, and the population infected is believed to be widespread, a strategy of prevention and treatment may be more effective. It should be noted that quarantine can potentially put more people at risk than they would have otherwise been. This can occur in instances where uninfected persons are quarantined with known infected individuals, increasing risk of transmission.

Legal Issues

In the USA, individual states have their own quarantine laws along with federal laws. In 1884, President Arthur issued the first proclamation granting federal authority to create and operate quarantine stations. Today, Title 42 U.S.C. § 267 provides the legal basis for the US government to create quarantine stations to deal with the control and prevention of communicable disease. The Surgeon General is in charge of creating and managing such stations, and has broad authority of their scope of power. In the UK, quarantine acts were often passed by Parliament as an outbreak began to occur.

The International Health Regulations is binding international law authored by the World Health Organization that deals with global health risks. This document reaffirms the State's right to implement procedures such as quarantine and isolation to prevent the spread of communicable diseases. The IHR document is not limited to specific diseases, but anything deemed to be a "health risk."

In the USA, the federal government has the legal right to enforce quarantine and isolation. However, this federal quarantine law is arguably unconstitutional because it allows detention without a hearing and counsel or due process, and this would appear to be a violation of the fourth, fifth, and sixth amendment of the Constitution. Although immigrants are noncitizens, the 14th amendment prohibits the states from denying persons in its jurisdiction due process. Recent court decisions have clarified that detainees have the right to counsel and a fair hearing. However, the CDC regulations call for short-term detention of several days without counsel or hearing. Many legal questions remain including how long and under what circumstances the government may enforce quarantine.

Social Issues

Quarantine can be stigmatizing for the persons detained. Because of 24 h news cycles and the relative rarity of quarantines, suspects may find themselves the center of intense media scrutiny, such as was the case with Andrew Speaker in 2007. Other persons, even friends and family, may see the person as "diseased" and want to avoid further contact with them even after cleared. If the quarantined victim is indeed responsible for spreading a contagious disease causing morbidity and mortality, the public may turn hostile toward the victim.

If the disease in question is associated with a particular race or ethnic group this can lead to stigmatization of that group. For instance, the SARS epidemic was largely associated with persons from

Southeast Asia. Outbreaks in California in the nineteenth century sometimes led to quarantine and detention of entire villages of Chinese immigrants.

Infected persons who are quarantined may be treated as if they were criminals by the persons responsible for detaining them. They may be subject to a detainment center that resembles a prison, and handling by guards with handcuffs and force. Because many outbreaks are a crisis, the government agencies responsible for controlling the disease may have to act quickly. Actions may be taken that in hindsight were overly abusive and put innocent persons at additional risk.

Enhancing public health may not be the sole reason or the driving factor behind quarantining immigrants. In the case of Ellis Island, medical inspections were instituted largely to appease certain groups such as "Nativists" who worried about "impure" immigrants ruining American culture, eugenicists, progressives, and moral crusaders. Tests for sexually transmitted diseases were largely ineffective, but placated moral crusaders. Tests of "feeble-mindedness" served no public health purpose, but yet resulted in the deportation of 75–100 would-be immigrants per month.

Ethical Issues

Ethical issues around quarantine generally revolve around the trade-off between individual civil rights and the public welfare. Quarantine, especially involuntary quarantine, involves a sacrifice of certain rights in that a person is held in detention. Persons who refused to be quarantined can be arrested and fined in many countries, despite the fact that they have done nothing criminal. This also potentially violates some international documents such as the UN treaty on human rights. Many people, when sick and dying, would prefer to spend their final days with family and friends, rather than detained in isolation.

On the other hand, individuals who refuse to be quarantined can place the health and well-being of others in danger. Typhoid Mary, an Irish-immigrant who arrived in America in the late nineteenth century, is known to have infected 53 people with typhoid fever, 3 of whom died. She spent the last 24 years of her life in isolation against her will, a clear violation of her civil rights. However, many people's lives may have been saved by her detention.

Conclusion

Quarantine and isolation are controversial acts that balance individual autonomy with the public's health and welfare. The social and ethical issues that arise out of quarantine are complex, and many of the legal questions surrounding quarantine have yet to be answered.

Race

Andrea M. Przybysz
Case Western Reserve University School of Law,
Cleveland, OH, USA

Race is the division of people by physical characteristics and is best understood as a social construct rather than an innate genetic or biological difference. Thanks to the recent work of the human genome project, we now know that there is greater genetic variance within what have been considered to be races than there is between races. Accordingly, the labels "Caucasian," "Black," and "Asian" convey meaning based on irrelevant characteristics such as a particular physical trait or the perceived presence or absence of such qualities as industriousness, reliability, cleanliness, and similar characteristics rather than the scientific truths that these characteristics were once thought to represent.

Though race-based distinctions may not be valid scientifically, societal labels based on race continue to help us as individuals living in a society to understand one another through social networks resulting from our various categorizations. Nevertheless, these distinctions are based on morally irrelevant characteristics and, as a result, are inherently dangerous. The problem with imposing various social categorizations upon groups of individuals based on irrelevant characteristics is that these characteristics are neither inherent nor inheritable. Rather, individuals constantly transcend these categorizations by marrying an individual of another race, passing for another race, and, perhaps most importantly, by not possessing the morally irrelevant characteristics on which we base our distinctions in the first place. What happens as a result is that we as a society become mired in distinctions of the past that in many respects no longer matter or matter only in the sense of accurately historicizing an era and its current impact.

From the immigrant perspective, it is difficult to understand why society continues to organize itself by an outmoded structure which has the effect of marginalizing and causing individuals to feel as though their only path is to act in accord with irrelevant and predetermined ideals. In many places, depending on the country and region of the receiving society and whether the immigrant has the necessary means, the immigrant may have the power to decide whether he or she will conform to the receiving society's race-associated expectations or navigate society according to a different identity. In the many circumstances where fluidity is not an option, immigrants often combine and accord themselves by ethnic similarities. While in practice this may look like the same ordering that morally irrelevant race-based distinctions accomplish, ordering by lines of ethnicity is different insofar as it hinges primarily on self-valuation and identification with a particular group's relevant characteristics as defined by the group, such as common mores, language, and religion.

A large body of published research suggests that health disparities persist as related to immigrant status and ethnicity even after adjusting for age, gender, education level, income, severity of disease, and other variables. These disparities have even been documented in countries (such as Canada) that have universal health care systems. Essentially, international reports suggest that nothing, not even universal care without a mandated waiting period to access care, equalizes disparities between immigrants and nonimmigrants with respect to health care access.

For example, in the United States, the US Census Bureau estimates that some 46 million American citizens and foreign nationals do not have access to health care. Additionally, some 25 million Americans are underinsured or have disproportionately high medical

Sana Loue & Martha Sajatovic (eds.), *Encyclopedia of Immigrant Health*, DOI 10.1007/978-1-4419-5659-0,

expenses relative to their incomes. The worst situated group appears to be noncitizen Latinos. The Census Bureau estimates that approximately one-third of this population is uninsured and without formal access to healthcare. American citizens who identify as Latino, on the other hand, fare better for a variety of reasons, including increased acculturation to US culture, as reflected in better mastery of the English language. As a result, English-speaking noncitizens have insurance levels comparable to non-Hispanic White citizens of similar income and employment levels.

Latino individuals who speak English and are US citizens are uninsured at a slightly higher rate than non-Hispanic White citizens (33% versus 28%). Noncitizen Latino individuals who speak primarily Spanish and are US citizens, however, have significantly higher uninsured rates at 41%. The gaps in coverage increase even more significantly for non-US-citizen Latinos. Among noncitizen Latinos who speak English, about 55% are uninsured, while among noncitizen Spanish-dominant speakers, 72% are uninsured. These data suggest that the USA may not be entirely welcoming with respect to ethnicity.

The implications of ethnicity in the context of healthcare access are confounded by citizenship status. In the United States, although an individual's English language competency may not compromise access to healthcare, citizenship status directly affects one's ability to participate in government-assisted care, such as Medicaid and State Children's Health Insurance Program (SCHIP). With few exceptions, federal legislation prohibits benefits to immigrants until they have resided in the USA legally for a period of 5 years. Even after this 5-year period has expired, legal barriers to reliance on such programs may continue to persist. This lag time bears directly on immigrant health insofar as many immigrants forgo primary and preventive health services until they are eligible for government services. When used appropriately, primary and preventive health services help to defray the exorbitant healthcare costs associated with critical care problems and emergency medicine.

Lack of adequate care extends beyond the ways in which immigrants are denied access to health care and the kind of care they ultimately receive. Immigrants at disproportionate rates are not included and are not required to be included in clinical research. It is possible that language differences and differing attitudes toward human experiments lead both to a reduced willingness on the part of investigators to include immigrants as research participants and on the part of immigrants to volunteer for participation in research. The effects of immigrants' exclusion from research are observed in three primary ways.

First, failure to include immigrants in research overlooks the ways in which culture impacts or could impact an individual's reaction to drug and/or psychological therapy. Second, the US government's mandate to include minorities in research does not ensure sufficiently large numbers of minorities in studies to permit subgroup analyses. Third, government guidelines perpetuate antiquated race-based distinctions. Because the guidelines cover minority, but not immigrant populations, the government implicitly accepts race as a force in the USA while failing to consider that immigrants can and do self-identify in ways other than race. Further, the guidelines do not require researchers to contemplate immigrants or the study's implications for immigrants. Accordingly, it appears that immigrants are largely deprived of both the benefits and burdens of clinical research.

Racial Disparities

Beverley Russell
Center for Community Health Education Research and Service, Northeastern University, Boston, MA, USA

Racial disparities are the unfair, unjust, unequal, or unnecessary care or treatment of a group of people predicated on their race. To accurately define the term racial disparities, it is important to give a brief definition to each word. The term "*racial*" refers to a genetically distinguished group of people or to a characteristic of race or races. Race is a social construct, meaning, rather than being a biological construct; the definition is constructed and imposed collectively by a society. Race, refers to a social group – often that shares a cultural heritage and ancestry. Hence the historical definition of race is a distinct type or species, sharing manifest characteristics such as structure, temperament, and mental abilities. Race is considered a social classification that can influence health by reason of exposure to social factors including: socioeconomic position, lifestyle habits, and the use of health care.

An insidious social problem in the USA since the founding of the country, "*racism*" is the belief that members of one or more races are inferior to members of other races. Historically in the USA, the non-Hispanic White majority has singled out racial groups for differential and unequal treatment in the areas of housing, employment, education, and criminal justice. Racism can manifest institutionally, individually, and internally. Institutional racism transpires when statutes or laws, classifications, and practices have an unequal impact across racial groups. Individual racism arises as prejudicial beliefs and discriminatory behaviors are applied to individuals of a particular racial group. Internal racism occurs when persons from the same racial group adopt the beliefs, attitudes, and perspectives about their own race that other races believe.

A "*disparity*" implies an inequity or an injustice rather than simple inequality. In the context of health care, the Institute of Medicine refers to *disparities* predicated on race or ethnicity – not explainable by access-related factors, clinical needs, preferences, or appropriateness of interventions. The World Health Organization (WHO) describes disparities as differences in health that are avoidable unjust. Notably, the term "disparities" is used frequently in the United States; however, in many European countries the term is replaced with "inequities," placing greater emphasis on morality and fairness.

It is well documented worldwide that people of color suffer disproportionally across and within countries. Persons are treated differently for appearing distinctive from the majority, for example, possessing a dissimilar skin color, more pronounced features, etc. Frequently these individuals may not be offered the opportunity to receive an education, are not afforded the same opportunities, have a lower earning potential, may live in poorer areas and housing, have fewer resources, and may suffer more than their counterparts who are considered typical.

Racial disparities are the variances between groups after factors to which the difference could be attributed have been controlled for. For example, despite similarities between two people, such as educational background, location of residence, access to health care, salary, etc., one individual is treated differently due to racial group status. It is important to understand how this phenomenon manifests in day-to-day life and its implications for immigrants of color. Racial disparities can be found in a variety of systems, including: health care, social, economic, educational, environmental, and criminal justice – many overlapping in their presentation.

In the context of health care, "disparities" is the unequal treatment of patients, or a difference in health status between social groups (e.g., socioeconomic, racial, ethnic, and gender) that is unnecessary, avoidable, unfair, and unjust. Furthermore, this includes discrepancies in access to screening, treatment options, or the availability of culturally or linguistically knowledgeable and sensitive health personnel. A health disparity should be viewed as a chain of events signified by a difference in the following: (a) environment; (b) access to, utilization of, and quality of care; (c) health status; or (d) a particular health outcome that deserves scrutiny.

Connected to issues of social advantage, disparities are differences in health processes or outcomes between population groups, for instance, the average life span for certain racial groups, or that the incidence of diabetes and hypertension are more prevalent in Blacks and Latinos than in non-Hispanic Whites even when many characteristics are similar across groups – age, education, health insurance coverage. Racial health disparities are considered in terms of the social determinants of health.

Social determinants of health – the social conditions in which people live and work – must be examined to address racial health disparities. These conditions are influenced by income, education, employment, social and physical environment, and housing. The physical environment includes traditional environmental exposures and aspects of the environment constructed by humans, including land use, transportation, street design, features of urban design, public spaces, and access to health resources.

The social environment consists of the degree and nature of social connections between neighbors, the presence of social norms, levels of safety and violence, and various features of the social organization of places. Physical and social features of neighborhoods may affect health through constraints on, or enhancements of, health-related behaviors, or through mechanisms involving the experience of stress and the buffering effects of social support and social connections. Those with poor education may have decreased opportunities for employment, may be employed with a low income, may have poor or no health coverage, and may have less adequate housing. Socioeconomic deprivation is a key mechanism through which other bases of social disadvantage, particularly those linked to race and ethnicity, result in poorer health status.

Racial residential segregation is a fundamental cause of racial disparities in health. The physical separation of the races by enforced residence in certain areas is an institutional mechanism of racism that was designed to protect Whites from social interaction with Blacks. Long history exists in the United States of segregated or separation of housing based on race. Historically, persons of color, or the racial minority, generally resided in the urban areas of most cities in the USA. Living in a poor, deprived, or socioeconomically disadvantaged neighborhood is associated with poor health outcomes including greater mortality, poorer self-reported health, adverse mental health outcomes, greater prevalence of chronic disease risk factors, greater incidence of diseases, and adverse child health outcomes.

Over time, residential segregation has led to highly segregated elementary and high schools and is a fundamental cause of racial differences in the quality of education. In large part, community resources determine the quality of neighborhood schools. Access to quality education and adequate community resources will enhance the likelihood of high school graduates and increase the probability of enrollment in college.

Disparity in criminal justice refers to inequity of arrests and sentencing for certain groups of people; it nearly always refers to racial and ethnic disparity. Unequal treatment of people of color has been well established at each stage of the criminal justice continuum, from profiling to sentencing.

Racial disparity has been verified, though it may not always be related to intentional discrimination. Legitimate legal factors involved in racial disparity include severity of the offense and previous criminal record. One type of racial disparity occurs when there is a marked difference in the percentage of a racial group represented in the general population and the percentage of the same group represented in the criminal justice process. For example, African-Americans make up 12% of the US population but account for approximately: 40% of all arrests, 50% of the prison population, and 50% of the inmates on death row.

Another example of racial disparity in the criminal justice system appears when, as compared to other races, there are a significantly larger percentage of members of a racial group involved in any part of the criminal justice system. For instance, greater than 9% of African-American adult males are in jail, prison, on probation, or on parole, compared with not quite 2% of non-Hispanic White adult males. To cite another example, Blacks are four times as likely as Whites to be arrested on drug charges – even though the two groups use drugs at almost the same rate.

Racism

Andrea M. Przybysz
Case Western Reserve University School of Law,
Cleveland, OH, USA

Racism is the belief that all members of each race possess characteristics or abilities specific to that race, especially so as to distinguish it as inferior or superior to another race or races (Oxford English Dictionary). This definition applies in four primary contexts, namely, individual, institutional, internalized, and horizontal or cultural racism. Individual racism is the belief and attitude set as well as an individual's actions that support or perpetuate racism. Institutional racism is a term coined by Stokely Carmichael and is best described as the collective failure of an organization to provide appropriate and professional services to people because of their color, culture, or ethnicity. This concept covers government, universities, and private business, and is perhaps the bleakest kind of discrimination due to the numbers of individuals who are affected by institutional policies and mores. Internalized racism happens when an individual knows that stereotyping or certain racial constructs are inaccurate, but because cultural conditioning, family objections, and media accounts that portray individuals of color in accord with stereotypes and inaccurate constructs, the individual who remotely empathizes with derogatory cultural concepts is said to abide by a racist code. The last kind of racism, horizontal or cultural racism, happens when individuals of one minority group act to discriminate against or oppress other minorities. Horizontal racism can occur between members of the same minority group or between members of different minority groups.

Racism is a prominent form of social exclusion. Consequently, each of the four kinds of racism factors into the immigrant experience. Because the 2007 WHO Commission on the Social Determinants of Health ("SDOH") explicitly recognized racism as a contributor to socioeconomic position, racism is seen as a key structural determinant of health. Thus, if the goal is to improve the immigrant experience and poor immigrant health associated with the experience, we must discern which forces work against immigrant populations within each kind of racism and the socioeconomics of those forces.

Before we discuss the kinds of racism presently inculcating the immigration experience, we must first consider whether any racial barriers to immigrating exist. Based on the fact that the USA gives preference to employment-based immigration, we know that the majority of preferred individuals are either fluent in English, have some English training, or the means to employ a tutor and be educated. While English is arguably the most widely spoken language in the world, the body of speakers is still primarily Western, or at least Westernized. Thus, while it is open for debate, the USA's preference for immigrants based on employment is a racial preference that likely favors non-Hipanic White individuals. The counterargument to race-based immigration policy is that the USA prefers immigrants based on employment status as a means to promote economic progress. The economic argument, however, loses credibility, given the overwhelming number of immigrants who successfully enter the USA each year and who contribute substantially to the economic well-being of the country.

At the individual level, hospital staff, nurses, and doctors bear directly on an immigrant's patient care. The most obvious ways for medical personnel to demonstrate racist attitudes toward an immigrant involve overt language, a lesser quality of care, and outright refusals to treat the individual. It has been suggested that racialized group members are less likely to be admitted to the hospital compared to their non-racialized counterparts, although they are more likely to use a general practitioner and equally as likely to see a specialist. Individual racism also encompasses immigrant perceptions of racism. The concept of perceived racism is based on one's notion that he or she was treated unfairly or inequitably, was uncomfortable around or not accepted by others, or was not treated with the respect and dignity generally accorded in the individual's culture. Many immigrants cite disrespect of historical or cultural backgrounds, and beliefs in alternative health systems as additional race-based problems surrounding provider care. Consequently, these potential problems likely contribute to recent racial immigrants' increased risk of declining physical and mental health over a period of time.

At the institutional level, immigrants without citizenship status experience racism that helps deter racialized immigrants from accessing and receiving quality health care. Government, hospital systems, insurance companies, and universities all contribute to racism perpetuated against immigrants. In the USA, the government compromises multicultural aims with Federal law requirements which prohibit immigrants from participating in Medicare and State Children's Health Insurance Program (SCHIP) until they have lived in the USA for at least 5 years legally. This lag time forces many immigrants to forgo primary and preventive health services until they are eligible for government services, and fails to touch on the millions without legal status who will never have access to what few Federal health provisions exist. A damaging consequence of immigrants forgoing preventive health services is that, often, they arrive at emergency care facilities in critical condition.

While every emergency department in the USA has an obligation to accept individuals pursuant to the Emergency Medical Treatment and Active Labor Act ("EMTALA"), private hospitals, at a disproportionate rate, camouflage their emergency services. This camouflage results in high numbers of poor and underinsured individuals being taken to public and disproportionate share hospitals. The risk involved with emergency services defaulting to public and disproportionate share hospitals is that many ambulance services will automatically bring individuals they perceive to be low income to these hospitals based strictly on "a gut reaction" that poorer individuals tend to utilize public and county systems at a greater rate than the affluent. Where individuals are perceived to be poorer based on race or ethnic status, and where individuals who are perceived to be affluent are given a choice of emergency medical services, immigrants are discriminated against. While the decision to take immigrants to a county hospital over the area's private hospital may not ultimately affect their quality of care, a race-based decision, has, nonetheless been made. Similarly, immigrants and racialized groups may have a difficult time accessing preventive care; immigrants typically are less likely to use preventive cancer screening services and mental health services. The inability to access health services, particularly those that maintain health and prevent disease, increases long-term health risks and is associated with negative health outcomes over time.

Internalized racism manifests itself in the experience immigrants detail over time. Recent studies suggest that racialized immigrants' perceptions and experiences of discrimination increase over time due to increased exposure to discrimination and greater recognition of discriminatory behavior over time. Unfortunately, the Gulf War and recent warfare in Iraq, Afghanistan, and Iran have reignited previously outmoded Middle Eastern stereotypes. Consequently, many Middle Easterners, citizens and immigrants presently attest to the fact that they feel unwelcome and have difficulty finding employment.

Horizontal racism is essentially the reverse of the minority alliances we saw from, in the USA, the late 1950s and through the mid-1960s. This era gained civil rights for African Americans as a result of cooperation from Black America, the women's movement, and also gay and lesbian groups. Today, race wars, prison gang wars, and cultural imperialism fragment minority groups. This fragmentation contributes to the negative reflections of self.

The four kinds of racism discussed each contribute to multiple and intersecting pathways that negatively impact an individual's health status. The idea is that racism exposes an individual to an increased amount of stress, generally sustained over time. Thus, individuals discriminated against undergo prolonged stimulation of the human body's physiological stress response. As a result, racialized immigrants experience negative physical consequences such as breakdown in immune responses and negative emotional responses such as anxiety, depression, and lowered self-esteem/identity at markedly high rights. To cope with these negative responses, racialized immigrants often forgo health care and turn to dangerous coping mechanisms such as substance abuse and self-harm.

While the USA has made several attempts to safeguard against, or rather, make amends for past racism, the primary mode of reparations largely involves affirmative action. Where present racism is perpetuated against immigrants in the form of health and health-related services, the government and health-providing institutions need to rethink their strategy and the ways in which the system continues to perpetuate subordination of various races.

Radicalization

Ryan C. W. Hall
Department of Psychiatry, University of South Florida, Tampa, FL, USA

Radicalization, especially violent radicalization, is the process of converting an individual of normal beliefs into an individual who believes and follows an extreme ideology and feels justified in taking extreme actions, such as breaking the law, committing acts of violence or assisting in such acts, in order to obtain a goal related to their beliefs. When the term radicalization is used in the current global environment, it is usually used in the context of extreme religious beliefs (e.g., "Islamic fundamentalists/radicals"); however, an individual can also develop radical nonreligious political beliefs, as occurs in protests to G7 Economic Summits or occurred in the famous case of Patty Hearst, who was abducted by the Symbionese Liberation Army (a radical political group) and "brainwashed" into adopting their radical political beliefs and terrorist (bank robbery) tactics.

Radicalization can occur through many different pathways. As in the Patty Hearst case, an individual can be kidnapped, terrorized, brainwashed, or be radicalized by rage. For example, Patty Hearst at one point was angry against authorities because she perceived them as trying to kill her verse trying to free her. Rage against and perceived mistreatment by authority can also lead to radicalization or identification with groups who present themselves as anti-establishment and anti-repression as is the case with anarchy groups such as Black September, the Baader Meinhof Gang or The Red Brigade. Radicalization can come from the need to belong to a group for safety, as occurs in prisons, where individuals will join gangs such as The Aryan Nation, Black Brotherhood, or the Crips or Bloods. Immigrants may join ethnic gangs like MS13 for similar reasons. Prisons serve as fertile breeding grounds for radical religious recruitment because many prisoners turn toward groups and shared religion for solace in prison; harbor negative societal views; are vulnerable, confused, and frightened when first incarcerated; and are housed with ethnically and culturally similar individuals who proselytize their religious ideas to maintain their own social position in the prison. Malcolm X provides a good example of this type of jailhouse conversion and potential radicalization in his autobiography, where he describes how and why he converted to Islam while incarcerated.

Radicalization often occurs over a period of time, through social contacts, where individuals meet others at religious meeting places, charitable groups, neighborhood community centers, book stores, and rallies and slowly become indoctrinated in radical theologies and ideologies that they incorporate into their existing belief systems. They are "absorbed" and "inculcated" into those "reputable" groups or subgroups, which harbor hidden radical beliefs and "plans for action." Radicalization can also occur when individuals join cults. Here, individuals lose their identity and belief system and replace them with the cult leader's mission and direction. They are promised answers, safety, identity, and purpose if they just believe the right things and follow the often-charismatic leader. Deviation from the cult's purpose results in punishment or expulsion (i.e., Jim Jones in Guyana, David Koresh at Waco Texas).

The birth of the Internet opened a new pathway for mass radicalization. Individuals can now be exposed to radical Internet material. The radical ideas of a few can now be seen as acceptable and coming from a community of many. Individuals begin to radicalize themselves without direct human contact with any radical individual or group. This method of Internet self-radicalization usually occurs among individuals or a small group of friends, with each encouraging the other to believe the group, increase fervor, and eventually defining one member to lead their crusade.

However radicalization occurs, it is important to remember that an individual's susceptibility to radicalization may be increased following some dramatic national, international, or personal event; international strife; wars; police actions, reported mistreatment, or torture; bombing; terrorist attacks; national/local police abuse; or personal tragedy where the system is blamed. All mobilize zeal and cause a change in radicalized thought, new interest in religion and politics, and the need to recruit new members and act.

Immigrants are often the targets of radical groups who see them as needy, uncertain, and vulnerable. They are perceived as potential members who will join ethnic movements. Immigrants are sought because they often have a weaker support network in their new country, may potentially be disenchanted by prejudice or poverty in their new nation, and are, therefore, more likely to feel like second-class citizens. They are often isolated by language, culture, education, and assimilation into their new homeland. They need to belong. In general, the two classes of immigrants most likely to join a radical group are isolated first-generation immigrants or second- or third-generation "immigrants," who have failed to successfully assimilate.

The two other groups prone to radicalization, but harder to identify, are new and zealous religious converts from any group (e.g., Jihad Jane – American suburban resident who turned terrorist) and immigrants of any generation who have successfully assimilated but who repudiate their role in society, seeing instead a need to avenge the ill treatment of all their brethren through a radicalized reawakening of beliefs in their heritage or faith (e.g., Umar Farouk Abdulmutallab, aka the underwear bomber who came from a position of privilege). Immigrants are easily targeted through their social institutions, which they attend to obtain support in the new country. They gather at houses of worship, ethnic college and work clubs, political organizations based on religion or country of origin, charities, neighborhood meeting places, ethnic restaurants, and sporting events and facilities. Here, the disillusioned or religiously radical are recruited and trained.

Radicalized immigrants are important assets for radical groups. Once an immigrant has been radicalized, they may assist in recruiting additional members in the immigrant community. They provide important resources such as money, safe houses, and materials used to carry out the radical group's "mission." Legal immigrants have the same constitutional (government) rights as natural-born citizens in most countries. Thus, they provide an international radical group with additional agents and protectors who have constitutional protection from local authorities if apprehended. Naturalized immigrants also travel on the passport of their new country, which may help reduce suspicion, and make it easier for them to travel from country to country while engaging in "radical business." The radicalization of immigrants causes fear in the host country's population, induces xenophobia and other concerns about immigrants in general, and thus creates tension between the immigrant and native-born community, which further alienates immigrants and makes recruitment and radicalization of new recruits easier.

Traditionally, nations seek safety through government control when acts of terror occur. Thus, civil liberties are often reduced when governments become engaged in reactive policies to acts of terrorism brought about by radical groups. Recently, more nations are placing emphasis on preventing their citizens and new immigrants from becoming radicalized in the first place, as part of their counterterrorism strategies. In general, there are two broad approaches for preventing the radicalization of immigrants. The first is the promotion of multiculturism in the host country. This strategy attempts to allow immigrants to maintain their culture of origin while still feeling included in the larger umbrella of national identification within the host nation. Immigrants are made to feel valued, needed, and secure. In order for the multicultural approach to work, all groups need at least some shared common beliefs, such as respect for the system of justice, respect and acceptance of other cultures and customs, and maintaining and following the democratic rule of law. Often radical organizations, such as radical fundamentalist Islamic groups cannot be placated by a multicultural view of belonging due to their strong belief that Sharia law must be applied to all and that infidels who do not embrace their culture must be defeated. Jihad prevents inclusion! The multicultural assumption is that if society encourages and promotes a strong moderate community, that community will feel safe and included, reject extremist views, police itself, and work with the national authorities to identify radicals who do not subscribe to democratic rule of law.

The other government option is to place an emphasis on the assimilation of immigrants into the existing host nation's dominant culture, which prevents these immigrants from feeling outside society, rejected, or like second-class citizens. They give up their past and become "new" and like other members of their new country. This approach may help prevent already established immigrants from becoming radicalized, but is unlikely to soften the anger or isolation felt by individuals who have already become radicalized over what they perceive to be social prejudice. For this process to work, the accepting nation needs to have relatively secure borders, a low rate of immigration, funds to support active assimilation programs, some tolerance of other cultures, and a stable economy, which can absorb, benefit from and provide jobs to immigrants of all skill levels.

A third approach toward radicalization has been utilized by Great Britain. The British tried to prevent radicalization using a multicultural approach integrated with the acquisition of a strong national identity embracing democratic rule. The country also, however, actively observed, monitored, and infiltrated radical groups using counterespionage techniques and operations, took active measures to shut down terrorist cells and organizations before they caused death and destruction. This approach was born out of the many years of dealing with the terrorist threats posed by the IRA in both Northern Ireland and the home isles. This level of governmental observation of radical groups was highlighted in the aftermath of the December 25, 2009 "underpants bomber," when the British government announced it was monitoring ten universities that it felt to be potential recruiting grounds for radicalization. It is widely believed that the "underpants bomber" was radicalized while attending one of those universities, where he was the president of an Islamic student group. Therefore, the government actively monitored these institutions in order to learn who else had become radical, who their associates were, and to find any actionable information that could be useful to prevent radicals from engaging in further terroristic activities.

Rape

Sana Loue
Department of Epidemiology and Biostatistics, Case Western Reserve University School of Medicine, Cleveland, OH, USA

Although rape is defined differently across various legal jurisdictions, it is generally conceived of as any forced or coerced genital contact or sexual penetration. This would include not only vaginal contact or penetration, but also anal and oral contact or penetration. Penetration can be effectuated with a genital organ (penis), another body part such as a hand, or an object.

Although rape can be committed against males and females, it is often used as a form of gender-based violence. Amnesty International has delineated three categories of gender-based violence: family violence, that is committed against a woman or girl by a family member, including marital rape; community violence, including rape committed in the context of prostitution or trafficking and rape committed by a stranger; and state violence, which includes rape that is committed or condoned by someone working for the government, such as a police officer, prison guard, soldier, or border official.

Rape has been and continues to be used as a weapon of warfare and genocide. As an example, women in Darfur who were members of the Fur, Masalit, and Zaghawa ethnic groups were systematically raped by members of Sudan's armed forces and security agents and tribal militia in an effort to dilute the blood of these ethnic groups and cause their extinction. The children borne from these rapes were often ostracized from their communities or, even worse, killed or abandoned to die.

Immigrants may become the scapegoats in their host country for groups that do not look favorably on individuals who appear different in any way. Immigrant men may be denounced in the media as the purveyors of rape. Women who attempt to cross national borders illegally may become the targets of vigilante groups, some of whose members may use rape as a tactic to "punish" them for crossing the border illegally. Men, women, and children who are trafficked illegally may be subject to rape by their traffickers, as a way of controlling them.

Immigrant women may be at particularly high risk of rape in some circumstances. In some countries, such as the USA, a citizen or permanent resident can petition for permanent residence for his wife to gain legal status in the country. Unless the law provides a mechanism for the woman to self-petition for legal status, she must depend on her marital partner to gain legal status. Consequently, even if her husband is abusive, she may feel that she has no choice but to tolerate the abuse, including rape, if she is to gain legal status. The US government recognized the injustice inherent in this situation and changed its immigration laws to allow battered women who are the wives of US citizens to self-petition for legal status under specified circumstances.

Immigrants whose primary language differs from that of their new host country or who are illegally present in their host country may face barriers in seeking medical treatment following a rape and/or in reporting a rape to law enforcement agencies. Women may have difficulties communicating to health care providers if they do not speak the language of the host country. Depending upon the norms of their culture or their religious beliefs, they may be reluctant to undergo a physical examination or to discuss a situation that is so highly personal and traumatic. Individuals who are undocumented may be afraid that the health care provider or law enforcement official will report them to immigration authorities and they will be deported, a situation that would further traumatize the rape victim.

Research suggests that the attitudes of individuals who migrate to more industrialized or Westernized countries from those that are less Westernized change over time. For example, one study conducted in Canada by Kennedy and colleagues found that the longer Asian immigrants had resided in that country, the less likely they were to tolerate myths about rape, for example, that women have an unconscious wish to be raped, and behavior that could be considered sexual harassment.

- ► Red Cross

Red Cross

Robert W. Stephens
Rynearson, Suess, Schnurbusch & Champion, L.L.C,
St. Louis, MO, USA

The International Red Cross and Red Crescent Movement is an international humanitarian movement which started to protect human life and health, to ensure respect for the human being, and to prevent and alleviate human suffering, without any discrimination based on nationality, race, sex, religious beliefs, class, or political opinions. The often-heard term *International Red Cross* is actually a misnomer, as no official organization as such exists bearing that name. In reality, the movement consists of several distinct organizations that are legally independent from each other, but are united within the Movement through common basic principles, objectives, symbols, statutes, and governing organs.

The International Committee of the Red Cross has a permanent mandate under international law to take impartial action for prisoners, the wounded and sick, and civilians affected by conflict. The International Committee of the Red Cross is headquartered in Geneva, Switzerland. The International Committee of the Red Cross is based in 80 countries and has a total of more than 12,000 staff. In situations of conflict the International Committee of the Red Cross coordinates the response by national Red Cross and Red Crescent societies and their International Federation. The International Committee of the Red Cross is at the origin of both the International Red Cross/Red Crescent Movement and of international humanitarian law, notably the Geneva Conventions.

The International Committee of the Red Cross' legal mandate is derived from two sources: (1) the 1949 Geneva Conventions, which task the International Committee of the Red Cross with visiting prisoners, organizing relief operations, reuniting separated families, and similar humanitarian activities during armed conflicts; and (2) the Statutes of the International Red Cross and Red Crescent Movement, which encourage the International Committee of the Red Cross to undertake similar work in situations of internal violence, where the Geneva Conventions do not apply. The Geneva Conventions are binding instruments of international law, applicable worldwide. The Statutes of the International Red Cross and Red Crescent Movement are adopted at the International Conference of the Red Cross and Red Crescent, which takes place every 4 years, and at which States that are party to the Geneva Conventions take part, thereby conferring a quasi-legal or “soft law” status on the Statutes.

The International Committee of the Red Cross has more than 1,400 people, both specialized staff and delegates, currently on field missions across the globe. This work is backed up by 11,000 local employees and supported and coordinated by 800 staff at the International Committee of the Red Cross' Geneva headquarters.

Refugee

Cristina Cazacu Chinole
Center for Ethics and Public Policies, Bucharest and Iasi, Romania

According to the 1951 Refugee Convention, a refugee is someone who “owing to a well-founded fear of being persecuted for reasons of race, religion, nationality, membership of a particular social group or political opinion, is outside the country of his nationality, and is unable to, or owing to such fear, is unwilling to avail himself of the protection of that country.” The Convention also defines a refugee’s obligations to host governments and certain categories of persons, such as war criminals, who do not qualify for refugee status.

Even if half a century has passed since its adoption, the 1951 Convention is the most important document that articulates the international system for protecting refugees. While the Convention offers the legal definition of a refugee, history has shown that there is a need for more legislation to address current refugee issues.

Although the definition of “refugee” seems quite straightforward, establishing who is a refugee is a rather complicated issue. According to United Nation High Commissioner for Refugees (UNHCR), over 200 million people are living outside their homeland and only a small fraction of them would qualify under the standards imposed by the 1951 Convention relating to the Status of Refugees as a “refugee.” Established in 1951, UNHCR is the international agency in charge of offering assistance to refugees worldwide, at the request of a government or the United Nations. The agency offers protection and support to many other categories of people in need, such as asylum seekers, stateless persons, refugees who have returned to their homeland and need help to rebuild their lives, and internally displaced peoples (IDPs).

An “asylum seeker” is an individual who seeks international protection and whose refugee status has not been determined yet. Once refugee status is granted, a person usually enjoys specific protections. In the United States, refugees are eligible for a variety of Federal assistance programs that entitle them to medical assistance, cash assistance, and social service programs. Most of the EU Member States have a similar policy.

The term “asylee” is used in the United States to describe a person seeking “asylum.” This status is granted by the US Citizenship and Immigration Services to an alien residing in the United States as a result of persecution or a well-founded fear of persecution in the individual’s country because of race, religion, ethnic group, social group, or political opinion. This status is similar to refugee status. The difference is that refugees are granted their status abroad, while individuals seeking asylum apply after they enter the United States.

“Internally displaced persons” (IDPs) are individuals in a situation similar to that of refugees. IDPs are defined in the 1998 Guiding Principles on Internal Displacement as “persons and groups of persons who have been forced or obliged to flee or to leave their homes or places of habitual residence, in particular as a result of or in order to avoid the effects of armed conflict, situations of generalized violence, violations of human rights or natural or human-made disasters, and who have not crossed an internationally recognized state border.” Yet, even if IDPs have a similar situation as that of refugees, they are not subject of a universally adopted treaty and therefore are not offered similar protections and do not qualify for the same benefits as refugees.

According to international refugee law, all States have an obligation to protect all refugees that arrive on their territories and seek asylum. International refugee law is a set of rules that seeks to offer protection first, to all persons that seek asylum from persecution and second, to those recognized as refugees under the relevant instruments. The sources of refugee law are treaty law such as the 1951 Refugee Convention and the 1967 subsequent Protocol, and customary international law that applies to all States regardless of whether they have ratified these treaties or not. Several regional instruments offer further protection for refugees, notably the 1969 Organization of African Unity Convention (for African States) and the 1984 Cartagena Declaration (for Latin America). Under Article 33 of the 1951 Refugee Convention, all party States have a duty not to expel or return a refugee to their country or territory where he/she would be at risk of persecution or where his/her life or freedom would be threatened. This principle, which is known as “non-refoulement,” is considered a part of customary international law and therefore binding to all States. The principle is incorporated in other international human rights treaties, such as the 1984 Convention Against Torture, which prohibits the forcible removal of persons to a country where there is a real risk of torture.

Yet, it is the States that determine whether an individual or groups of individuals entering its territories are refugees, legal migrants, or illegal aliens. Since the procedures for determination of refugee status are not indicated in the 1951 Refugee Convention or in the 1967 Protocol, it is left to each State to establish the procedures that it considers most appropriate, taking into account its particular constitutional and administrative structure. For this reason, such procedures vary considerably: in some countries, refugee status is determined under a formal procedure specifically established for this purpose; in others, determining refugee status is considered within informal arrangements or on an ad hoc basis for specific purposes, such as the issuance of travel documents. Therefore, one country may recognize the refugee status of a group of asylum seekers while another would view the same group as illegal migrants, and treat them as illegal aliens.

Currently, there is a considerable movement of people from one country to another, many seeking better employment or educational opportunities and others trying to reunite with family members; only a small number are fleeing persecution, conflict, or violence in their home country. Faced with an increasing afflux of immigrants, officials across the world have a difficult challenge in discerning the status of this mobile population. Even if individuals who meet the legal definitions of refugees and asylum seekers account for only a small proportion of the global movement of people, they frequently travel alongside illegal migrants who may use similar stories in order to obtain legal status and additional benefits in a new country. Since these large movements of people are irregular, and because most travel without the requisite documentation or use unauthorized border crossing points (which may involve smugglers), many States perceive such movements as a threat to their sovereignty and security. Therefore, in spite of existing international regulations for the protection of refugees, there is no guarantee that an asylum seeker will be granted refugee status even if their claim is legitimate; in fact, many end up being deported to their native country.

Health Status

Most countries have compulsory medical exams for asylum seekers on their arrival, especially for contagious diseases. For example, people suffering from communicable diseases of public health significance, serious physical or mental disorders, or drug addiction are denied entrance to the United States. There are many studies that demonstrate that refugees and asylum seekers are prone to health problems, which are due to complex and wide-ranging causes. Asylum seekers are not a homogeneous population as they come from different countries and cultures. Yet, there are some common premigration factors, such as life experiences that have an impact on health and nutritional state, and traumatic experiences such as torture and acts of violence. In the host country, refugees may suffer from the effects of poverty, dependence, and lack of social support, which affect physical and mental health. Moreover, due to racial discrimination, they may face numerous obstacles in accessing health care services.

Refugees living in refugee camps may experience deterioration in their health because of a lack of resources to fulfill simple human needs, such as access to clean water, food, shelter, or medical services and drugs. They are particularly susceptible to illness since diseases can spread quickly throughout an entire camp population as a result of precarious living conditions. Most common are diarrheal diseases, cholera, measles, meningitis, tuberculosis, and malaria. Asylum seekers and refugees living outside refugee camps often encounter hardships in accessing medical systems due to language barriers, cultural differences, institutional obstacles, lack of material resources, and limited knowledge on how the medical system works. Another contributor to poor health status is the trauma resulting from the horrifying experiences they have been through during their flight to freedom, navigating through difficult and unfriendly asylum procedures, or simply from culture shock. There are many studies documenting various mental health problems due to the specific traumas encountered during and after their flight into asylum and eventual resettlement. In addition, factors such as separation from family, life events after exile, employment status, level of education, gender, and marital status may have a significant influence on a refugee's psychological status.

From a public health point of view, it is worth considering that refugees bring varied epidemiological profiles as they come from different environments and exposures to diseases in their countries of origin, and may fall ill as a result of their emigration experiences. As cultural beliefs and representation of illness and health may be different from those of the host country, cultural competency in health services is needed to meet the special physical and mental health needs of refugees.

Refugee Camp

Katherine Crow
WebMD Health Foundation, Rancho Santa Fe,
CA, USA

A refugee camp is a temporary shelter built to house people who have fled their homes due to conflict or natural disaster. Refugee camps are run by governments, the United Nations, international organizations, or nongovernmental organizations (NGOs). Most people who live in the camps are refugees who have fled their home country but can also be Internally Displaced Persons (IDPs); refugees and IDPs are civilians displaced by persecution, war, or violence. Approximately 67 million people have been forced to leave their homes due to conflict or natural disaster: 16 million are refugees and 51 million are IDPs.

When people flee their homes, they are usually forced to leave behind their belongings. The government or humanitarian agency running the refugee camp provides refugees with clean water, food, and basic health care, but depending on the location of the camp and the political climate of the country in which the camp is located, it may take weeks for the camp inhabitants to receive any assistance. Security for a refugee camp is usually the responsibility of the host country and is provided by the military or local police. The number of people living in the camp depends on the crisis from which they have fled. Camps are usually established on the outskirts of towns or cities, away from the border, in a secure area. Some countries mandate that camps be enclosed with barbed wire fence so the refugees do not interact with the local people.

There is a reception center where newly arrived refugees check in and are counted. This is important in order for aid agencies to keep track of the number of people in the camp, assess their needs, and provide enough food, water, and medical supplies. When a new refugee is registered, he/she is given relief items such as clothing, blankets, and cooking utensils.

Food is kept in a storage warehouse and is distributed to the women in the camp on a set schedule. Food is given to women since they are responsible for the cooking and will ensure everyone is fed. Rations that adhere to cultural diets are provided. The minimum recommended daily ration is 2,100 calories per adult. Breastfeeding mothers may receive additional food. Examples of the types of food distributed include rice, wheat, or maize; beans, lentils, or peas; vegetable oil or butter; a fortified blended food such as corn soya blend; sugar; and salt. The minimum amount of water each person in the camp should receive is one gallon per day in an emergency situation. The amount should increase to 6 gallons per day so people have enough water for cooking, personal hygiene, and washing clothes and dishes.

Though the camps are meant to be temporary solutions, giving people a place to live until they can return home, refugees and Internally Displaced Persons can live in camps for years while they await resettlement in other countries or, for IDPs, conflict to be resolved in their home countries. In some cases, camps have existed for decades and turn into permanent settlements or become part of the local community where the camp is located.

Refugee Health and Screening

Nadia El-Shaarawi
Department of Anthropology, Case Western Reserve University, Cleveland, OH, USA

According to the United Nations High Commissioner for Refugees (UNHCR), there are currently 15.2 million refugees worldwide. Most refugees and displaced persons reside in urban areas or camps in the Global South. The health of refugees is a complex topic with important implications for policy and practice on a global scale. The complex humanitarian emergencies often associated with refugee flows pose significant challenges to the health of displaced peoples. In addition to morbidity and mortality directly resulting from war or other violence, disruption in infrastructure associated with humanitarian emergencies pose great challenges for public health and medical care. The process of migration from conflict or disaster can be associated with further injury and illness. Following migration, encamped refugees and those in urban settings of asylum experience a variety of health concerns as do the much smaller number of refugees who are resettled to places such as Europe, North America, or Australia.

Forced migration often occurs at times of massive social upheaval, such as war or disasters, which can include disruptions to water, food supply, shelter, and health care, all of which have implications for health. Precipitating factors and the often-stressful migration process, combined with factors in the place of asylum, influence refugees' health and well-being. Refugees and other forced migrants suffer from a wide range of health problems including chest, back, and stomach pain; psychological disorders; heart disease; hypertension; tuberculosis; diabetes; and nutritional problems, among others. Before the 1980s, refugee health and humanitarian aid were primarily understood in terms of necessities such as food, water, and basic medical care, but recently, refugee health has also been understood in terms of psychological trauma and psychosocial well-being. Research has demonstrated that refugees are vulnerable to a variety of health problems because of factors including poor living conditions, lack of access to health care, stressors related to the refugee experience, conflict between health beliefs in place of origin and displacement, and lack of financial resources for food and medicines.

Legal Aspects of Refugee Health

Refugees are defined under several conventions in international law as persons who have fled their country of origin because of a well-founded fear of persecution on the basis of race, religion, nationality, political opinion, or membership in a social group. Under the United Nations 1951 Refugee Convention and its 1967 Protocol, some aspects of refugee health are explicitly considered. Under Article 24 of the Convention, ratifying countries agree to treat refugees the same as nationals with respect to social security, including health and maternity care. Additional legal protection relevant to health is available under Articles 20, 21, and 23 which provide for refugees' rights to access rationing, housing, and public relief, respectively. Ratifying countries vary in the ways in which they implement these convention obligations. Other branches of international law, namely human rights law and humanitarian law, are also relevant to the health of refugees, and are particularly useful in cases when forced migrants may not meet the Convention definition of a refugee, as in the cases of internally displaced persons and non-Convention refugees. In many cases, the health status of Convention refugees and other forced migrants may be similar, but in some cases the health of forced migrants such as internally displaced persons (IDPs) may be worse because they may still be exposed to conflict zones, may be inaccessible to aid efforts, and have less protection under international law.

Refugee Health in Complex Humanitarian Emergencies

In complex humanitarian emergencies such as war or disaster, forced migration is associated with significant risk of increased morbidity and mortality. During or immediately following such disasters, when large numbers of people are in flight, rates of morbidity and mortality can be extremely high. In Asia and Africa, population migration and associated food shortages have been associated with more deaths than direct conflict. In times of social upheaval and war, health is threatened through limited access to health services, disruption of infrastructure, disturbances in the food supply, and problems with shelter in addition to injuries and trauma sustained from violence. The process of migration itself can pose threats to health, as can conditions in refugee camps or other places of asylum.

Measuring the health impacts of displacement under emergency conditions is challenging, with upheaval often leading to the underreporting of mortality and morbidity rates and an inability for observers to accurately document health conditions. The crude mortality rate is one measure that is often used to determine the impact of an emergency on a displaced population, and research shows that for mass population displacement, mortality rates are often highest immediately following arrival in a place of asylum such as a refugee camp. While mortality rates vary by population and over time, children under 5 years of age are at highest risk of death. The leading causes of mortality among refugees in humanitarian emergencies are infectious diseases, such as measles, malaria, acute respiratory infections, and diarrheal diseases.

For refugees housed in camps, a range of causes of morbidity and mortality have been documented. Among these, epidemics of diarrheal diseases are perhaps the most common, often attributable to contaminated water. In complex humanitarian emergencies, infectious disease rates typically increase. Measles is one of the leading causes of death for children in refugee camps as a result of low immunization rates combined with nutritional deficiencies. Protein-energy malnutrition, iron deficiency, vitamin A deficiency, pellagra, and other types of malnutrition have been documented in refugee camps and are often associated with insufficient food rations or food that is deficient in micronutrients. A high prevalence of acute respiratory infections in refugee camps, especially among young children, has been associated with poor conditions and crowding. Malaria occurs in refugee camps particularly when populations from areas of low endemicity migrate into areas where malaria is endemic. Elevated rates of meningitis, hepatitis, HIV/AIDS, and other sexually transmitted infections have also been documented among encamped refugee populations. With respect to HIV/AIDS, complex and protracted refugee situations can affect infection rates, challenge the treatment of those living with the disease, and affect prevention efforts by, for example, limiting a person's ability to access preventive care, such as family planning supplies, in a refugee camp.

Refugee Mental Health

Much of the literature on refugees and other forced migrants focuses on the psychological effects of displacement, particularly in terms of trauma, and on coping strategies. Migration does not necessarily lead to poor mental health. Instead, a number of forces and processes, including traumatic events, housing conditions, and others can threaten psychological well-being and lead to high rates of psychiatric trauma and stress-related disorders. Desjarlais et al. (1995) identify three key factors which influence a migrant's well-being. These are: (1) adaptation to the changes wrought by migration; (2) the environment in which the migrant resides; and (3) whether the migrant can live a meaningful, productive, and culturally integrated life. Most research on the health of forced migrants has considered the direct effects of violence on health. Some other, less discussed factors that influence forced migrants' health include the disruption of civil society and social relationships, flight, and separation from one's homeland.

Research demonstrates that depressive disorders, anxiety, and posttraumatic stress disorder are prevalent in refugee populations and that refugees have high levels of stress as well as other problems that affect their quality of life. Reported rates of PTSD vary widely in refugee populations, with the lowest rates observed in epidemiological studies, higher rates in studies employing convenience samples, and the highest rates being observed in clinic populations. PTSD is often associated with other disorders such as depression, anxiety, somatoform disorders, dissociative disorders, or substance abuse. A higher incidence of depressive disorders has been found in some displaced populations.

Somatization, or the cultural patterning of psychological and social disorders into physical ways of expressing distress, is widely observed in displaced populations. Refugees have been shown to have higher rates of somatization than immigrants in some cases. Given cultural differences in lay and professional disease classifications globally, it is perhaps not surprising that clinical encounters and diagnosis are issues of concern in the health of forced migrants. Western diagnostic criteria are overwhelmingly used to assess the health of displaced populations, although these are increasingly being validated for major forced migrant groups. The use of such standardized instruments, both for diagnosis and also for indices of concepts such as stress, well-being, or self-esteem may be inconsistent with local and indigenous classifications of health and ill health.

Health in Resettlement

Much research has considered the health of refugees resettled to the United States, Canada, Australia, and Europe. Conclusions about the health of resettled refugees vary. Some studies show continued rates of traumatization and stress, while others have shown a decrease in psychopathology over time. As refugees become acculturated to their new environment, patterns of disease and health habits may change. Rates of chronic diseases, such as cancer, coronary heart disease, diabetes, hypertension, and obesity may increase, as may health behaviors related to diet and substance use, for example. Refugees may also experience barriers to accessing medical care and preventive services in countries of resettlement.

The process of becoming acculturated to a new environment may in itself be a source of stress that affects health. While exposure to traumatic experience is the most consistent predictor of psychiatric disorder among refugee populations, other factors, such as social environment, living conditions, preexisting vulnerabilities, and demographic factors, also affect mental health. In contexts of resettlement, insecurity, low socioeconomic status, unemployment, and other post-migration stressors are associated with increased and prolonged psychopathology.

More research is needed in order to understand how to address the mental health needs of refugees and other forced migrants. Religion has been shown to have protective effects in some cases, as have political and ideological commitment. Social linkages and support have also been shown to be important for mental health. Social and personal factors mediate the risks for ill health among forced migrants in various contexts. In terms of scholarship, work that considers the mental health of forced migrants from a more holistic perspective is increasingly available. In asylum and resettlement, acculturation and social integration can pose challenges for health. These challenges include role reversal in families, downward mobility, loss of social support, and intergenerational conflict among others. The implications include loss of self-esteem, stress, and substance abuse. Loss and separation also pose challenges to health in resettlement.

Refugee Health Screening

Refugees are often required by law in countries of asylum to undergo a health assessment. In the United States, refugees accepted for resettlement are required to have a health screening in their country of first asylum before they can travel to the United States. The historical purpose of such assessments was to identify refugees who were afflicted with certain diseases, especially infectious diseases, for the purposes of potentially providing treatment before travel or, in some cases, for excluding a refugee from resettlement. Once resettled, refugees are usually offered a health screening. In the United States, refugees enter the country through an airport that has a quarantine station, where officials review their medical documents. In addition, a domestic health screening is recommended under the Refugee Act of 1980. The purpose of this screening is to address and treat health conditions that may have been identified in a pre-travel screening. Historically, health screening measures were primarily focused on infectious diseases of major importance for public health but now tend to be more comprehensive general health assessments. Refugee health screening is complicated by differences in the number and type of measurement and diagnostic instruments, and by issues of language and culture. However, refugee health screening is important as it often serves as an introduction between the refugee and the host country health care system, may provide refugees with access to treatment that can alleviate suffering and facilitate self-sufficiency, and identifies refugees with health conditions of public health importance.

Conclusion

Studies of populations of migrants around the world show that refugees tend to suffer from more mental health and medical problems than immigrants of other types. Refugees, by definition, have fled from persecution, which often may include traumatic experiences including war, violence, and physical or psychological torture. That refugees are vulnerable to health problems specifically related to displacement has been established in the literature. In terms of health concerns, significant attention has been paid to infectious diseases and forced migration, although the significance of these diseases largely depends on the population of interest. Increasingly, the mental health of refugees is a topic of considerable research and intervention. Refugees housed in urban areas or camps in developing countries have specific health concerns related to the conditions of their asylum. Most studies of refugee health consider the relatively small number of refugees who are resettled to North America, Europe, and Australia. With millions of people displaced by conflict around the world living in a wide range of conditions, refugee health varies from place to place, suggesting that interventions to improve refugee health should be based on rigorous assessment of local needs and concerns.

Refugee Resettlement

Katherine Crow
WebMD Health Foundation, Rancho Santa Fe,
CA, USA

A refugee is a person fleeing his or her country because of persecution or a well-founded fear of persecution on account of race, religion, or nationality; membership in a particular social group; or political opinion. Refugees are different from other immigrants in that they do not have the choice to remain in their home country.

The refugee resettlement process varies from country to country, but all programs offer immediate aid including food and shelter. Longer-term services offered at refugee centers in resettlement host countries can include permanent housing, employment skills and job placement services, clothing, medical attention, education, language classes, and community orientation. Some refugee centers also provide day care, transportation, case management, translation services, assistance obtaining employment documents, and support during the process to become a permanent citizen.

According to the 2009 World Refugee Survey by the United States Committee for Refugees and Immigrants, as of December 31, 2008, the number of refugees and asylum seekers worldwide totaled 13,599,900, with the majority (6,343,800) located in the Middle East and North Africa. The report also notes that, of the worldwide total, only 86,460 refugees or asylum seekers were resettled in 2008. As a result of the discrepancy between the number of refugees and asylum seekers compared with the number actually resettled, most refugees live in camps. Though the camps are meant to be temporary solutions, refugees can live in the camps for many years. Most camp host countries do not allow freedom of movement, which is defined as the right to choose one's place of residence and move freely in the host country. As a result, refugees are "warehoused"; they are usually confined to camps or segregated settlements where they are dependent on humanitarian assistance.

There are 16 countries with formal refugee resettlement programs including Australia, Canada, Sweden, the USA, Norway, New Zealand, Finland, Iceland, Denmark, the Netherlands, Ireland, the UK, Chile, Argentina, Brazil, and Italy.

Refugee Status

Ken Crane
Department of History, Politics, Society, La Sierra University, Riverside, CA, USA

War, communal conflict, and persecution based on religious, ethnic, or political affiliation are the primary reasons that over 10 million people are considered to be refugees by the United Nations. According to both United Nations protocols and US immigration laws, the generally accepted definition of a "refugee" is a person who has fled across international borders because of a well-founded fear of being persecuted "for reasons of race, religion, nationality, membership of a particular social group, or political opinion." The UN Refugee Protocol of 1951 mandates the global community to give protection for those with a "well-founded fear of persecution" in their home country. Nevertheless, despite clear protections promised by widely accepted international law, refugees are frequently subjected to the vagaries of political self-interest. The reason for this is that refugees are an indicator that a state allows, either intentionally or unwillingly, the persecution of part of its population based on religious, ethnic, or political affiliations.

To maintain good political relationships, countries may be reluctant to accept asylum seekers from their allies. Thus, North Korean refugees in China are considered "economic migrants" and are forcibly repatriated (refoulement) back to their homeland despite the likelihood of imprisonment and capital punishment. Christians from Iraq were denied political asylum by the United States during the Iran–Iraq war (1980–1988) because American foreign policy at that time favored Iraq. Refugee status can also be rejected based on grounds that people are fleeing a poor economy rather than harm. Haitians intercepted by the US Coast Guard in international waters are considered "economic refugees" fleeing desperate poverty rather than persecution for their political or religious persuasions. Refugees therefore frequently experience the vulnerability of being "asylum seekers," who have not yet been given refugee status but are in the process of presenting their case of a "well-founded fear of persecution."

The United Nations High Commission for Refugees (UNHCR) was formed to protect refugees, coordinate international assistance, and work out long-term solutions, such as orderly resettlement to "third countries" or repatriation (return to home country). Providing emergency relief and shelter in countries of "first asylum" is considered a temporary arrangement but can mean years of uncertainty while waiting for protracted conflict situations to play out and resettlement options to be arranged. The approximately 2 million Iraqi exiles in first asylum countries of Syria, Jordan, and Lebanon have waited 5 years for conditions back home to improve, with no end in sight. Even UN-monitored refugees camps are not necessarily safe havens and may be vulnerable to raids by armed militias (current examples being Darfur and northern Uganda). Governments can also force the UNHCR and aid agencies to close camps, as the Ethiopian government did to camps housing Sudanese refugees in the late 1980s.

The USA routinely accepts more refugees for resettlement than any other country in the world. In 2009, the ceiling was set at 80,000, and 74,602 refugees were resettled that year. The US Refugee Act of 1980 aimed to eliminate the practice of granting asylum primarily to escapees from Communist controlled countries, although it continued to resettle large numbers of Vietnamese (759,482 from 1973 to 2002) and Cubans.

The US Refugee Admissions Program (USRAP) coordinates the admission of refugee applicants referred from the UNHCR and works with private voluntary organizations (such as International Rescue Committee and Catholic Charities) that sponsor refugees in the USA. Once given full refugee status, the US government provides cash and living assistance support for a given period of time; in California support is for about 8 months. Nonprofit agencies with both private and public funding may give additional assistance in the form of job training, language classes, health care, counseling, and cultural orientation. Scarcity of funding forces resettlement agencies to depend heavily on sponsoring or "anchor" families to help refugees get on their feet.

Besides the many difficult adjustments that all immigrants must make in a new society, finding jobs, changing careers, learning a new language, refugees face the additional strains of having experienced traumatic events in their lives. Many have faced dangerous journeys and witnessed family members and conationals killed, tortured, and raped. They often feel tremendous responsibility to family and friends left behind who are in danger or whose whereabouts are still unknown. They commonly channel a great deal of their resources, both financial and emotional, toward supporting and protecting family members who are still facing difficult and dangerous circumstances in their country of origin or refugee camp.

Refugee Youth

Marisa O. Ensor
Department of Anthropology, The University of Tennessee, Program on Disasters, Displacement and Human Rights, Center for the Study of Youth and Political Conflict, Knoxville, TN, USA

Refugee children and adolescents constitute over 45% of the refugee population worldwide. While a number of guidelines and standards have been developed to promote their protection and care, in practice, refugee youth are not always paid sufficient or adequate attention. Their needs and priorities have until recently been considered "on-the-sidelines" of core protection and aid programs, or else subsumed under those of their adult counterparts. One notable exception is the increasing focus on health issues, with a particular emphasis on mental health. Psychosocial research in the area of refugee youth mental health suggests a complex relationship between displacement and health. Studies also suggest that refugee youth have many of the same physical health issues or conditions seen in non-refugee children and adolescents, although with differing prevalence rates.

Mental Health

Refugees of all ages must not only contend with experiences of violence, persecution, and other potentially traumatic experiences. They also face additional long-term stressors related to displacement such as changes in language and culture, and loss of social and economic status. The conditions of chronic stress to which some refugee youth are subjected may manifest as physical symptoms including headaches, abdominal pain, indigestion, fatigue, or insomnia that have not clearly identifiable physical cause. Traumatized youngsters may experience depression, adjustment difficulties, posttraumatic stress syndrome, and other psychological disorders. In these cases, psychological and psychosocial interventions can be instrumental in helping refugee youth regain their mental health. Approaches that focus exclusively on mental problems, however, have been criticized for treating all young refugees' as a homogeneous, universally traumatized group, for disregarding the sociocultural dimensions of mental health, and for interpreting the responses of Non-Western youngsters by means of predetermined Western psychiatric categories and symptom checklists.

Physical Health

In addition to psychosocial factors, refugee youth may manifest a wide array of common physical health issues. Poor oral health (dental caries, gingivitis, and orthodontic issues related to cultural practices such as tooth extraction) is prevalent. Anemia and micronutrient deficiencies (particularly of iron, zinc, and vitamin A) are also common. Similarly, growth abnormalities, including low weight-for-height (an indicator of acute malnutrition) and low height-for-age (an indicator of chronic malnutrition) are more frequently found among refugee youth than among their non-refugee counterparts. Common infectious diseases include tuberculosis (typically in its latent or asymptomatic form), intestinal parasites, fungal skin infections, and hepatitis B among refugee youth from endemic countries.

Conclusions

The mental and physical health practices and beliefs of refugee populations are influenced by variables such as ethnic values, cultural orientation, religious beliefs, and linguistic considerations. Additional factors such as distrust of unfamiliar medical practices, lack of transportation, financial barriers, lack of health insurance, and lack of information may seriously affect refugee youth's access to health services. While the enormous challenges many young refugees face must be acknowledged, their resourcefulness and capacity to adapt to difficult circumstances must also be recognized. Whatever their country of origin or circumstances of arrival, a respectful and well-informed attitude toward their health beliefs, customs, and practices is likely to contribute to more effective and culturally appropriate health care options for refugee youth and their families.

Religion, Religiosity, and Spirituality

Ana F. Abraído-Lanza[1], Anahí Viladrich[2]
[1]Department of Sociomedical Sciences, Mailman School of Public Health, Columbia University, New York, NY, USA
[2]Department of Sociology, Queens College, City University of New York (CUNY), Flushing, NY, USA

Introduction and Overview

Social scientists have long been interested in the study of religion, human behavior, and well-being. In fact, scholarly writings on these issues trace back to the emergence of some disciplines. Influential works on religiosity include (among others) an early 1900s publication by William James, who is credited as laying the groundwork for American Psychology, as well as classic pieces on suicide published in the late 1890s by Emile Durkheim, the prominent sociologist whose work drew heavily on religious affiliation as a form of social cohesion. Despite the interest in religiosity generated by these early works, throughout the twentieth century, research on the topic dissipated with the growth of empiricism, behaviorism, and scientific paradigms grounded in biomedical models. These ideologies created barriers that forestalled and marginalized research on religiosity. Over the past few decades, however, dissatisfaction with the narrow focus of biomedical models paved the way for broader biopsychosocial paradigms. Due, in part, to the popularity of these biopsychosocial approaches, and sparked by research initiatives in the 1990s of the National Institutes of Health, which provided additional legitimacy to the topic, research on religiosity and health proliferated.

Negative effects of religion on health have been documented. For example, spiritual trials or "religious struggles" (which may involve questioning the existence of the divine, internal religious conflicts, or discord with others on spiritual matters) are associated with psychological distress and worse physical health outcomes (e.g., poor recovery). Nonetheless, several reviews of this growing literature conclude that, in general, there are beneficial effects of religiosity and spirituality on health. This body of work is not free of critiques, however. Criticisms center on such serious methodological problems as overreliance on cross-sectional studies, inadequate controls for confounding factors, and failure to adjust for multiple comparisons. In a review accounting for some of these concerns, Powell and colleagues concluded that the strongest and most consistent evidence for the effect of religiosity on health is found in research on religious involvement (e.g., church attendance) and all-cause mortality. However, they noted that the association between religiosity and health may be underestimated due to lack of precision in measures of religiosity and spirituality. Furthermore, there is a shortage of studies on spirituality and health.

A brief definition of terms and an overview of explanations or hypotheses posited to explain the association between religiosity and health are provided. It is important to note that very few studies focus on religiosity and health among immigrant populations. Nevertheless, particular focus is placed on describing models for which there is some research on immigrant populations in the United States. Although the entry draws mainly on studies from the U.S., in some instances, parallels are drawn to global findings. Following a biopsychosocial approach, this entry will highlight psychological, social, and cultural factors in the association between health and religion, religiosity, and spirituality. Specifically, we adopt the perspective that psychological variables at the level of the individual, such as cognitions, religious coping responses, and behaviors, influence and are influenced by broader social contexts that include interactions with other persons, groups, and institutions. Finally, individual and social factors operate within cultural contexts.

Definition of Terms

The terms religion, religiosity and spirituality often are used interchangeably. *Religion* refers most commonly to formal and institutional expressions of the sacred. Particular beliefs, practices, memberships, and social organizations characterize religions. *Religiosity* derives from the adherence to the religious doctrines (e.g., beliefs and practices) of formal institutions. The literature on religiosity sometimes distinguishes between "private" (e.g., prayer, reading the Bible) and "public" (e.g., attendance of religious services) forms of religiosity. *Spirituality*, on the other hand, generally refers to subjective experiences of that which is sacred in life, which may involve the search for essential meaning, transcendence, and connection with others, including nature and/or a supreme being. Spirituality may or may not include involvement in religious organizations or groups, or adherence to religious traditions. When considering the beliefs and practices of ethnically diverse communities and given their unique explanatory models of disease and indigenous views of health and illness, the distinction between religiosity and spirituality becomes more complex.

Despite the theoretical differences between religiosity and spirituality, in practice, there is a high degree of interrelationship among them. Therefore, some argue that it is misleading to uphold the theoretical separation between these terms. Moreover, distinguishing between the terms ignores the organized form in which all spiritual experience takes place, that is, the religious domain. Nevertheless, the distinction between spirituality and religiosity may be useful particularly with reference to the notion of spirit in non-Western philosophical perspectives. In the following sections describing the primary hypotheses concerning religiosity and health, the terms *religion*, *religiosity*, and *spirituality* are used interchangeably unless otherwise noted.

Hypotheses on Religiosity and Health

Various hypotheses are proposed to explain potential pathways or processes by which religiosity might impact health. The most prominent hypotheses, for which there is some research relevant to immigrant and ethnically diverse populations, fall into three broad categories: (1) individual-level explanations that focus on psychological factors, such as cognition and coping processes; and behavioral factors; (2) social explanations; and (3) culturally based explanations. Of note, these categories are not mutually exclusive. Moreover, the overlap among categories might involve interacting factors that produce various health outcomes. For example, social factors can interact with psychological coping processes, as when emotional support from fellow congregants leads to coping with stressful life events by praying, resulting in less psychological distress. The interaction among these factors is seldom, if ever, studied.

Despite the biopsychosocial approach adopted in this entry, biological models are omitted from the discussion below. There are few well-controlled studies on physiological pathways linking religiosity and health. The most conclusive evidence concerns studies on transcendental meditation, and none involved immigrant groups. The suggested readings and resources at the end of this entry provide more detailed discussion of these and the other hypotheses described in the following sections.

Individual-Level Explanations

Cognitive Processes

Spiritual belief systems could engender a sense of direction, purpose, comfort, and motivation and direction for living, especially during stressful periods. Because religious frameworks may offer a specific philosophy of life or world view, cognitive mechanisms may explain the relationship between religiosity and health. For example, religious beliefs (e.g., that prayer enhances closeness with God or divine intervention) may promote a sense of control over stressful events or generate strength to tolerate adversity. In addition, by providing a framework of a greater purpose or “grander plan,” some religious doctrines may render optimism, hope, and a sense of acceptance for situations or events that cannot be changed or controlled, helping individuals find meaning for troubling events or ongoing hardship.

Despite various hypotheses concerning potential cognitive mechanisms that may mediate the association between religiosity and health, there are only a few studies (of nonimmigrant populations) testing these effects, and they yielded mixed results. There are even fewer studies of immigrant or ethnically diverse samples. Simoni & Ortiz report that mastery (as well as self-esteem) mediated the relationship between religiosity and depressive symptoms among Puerto Rican women living with HIV. These results support the hypothesis that, in the context of a chronic illness, religiosity helps individuals to achieve a sense of self-efficacy, which, in turn, leads to enhanced psychological well-being.

Religiosity as a Coping Strategy

Religiosity may benefit health by providing a means of managing difficult life circumstances. Rooted, in part, on broader coping theory, *religious coping* refers to spiritual methods or strategies for dealing with the emotional and other demands of stressful events. Thus, it is distinct from global *religiosity* (e.g., intrinsic or self-rated religiousness, church attendance). Religious coping may involve cognitive (e.g., seeking comfort or strength from faith or God) or behavioral (e.g., praying) strategies based on religious beliefs or practices. Although research on immigrants and other culturally diverse groups is limited, there is evidence that ethnic minorities frequently rely on religious forms of coping (e.g., prayer) in response to difficult life circumstances, such as coping with chronic health conditions. The most consistent observation in the limited available literature is that rates of religiosity and religious coping are higher among racial and ethnic minorities as compared to Whites.

Compared with the broader literature on religiosity, research on religious coping is unique in its focus on both the positive and negative sides of coping. In response to stressful life circumstances, religious coping may involve negative reactions, such as anger towards or a sense of punishment by God. Compared with strategies that involve calling on God as a "partner" or benevolent being, these negative responses are associated with worse psychological and physical well-being. It is also interesting to note that conventional coping theory tends to conceive of religion as a passive form of coping, which is considered less effective than "active," behaviorally oriented strategies. Little evidence, however, supports the proposition that religious coping reflects passivity or avoidance. To the contrary, when viewing God as a partner, religious coping engenders a sense of personal power and efficacy.

Behavioral Explanations

Religiosity may lead to better health outcomes as a function of proscriptions against risky behaviors; internalized moral codes; or adherence to other religious, philosophical doctrines that influence health behaviors, such as the belief that, as a temple of the sacred (e.g., the Holy Spirit), the body's health should be maintained. As a result, behavioral explanations suggest that religious individuals engage in healthier activities and lifestyles than do those who are less religious. Supporting this hypothesis, rates of cardiovascular disease and lung cancer are lower among members of denominations with strong proscriptions against smoking (e.g., the Church of Jesus Christ of Latter Day Saints) compared with the general population. Smaller-scale studies provide mixed evidence of the hypothesis that religiosity is associated with healthy behaviors. More support for the hypothesis is found in larger-scale studies. A multiethnic, statewide probability sample of Texas adults found that, adjusting for potential confounders, religious involvement was associated with healthier behaviors, assessed as an index of 12 items that included exercising, not smoking, and visits to the dentist. Of note, the association was similar for men and women and for the various ethnic groups (Blacks, Mexicans, other race/ethnicity, or non-Hispanic Whites) in the study. In addition, large-scale studies show that, relative to those who attend religious services less frequently or not at all, individuals who attend weekly are more likely to quit smoking, become physically active, not become depressed, and increase social relationships.

Social Explanations

Social Support

One class of explanations for the association between religiosity and health focuses on social processes, more specifically, social support. An expansive body of evidence documents the effects of social support on physical and psychological well-being. Social support entails a variety of emotional, tangible, informational, and other resources made available from social relationships and networks. In addition to the direct benefits of social support on health (e.g., via the provision of instrumental assistance), social support may operate indirectly via several mechanisms, including the promotion of healthy behaviors, and other psychosocial processes.

Many religious denominations foster social networks through regular gatherings in places of worship (e.g., churches, synagogues, and mosques). Social explanations suggest that the social support derived from membership in these religious organizations accounts for the association between religiosity and health. Perhaps more than any other issue, critics of the literature on spirituality and health assert that the social processes inherent in these religious groups, chiefly among them social support, explains the beneficial effects of religiosity on health. In essence, the debate centers on the premise that it is the social – not religious – aspect of “religiosity” that confers health benefits. In at least two ways, however, religious support from congregation members, clergy, or other religious leaders might differ qualitatively from and provide added benefits over other sources of support. First, although individual members of a congregation might change, the institutional and social structures remain, providing stable sources of support throughout the life course. Second, the religious content of the support (e.g., being surrounded by individuals who share a similar philosophy of life or world view, or who offer prayers) might provide additional comfort or other psychological benefits. Given the psychological distress that they experience due to losses in their social networks, the social supportive functions of religious institutions might be particularly important for immigrants. There is a lack of research that explains the extent to and mechanisms by which religious organizations assist immigrants in rebuilding social networks.

Religious Involvement

A common method for testing the hypothesis that religiosity benefits health consists of assessing the association between a specific type of religiosity – religious involvement. Because religious involvement is measured often as participation in religious activities with other members of a religious group (e.g., attending church services), it occurs in a social context. A small number of epidemiologic studies of Latinos (predominantly Mexican Americans) provide evidence of the beneficial effects of religious involvement on health. One of these examined the effects of religious attendance on mortality over 8 years of follow-up data from the Hispanic Established Populations for Epidemiological Studies of the Elderly (the Hispanic EPESE), a study of over 3,000 Mexicans aged 65 or older who reside in the Southwestern section of the United States. After adjusting for numerous potential confounding variables at baseline (sociodemographic characteristics, cardiovascular health and risk factors, and functional and activity limitations), the mortality rate was approximately one-third lower among respondents who reported attending church or religious services once per week compared with those who never or almost never attend. Furthermore, this association held and remained virtually unchanged when a number of potential mediators were included in the analysis: social support, health behaviors (smoking and problem drinking), depression, cognitive impairment, and poor health. Of note is that the association between religious attendance and mortality occurred only among once-per-week attenders, not those who attended services yearly, monthly, or more than once per week. Overall, these findings are consistent with conclusions drawn by reviews of the literature that, by far, studies of religious service attendance and mortality provide the strongest evidence of a link between religiosity and health. However, that the association does not hold for attending services more than once per week runs counter to a dose–response effect.

Structural Explanations: Faith-Based Institutions

Structural explanations focus on the role of formal institutions, such as religious and faith-based institutions or organizations in promoting health and well-being. Faith-based organizations, such as churches, historically have offered critical mental and physical health care-related resources to immigrant and minority groups in the United States. By providing spiritual, material, and social assistance to newer and less integrated immigrants, as well as others in need, churches play pivotal roles in promoting the health and well-being of diverse immigrant groups and in protecting them against material deprivation and emotional distress. More recently, faith-based institutions of diverse denominational affiliations led significant political and grassroots initiatives aimed at protecting immigrants' rights, a growing phenomenon given the rising anti-immigrant environment in the United States.

Faith-based organizations also provide another important resource: clergy. Clergy are among the most frequently sought-after sources of help for psychological distress – particularly among minority groups, including immigrants. A growing literature documents the underutilization of mental health services among immigrants and their preference for religious substitutes for these services. Clergy have unique advantages in providing assistance with personal problems, including affordability and access. Their shared religious faith, particularly during stressful periods of social and individual accommodation to the recipient society, facilitates the ability of clergy to address the mental and emotional distress of their immigrant congregations. Clergy are the only professionals that most congregants encounter throughout their lifetimes, making them critical sources of counsel. In addition, clergy and other church leaders are key figures in some successful faith-based health programs.

Despite the key role of clergy in promoting well-being, they are seldom considered partners in healing by the medical profession. Such partnerships are hampered by dissimilar goals, philosophies and lack of resources. Thus, clergy provide mental health counseling that is seldom recognized by the medical profession or other organizations. Because most clergy do not receive extensive training in mental health counseling, they may deal with mental and social service problems that are beyond their level of expertise. Therefore, in general, there is little consensus on the role of clergy in service delivery and mental health counseling.

Culturally Based Spiritual and Folk-Healing Practices

In recent decades, what have been termed traditional healing or folk-healing practices have grown in popularity in the United States, spurred by the holistic health movement commencing in the 1970s and succeeded by the New Age movement, as well as the rise of the field of complementary and alternative medicine. Traditional healers of Latino origin, ranging from *curanderos* to *herberos*, are largely multidisciplinary practitioners who combine religious healing practices rooted in traditional-belief systems, predominantly *Santeria* and Spiritism. These religious-therapeutic movements share a common belief in communication with and possession by an array of incorporeal spirits.

Research by Viladrich reveals the role of *botánicas* as an entry to the concealed world of Latino healers. *Botánicas* provide health care products, informal health services, and referrals to informal and formal health care practitioners, and they function as community resource information hubs. They provide a physical and a social space to support informal faith-healing on the basis of religious belonging, connecting immigrants with alternative networks of care within a culturally meaningful explanatory model of disease and healing. The services that *botánicas* offer, healing practices that are low cost and highly available, provide a viable means for confronting the numerous barriers to health care that their largely uninsured immigrant and other clients face. Latino immigrants use *botánicas* and healers to obtain holistic care for emotional and psychological problems that extend beyond physical complaints. Healers combine natural and supernatural treatments while searching for cost-effective remedies for a variety of ailments, including stress-related conditions (e.g., *nervios* due to financial difficulties or undocumented status) and other chronic disorders. Most healers use diverse therapeutic methods, including referrals to professionals (e.g., psychotherapy, Western medicine), especially when clients' problems are evaluated as severe and beyond their expertise.

In a somewhat analogous fashion to that of clergy and the medical profession, healers hold strained relationships with biomedical providers in general and with mental health professionals in particular. Although healers acknowledge their limitations in treating serious mental illnesses (e.g., major depressive disorders), they criticize conventional medical practices, such as pharmacological treatments (perceived as the use and abuse of chemical substances), the limited reliance on verbal therapies, and the narrow scientific focus that ignores Latinos' spiritual and religious beliefs. Similar to religious healers in other countries, such as Uganda and Taiwan, Latino healers experience a lack of acceptance by organized medicine, which views them as charlatans or as mentally unstable. As a result, despite the visibility of *botánicas*, Latino traditional healers mostly remain a hidden population in urban settings, and conceal their identity to outsiders.

Given this hidden population, little work exists evaluating the effectiveness of traditional healing on physical and mental health. That healers tend to view emotional problems as normal indicators of stress may deter clients from seeking professional care when needed. Also unknown is the extent to which religious healing systems (e.g., *Santería* and Spiritism) disguise psychotic symptoms under the notion of spirit possession or intrusion. On the other hand, these same spiritual interpretations of distress may lead to misdiagnosis of psychotic illness. Finally, misunderstandings concerning *Santería,* often misconstrued as a cult related to witchcraft and Satanism, or other spiritual practices, may prevent practitioners of these faiths from seeking formal health services in the United States. Policies and practices that bridge Western and religious healing systems should be put in place to overcome the fear of retaliation that keep traditional practitioners, as well as their patients, from sharing their beliefs and practices with mainstream health professionals.

Conclusion

Interest in studying the relationship between religiosity and health continues to flourish. Although various hypotheses have been advanced to explain this association, there is a paucity of research on the processes and mechanisms by which religiosity might affect mental and physical health among general populations, and even less focusing on immigrants. Additional studies on biopsychosocial factors associated with religiosity and health among immigrant groups could provide important tests of existing hypotheses and models, and identify areas of divergence. In addition, given the lack of studies on spirituality among immigrant and nonimmigrant populations, future research should focus more closely on this issue. Also warranted is a closer look at the overlapping and complementary effects of religion and spirituality at individual, social, and institutional levels. Finally, interactions among individual and broader social and cultural factors should be examined. Such models offer the potential to advance our understanding of the pathways by which religiosity may lead to a variety of health outcomes.

Reproductive Characteristics

MARGARET D. LARKINS-PETTIGREW
University Hospitals MacDonald Women's Hospital,
Cleveland, OH, USA

Reproductive characteristics are defined as the behaviors that are acceptable, unacceptable, and the societal expectations of a particular immigrant group as they relate to sexual activity, marriage, and childbearing.

Most countries recognize marriage as the societal norm, but many have been faced with teen and unwanted pregnancies which add to the burden of poverty. This is a growing problem in many countries as the result of the limited availability of contraceptive education and affordable options. Family planning and the availability of birth control still evade women as preventive methods to control unwanted pregnancies. The issue of reproductive rights still remains a topic that is not discussed in many communities.

The number of children that a couple conceives is usually not predetermined unless they are living in countries that limit the number of childbirths as an economic incentive. Many communities believe that a greater number of children conceived is a significant sign of religious blessings. This practice remains within many immigrant populations in spite of the significant challenges facing couples as they attempt to integrate into a new community.

Religious beliefs play a major role in the day-to-day lives of many immigrant populations. Although the Christian, Jewish, and Muslim faiths are frequently encountered, traditional healers and religious counselors remain a strong force. It is critical to incorporate traditional practice when appropriate to secure needed trust for optimal care delivery.

The inability to conceive or the loss of child may be interpreted by some individuals as a curse or missed blessing. Many times, this experience may result in family discord, loss of financial and social support, and major depressive disorders.

Infertility is a troublesome issue for all women. Although documented causes of infertility such as tubal disease and premature ovarian failure may be the root of many cases, unknown causes remain as the most common reason given to most couples.

The data on the psychological impact childbirth, loss, and infertility have on immigrant women are scarce. Although health care workers assist immigrants with the adjustment process, many women and their families continue to experience psychological stressors. Women who remain in countries away from their countries of origin for long periods of time have more documented anxiety and depressive disorder.

Lesbian relationships are rarely accepted and, as a consequence, may not be openly presented. Many women in lesbian relationships only rarely present for health care. Those that do seek health care are often given suboptimal care.

Workforce, persistent paternalist policies, and polygamy place demands on women that confuse reproductive choices. Shame and isolation may be common among women in communities that use these methods to control unacceptable societal behaviors. Battered women live in shame as they face issue of poor self-confidence and image. Many believe the abuse is warranted as they label themselves as failures. Unveiling this practice is very difficult and can often place the women in greater danger. In some countries, illegal abortions result in great loss of maternal wellness and life.

Menopause ("change of life") is a valued experience in many immigrant populations because it is perceived as a validation of maturity and wisdom. Many older women do not complain of many of the discomforts experienced during menopause. These women are at risk for osteoporosis and various reproductive cancers. Education that informs these populations of the hallmark warning signs of disease is essential.

The prudent health care provider must be culturally aware, if not culturally competent, to treat immigrants. Most immigrant women have a proud legacy of motherhood and family values. Understanding cultural and societal norms, religious practices, and self-healing practices will help a global provider give optimal care.

Reproductive Health

Margaret D. Larkins-Pettigrew
University Hospitals MacDonald Women's Hospital,
Cleveland, OH, USA

Reproductive health has diverse definitions for women from various parts of the world and poses several challenges for practitioners. Reproductive health encompasses reproductive choice, sexuality, birth control, infertility, pregnancy loss, and general gynecologic health.

A discussion of reproductive health cannot be discussed without understanding the political and societal norms that dictate the level of importance or significance of women in a given society. These norms are an integral part of each woman's self-worth and may influence choices made that promote or inhibit optimal health.

Societal status often predicts what the role of the women often plays in a society. Age, sexual activity, and marriage in many communities are customs as well as rites of passage. Expectations of family and community often dictate when childbirth should occur in the lives of women who are often children themselves. It is interesting to monitor the change in gender equality and equity in developing countries. For centuries, the value of women has focused on their sexuality and their ability to have children. Protecting legacies as well as enriching the workforce through childbirth are a few examples of the role of women in many societies. The increasing number of women involved in parliament and policy development is increasing their value in many societies. This progressive development has opened doors to the education of females and potentially allows them to move away from hard labor as a way of life. This also gives them access to reproductive choices such as birth control and safe terminations. As immigrants, many women are finding access to choice a new but sometimes fearful phenomenon.

Family planning methods vary from the most highly advanced technology to the rhythm method, but infertility is an unwelcome subject in many groups. Family planning is almost nonexistent in many developing countries. Through many nonprofit organizations, limited birth control options are available including, birth control pills. Intrauterine devices and injectable contraceptives are also popular. These are convenient methods and allow many women to control their fertility in a non-visible confidential manner.

Abortion may be an option to many women but cost is almost always the limiting factor. Most women may purchase medication at a local pharmacy that initiates an abortion; such abortions may be complicated by hemorrhage and infection. Unsafe abortions still remain a major cause of unnecessary death among young women. Self-proclaimed health experts continue to attempt abortions without training. This practice cost the lives of many young women. Health practitioners have fallen victim to this controversial health care challenge with the threat of incarceration for delivering postabortion and/or life-saving care. Postabortion care has been funded by many philanthropic organizations in an effort to save lives.

Female genital cutting may also pose a significant problem to caregivers who have not cared for women with an obvious alteration in physical appearance and may challenge the implementation of contemporary medical practices. Rape is often commonplace and places both physical and psychological stressors on the victims whose perpetrators are often visible within the community. The victim may be held responsible for this violent behavior and may consequently be further victimized.

Research Ethics and Immigrants, Incorporating Community and Diversity Needs

Research ethics training is needed in many disciplines that engage immigrant groups and their communities in research or other intervention efforts. It is reported in several key articles that research ethics training is not adequate in student training, that human subjects training requires more extensive development than that provided by compulsory online training from federal agencies. Additionally, many academic professors are not fully trained in research ethics so that they report that their ability to cover in-depth ethical issues is inadequate. Researchers often will provide a standardized response to Institutional Review Board (IRB) applications that can be approved to ensure standard human subjects protections. Yet, some researchers and health professionals will go beyond standard protections and demonstrate innovative approaches to the ethics of research with very diverse groups, such as immigrant communities, in an effort to help their field gain sensitivity, cultural competence, and effective interventions with immigrant groups. These new sources of advice are worth compiling and examining periodically for the important lessons learned in the field. Additionally, it is worth being aware of some international codes of ethics and applied ethics articles that offer new advice to working with cultural groups, economically disadvantaged groups, and community-based research projects.

Considering both Individual and Community-Based Approaches to Human Subjects Protections

Many research practitioners have recommended the need to see individual persons as part of group identities or place-based communities. This expanded understanding of the individual human subject is not well taken up by research ethics boards for the emphasis is on the common morality on individual autonomy. The moral requirements of individual human subjects protections are based on these principles: beneficence, respect for autonomy and justice. For example, beneficence refers to the ethical obligation to maximize benefits and to minimize harms for the individual. The risks of research should be reasonable for the expected benefits. The beneficence principle has certain rules: The need for scientific veracity ensures the research design be sound, and investigators are competent both to conduct the research and to safeguard the welfare of the individual research subjects. Beneficence guards against the deliberate infliction of harm on individual persons, which can be expressed as a separate principle, nonmaleficence – the need to do no harm. Truthfulness, privacy, confidentiality, and fidelity are other rule obligations of beneficence and the respect for autonomy to the individual patient or research subject.

So, as of yet, there is not much authoritative advice on working ethically with individuals who are strongly tied to cultural identities, as immigrant groups may be, nor is there adequate authoritative advice on research subjects whose individual conditions are part of place-effects, such as an environmental threat to a whole geographic community or neighborhood or a prevalence of a disease that is tied to community-wide conditions.

In the past decade, new articles have been published on the need to consider the community or cultural group as a collective research subject and to provide the same ethical protections to the collective as one would to the individual. Some have written about the duty to protect the community, the need to understand how the community of study requires an assessment of risks and benefits as a whole collective. Many culturally diverse community leaders have become involved in research partnerships and collaborative projects in order to ensure that the research being proposed for the geographic community will have local benefits to community members. Some have stated that when a diverse community has economically disadvantaged conditions, the researchers are morally obligated to ensure that the community members have benefits from the research project.

Community-Based Beneficence

US research ethics committees will recommend that certain rules of beneficence be applied to the collective community of study. For example, a community of study should be consulted in terms of assessing risks and benefits. They do not require more than that for a researcher's obligation to the collective group. However, many practitioners of public health, housing, environmental, mental health, and other community research projects are utilizing community-based research (CBR) approaches in order to increase beneficence and provide more social justice for the disparities in economically disadvantaged and immigrant communities. CBR models are designed to create benefits on multiple levels for diverse community members that may alleviate multiple burdens affecting the community of study. Studies of asthma or pesticide exposure with CBR designs will provide capacity-building to local residents with research and health care needs. Community staff and advisors are trained in research skills, community outreach and education projects, and administrative activities, even grant-writing. Community members provide consultation on research actions/outcomes that benefit local residents (media venues, exhibits, radio shows, walkways, education programs, many more activities). These multiple benefits can meet the requirements of some international guidelines for research which require that a research project provide beneficial change to the community of study. Most of all, such benefits allow the community to have the skills and experience to take control of the health or environmental threat. This is essential to the sustainability of a research intervention.

Still, CBR practitioners and other researchers need to be aware of community-wide and cultural risks from research interventions and should consult community members and cultural representatives for this assessment. Such an assessment is new to research ethics but some researchers have done this in genetic research and also in environmental health and other studies. Members of immigrant communities can alert the research team that certain questions in a survey would bring harm to community members, that some research activities would be culturally inappropriate and cause distress to cultural groups, and that certain types of studies may not be effective and other approaches may be more worthwhile. Research teams need to spend some time eliciting this advice from community members and developing some community-based tools to adequately obtain this advice.

Some researchers have used an extensive interviewing process with a sample of community members to assess risks and benefits. Community advisory boards or research committees can review the research questions, designs, and methods with a research team and thoughtfully examine the impact of such activities with community members. In environmental health, it may be useful to examine the impact and outcomes of similar research designs/methods already published in case studies by reviewing how effective they were in other communities of study and how did those community members react to such studies.

Intercultural Research Designs/Methods

Another important extension of beneficence for immigrant communities is the creative design of intercultural research interventions. Postmodern ethics stresses the need to incorporate multiple voices and forms when dealing with groups that are marginalized; to overcome ethnocentric privilege and allow an expression of diversity or otherness in traditional or standardized models of research. Immigrant groups who are involved as research advocates, advisors, or community-based staff will want to see that a research team is willing to share power and not keep an oppressive technical control over the research process.

By working with immigrant community members to allow an expression of their culture, be it Vietnamese, Latino, Cape Verdean, Indian, or other groups, a research team can allow qualitative methods to be culturally based. There are examples in case studies of types of ceremonies, ritual gatherings, and storytelling projects that are integrated with data collection needs. These activities help to break forms of White or academic privilege by building up cultural identities while accomplishing research tasks. These activities can strengthen individuals and groups in the community with capacity-building, community cohesion, and a sense of solidarity for dealing with a health or environmental threat. By providing community-based funding and technical assistance, a research team will create more sustainability for an intervention that will be needed over time.

Respect for Persons and Informed Consent with Immigrant Communities

The principle of the respect for persons is of paramount importance in human subjects protections. Respect for persons involves two critical considerations. First, the respect for autonomy requires that each research subject or patient be capable of deliberation about their personal choices and be treated with respect for the right to self-determination. The second consideration is the protection of persons with impaired or diminished autonomy, which requires that those who are dependent or vulnerable be afforded security against harm or abuse.

The respect for persons is upheld in human subjects protections through informed consent. Informed consent requires an assessment of two key preconditions: competence and voluntariness. Competence requires that the individual subject or patient is psychologically, cognitively, and legally capable of adequate decision-making. Voluntariness is an assessment of substantial autonomous choice in the person's decision-making to consent or not to consent. It requires that all individual persons have adequate knowledge about an intervention or procedure and are free from controlling influences such as coercive force or undue persuasion in their decision-making.

In obtaining informed consent, a researcher or doctor must carry out these elements of consent: disclosure (complete and accurate information about the research or medical procedure), comprehension or also termed "understanding" (a complete and realistic comprehension of the procedure or research intervention being proposed), the voluntary decision (the substantial, autonomous decision to consent or not to consent to a medical procedure or research intervention), and consent (the actual authoritative act of consent, signing a written form or providing oral consent).

In obtaining advice about informed consent with immigrant communities, researchers in several recent case studies have recommended that beneficent approaches to informed consent be allowed. These researchers are advocating more of an ethics of care than just a standardized, rationalistic approach to obtaining informed consent from individuals. In the ethics of care, advocates of this ethical framework are concerned about the need to build relationships, to have empathy and compassion with patients and research subjects and not just value neutral approaches to individual autonomy (using a standardized consent form in an impersonal approach to the subject). Such advocates will be respectful of immigrant cultural traditions that may require the need to share individual decisions as a family. Such empathy does not mean that the individual's consent will not be obtained but that researchers will strive to accommodate special needs around gaining that consent with care. It may mean allowing the family to make the decision with the individual if that has been a longtime tradition, yet the individual will still sign the form. If individuals and their families fear official forms, there are forms of oral consent that are acceptable to IRBs.

Practitioners may need to be aware of cultural attitudes about communicating health or environmental adversities. Different uses of language and the meanings of words, such as illness or harm to the body require a culturally based understanding. Cultural competence training (gaining cultural skill, knowledge, and humility) can help practitioners be more sensitive to these cultural needs. Researchers may need to be familiar with the spiritual beliefs of different cultures in preparing for the consent process – the symbolic meanings of physical and environmental harms and adversities. Many academic and medical practitioners prefer to avoid spiritual beliefs but this may deeply offend some immigrant communities. It is better to work with cultural liaisons than to ignore these needs.

Nonetheless, the approach to obtaining informed consent still must be adequate. Research violations occur when informed consents are found to be inadequate and researchers did not assess preconditions for competence and voluntariness and follow all the rules of disclosure, comprehension, decision, and consent. In conducting research with some elderly immigrants or new immigrants, be aware that researchers and doctors are intimidating agents to them. They may quickly agree to participate out of a fear of authority or retribution. Some immigrants are very fearful of government officials or those with a sense of authority. It is essential that researchers realize that they cannot secure this consent without allowing the subject, free, autonomous, and noncontrolling voluntary choice. Efforts at persuasion, manipulation, or coercion violate the standards for obtaining consent and these controlling factors are easily used with some immigrant communities.

Researchers must make every effort to fully disclose their interventions to immigrant groups who may need special help in understanding procedures for themselves or for an intervention for the community as a whole. Ethicists recommend that researchers realize what pictures are in the mind of participants as they confirm that they understand a research procedure. Make sure that the pictures are appropriate. Time must be spent with adequate understanding for the intervention. Comprehension is a rule that requires some literacy and training for research subjects on complex topics. Translators, visual graphics, and videos are common now for informed consent preparation. Immigrant communities may be helped by community advisory boards or cultural liaisons (community health/other workers) as community staff/advisors can help other community members understand interventions that are for individuals or the whole community.

Justice Needs with Immigrant Communities

The principle of justice within human subjects protections requires a fair distribution of benefits and burdens from research. These protections explicitly require fair selection and recruitment of subjects for research and an assurance that vulnerable subjects are not used for exploitation. The justice principle will require that those who have power and resources do not benefit from interventions where the less powerful are burdened by such interventions. With immigrant communities, researchers often need to do more to ensure fair subject recruitment and selection. Often researchers may not have adequate demographic information about the places where they are selecting subjects and will not have a representative group from their research recruitment process. Immigrant communities require special outreach mechanisms. Often, many do not have access to clinical trials or other research projects because of hardships such a lack of health care coverage which prevents them from using clinic services or having local physicians. There are articles written about low disease screening of immigrant groups. Some groups fear racist attitudes, intimidation, and discriminatory practices. Evidence of these negative practices by researchers and physicians do exist. Many individuals need translators for their health care. Some have no transportation, day care, or special support to seek health services.

Again, community-based outreach and research projects have had some success with these barriers. In some reports, researchers recommend the need to conduct research efforts with the partnership of a church, an immigrant center, or other social support group. Culturally based activities are used to recruit immigrant residents to research-related recruitment or engagement activities. Much new training is being undertaken to provide a cadre of community health workers who are local community members, known to many other immigrant community members. They are able to enter their homes and assist immigrants with much-needed support services.

One last rule of justice is the need to ensure that benefits are provided to economically disadvantaged groups in a research activity that also stands to benefit researchers and other well-off social groups. Too many researchers have conducted research in low-income, disadvantaged communities, burdening the local people and not providing any benefits back to these communities and not reporting results back to them.

The recent reports from community-based research provide many innovative forms of research benefits that researchers can consider for their projects.

Resilience

Laura Janine Mintz
Department of Epidemiology and Biostatistics, Case Western Reserve University School of Medicine, Cleveland, OH, USA

In the social sciences, resilience is commonly used to describe a person or community's ability to withstand and rebound from adversity. Resilience is a complex idea, and so when people measure it, they tend to measure factors that describe the adversity in question (abuse, violence, war, torture, migration, etc.), and then to use markers that describe success. For example, much of the early research on resilience focused on academic achievement in school children, and what the differences were that allowed some young people who had faced significant challenges to do well in school, while other young people that had similar experiences struggled in school. Research on resilience in adults often focuses on mental health status after difficult events, and measures things like depression, posttraumatic stress disorder (PTSD), and other mental health concerns.

Many studies on resilience tend to focus on which factors grouped together among those people that were successful by the markers of the society they lived in – for example, they achieved in school, went to or completed college, did not use drugs or participate in the street economy, did not get pregnant if they were teenage girls, etc. Then, researchers have measured factors which are risks for being less successful by societal standards – these things have tended to be factors like living in poverty, having an incarcerated parent, having a parent not in the home, or not being connected to extended family.

Additional research on resilience is about persons that have been through particular sorts of difficult events – torture, physical or sexual abuse, war, or other forms of violence. Researchers that study these events look for which persons survived them and continued on with life in a way that is approved by the society in which they live.

This same framework is often used to study resilience in immigrants. Immigration is often a tremendously difficult experience, and immigrants may experience adversity in their countries of origin that provokes immigration such as violence, abuse, persecution, and war, difficulty during the actual process of immigration such as difficulty crossing borders or attaining documentation for legal immigration, and difficulty adjusting to the new culture where they live – both the culture of the immigrant community where they reside if there is one, and adjustment to the new country where they live – language, customs, expectations, services, government, policing, and general cultural expectations. Often, these adversities are interlocking and multilayered, so researchers look for the individual and community characteristics that allow immigrants and their children to adjust and thrive in the new society where they live.

Studies that have looked at resilience among refugees and asylum seekers have looked at the impact that traumatic events in parents have in the lives of their children. A study of refugees in Sweden looked at those who had survived torture in Iraq versus refugees from other parts of the world who had not experienced torture. The children of the torture survivors were more successful in adjusting to Swedish life when they had good emotional expression, supportive family relations, good peer relations, and more outgoing behaviors. Other studies in different immigrant groups have had similar results – those children that have supportive parents, are more connected to communities, are more outgoing, and feel comfortable asking for help when they need it and are also independent thinkers tend to weather the multigenerational trauma from their parents as well as the stress of migration more easily. The difficulty with these studies is that children that had more support at home may generally be from more economically and culturally resourced backgrounds, and thus had more concrete tools, as well as psychological tools, to help them adjust to life in a new place.

Scholastic achievement in general has also been studied in the children of immigrants. Immigrant youth face multiple challenges in school. They may face difficulties in language access, social interaction, poor treatment from peers and school authorities, and difficulty in negotiating school policies in a new country. Coming from a home where the primary language was something different than the language spoken in school has been described as a risk factor in many different studies on resilience, but children from immigrant families that have been described as resilient consistently achieve in school. Personal characteristics of young people that emerged across studies that predicted greater resilience and success academically are having a sense of purpose and a future, good social skills, personal autonomy, good problem solving skills, and a personal belief in their own academic skills. Parental qualities that help children of immigrants be successful are having parents in the household, having parents that are invested in their children being successful in school, having parents involved in community or school activities, and having parental approval for success in school. These issues become difficult when parents of immigrant children may speak a different language from the one spoken at school, or may have job commitments that do not permit them the level of involvement with their children's schooling that they might like. Immigrant children may live separately from their parents, and so supportive family networks, which also help to increase resilience, become even more critical for those young people. For those children from racial or ethnic minority backgrounds, having ethnic pride relates strongly to success in school, and to the capability to withstand a racist society. Additionally, the immigrant children's skill at acculturation, or understanding the values and norms of the culture in which they live are also related to success in school.

Supportive communities also emerged as a factor that encouraged student success. If young people could access activities, mentorship, and support from other people in the community they tended to be more successful in school. The environmental risk of racism was also a significant factor in evaluating the potential for student success. Community-based resilience is one of the emerging topics in research on resilience in general, and in immigrants in particular. Research on this topic looks at resilience from an ecological or community-based model, in order to try and capture the context that produces successful children. This angle at research on resilience in immigrants looks to examine factors that are beyond the individual in order to help build success.

Research about resilience in immigrant adults focuses on the process of acculturation, mental health status after migration, and the stresses of both immigration and acculturation. Successful acculturation is a mark of resilience, because it means that the person in question has fully adjusted to the new society, and is able to earn a living, negotiate state and government systems, and live successfully in the new country. Additionally, markers of mental health like depression and posttraumatic stress disorder (PTSD) are used to study resilience because these conditions are unusually high in immigrant populations. This may be due to the stressful nature of migration; groups that become immigrants tend to do so because of unacceptable conditions in their home country due to economic opportunity, war, and other stressors. Additionally, immigrant families often have fewer resources available to them, less money for which to avail themselves of resources, mistrust of resources that are available, and sometimes a lack of awareness of the resources that are available. Research on these topics tends to show that some of the same factors that help children to succeed in school are the same things that help adults to succeed with acculturation and to treat mental health problems – strong relationships with family, a large network of community members, a community to which they belong (including both religious and secular communities), a personal notion that they can overcome adversity, an ability to ask for help when they need it, a strong community where they resettled, and ethnic pride all seemed to support acculturation. In addition, language fluency in the new language, income, and the ability to do the same work as they were doing in their home country have been found to be associated with lower rates of depression and other mental health concerns. Mental health concerns are explained in many different ways internationally by different immigrant groups, so different groups have different strategies for coping. Immigrants from nations where psychological counseling is not a part of society, or is stigmatized within it, may be less likely to seek out therapy as a method of coping with immigration-related stress. However, they may seek out traditional healers, community leaders, religious resources, and utilize other strategies to deal with their own mental health concerns. Additionally, they may frame these concerns as a normal extended mourning resulting from forced migration and other forms of trauma.

These alternate readings of their own situations begin to call into question some of the historical ways that people have researched resilience. Some researchers are beginning to respond to that alternate understanding by conducting resilience research in a different way. These researchers question the notion that success, as defined by mainstream values in the new society, is or should be a goal of new cultural groups. This sort of research asks people in those groups how they frame resilience, and often manages to reframe previously stigmatized activities, such as gang membership, as resilient behavior – the notion that belonging to a gang may provide some degree of safety, security, and survival in the new society that was not felt before joining. Mental health may be framed differently in nations where immigrants are coming from and where they are going to, and so the notion of resilience becomes more complicated when notions of what "health" is are different. In addition, the focus on mental health has left a hole wherein resilience might be studied as it relates to physical health. As models of community health are developed, the physical health of persons in resilient communities is a potential topic for research and discovery – currently, not much is known.

Respeto

ROSALYN NEGRÓN
Department of Anthropology, University of Massachusetts-Boston, Boston, MA, USA

Among Hispanics, *respeto* (respect) refers to a way of relating to others that acknowledges differences in social status. These differences include age, gender, socioeconomic class, and occupation. While *respeto* often entails deferential treatment toward a higher status person, as a cultural ideal in Hispanic communities, *respeto* is a necessary quality of many social encounters. Therefore, while *respeto* may require that a lower status person defer to the actions and wishes of a higher status person, *respeto* compels people to behave in ways that protect the dignity of participants in an interaction, regardless of their social position. Given this, politeness and discretion are important ways to express *respeto* in social interactions.

Traditional Hispanic cultural expectations dictate that women defer to men, youth to elders, employees to employers, and children to parents. Between individuals of equal status, *respeto* may be expected in first-time meetings or in acquaintanceships where intimacy or comfort has not been established. Appropriate displays of *respeto* may include using polite titles or greetings, avoiding eye contact, and withholding questions that may be perceived as a challenge to a person's authority. Failure to use formal *usted* (you) when speaking to an authority figure in Spanish may be taken as a face-threatening act.

In healthcare contexts, knowledge about the unspoken rules of *respeto* is important for a culturally competent approach to work with Hispanic patients. The power differences inherent in the patient–provider relationship lead Hispanic patients to assume a submissive role as a way to show *respeto.* For example, Hispanics may view questioning a doctor as disrespectful. Providers could misconstrue silent nodding as a show of understanding or agreement when in fact it could indicate the Hispanic patient's lack of understanding or reluctance to show disagreement. Hispanic patients may not admit deviations from treatment plans, such as taking medication irregularly, for fear of offending a provider. Where a Hispanic patient may view formality as polite, a provider unfamiliar with the concept of *respeto* may read formality as impersonal or a patient's way to maintain a distance.

Even as a Hispanic patient is deferential to a provider during a healthcare encounter, a provider's respect is expected. Greater formality, such as in the use of polite terms of address, is an appropriate way for younger providers to show *respeto* to older Hispanic patients. In demonstrating *respeto* to parents, pediatric providers should be mindful to not undermine parental authority in their interactions with a child patient. Such missteps could lead to patient dissatisfaction with care, treatment under adherence, or termination of medical care.

While behavioral norms and attitudes associated with *respeto* apply generally to Hispanics, it should not be assumed to apply uniformly and to the same extent within different Hispanic subgroups. Hispanic subgroups can differ in the importance placed on proper displays of *respeto* or deference to high status individuals. Hispanic immigrants from countries with less hierarchical power structures and greater levels of equality, such as Costa Rica, will differ in the importance placed on status differences when compared to Hispanic immigrants from countries where the opposite is true, such as Mexico. Overall, it is important to keep in mind that the value attached to *respeto* and how it is defined can change across immigrant generations, with exposure to new norms, or as a result of assimilation.

Reverse Migration

Ken Crane
Department of History, Politics, Society, La Sierra University, Riverside, CA, USA

In current patterns of international migration, an often-overlooked dynamic is the practice of a sizable number of people who sooner or later return to their respective countries of origin. This was one of the observations made about earlier waves of migration by Michael J. Piore in his book *Birds of Passage*. Less attention is given to practices of reverse migration, that is, on those returning home. Most data collected in the USA focuses on the sheer numbers of people who enter a country as immigrants, their national origins, and their patterns of settlement. But immigrants rarely follow stable patterns of settlement. Many move to other regions of a country (secondary migration) as employment, housing, education, and better opportunities for advancement dictate. Refugees may be sponsored and settled in a particular city, but later decide to relocate closer to co-ethnic social networks. Little attention is paid to immigrants who actually return home, either temporarily, as is common for transmigrants engaged in a pattern of circular movement, or on a more permanent basis.

Various factors come into play in influencing the behavior of immigrants who choose to return home. In cases of voluntary migration, it is often assumed that economic conditions are the dominant influence in the overall calculus of choice. Beginning in 2008, the impact of the “great recession” in the USA has indeed caused some immigrants to return home. Labor migrants such as those in construction or manufacturing, like their native counterparts, are in sectors of the economy highly vulnerable to recessionary effects. Research on communities that have historically been recipients of large numbers of labor migrants from Mexico have documented a considerable downturn in new arrivals, and some evidence of people leaving. For example, interviews with educators and human service professionals in Indiana (US Midwest) communities most severely affected by the demise of manufacturing, reveals that some families have returned to Mexico, and families who have stayed are trying to cope with the emotional and financial stress of less employment and reduced incomes.

However, the impact of economic conditions on migrants’ decisions to leave or stay may be overestimated. Immigration policy in the USA is primarily based on family unification, and secondly on government determinations of labor market needs, primarily in occupations that require certain high levels of specialization and education, such as software engineers, physicians, nurses, and other technical fields. These types of professions may be less vulnerable to downturns in the economy.

The other major factor in reverse migration is when geopolitical events precipitate changes to policy and the forceful deportation immigrants. For example, in 1992, after the first Gulf War, Jordanians working in the oil-rich countries of Saudi Arabia, Kuwait, and UAE had their work permits revoked and were forced to return home. Jordan's support for the Iraqi regime which had invaded Kuwait angered many of Kuwait's allies, prompting those countries to expel Jordanian expat workers.

Other forms of forced reverse migration are when domestic politics shapes the way existing immigration policy is enforced. Mexican migrants in the USA have recently faced greater threats of deportation as ICE (Immigration Customs and Enforcement) officials have targeted raids on workplaces (meatpacking plants, food processing) known to hire undocumented persons. An economic slowdown in Spain also led to renewals of fewer work permits for immigrants who had been drawn there by labor needs in its previously booming economy.

Whether forced or voluntary, all types of reverse migration have social, economic, and psychosocial consequences for individuals and families. Because of their sudden nature, deportations frequently cause family dislocation and trauma, as parents or guardians are arrested and deported, or detained in facilities far away from relatives and children, their whereabouts unknown. All migration affects families in some substantial way. Each of the conditions and contexts of reverse migration may affect families in different ways, but it will have some kind of substantial impact. Children are the most vulnerable, since they may be going to cultures and countries for which they have very little cultural affinity, albeit considered "home" to their parents. Having grown up in one society in which they consider home, reverse migration may bring them to a society where they have very little language ability or cultural competency. Likewise, the return migrants bring their own cultural influences in the form of new ideas and values back to home communities, what Peggy Levitt terms "cultural remittances."

Another impact of reverse migration is the economic impact of a migrant's return to their home country. For many years, research suggested that return migrants brought back few real substantial new skills to support economic and social development. This was because the skills acquired by immigrants were not necessarily significant or relevant to home communities. For example, a physician from Mexico who migrates to the USA to do agricultural labor brings very little back to his/her home community in the form of new skills. Or a recent graduate from university who migrates to do factory work likewise returns without any significant human capital investment that will affect economic development.

The impact of investment capital is another matter. Recent research from the Mexican Migration Project has documented that many migrants return home with substantial savings that is invested in new business start or community infrastructure. Similar patterns are emerging around the world, as in India, where reverse migration is playing a significant role in new investment and entrepreneurial initiatives.

Risk Factors for Disease

Connie H. Carr
Center for Research, The Institute for Palliative Medicine at San Diego Hospice, San Diego, CA, USA

A risk factor is something that increases your chances of getting a disease. The factors can be environmental, behavioral, or biologic in nature. If these factors are present, it increases the probability of a disease occurring. In research terminology, risk factors are exposures that are statistically related in some way to an outcome. Biologic risk factors are hereditary and genetic features such as age, race, or gender. These factors cannot be altered. Behavioral risk factors include smoking, overeating, and lack of exercise, among others. These factors can be modified to some extent to prevent a disease from occurring.

Environmental risk factors include air and water pollution and poor sanitation. The World Health Organization (WHO) reports that many diseases could be prevented through better management of the environment. Studies by WHO have examined the impact of environmental risks on diseases and injuries. It has been estimated that one quarter of the world's diseases and injuries can be attributed to environmental causes. The environmental disease burden is greater in developing countries. Immigrants may therefore develop diseases not commonly seen in their new home country due to exposures to the risk factors in their country of origin. Immigrants also tend to take jobs that are unattractive to the local work force. Many of the available jobs in mining, manufacturing, and agriculture have poor environmental conditions and lack proper safety equipment. For example, the number of industrial accidents in France and Germany is much higher among migrants than citizens and 30% of all accidents resulting in permanent disabilities involve nonnationals. In the agricultural sector, unprotected exposure to pesticides in migrant workers in Spain has been linked to higher rates of depression, neurologic disorders, and miscarriages.

The U.S. Centers for Disease Control and Prevention (CDC) describe chronic illnesses as common and costly health problems. These illnesses are responsible for approximately 70% of the deaths in the United States and one trillion dollars in health care costs annually. Approximately half of all Americans live with at least one chronic illness such as heart disease, diabetes, cancer, obesity, and arthritis. These diseases affect people's activity, work, and quality of life. Although chronic diseases are common, many are also preventable to some degree by controlling the risk factors for the disease.

Heart disease is a leading cause of death in the United States. Many studies have identified specific factors that increase the risk of developing heart disease. Some of these risk factors can be controlled while others cannot. Risk factors that cannot be changed include advancing age, race, gender, and heredity. Some risk factors can be treated or controlled by changing one's lifestyle or taking medications. Risk factors that can be modified include smoking, high blood pressure, cholesterol intake, obesity, sedentary lifestyle, and diabetes mellitus. High blood pressure, cholesterol levels, and diabetes mellitus can be controlled with medications. Regular exercise, weight loss, and a diet low in animal fats and high in fruits and vegetables may lower cholesterol levels. Smoking cessation is essential for lowering the risk of heart disease as cigarette smokers have two to four times the risk of developing heart disease as nonsmokers. Immigrants to the United States that adopt the American sedentary lifestyle and fatty diet are at greater risk of heart disease.

Many believe there is a strong relationship between socioeconomic status and risk factors for chronic disease. Socioeconomic status includes education, income, and occupation. Although all these factors are important predictors of disease, the strongest socioeconomic risk factor appears to be education. Education develops positive social and psychological skills which influence health care choices. Therefore, education may be key to the prevention of chronic illness through the control of risk factors in immigrant populations.

Risk Perception

Oana C. Stîngă
University of Medicine and Pharmacy "Gr. T. Popa", Iasi, Romania

"Risk" is a term used to define a situation that might have an undesirable outcome and that we would likely prefer to avoid. The same term can be associated with others like: peril, threat, harm, injury, jeopardy, and unsafe. We can talk about financial risks, health risks, and life threatening risks. In order to quantify "the risk" we confer *levels* such as minimal risk or increased risk to describe the intensity of the real danger someone is, or might be in. A risk can be described as being foreseeable or unforeseeable, avoidable or imminent; it can be minimized or uncontrolled due to various unpredictable factors. It also can be exacerbated by the concurrence of other threatening factors.

Risk perception differs with age, culture, state of mind, awareness, consciousness, culture, and many other variable elements that can be involved in making individual level assessments of a situation. In general, people will perceive a risk and take measures to avoid increasing its level. We can speak about social risk judged within the context of personal, individual, or communities' achieved values. Natural instincts lead us to develop strategies to avoid exposure to risks; Darwin's principle of "survival of the fittest" offers a good explanation of this ability.

Avoidance of risks can be studied at individual, community, or worldwide levels because not only do individuals take measures to protect themselves, but also communities acting like unitary groups. The fact that risks are everywhere is more or less acknowledged. We can describe them as everyday risks, minimal risks, or extremely high risks. Differences, in determining what is a risk and its level, are evident between individuals and cultures. What can be seen as being extremely harmful for one person or society can be acceptable or not even be considered a threat to another. Research participation may be seen as more risky to healthy persons than a sick patient, who thinks he/she has nothing to lose.

Appropriate risk perception prevents avoidable exposure to the harmful situation. It may also save the life of individuals. For instance, drug use is frequently cited when discussing factors that diminish or increase risk perception. Studies of the degree of influence have shown that among nonusers of marijuana, perception of risk of drug-related consequences was greater than for those who reported marijuana use and, in turn, were more likely to have actually experienced a drug-related consequence. Among marijuana users, risk perception was not influenced by the frequency of marijuana use nor by the actual experience of a drug-related consequence. Individuals who drink alcohol also seem unable to assess risk in appropriate ways. Agostinelli and Miller report that abstainers or light drinkers were more likely to perceive that daily heavy drinking would put a person at higher risk for health problems or accidental injury than did heavy drinkers. They suggest that the distinction in risk perception results from either self-protective motives that are aroused when potentially harmful or damaging self-information is apparent, or self-enhancing motives that are aroused when desirable self-information is available. Thus, it is likely that one minimizes perceived risk as one is exposed to or experiences the negative consequences of alcohol use. Another study showed that smokers are more likely to try to quit if they are confronted with serious health issues than smokers who are apparently healthy. Smokers who are depressed also seem more aware of the dangers they expose themselves to by smoking.

In addition to the everyday risks discussed above, guidelines have been developed which require research projects to assess the risks to which study subjects may be exposed and under which situations. Designing appropriate informed consent processes presupposes the need to offer research participants information in steps adapted to their ability to understand the information, allow enough time for them to evaluate their risk of participation, and make an informed decision. The existence of Institutional Review Boards, Ethics Committees and human subjects' protection guidelines is reinforced worldwide. The creation of such oversight bodies highlights the important aim of preventing human exploitation and exposure to unforeseeable, unavoidable, imminent, and uncontrollable risks. These bodies and guidelines specifically focus on vulnerable groups' exposure to risk as the ways members of a vulnerable population perceive foreseeable risks might differ. For instance, mentally impaired individuals such as those with paranoid schizophrenia may perceive everything as being dangerous to them while children, due to their lack of experience might be unaware of the danger they are exposed to; hence the need for special protection of these groups. For immigrants coming from different parts of the world, harsh living situations may have exposed them to illnesses without their awareness or due to a lack of education and information on how to protect themselves from the risk of disease. Therefore, not only is risk assessment important but also the management of risk; the development of strategies to avoid risk exposure and methods to address misinformation and misperceptions about the risks are necessary.

Risk Reduction

► Health promotion

Rodino, Peter

Paula A. Franzese
Seton Hall University School of Law, Newark, NJ, USA

Congressman Peter W. Rodino, Jr., (1909–2005), who famously presided over the Watergate hearings, helped to shape immigration policy during his 40 year tenure in the House of Representatives. Born and raised in Newark, New Jersey, Congressman Rodino represented the state's Tenth District and, for a number of years, chaired the House of Representatives' Committee on the Judiciary. Before entering Congress, he served in the US Army. After retiring from Congress, Congressman Rodino taught at Seton Hall University School of Law until several months before his death in 2005.

Congressman Rodino held the Preamble to the US Constitution in the highest esteem, regarding it as providing a set of guiding principles. He labored to weave the Preamble's goals into the legislation he proposed. A shining example of his Preamble-centric philosophy came during the hearings on the Social Security Act of 1965, which provided for Medicaid and Medicare. In a statement in support of the legislation, Congressman Rodino expressed his belief that the bill should not be seen as "a radical proposal," but rather as "simply just the next step in providing services and finances to select groups of those who are in need."

This same philosophy carried over to his work on immigration reform. Congressman Rodino had a unique, personal experience, as his father and stepmother – the Congressman's mother passed away in 1913 – were both Italian immigrants, an upbringing that undoubtedly gave him a rich perspective on and empathy for the challenges immigrants faced. His work in the area of immigration policy is varied and great, but several examples are especially noteworthy. For instance, Congressman Rodino believed that the national quota system, which had been in place since the Immigration Act of 1924, fostered discrimination and did not appropriately embody the welcoming message intended by the Founding Fathers in the Preamble. From his first session in Congress, he repeatedly introduced legislation aimed at ending the national origin quota system.

Progress finally came in 1965 on the heels of the Civil Right Act of 1964. Congressman Rodino drafted a provision of the Immigration Act of 1965 that read, in language mirroring that of the Civil Rights Act, “no person shall receive any preference or priority or be discriminated against in the issuance of an immigrant visa because of his race, sex, nationality, place of birth, or place of residence. . .” (Rodino Jr 1990, p. 693 (quoting § 2 of act)). The act effectively ended the national quota system and recognized immigrants for the “dignity of the individual,” regardless of their country of origin.

Additionally, Congressman Rodino worked hard to ensure that the same principles and ideals were reflected in the Immigration Reform and Control Act of 1986 and that the pattern of discrimination pervasive during the first half of the twentieth century did not reappear.

Throughout his congressional career, relying on the language of the Preamble as his guide, Congressman Rodino fought for immigration reform and to improve quality of life for immigrants. The spirit of his initiatives inspired and informed the inclusion of immigrants within the ambit of essential services including access to quality health care.

Roma

BETTINA RAUSA
Salk Institute for Biological Studies, La Jolla, CA, USA

Roma, or Romani people (often referred to as “Gypsies,” a term considered to be pejorative), are considered European, but originate from the northern part of India. They migrated out of India approximately 1,000 years ago and first settled in the Balkans (Southeastern Europe), then moved to the Carpathians (Central and Eastern Europe), and from there to Greece, Finland, Russia, and into Western Europe (Spain, Portugal, France, Germany, and the United Kingdom). Now, Roma live throughout all of Europe, in Canada and the United States. In Europe alone, there are 10–12 million Roma, with the largest populations in Romania and Bulgaria; Canada reports an estimated 80,000 Roma as of 2008; and approximately one million Roma reside in the United States. It is important to note that these numbers are estimates: there is no official count of Roma anywhere they reside because Roma do not record births or deaths, they are undercounted in national census, they often do not identify themselves as Roma due to their long history of persecution, and there is no “Roma” category identified in most census counts.

Roma were traditionally nomadic, but they adopted a more sedentary lifestyle during the fourteenth century and up through the 1850s in the area of Moldavia and Walachia (now Romania) where they were enslaved. Roma have experienced waves of migration to different parts of Europe due primarily to political and economic upheavals, and armed conflicts and wars in their host countries. One of the latest waves of migration for the Romani people occurred in the 1990s when the former Yugoslavia was engaged in a regional war. Prior to the beginning of the war, Albanians living in Serbia, which was part of the Yugoslav Republic of Croatia, began a secession movement and this event turned out to be one of the precursors of this war. Roma, who lived in various parts of Yugoslavia, but also in the Albanian areas of Serbia, ended up fleeing in large numbers in fear of persecution and genocide by the Serbs who considered them allies of their Albanian enemies. In the aftermath of the war, the migration of Roma continued as the entire region experienced fundamental changes from government-run economic systems to market-based economies. Roma, who live in extreme poverty throughout Europe, had made some social and financial gains under the former communist and socialist governments of Europe. However, the new market-based economies, in conjunction with the systemic discrimination Roma commonly experience, lead to severe socioeconomic declines for Roma. After the end of the conflict in the former Yugoslavia, Roma experienced 80–100% unemployment.

Roma are not ethnically or religiously homogeneous, but are made up of distinct groups who often assume the nationality and religion of their host country. The Romani language has been influenced by Greek, Arabic, Slavic and Sanskrit, and the language and dialects vary from group to group.

Roma have very distinct cultural norms, especially from those of Western societies. Large extended families are the core of their social organization and family devotion is extremely important. Both men and women marry young; the average age for men is 18, and for women it is 15.5. Most marriages are arranged within the Roma community, although young Roma are beginning to marry outside of their ethnic communities. Family customs call for young mothers to defer to their mothers-in-law in regards to child rearing and any health care–related decisions. Much of Romas' social behavior has been traditionally restricted by "purity laws," although these rules are becoming more lax in younger generations. Purity laws regulate many behaviors including how certain body parts are treated. For example, the lower body, especially the genitals, is considered impure and clothes worn on the lower body must be washed separately from other clothing. The Roma believe that good health is the equivalent of good luck and that weight is a reflection of both. Therefore, the more a person weighs the healthier and luckier he or she is. Some Roma have very strong objections to immunizations and prefer to place their faith in traditional medicine and healing rituals. Roma are not convinced that bacteria and viruses cause certain diseases, but instead attribute disease and illness to impurities and dirty places.

Roma have suffered from extreme forms of discrimination and persecution throughout their history and they have been, and continue to be, one of the most misunderstood and mistreated groups of people. They are commonly referred to as Gypsies, which they consider to be offensive and derogatory. The word "gypsy" is often associated with swindling or theft. During World War II, the Nazis judged Roma as racially inferior and historians estimate that 25% of all European Roma were killed by the Nazi regime. It was not until 1979 that the Federal Republic of Germany recognized that Roma were persecuted based on race during the Holocaust. Examples of racism against Roma still exist today. There are numerous news accounts coming out of Europe citing examples of Roma as victims of racially motivated violence, with few perpetrators of that violence being prosecuted due in great part to prejudice against Roma which often permeates the law enforcement and legal systems. In fact, police abuses of Roma are well documented. Roma are also overrepresented in various poverty crimes, especially theft, and are more likely to receive harsher sentencing than non-Roma who are convicted of the same crimes. This pervasive discrimination can be attributed in great part to the negative perceptions about Roma, their culture, values, and traditions. Roma are socially, politically, and economically excluded from mainstream society and therefore unable to fully participate in it. In 2008, Amnesty International expressed alarming concerns about the treatment of Roma in Italy. Italy is home to 170,000 Roma, half of whom are also Italian citizens. At the time of the Amnesty International report, Italian authorities and media had begun making anti-Roma statements in public, using anti-Roma rhetoric in political campaigns, and some elected officials proposed that during the next Italian census, all Roma individuals, including children, should be fingerprinted for security purposes. Mayors of various Italian cities had also signed Security Pacts, with the aim of addressing security threats, including those reportedly posed by the presence of Roma communities. The Security Pacts proposed to unlawfully force the evictions of Romani communities and specifically designated four Romani camps outside of the city of Rome. Furthermore, these communities would be under surveillance by up to 100 law enforcement officials. Forced evictions of a number of Roma communities had already taken place without prior notice to the Romani people living there. These evictions also included the complete destruction of their settlements. No housing alternative had been planned nor was offered to those evicted. Similar events also occurred in the cities of Milan and Turin. The Amnesty International report cited aggressive and stigmatizing rhetoric against Roma by politicians and the media, creating an atmosphere in which vigilante style attacks against Romani settlements were becoming increasingly frequent and tolerated.

In Kosovo, Roma communities are described as shanty towns with faulty electrical systems, inadequate sewage facilities, and very scarce water availability. Homes are constructed out of any available materials such as wood boards, metal and plastic sheeting, and cardboard. Residents often search through garbage for food and reusable items. The living conditions of Roma are similar in much of Europe. Their socioeconomic situation is often dire and rates of illiteracy range from 26% to 40%. A 2005 survey of Roma in Albania, Bosnia and Herzegovina, Bulgaria, Croatia, Hungary, Macedonia, Romania, Serbia and Montenegro, Slovakia, and Kosovo showed that only two out of ten Roma had completed primary education. School enrollment for Roma children averages less than 80% and for 15-year-olds, the enrollment level drops to 40% – even though surveys show that Roma, especially Roma mothers, agree that school attendance for children is very important.

Rates of unemployment for Roma are very high, some places reporting at 100%. For those who are employed, 80% work in informal employment sectors (also known as underground or black market jobs). This is due primarily to Romas' low job skill levels, low literacy levels, and pervasive discrimination. They have little or no advantages when it comes to competing for jobs. Even among Roma with higher education and literacy levels, the rate of unemployment falls much more slowly compared to the non-Roma population wherever they live. This may also suggest, at least in part, why Roma remain in school for less time than young people from surrounding non-Roma populations. Since the gains from education are more limited for Roma, the incentives to remain in school are clearly less.

The poor living conditions of Roma have a profound effect on their health status, yet there is a lack of information regarding their specific health issues. Their cultural norms regarding health create additional barriers to improved health outcomes. For example, many Roma prefer to adhere to traditional health remedies that include the use of healers, magic, prayer, or herbal remedies for illnesses. They often delay seeking medical help until all other methods fail. Roma refuse immunizations because they believe that this will cause sterilization of their children. There is a general mistrust of the medical community, with Roma often believing that health care workers want to harm them. On the part of health care providers, there are many instances reported by both medical personnel and Roma individuals of doctors turning down requests by Roma patients for medical services. Doctors, nurses, and others have claimed that Roma are "difficult" to deal with, they are not able to communicate effectively about their health and treatment, and their customs and practices bring a "negative" element to the medical facilities they visit. For example, Romas' traditional extended family structure often means that when a Roma individual visits a doctor or has a medical procedure, he or she often arrives with many members of his or her extended family. This type of behavior is often in direct conflict with the ways medical services are generally organized and offered, which tend to be geared toward privacy, rules for patient visits, and a general desire for quiet in hospitals and other medical facilities.

Extreme poverty, lack of information regarding health issues in general, and discrimination encountered by Roma combine to bring about some of the worst health outcomes of any group of people. Access to preventive and curative health care services is very low. Roma often live on the outskirts of town far from medical facilities with few or no transportation options. Medical personnel admit that they do not like to go into Roma communities, citing security concerns and a general dislike for Roma people. Among the scarce information that has been published on specific health issues of Roma, indications are that they tend to have high rates of diabetes, high cholesterol, coronary artery disease, obesity, and respiratory diseases. Obesity, and the diseases that often accompany it, are likely caused by poor nutrition coupled with the cultural belief that the more a person weighs, the more good luck he or she has. Among Roma, weight is considered a sign of affluence and good health. Compounding these health issues is the fact that the Roma are excessive smokers. Although there is very little data on smoking rates among Roma, they are known to be very heavy smokers, often beginning to smoke in early childhood. Smoking is considered part of family life and part of their ethnic identity. Where efforts to convince Roma to quit smoking or to implement smoking cessation programs have been attempted, there has been very little measurable success.

Studies of life expectancy rates among the Roma living in Bulgaria, Ireland, and the Czech Republic, show that Roma men live on average to 61 years and women to 63 years. This is 10–15 years less for each compared to non-Roma in the same countries. Rates of infant mortality are very high, averaging 72.8 per 1,000 live births of Roma living in Romania compared to 15 per 1,000 live births in Romania among the general population; it is double that of non-Roma in the Czech Republic; and in Italy, it is three times higher compared to non-Roma. There is little use of birth control, only about 10%. Mistrust of doctors and medicine, lack of knowledge about birth control, and the burden on women who are solely responsible for its use, contribute to this low rate. Where birth control usage is low, abortion rates, however, are high. A survey of Roma women in Albania found that 56% had had one abortion and 77% had had two or more. Seventeen percent of those women reported performing their own abortion. Other health issues facing Roma include widespread infectious diseases such as tuberculosis. Drug abuse and smoking, especially among Roma youth, are also significant.

There are many obstacles to better health outcomes for Roma yet the efforts to promote the health of Roma populations often do not confront the social structures that shape health in the first place: inequity and discrimination in education, employment and housing; poor access to clean water and sanitation; lack of social integration; minimal or no political participation; poor access to food; and disparities in income distribution. In most places where Roma live, there is, at best, inadequate public response to minority health issues and at worst, outright discrimination by health care providers who refuse to see or treat Roma patients. Roma often lack information about the health care reforms that affect them either by increasing their access to medical care, or restricting and/or denying it. Efforts and recommendations to turn the tide on the dismal health status of Roma wherever they reside, include: (1) involvement of Roma women in the development of policies and programs since they are responsible for many health care–related decisions in Roma families; (2) facilitation of school attendance by Roma youth not only to ensure better literacy rates, but also to take advantage of a captive audience and provide more information in schools about hygiene, nutrition, disease prevention, and access to the health system; (3) improvement of Roma housing conditions and the cessation of illegal evictions; (4) increasing access to medical services to the Roma via mobile health clinics; (5) ensuring that Roma communities are well informed of the health care services available to them; (6) utilization of health mediators between medical professionals and Roma patients to facilitate better communication and to establish trust; and (7) the inclusion of Roma in health policy development and implementation. There is a significant effort in place in Europe to help change the dire fate of the Roma called "The Decade of Roma Inclusion 2005–2015." This is a multinational effort to change the prejudicial and discriminatory attitudes against Roma people and improve their socioeconomic status and social inclusion by focusing on the improvement of several priority areas including health, housing, education, and employment. In addition, The Decade of Roma Inclusion campaign includes numerous media efforts to promote Roma culture positively and celebrate its rich heritage and history in an effort to educate the general public about Roma as a people and turn the current pervasive discriminatory attitudes toward the Romani into an appreciation for their rich culture and diversity.

Romania

Oana C. Stîngă
University of Medicine and Pharmacy "Gr. T. Popa",
Iasi, Romania

Romania is an East European country, with a total surface of 237,500 km^2 and a population of 21,680,974 inhabitants according to the 2002 census. The capital of Romania is Bucharest. Romania is bordered by Ukraine and Republic of Moldavia to the North-East, Bulgaria to the South, Hungary to the North-West, and Serbia to the South-West.

Before 1989, Romania was under a communist regime. Ceauşescu's dictatorship isolated Romania not only politically and culturally, but also economically.

In the 1980s, the Romanian borders were strictly controlled. During the communist regime those who had the opportunity to leave the country immigrated mostly to Germany, Hungary, and Israel. The poor living conditions during communism caused the population to revolt against the regime in 1989. In December 1989, the communist regime collapsed and a democratic regime has been established and the gate to individual freedom was widely opened. The initial happiness of the Romanian population of being free, transformed rapidly into desperation, confusion, disappointment, and fear. The guaranteed jobs and the protection of the jobs disappeared and Romania was confronted with a new phenomenon that greatly differentiated between social classes. People started to experience unemployment and insecure living conditions.

Before 1989, internal migration, i.e., migration of force labor from rural to urban sites was the dominant phenomenon in Romania. After 1989, the trends changed as the internal migration decreased and external immigration in search of professional accomplishments and better living conditions increased.

The increase of international immigration is facilitated by the relaxation of the Romanian legal system regarding the free circulation of individuals across Romanian borders. After 1992, the number of legal immigrants increased continually due to the existing option of working temporary across the borders.

Figures of March 2002 showed a number of about 360,000 people as temporary immigrants from Romania. For a country of 21,680,000 people, this means a temporary emigration rate of about 17%.

After 1996, the dominant streams were those directed toward the United States and Canada. In 2003 immigration became more dispersed, with relatively equal streams going to Germany, Canada, the United States, Italy, Spain, and Hungary. The settlement of relatives in different countries facilitated migration.

In 2004 the official figure of Romanian legal immigrants in Italy, was 62,300, which made Romanians the largest immigrant nationality in this country. Romanian migration to Italy started in the early 1990s (after the fall of Ceaușescu's regime in 1989), and according to Organization for Economic Cooperation and Development (OECD, 2007) Romanian immigrants have now become the largest ethnic community in this country (48.4% of the total number of immigrants during 1990–2004 and 56.6% of the total number of immigrants in 2005). Regarding the qualifications of the Romanian immigrants, the statistics showed that of 15,000 foreign doctors working in Italy, 555 are Romanians and 25% of the foreign nurses (8,479 individuals out of 35,000) are Romanian immigrants.

In Spain, from 1998 through 2007, Romanians ranked as the second largest immigrant group (2,000 immigrants in 1998, 208,000 in 2004, and 527,000 in 2007) and become the first in 2008 (716,000 Romanian immigrants).

The main causes of migration from Romania are the increasing levels of unemployment along with the low paid jobs and high expenses of daily life. Related to age, the statistics show that 45% of the immigrants are over 35 years old, 35% are 25–35 years old, and approximately 20% are 18–25 years old. Therefore, the profile of the Romanian immigrant is male, 35 years old, married, with different levels of qualifications coming from areas with high unemployment levels and very low incomes. According to the National Employment Agency the targeted domains in the destination countries are construction, agriculture, and hotel industry. These trends suggest that migration has become a phenomenon of highly skilled and educated individuals who are trying to find professional opportunities in the field in which they were trained.

In the last years, the "brain hunting" phenomenon heavily influenced the process of immigration. The "brain hunting" is oriented to individuals between the ages of 18 and 24 years old, who graduated or are enrolled in the last years of school. In this way, graduates represent 10–12% of all the individuals that legally immigrate. Most of the jobs obtained by the Romanian immigrants are temporary.

Some of the countries, such as Germany, Great Britain, Ireland, France, Austria, Belgium, Italy, Luxemburg, Holland, and Malta are imposing restrictions related to force circulation. The immigration of Romanians to these countries is permitted due to the bilateral agreements between countries but they need to possess work permits. Spain, Portugal, Greece, and Hungary decided that Romanians do not need a work permit starting with January 1, 2009. Beginning May 1, 2009, Denmark allowed Romanians to immigrate on the same terms as other citizens of the European Union.

[2]Department of Political Science, University of Akron, Akron, OH, USA

As the largest independent state in the former Soviet Union, Russia – or the Russian Federation, as it is properly known – is the largest country in the world, at almost 6,600,000 square miles. It has a wide range of geographical features and climates. It shares borders with almost a dozen other countries, including Norway, the Baltic States (Latvia, Estonia, and Lithuania), Belarus, Kazakhstan, China, and North Korea. Russia has enormous quantities of natural resources, including oil, natural gas, forests, and approximately a quarter of the world's fresh water. Russia's population is about 140,000,000, although it has been on the decline due to a high mortality rate, especially among males, from a variety of causes such as a high rate of alcohol abuse and tobacco use. The literacy rate in Russia is one of the best in the world, at 99.4%, and the majority of Russian citizens are urban dwellers.

The Russian Federation has struggled to transition from the centrally planned Soviet-era economy to a market economy, and the transition has only been partially successful. Particularly in the early 1990s, when price controls were abolished, many Russians were suddenly impoverished after two episodes of hyperinflation. In 1998, the Russian economy collapsed, but has rebounded substantially under President Vladimir Putin's management of oil and gas revenues in the early 2000s. Politically, Russia has reversed many of its democratic gains and is currently viewed as a semi-authoritarian regime, although without the overt repression that characterized the Soviet period. Russia was hit hard by the economic crisis that began in late 2008, but at the time of this writing, appears to be rebounding – again with oil and natural gas revenues driving the recovery.

There have been several waves of emigration from Russia. The first and main wave of emigration was from Czarist Russia in the late nineteenth and early twentieth centuries. Key destinations for émigrés were Western Europe, particularly France, the United States, and, since the 1970s, Israel. The majority of Russian immigration happened before and after the Soviet period, because in the Soviet era it was considerably difficult even to travel abroad as a private citizen. Between 1890 and 1920, approximately 2.5 million Russians immigrated to the United States, making this period by far the largest influx of Russians to the USA.

This first wave of immigration to the United States occurred in the late 1800s and in the years immediately following the 1905 and 1917 revolutions in Russia. The persecution of Russian Jews by the czarist regime, and political turmoil associated with the revolutions provided the impetus for many Russians to leave the country. Prior to the First World War, 1.6 million Russians immigrated to the United States alone. After the start of the war, and with the Russian revolution in full swing, some 921,000 Russians managed to immigrate to the United States.

In contrast to the relative ease of emigrating from Russia in the early twentieth century, the Bolsheviks' consolidation of power and their heavy-handed utilization of the newly formed security services shut the Russian borders almost completely. During the time of the Cheka – the first political police in the new Soviet state – in the 1920s, only 62,000 Russians arrived in the United States. In the time of the Cheka's successor organization, the NKVD – made infamous as the tool of Stalin's terror in the 1930s – this number dropped to only 1,400.

By the late 1970s, the plight of Russian Jews living in the Soviet Union became a political issue in the United States and a cause for Jewish organizations who wished them to be permitted to emigrate. Political pressure by the USA was brought to bear on the Brezhnev regime, which was seeking increased trade with the United States at the time, and substantial numbers of Russian Jews and non-Jewish dissidents were allowed to emigrate from the Soviet Union. While many of these immigrated to the United States, Israel was also a key destination because of the special status of Russian Jews in the eyes of the Israeli government (Israel has an "open-door" immigration policy for Jews, whatever their nationality). The choice of Israel as a destination was also due to changes in US immigration policy in the 1980s which made it more difficult for Russian Jews from the former Soviet Union to enter the United States.

In the 1990s, there was a large wave of immigration to Israel from Russia. Substantial movement of Russians to other countries occur red due to the removal of many emigration restrictions under Soviet Premier Mikhail Gorbachev in the late 1980s, and the subsequent collapse of the USSR in 1991. From 1990 to 1997, almost a million Russian Jews immigrated to Israel.

At the same time, US lawmakers passed the Immigration Reform Act of 1990, which loosened the restrictions on immigration to the USA from Russia that had been laid out in the 1980s. The new law allowed an increased number of up to 50,000 refugees from the former Soviet Union to enter the USA per year. Additionally, the US government actively sought to attract former Soviet engineers, physicists, and other scientists who were disenchanted with economic conditions in the former Soviet Union. Wage arrears and salaries that now amounted to almost nothing following several economic crises in Russia combined to make the West highly attractive to those with advanced technical and scientific know-how. The number of Russian Jews who arrived in America during the period mentioned above, 1990–1997, was approximately a quarter of a million.

The opportunity to earn higher wages, however, came at the expense of leaving the familiarity of one's homeland to start over again in a country very different from the country with which one was accustomed. A new language must be learned, and new social customs must be picked up.

The "culture shock" experienced by many immigrants to the United States is certainly not unique to Russians. To be sure, dramatic changes in surroundings can have an alienating effect on anyone. However, in the case of immigrants from the former Soviet Union, they experienced drastic changes on many levels. Economically, change from Soviet to Western culture meant a drastic difference in the availability of consumer items in a market capitalist society, as compared to what was available under the centrally planned Soviet economy. The availability of foodstuffs and consumer goods in the West was almost overwhelming to many Russians.

The difference between the political systems was also an important adjustment for Russian immigrants to make. Political ideology in the Soviet Union was a pervasive, almost ubiquitous presence in the daily lives of Soviet citizens. To some, if not most, Soviets, however, the ideology was bankrupt even before Gorbachev's policy of glasnost opened the floodgates to criticism of Marxism–Leninism. Nonetheless, the change from a closed society in an authoritarian system to an open society in a liberal democracy created problems for some Russian immigrants to the USA.

Additionally, Western nations have familial structures that are very different than what is customary in Russia. In Russia, family members are dependent on one another to a much greater extent than is customary in Western nations. It is common to find multigenerational households in Russia, and adult children traditionally assume the role of caring for aging parents. This level of familial interdependence is not common in the USA, a nation in which independence is highly valued. During the 1990s, many older Russians came to the USA to reunite with children who had immigrated to the country to take professional jobs. After moving to the USA many of these older Russian immigrants felt as though relying on their children to help them settle and assimilate, which would have been a reasonable expectation in Russia, would be unacceptably burdensome. Therefore, for Russians, the adjustment to the Western customs regarding family structure involved learning to decrease one's reliance on the people who would traditionally have been one's greatest sources of support, at a time when the need for support and guidance is extremely high.

Yet another adjustment that had to be made by Russian immigrants was an adjustment to health care systems that differed greatly from the system that they had depended on for health care when living in Russia. Russian immigrants have to learn to navigate foreign medical systems to meet their health care needs, which can be a very daunting task in the Western countries where the immigrants settled. Russian immigrants in both the USA and Israel have the disadvantage of not being familiar with Western medical interventions. This unfamiliarity can interfere with Russian immigrants' access to services from which they could benefit. Additionally, Russians, who come from an authority-oriented country, are at a disadvantage in Western health care systems which place great emphasis on patient autonomy.

Immigrants who moved from Russia, a country with a universal health care system, to the United States, where the health care system is multilayered and does not guarantee universal access, can have a lot of difficulties navigating the medical system in their new country. Phenomenological research has shown that Russian immigrants see the US health care system as extremely complex. Russians also see the US health care system as cold. In Russia, physicians are modestly paid individuals who make house calls as part of their routine practices. Therefore, Russian immigrants are put off when they learn that it is the custom in America to deliver health care primarily through prearranged office visits performed by doctors who are of elevated social status.

Furthermore, since the acquisition of a new language is one of the most difficult – if not the most difficult – task for immigrants, Russians experience language barriers when seeking health care in their new countries. Unfortunately, it is not common for doctor's offices in the United States to have Russian language translators readily available. Immigrants who do not yet have good command of the English language are therefore forced to rely on family members to translate their physical symptoms to doctors, and translate the doctors' questions and recommendations to them. A main problem with the practice of relying on family members to translate is that Russian immigrants are reluctant to ask their relatives to accompany them to appointments, because immigrants who are adjusting to American expectations of social independence do not want to over-rely on their families. Immigrants' reluctance to ask for help can lead them to delay seeking medical care because of language barriers. Russian immigrants in Israel also face language barriers when attempting to visit health care professionals.

The Russian concept of health is being free of illness, and Russians equate being ill with being in pain. Because they have this conception of health, Russian immigrants seek medical care when they are obviously ill or in physical pain. In Western nations, a high priority is placed on preventive care, and patients of the health care systems in Western countries are expected to attend routine well care visits and take proactive measures to achieve a state of health that involves more than just the absence of illness or disease. This dramatic difference in the country-based expectations of how citizens seeking medical care should interact with the health care system presents yet another adjustment for Russian immigrants.

It has been shown that Russian immigrants participate in routine health visits and disease screening to a lesser degree than citizens of Western countries. Data from Israel show that Russian immigrants are less likely to have pap smears as recommended. They are less likely to have mammograms, which are recommended for early detection of breast cancer. They are less likely to have their cholesterol levels checked and have their blood pressures screened. Interestingly, it has also been found that Russian immigrants to Israel had lower rates of compliance with cancer screening than Russian citizens who remained in their home country.

Research shows that Russian immigrants visit Western doctors primarily when they are ill. When they do visit the doctor they voice many complaints, and are often seen by doctors as exaggerating their symptoms or somatizing. Unfortunately, this culture clash often leads to less than ideal medical treatment of Russian immigrants.

It has also been demonstrated that Russian immigrants are very suspicious of health messages (public service announcements) portrayed through the media. They suspect that health messages are projected to the public for political agendas rather than because of a genuine effort to improve the nation's health. Russian immigrants have been known to lose the benefit that they could gain from following media advice about healthy eating, for example, because of commonly held suspicion that the message is intended to increase sales of a particular type of crop.

Difficulties navigating Western health care systems are likely to partially explain why Russian immigrants have worse life expectancy and higher infant mortality rates than native citizens of Western nations. The following data provide a comparison of the health of citizens in Russia and those of the countries where Russians primarily settled during the most recent wave of immigration from Russia. In 1990, men in the Soviet Union could expect to live between 60 and 68 years, whereas men in the USA could expect to live approximately 72 years on average. Soviet women had a life expectancy between 68 and 75 years, while women born in the USA lived nearly 79 years on average. The average life expectancy for citizens of Israel was 76 years of age. The infant mortality rate in the Soviet Union was likely over 35 per 1,000 live births; in the USA and Israel alike, about 10 infants per 1,000 born died within the first year of life. Life expectancy and infant mortality data for Russian immigrants in the USA and Israel fall in line with the health statistics for Russia, rather than with the statistics for the Western nations in which the immigrants are living.

Another reason why Russian immigrants are not as healthy as the citizens of the countries in which they settle is that people who have lived in Russia commonly have poor health practices. In Russia, it is common for citizens to smoke very heavily. Physical fitness is not a national priority in Russia, nor is the development of healthy eating habits. When Russians immigrate to new countries, they take their unhealthy lifestyles with them. As a result, Russian immigrants have high rates of obesity. Many suffer from diabetes and hypertension. Furthermore, there are very high rates of cardiovascular disease among Russian immigrant populations in both the United States and Israel.

A habit that carries particularly serious health consequences, and one that is very common among Russians, is heavy alcohol consumption. In Russia, heavy alcohol use is commonplace, and it is a major determinant of mortality among the country's citizens. Russians who consume alcohol heavily die of accidents, violence, and alcohol poisoning. They also die of complications owing to long-term alcohol use, namely heart disease, liver cancer, and pancreatic disease, as well as infectious diseases, such as tuberculosis, that chronic heavy alcohol users are at higher risk of contracting. Russian immigrants to Israel, a country whose citizens have a relatively low rate of alcohol consumption, continue drinking as if they were still living in Russia. They report higher rates of drinking and higher rates of drinking to the point of intoxication than native citizens of Israel report. Alcoholism is also very common among Russian immigrants in the USA, and the same health consequences are seen in the Russian immigrant populations of Western nations as are seen in the general population of Russia.

Russian immigrants are also shown to suffer from depression at rates that are significantly higher than rates of depression among the general population of the countries in which they are living. US studies have shown that depression rates among Russian immigrants approach 10%. Unfortunately, despite the availability of effective treatment for depression in Western countries, Russian immigrants have very high rates of untreated depression because they have a great degree of mistrust of psychiatry. This stems from the historical Soviet practice of psychiatric detention, in which anyone who disagreed with the government, or acted in a way which was not approved of by the government, was labeled insane, detained in prison-like hospitals, and forcibly and excessively medicated. Russian immigrants' reluctance to seek psychiatric care, although understandable given the historical context of their past experiences, leads to morbidity and mortality from depression as well as from alcoholism.

S

Safety

Megan-Jane Johnstone[1], Olga Kanitsaki[2]
[1]School of Nursing and Midwifery, Deakin University, Melbourne, VIC, Australia
[2]Nursing and Midwifery, RMIT University, Melbourne, VIC, Australia

Safety is an important issue for immigrants and includes safety in health care. All patients have the right to expect that the health services they receive will be safe, reliable and of high quality, and that they will be kept free of the dangers and risks of preventable injury when receiving hospital and other forms of health care. Although modern health care systems generally provide safe high-quality services, sometimes things can go wrong. And when things go wrong, patients can sometimes suffer preventable harm, including death.

In contexts involving the health care of immigrant patients of minority language and cultural backgrounds, the risk of things going wrong can be disproportionately high compared to patients whose language and culture are congruent with the majority population and health service providers. Despite this imbalance, immigrant disparities in patient safety (more commonly referred to as "ethnic disparities in patient safety") have received relatively little attention in the international patient safety literature.

Due to a lack of research into patient safety events in minority immigrant populations, their true incidence and impact are unknown. What is known of their incidence and impact is probably an underestimation of what has occurred. The absence of "gold standard" research into immigrant disparities in patient safety (e.g., the kind of patient safety events that occur, their incidence, impact, and contributing factors) arguably stands as one of the most significant barriers to reducing and preventing their occurrence in real terms. This is because: "*What is not known about cannot be fixed.*"

Risk of Harm in Health Care

The risk of patients experiencing adverse events in health care is significant. Since the mid-1990s, various reports published, respectively, in the United States, Australia, the United Kingdom, Canada, New Zealand, and other countries have suggested that between 4% and 16.6% of patients have suffered some kind of harm, including permanent disability or death, while in hospital. These reports further suggested that around 50% of the harmful outcomes recorded could have been prevented, that is, were *preventable adverse events.*

Adverse Events

An adverse event is generally defined as an unintended injury or complication, which results in disability, death, or prolonged hospital stay and is caused by the *health care management* of the patient rather than the patient's disease. Although commonly attributed to human error (e.g., mistaken judgments or conduct) not all adverse events are the result of errors. Conversely, not all errors result in harmful outcomes or adverse events for patients. For example, a patient with no known drug allergies may suffer a severe adverse reaction after being administered a correctly prescribed drug. Although obviously an "adverse event," it was not the result of a mistake being made. In contrast, a patient may be given the wrong drug or an incorrect drug dose, yet suffer no serious consequences.

It is widely accepted that the risk of error and threats to patient safety have multiple causes. Chief among them are what have been termed: "active failures," events usually due to human factors; and "latent failures" mainly caused by *underlying organizational problems or "gaps" in the system* and which predispose individuals to making mistakes (active errors). Contrary to common belief, the vast majority of adverse

Sana Loue & Martha Sajatovic (eds.), *Encyclopedia of Immigrant Health*, DOI 10.1007/978-1-4419-5659-0,

events in health care are not the result of a single act by an individual. Rather they are usually the end result of failings in *complex systems of care*.

Human Factors

Human factors encompass all those factors that can influence people and their behavior. In a health care context, these factors encompass the environmental, organizational, and job factors, as well as the individual characteristics (e.g., an individual's culture, personality, character), which influence a person's behavior at work. Human factors are commonly implicated in human error (active failures) and contribute the most common threats to patient safety. Although sudden and unexpected failures in equipment also contribute a threat to patient safety, such events tend to be rare.

When caring for immigrant patients of minority language and cultural backgrounds, the risk of making a mistake can be compounded in instances where, because of language and cultural barriers between the providers and the recipients of health care, critical information about a patient is not obtained. Ethnic stereotyping, ethnocentrism, bias, and discrimination can also contribute to unsafe patient care.

System Processes

System processes encompass underlying organizational problems or "gaps" in the system, which predispose to unsafe patient care. These gaps are sometimes referred to as "accidents waiting to happen." Like a dormant volcano, these gaps can erupt in the system at any time. While one gap alone (e.g., understaffing, the lack of credentialed on-site interpreters, a poor mix of skilled and experienced hospital staff, the supply of outmoded equipment, poor drug package labeling, and so on) may not result in an error, *were all the gaps or flaws in the system to align* – even for just a moment – then there is a high probability that an "accident" (active error) will occur – e.g., the administration of a therapeutic drug to the wrong patient, or the wrong assessment and related misdiagnosis of a patient. Had even one of the gaps been detected (e.g., failure to use a credentialed health interpreter) and a system defense activated to "interrupt" the trajectory of accident opportunity (e.g., check list prompting language needs assessment), then the adverse event may not have occurred.

Global Patient Safety Movement

In 2002, the World Health Organization acknowledged that the incidence of preventable adverse events was a challenge to quality of care, caused significant avoidable human suffering, and had a high toll in terms of financial loss and cost opportunities to health services. This resulted in the World Health Assembly adopting a resolution on patient safety that set the stage for the development of global standards and guidelines for patient safety and quality care, and encourage research into this fledgling area. The resolution highlighted a range of strategies including preventive action, implementation of system measures to reduce risks, promotion of evidence-based policies and practice, fostering a culture of safety within health care organizations, and the development of mechanisms for recognizing benchmarks for excellence in patient safety internationally.

The adoption of this resolution resulted in patient safety being recognized on a global scale for the first time. In response to this resolution and mindful of the financial, social, and political implications of the costs caused by adverse events, governments and health services around the world took unprecedented action to develop and implement robust patient safety programs with the specific aim of improving the safety and quality of hospital and related health care services.

Patient Safety

Patient safety is fundamentally concerned with reducing the incidence and impact of preventable adverse events associated with patient care and treatment. In keeping with this concern, patient safety programs encompass the collective efforts made by patient safety organizations, health service providers, policy makers, health consumers, and other stakeholders to reduce to an "acceptable minimum" the incidence and impact of unnecessary harm associated with health care. According to the World Health Organization, an "acceptable minimum" in the incidence and impact of harmful events is determined by current best available knowledge, the resources available, and the context in which care was delivered weighed against the risk of nontreatment or alternative treatment.

To help prevent things from going wrong and to improve patient safety outcomes, health care organizations are now required to have in place a system that will enable them to continuously improve the quality and safety of patient care. Such a system is expected to minimally include processes:

- For identifying deficiencies (gaps) in the system that could allow or have allowed adverse events to occur, and acting to address the deficiencies identified
- For managing risks and minimizing the harm from adverse events should they occur
- For supporting generally a culture of safety and excellence in patient care.

Immigrant and Ethnic Disparities in Patient Safety

There is emerging evidence that, despite the internationalization of patient safety initiatives, patient safety events occur more often in immigrant than nonimmigrant populations, and that patients who do not have language and cultural congruence with their health care providers may be at disproportionate risk of experiencing harmful outcomes compared to patient groups who have language and cultural congruence with their health service providers. Immigrants (like ethnic minority patients) have been identified as being more prone to patient safety incidents such as medication errors and adverse drug events, postoperative complications, nosocomial or hospital acquired infections, and “failure to be rescued” by health care providers when things are going or have gone wrong.

In the United States, pilot research has shown that immigrant patients with limited English proficiency (i.e., patients whose spoken or written English is insufficient to enable them to negotiate the health care system or to interact effectively with their health service providers) are almost twice as likely as proficient English speakers to experience physical harm from an adverse event (49.1% compared to 29.5%) and are almost twice as likely to experience physical harm at a level ranging from *moderate temporary harm* to *death* compared with proficient English speakers (46.8% compared to 24.4%). Research has suggested that patients with limited English proficiency are also more likely to experience an adverse event related to communication errors than are patients who speak English proficiently (52.4% compared to 35.9%).

Ethnic minority patients have been found to be similarly at risk. For example, pilot research in the United States has shown that Black patients are 20% more likely to experience a patient safety event than are White patients. Studies outside of the United States have similarly identified immigrant and ethnic disparities in patient safety events, including wrong-site surgery, omission of prescribed pain relief, and misdiagnoses with related delays in treatment leading to irreversible harmful outcomes, including permanent disability and death. Language barriers and errors in communication have been implicated in these patient safety incidents.

Contributing Factors to Immigrant Disparities in Patient Safety

Socioeconomic and health access issues are known to contribute to health and patient safety disparities in both immigrant and nonimmigrant populations. Immigrant and ethnic disparities in health and patient safety outcomes, however, are not always explained by socioeconomic or other health care system variables. US data show that when adjustments are made to account for these variables, not only do the disparities remain, but are remarkably consistent across a range of illnesses and health services. Some commentators have concluded that racial/ethnic bias, stereotyping and discrimination leading to inappropriate responses, and the provision of inappropriate/ineffective care are significant contributors to immigrant and ethnic disparities in health and patients’ safety outcomes.

Other factors contributing to immigrant and ethnic disparities in patient safety include a lack of cultural competency among health service providers at both an individual practitioner and whole-of-organization level; ineffective cross-cultural communication; failure to capture and include immigrant/ethnic minority viewpoints about safety and quality in health care in patient safety programs; and an embedded organizational culture of “getting by” instead of safety being accorded a high priority. Each of these factors contribute to cultural misunderstandings, misperceptions, and expectations concerning health, illness, care, and treatment which, unless addressed, unnecessarily expose immigrant and ethnic minority patients to care pathways that are rife with the risk of “an accident waiting to happen.”

Communication Errors and Patient Safety

Patient safety research has revealed that the two most significant factors contributing to preventable adverse event occurrence in health care are *failures in communication* and *failures in team work* (noting that effective team work is also inextricably linked to effective communication).

Communication has long been recognized as "the tool" by which all interactions in the hospital environment are governed. Today, effective communication is widely regarded as *the* core component of health care. Oral and written communication between members of the health care team, the patient, and the patient's family are vital to the proper assessment of patients, and to the effective planning, implementation, and evaluation of their care and treatment.

There is a strong link between "communication failures" and poor patient safety outcomes. The US Joint Commission on Accreditation of Healthcare Organizations (JCAHO) has identified communication failure as a pivotal factor in around 70% of over 3,000 sentinel (catastrophic) event reports since 1995. The US Veteran Affairs National Center for Patient Safety has similarly implicated communication failure in almost 80% of more than 6,000 Root Causes Analysis reports to its agency.

There is increasing recognition that if communication errors are a threat to patient safety in the general (majority) patient population, then patients of minority language and cultural backgrounds are in "double jeopardy" of communication errors and their associated risks to the safety and quality of patient care. This recognition has led to heightened calls for "communicative competence" to be used as a framework for understanding and redressing language and cultural barriers to patient safety in hospital and other health care domains.

Communicative Competence and Patient Safety

Effective cross-cultural communication between patients, their families/friends, and health service providers is critical to the delivery of safe patient care. Such communication does not always occur, however, because of language and cultural differences between health care providers (e.g., doctors, nurses, hospital receptionists, administration staff, and so on) and patients, and low health literacy among some patient groups. So significant are these variables that the JCAHO has identified "effective communication," which takes into account language difference, cultural difference, and health literacy as a fundamental prerequisite to safe health care.

Language Differences

Language differences (oral and written) between patients and health service providers have been systematically identified as being a key barrier to effective communication. In some cases, the misinterpretation of just one word has led to a catastrophic outcome for the patient, which might otherwise have been avoided had the communication needs and requirements in the clinical encounter been properly assessed and responded to (notably by engaging the services of a qualified health interpreter).

Research is demonstrating that *language differences as a barrier to effective communication* and hence patient safety is not always immediately apparent and tends to be underrecognized and underestimated by the providers and recipients of health care alike. Professional caregivers (doctors, nurses, and allied health professionals), patients, and their families/friends have all been found to overestimate their "second language" proficiency and underestimate their capacity for making mistakes in health communication. Compounding this oversight is the underrecognition (and even denial) of the nature and harmful impact of language prejudice (a form of racism) on the clinical encounter and related patient safety outcomes.

Cultural Differences

Cultural differences between health service providers and their patients have been systematically identified as being a significant barrier to effective communication. Although commonly associated with language differences, cultural differences entail considerably more than mere differences in a spoken sound or use of conventional symbols. As can be readily demonstrated, two people from different cultural backgrounds may speak a common language, yet lack shared cultural knowledge and understanding of the meanings of particular words and of what is being communicated. For example, a bilingual physician may use the correct words when interpreting a cancer diagnosis to a patient, yet totally miss (and underestimate) the cultural meanings which the patient attributes to the word "cancer" and the harmful consequences of using this "conventional" term. Although the frank disclosure of the cancer diagnosis may well have been congruent with mainstream medical and lay cultural practices, in the context of the cultural worldview held by the patient such an action may be tantamount to "cultural imposition," a violation of the patient's right to cultural liberty, and ultimately clinically ineffective and even "toxic" (harmful) care.

What is not always understood in the health care environment is that intercultural communication requires not just an exchange of words, but also an exchange of *shared meanings*. Thus, to be effective, interpreters and bilingual staff must not only "translate words," but establish and verify their "shared meanings." This requires knowledge and skills not only in speaking a second language, but cultural knowledge and skills to ensure the "cultural appropriateness" of health communication in the clinical encounter. Without this understanding there is a risk not only of communication errors occurring, but of them going undetected, which in either case could result in preventable harm to patients.

Health Literacy in Relation to Patient Care

Health literacy, to be distinguished from "general" literacy (i.e., the ability to read and write proficiently), is a discrete form of literacy. Although the subject of various definitions, the term is widely accepted and used to refer to an individual's capacity to obtain, understand, and use information relating to health and health care services to make appropriate decisions concerning their health, disease prevention, treatment and management, safety and accident prevention, and to generally promote and maintain good health.

Low health literacy is a recognized barrier to effective communication with immigrant patients of minority language and cultural backgrounds. Although *any* patient who is functionally illiterate may have low health literacy, patients of minority language and cultural backgrounds face particular disadvantage in contexts where pertinent health information is available only in a country's "official" language. For example, in English-speaking countries, patients and their families who do not speak, read, or write in English – and who may also be functionally illiterate in their own native language – are at significant risk of experiencing disparities and inequities in health and health care. US research, for example, has shown that non-English speaking Latinos (8% versus 51%) and Asians (11% versus 51%) were less likely to receive needed health services than did their English-speaking counterparts.

Although the identification of language and cultural barriers may alert clinicians to the possibility that their patients may have low health literacy, this may be overlooked if the patient or family members fail to ask questions, and assumptions are made by attending health care providers that the patient "understands" the care and treatment information he or she has been given, and has the capacity to act on that information, when in fact the patient does not.

Cultural Patient Safety

Some commentators have suggested that conventional contemporary patient safety theory and practice are inadequate to the task of improving and achieving health care safety for racial/ethnic minority patients and their families. Moreover, what ethnic minority patients and families regard as "preventable harms" and "safety priorities" in health may vary from traditional patient safety typologies. An example of this can be found in a small US study, which suggested that patients were more likely to report psychological and emotional harms (manifest as anger, frustration, belittlement, loss of relationship, and trust in the clinician) occasioned by racist treatment by health care providers, than they were to report harms related to adverse drug events and surgical mishaps.

To redress the inadequacy of conventional patient safety processes across diverse populations, a cross-cultural model of "cultural patient safety" (to be distinguished from cultural competency) has been proposed. Cross-cultural patient safety takes a distinctive patient-centered approach to health care safety. Among the core risk factors it aims to address are *linguistic issues* (e.g., the potential for miscommunication), *cultural issues* (e.g., potential for cultural misunderstanding), *medical literacy* (e.g., taking into account that native languages do not always include conventional medical or related terminology which thus cannot be translated meaningfully; inability of patients to navigate the health care system), *practice issues* (e.g., where conventional services may contrast or clash with traditional healing practices), *contextual issues* (e.g., potential for misunderstanding due to differences in cultural knowledge or cultural habits), *systemic issues* (e.g., access and availability issues), *genetics* (e.g., failure to take into account issues specific to certain racial/ethnic populations), and *racism/discrimination* (e.g., manifest as prejudice, indifference, intolerance, unjust differential provision of health services).

Cross-cultural patient safety is depicted as extending beyond and being distinguishable from a more conventional model of patient safety. The basis upon which cultural patient safety is distinguished from conventional patient safety lies in its apparent emphasis on the safe and successful delivery of health care services *across cultural, linguistic, and related barriers* to the understanding and identification of racial/ethnic minority patient needs. To this end, cross-cultural patient safety is heralded by its proponents as encompassing a broader set of processes than those which are conventionally associated with patient safety, such as adverse events, medication errors, hospital-acquired infections, falls, and other patient safety incidents. Under a cross-cultural patient safety model, psychological and emotional harms causally related to cultural imposition, cultural insensitivity, racist and prejudicial treatment, the failure to observe traditional healing practices, and the like, would also be included in patient safety taxonomies.

The main objective of a cross-cultural patient safety model is to achieve the enrichment and empowerment of minority group *culture* and the protection of *traditional cultural practices* (e.g., cupping, herbal remedies, massage and other health practices, shown not to be harmful) in conventional health care contexts. Whether cultural patient safety has the capacity to achieve patient safety outcomes independently of, and more effectively than, conventional patient safety programs, however, has yet to be shown.

Redressing Immigrant Disparities in Patient Safety

Formally identifying the cultural and linguistic needs of immigrant patients and taking a systemic response to ensuring the provision of culturally and linguistically responsive health care are being increasingly recognized by patient safety agencies, governments, health service providers, health consumer advocacy groups, and other stakeholders as a key domain for patient safety. This recognition is seeing unprecedented emphasis being placed on the need for broad screening for potential safety events in immigrant (and ethnic minority) patient groups, evidence-based assessment of health interpreter needs, and systemic cultural responsiveness. Unprecedented emphasis is also being placed on the need to develop a health care workforce which has appropriate qualifications and experience to provide safe, high-quality care to patients of diverse cultural and language backgrounds, encouraging immigrant and ethnic minority patients to actively participate in care processes, engaging clinicians in redesigning systems and processes aimed at improving patient safety outcomes for immigrant and ethnic minority patients, and the full integration of "cultural diversity" services into the health care system and associated clinical risk management programs.

The adoption of a policy-orientated approach to cultural responsiveness in health care has underscored the need for a "systems approach" to improving the safety of health care services for immigrant patients. Currently little is known about risk perception, preferences, reasoning, and decision-making, and the complex interplay of variables that may influence these processes in contexts involving the health care of immigrant and ethnic minority patients. Comparative research investigating immigrant and ethnic disparities in patient safety is required.

Sanctuary

J. David Kinzie
Department of Psychiatry, Oregon Health & Science University, Portland, OR, USA

Sanctuary originally meant "a sacred place" – as the holy of holies in the innermost temple of Solomon (Judaism) or The Noble Sanctuary at Al-Haram al-Sharif in Jerusalem (Islam) or, in the Christian church, the place around the altar. Sanctuary also meant a place to be safe from arrest, as in a church or temple. The earliest mention of sanctuary was in an English code of law (AD 600), confined to the church itself. It was later expanded but ecclesiastical right of sanctuary ceased after the Reformation.

The Sanctuary movement in modern times began in the 1980s as part of a broader antiwar movement. By 1987, 440 sites were open to migrants escaping the civil wars in Central America. The sites included churches and university campuses for migrants facing deportation in Europe, Australia, Canada, and the United States. The "New Sanctuary Movement" organization estimated at least 600,000 people in the United States had at least one family member in danger of deportation. At its heart, the movement was to protect refugees and immigrants who were in realistic danger if forced to return to their own country.

The United Nations spelled out specific rights that nations should offer refugees and asylum seekers. Its provisions were put into US law in 1980. Having a legal way for protection and obtaining asylum has lessened the need for the sanctuary movement. However, since 9/11, laws require that anyone providing "material support" for terrorists be refused asylum. The sanctuary movement predated the ongoing American tension regarding immigration. The current tension divides the American population between those who, on the one hand, hold the historical position of providing safety for those immigrants who have been persecuted and tortured and those who, on the other hand, want to limit immigration to protest illegal immigrants and protect the country against potential "terrorists."

Sangue Dormido

James M. Ellison[1], Robert C. Like[2]
[1]McLean Hospital, Belmont, MA, USA
[2]Center for Healthy Families and Cultural Diversity, Department of Family Medicine and Community Health, University of Medicine & Dentistry of New Jersey, Robert Wood Johnson Medical School, New Brunswick, NJ, USA

Sleeping blood or *sangue dormido* is listed in the American Psychiatric Association's DSM-IV-TR manual as an example of a "culture-bound syndrome" found among Portuguese Cape Verde Islanders (and immigrants from that area to the United States). Individuals affected with this syndrome are described as having "pain, numbness, tremor, paralysis, convulsions, stroke, blindness, heart attack, and miscarriage." Cited over 1,000 times on Google, *sangue dormido* has been reprinted in many languages and is typically listed alongside such well-documented culture-bound syndromes as *ataque de nervios*, *susto*, *amok*, and *pibloktoq*.

The condition was originally described by the authors in the journal *Culture, Medicine, and Psychiatry* (1981) in a single clinical case report of a 48-year-old Crioulo-speaking Cape Verdean woman who was admitted to Massachusetts General Hospital in Boston for further diagnostic evaluation and treatment of resistant right arm paralysis, numbness, pain, and tremor. The patient had sustained bilateral Colles' wrist fractures and subsequently developed the above symptoms which failed to respond to 2 years of conventional medical treatment and physiotherapy. An extensive diagnostic work-up including laboratory testing and imaging studies did not reveal any definitive organic neurologic pathology. A psychiatric diagnosis of conversion disorder (DSM 300.11) was made.

In order to develop a therapeutic alliance and negotiate a culturally sensitive treatment plan, the clinicians elicited what Dr. Arthur Kleinman and other medical anthropologists have termed the patient's "illness explanatory model" (i.e., her personal perspective about the cause, onset, name, course, fears, impact, and treatment of her condition). The patient shared her beliefs that a jealous family member or neighbor may have caused her original fall, wrist fractures, and resulting neurological symptoms through the evil eye (*mal olhar*) or witchcraft (*feitiçaria*). She further elaborated on this explanation by describing a belief held by the inhabitants of the Cape Verdean village where she had been raised. In her view, "living blood" (*sangue vivo*) could be caused by injuries such as the wrist fracture she had previously sustained to leak into the skin, blacken, and become "sleeping blood" (*sangue dormido*) or "dead blood" (*sangue morto*). If not removed, the blood's expansion over time in response to diet, climatic conditions, or temperature changes, could result in terrible consequences including pain, numbness, tremor, paralysis, convulsion, stroke, blindness, heart attack, infection, miscarriage, and mental illness. She was also a devout Catholic and believed that perhaps her condition was a divine punishment (*castigo*) for "bad thoughts" that she had about her family member and neighbor.

The patient described the following traditional treatment approach from her homeland: administration of a calming medication, making an incision in the shape of a cross to remove the sleeping blood, and offering a prayer for healing. After negotiating with the patient and with medical authorities, a procedure modified sufficiently to allow for implementation within a major metropolitan teaching hospital, the clinicians gave her an intramuscular injection of 5 mg of diazepam intramuscularly; drew 12 cc of blood from a wrist vein, a portion of which was sent for laboratory testing, and the rest was shown to her as coagulated blood in a cup; and stayed with her as she offered a prayer for divine assistance. The patient's tremor completely resolved the following day. Her paralysis, however, remained but slowly improved following discharge with outpatient physical therapy and psychosocial support over the next 5 months.

A subsequent interview with the patient's family during a home visit provided further background linking blood injury beliefs to adverse medical outcomes and suggested that concerns about *sangue dormido* were a common reason for visits to healers and physicians in their Cape Verdean village. A careful search of English-language citations, however, has failed to identify any empirical or ethnographic evidence of this condition that appears separate from the original case report, though it is possible (as one Internet discussion claims) that the original sources are in Portuguese.

The concept of "culture-specific" or "culture-bound syndromes" is a controversial one in psychiatry and medical anthropology requiring additional research, and is currently being reexamined in the planned revisions to DSM-V. Based on this single case report, the authors believe that *sangue dormido* should be seen as representing this individual patient's "illness attribution" and "idiom of distress" relating to beliefs about the connection between blood injury and illness. Community-based studies with Cape Verdean populations are needed to determine if these beliefs are more widely held. The inclusion of *sangue dormido* among evidence-based "culture-bound syndromes," is no longer appropriate and represents a powerful example of "disease reification" in an age of global electronic information dissemination. It is urged that this "syndrome" be eliminated from future DSM listings and allowed to rest in peace.

Sanitation

Dora Hui
Wellesley College, Wellesley, MA, USA

Historically, the immigration experience is often associated with unsanitary living situations. This concern has divided recent immigrants from the rest of the population because their tendency to reside in more urban, densely populated areas has pitted them as the unhygienic "other." Sanitation concerns not only stem from close living quarters but also from exposure to various diseases either in the arrival nation or in the nation of origin due to hygienic practices. In the nineteenth and early twentieth centuries, immigrants tended to migrate from poor sanitary conditions to better sanitary conditions, but as the migrant population diversified to include the very poor and the very affluent, sanitation concerns have also varied in response. Immigrants can be from higher socioeconomic status who choose to migrate or are refugees escaping persecution in their land of origin. This wide spectrum of reasons for immigration makes it difficult, if not impossible, to simply declare that sanitation issues are applicable to all.

In nations where cleanliness is commonplace, sanitation not only divides the clean from the unclean but may also play a role in social stratification. Because it can be an important social value, observable sanitation conditions become physical embodiments of the stark contrast in socioeconomic status between the upper and lower classes. Members of the upper class who value cleanliness and can afford to maintain hygienic practices may view members of the lower class as inferior or even dangerous because they do not share these values, and this difference in priorities and ability to adhere to these norms make sanitation a perpetuator of class differentiation as well as a potential cause of mental trauma due to membership in a lower social class.

In the early 1900s New York City, in an attempt to battle the lack of sanitation in immigrant homes, used its public schools as an instrument of health reform by implementing a series of curricular changes to include physical education (which included all aspects of physical health) and home economics. The idea behind this reform was that the children of immigrants who attended these schools would then bring these newly learned skills regarding health and sanitation back to their homes and teach them to their families.

Immigrants who transition from poor sanitary conditions in their homeland to better conditions at their destination are faced with the need to conform to US standards of hygiene. Among the many items marketed toward a hygiene- and health-cautious audience is bottled water, which is internationally touted as the symbol of clean water. Depending on the brand of water, each company's water may be filtered more or less than tap water, which is often regulated in terms of contaminants. Fluoride, which helps combat tooth decay to maintain oral health, is found naturally in or is added to many water sources. However, bottled water may not have much fluoride. A study found that in a largely immigrant neighborhood in the USA, the immigrant residents tended to drink more bottled water than their American counterparts, possibly as a result of easier access to this icon of cleanliness than in their homeland. As a result, their oral health may not be as good as their American counterparts. Maintaining oral health is important because it is linked to the individual's diet – oral discomfort can lead to a selective, imbalanced diet, which could then create other health-related issues.

However, immigrants' experiences in poorer sanitary conditions may not necessarily be detrimental to their health. The hygiene hypothesis posits that immigrants who are exposed to certain infectious diseases in their native home due to unsanitary or underdeveloped conditions may be less likely to develop certain diseases that are prevalent in the USA, such as asthma and allergic rhinitis.

Immigrants also transition from good sanitary conditions to poor sanitary conditions upon arrival to the USA. Some individuals might have chosen to relocate with or without family members from comfortable accommodations to tenement-style living in the USA in hopes of starting better lives. In these cases, personal hygienic practices may still be employed, but many of these individuals ultimately find occupations where they labor in unsanitary conditions (such as garbage collection or janitorial services). They may be stuck in these jobs due to language, lack of specialized skills, or inability to transfer academic degrees.

This transition from good to poor conditions may even occur before arriving on US soil. Some individuals who might have been considered wealthy in their native country were compelled to relocate to refugee camps in order to avoid persecution. Refugee camps are notorious for their crowdedness and lack of sanitary facilities, which create a breeding ground for a host of diseases that can be easily spread due to the cramped quarters. The state of refugee camps and their lack of resources also pose particular health concerns for women. Most camps are ill prepared for childbirth, with facilities so lacking that many women choose to give birth within the privacy of their own quarters. Sanitary napkins and other menstruation needs are also deficient in quantity and quality.

Individual health may also be a factor in whether immigration is an option. The "healthy migrant" theory suggests that many contemporary immigrants tend to be healthier than the citizens of the destination country because the healthiest individuals choose or are selected to make the journey. However, studies have shown that although these immigrants are healthier than their nonimmigrant counterparts, their health, both physical and mental, deteriorates with increasing years residing in the new country. This observation is known as the acculturation hypothesis, and it could be a result of a variety of factors such as less than ideal occupations, acculturation to poor American diets and habits, and crowded housing situations where sanitation regulations are lax.

Because new immigrants tend to not be familiar with housing regulations in the USA, some landlords are able to take advantage of them. New immigrants, especially refugees, are less likely to report poor living conditions to officials because of their undocumented status and fear of deportation if discovered. This combination of inattention and hesitation to report negligence creates a cycle that usually is not broken until the residents relocate. Such residences tend to be filled quickly by other recent immigrants.

Throughout immigrant history, many new immigrants have found respite in urban ethnic enclaves that tend to be closer to their workplaces or to immigrant services. But living in urban or industrial conditions often brings with it exposure to tobacco smoke, smog, vehicle exhaust, and lack of sanitation, all of which can be detrimental to personal health and can lead to various cardiovascular, respiratory, and infectious diseases.

With increasing numbers of immigrants, it is imperative that clinicians and doctors be aware of issues of sanitary conditions and the prevalence of diseases that are not common in the rest of the population. Immigrants' crowded living conditions (refugee camps, tenement-style living, etc.) elevate their risk of contracting infectious diseases such as tuberculosis or hepatitis B. Densely populated quarters create an environment where infectious bacteria can be easily spread, and because vaccines may not be readily available for immigrants due to a lack of resources or access to health care, this population may be at increased risk for diseases that are less common in the native born population.

Santería

Elaine Willerton
Military Family Research Institute, Purdue University, West Lafayette, IN, USA

Santería, meaning the way of the saints or worship of saints, is a religious tradition stemming from West African and Caribbean origin. Santería began in the nineteenth century in Cuba when hundreds of thousands of captives from Africa were brought to the New World to work in the sugar plantations. The slaves brought over their African religious beliefs and practices and transformed them by blending their traditions with ideas borrowed from Catholicism and spiritism.

Origins and History

The religion known today as Santería was brought to Cuba by the Yoruba-speaking tribes of Southwest Africa (today known as Nigeria) and the Bantu from Congo. From the sixteenth to the nineteenth century, hundreds of thousands of captive Africans arrived in Cuba as part of the Atlantic Slave trade with the majority of Yoruba-speaking people arriving in the mid-1800s. During this time, Cuba's sugar commodity had become popular worldwide increasing the demand for laborers. Practice of the traditional African religion known as *Regla de Ocha* or *Lukumi* was discouraged and often prohibited by the slave masters in Cuba. Santería is one of many West African and Caribbean religions being practiced in both developed and developing countries. Other religions with Yoruba roots also took hold in Cuba and elsewhere in Latin America including Palo Mayombe and Vodou. Each of these religions is distinct but may share some of the Yoruba itan, or the sum of Yoruba religious beliefs, songs, stories, and cultural practices.

Despite the constraints of their oppression, the slaves persisted in their worship and began to transform their beliefs by incorporating elements of Catholicism. Upon arriving in Cuba, the slaves became aware of similarities between their African religion and Roman Catholicism. Both religions believed in a high god and creator as well as a pantheon of intermediaries between the high god and those who worshipped him. They recognized that the Catholic saints embodied characteristics similar to the orisha gods of the slaves and they began to pair each orisha god with a saint. For example, the god of thunder and lightening, Chango, was worshipped using the image of Saint Barbara, whose father was struck by lightening as he killed her for her faith.

Santería is the fusion of the African religion of the slaves, the Catholic saints of their masters, and a third influence known as spiritism developed in France by Allan Kardec in the 1850s. The combination of two or more belief systems into a single system is known as syncretism. The Yoruba culture is known to have been open and flexible about its religious belief system and so it worked to their advantage to combine traditions in a way that allowed them to continue to practice. Santería expanded to the USA and outside of Cuba in two major waves. The first was after the Cuban revolution in 1959. The second consisted of approximately 125,000 Cubans who came in the 1980 Mariel boat lift, a mass exodus from Cuba to the USA.

The terminology used in the practice of Santería includes a mix of Yoruba, a creole version of Yoruba known as Lucumi, Spanish, and Congolese words. Ceremonial songs are sung in Yoruba and communication with orishas is usually done in Yoruba as well. The term "Santería" itself is somewhat controversial. Also known as *La Regla de Ocha* (the rule or law of orisha), a mixed Yoruba-Spanish phrase, or *La Regla de Lucumi* (sometimes spelled Lukumi), the term *Santería* was developed in the mid-1930s by an Afro-Cuban scholar named Rómula Lachatañeré. Some consider the term Santería to be a misnomer, Eurocentric, and derogatory and prefer to use the more neutral term "Ocha" which is a derivative of orisha.

Beliefs and Rituals

The Yoruba in Africa believed in a high god, Olodumare, who was thought to remain distant from the everyday lives of his worshippers. Instead, secondary deities known as orishas serve as the divine intermediaries between devotees and the high god. Santería revolves around orisha worship. It is estimated that the Yoruba in Africa recognized between 400 and 1,700 orisha. Today only 16 major orishas are recognized. Each orisha is paired with a Catholic saint and is believed to control certain aspects of life; each represents an aspect of nature and a human characteristic. Some speculate that orishas were originally paired with saints as a way to disguise or mask the ongoing worship. Whether this was true or not, the transculturation of the orisha had strong appeal for the White Cuban population. Over time, the orishas lost some of their original characteristics and assumed some of the personality, attributes, and powers of the saints.

Divination is utilized when a Santería devotee seeks advice or solutions for the problems they find most troubling such as illness, financial issues, employment, love, or friendship. Various forms of divination are used and are performed by a *santero* (priests) or *babalawo* (high priest). Each diviner uses specific objects: *oguele*, a divining chain; *obi,* coconut pieces; *dilogun*, cowry shells; or *ikin*, palm nuts. The diviner must also commit to memory the many patterns and corresponding verses which will determine a suitable remedy to solve the client's problem.

Devotees respond to the assistance they find in divination from the orishas by expressing gratitude through sacrifices and offerings. A specific food offering is associated with each orisha such as fruit, stew, cake, and drinks. Live animal sacrifices are practiced to cleanse the soul and give strength. These rituals are performed quickly and cleanly in accordance with ritual rules. The blood of the animals is poured on the heads of new adherents during initiation ceremonies or sprinkled on sacred stones which symbolize the heads of the orishas. The sacrificed animal is cooked and the food offerings are eaten by the participants after they have been offered to the orishas.

Santería involves an elaborate system of rituals. Followers believe that the powers of the orishas reside inside stones. Water is thought to be a powerful defense against evil. Santeros may advise devotees to keep a bowl of water under the bed, to throw it out when no one is looking, and to change it every day. Another method of eliminating evil is to burn brown sugar and garlic skins and allow the smoke to permeate all corners and closets where it is believed evil spirits hide. Followers may also wear necklaces and bracelets given to them by santeros as protection against evil.

Dance and drum festivals, known as *bembe*, *guemileres*, or *tambores*, are held to honor the orishas and invite them to join by playing specific drums, performing dance, and acting out the behavior of the orishas in pantomime. Each orisha is associated with a specific drum rhythm and dance posture. These dances are used to attain a trancelike state of consciousness or spirit possession as a means to receiving the orishas' presence and to hear their advice, cautions, and reprimands.

Santería as a Health Care System

During the colonial period (sixteenth to nineteenth centuries), Cuba was a poor and undereducated country and sources of health care were scarce. Spanish and African folk healers and their pharmacopeias were the only sources of medicine available for the majority of the population, both Black and White. During the Cuban Republic (1902–1959), education and health care became more widespread. As a result of the new reliance on more traditional medicine, the Afro-Cuban practices shifted toward the treatment of personal crises and emotional problems.

Santería is still a source of health and healing for followers today. Santero and santera priests are consulted to advise on ailments ranging from physical to personal. The Santería model of disease espouses the connection between body and mind but also physical and social environment. In other words, causation for ailment may be blamed on harmful energies from friends, relatives, or wandering spirits seeking a host. During a consultation, Santero/a priests will seek assistance from the orishas to reach a diagnosis. The priest will then direct the client to eat certain fruits, vegetables, or plants to find relief.

Botánicas are often the source of health care products and informal health care services for followers of Santería as well as practitioners of other folk religions or healing such as spiritism or reiki. Sweet and bitter herbs sold in botánicas are usually prescribed by a healer and are used in teas, baths, or rubbing formula. Botánicas may have a separate room in which a healer provides consultations for clients. Santería as a health care system may be especially appealing to immigrants who adapt their practices through exposure to multicultural contexts, particularly in large cities where such services are available and affordable. Further, immigrants and followers of Santería may find health care through botánicas more accessible in contrast to the barriers of formal health care.

Today, there are more practitioners of Santería outside of Nigeria where now the majority of the population is either Christian or Muslim. High concentrations of Santería followers can be found in global cities throughout Europe, in North American locales such as New York and South Florida, as well as Puerto Rico, Venezuela, and Cuba. Santería is practiced by people of African and Latin descent and over the years has attracted new followers from diverse racial backgrounds and socioeconomic standing. It is difficult to determine accurately how many followers exist today. Santería has a long history of secrecy due to oppression and misunderstanding. Santería worship is mostly home-based and private although practitioners are slowly and cautiously practicing more openly. Many immigrants, especially Latin American and Caribbean, may find Santería to fulfill their need for a religious community. The beliefs and practice of Santería continue to evolve as some regions take on new characteristics such as Puerto Rican spiritism and ethical principles of Christianity.

Scale Validation

Curtis Tatsuoka
Neurological Outcomes Center, Case Western Reserve University, Cleveland, OH, USA

Scales that measure various components of health are an important manner through which to gain insight into the nature of underlying constructs that are of interest in evaluating health outcomes. Self-reported or rater-scored surveys can be used to measure a wide range of constructs, such as quality of life, health beliefs, depression or anxiety, etc. Scales are generally most appropriate for constructs that can be viewed or summarized as being unidimensional, in the sense that the possible conditions or states within the construct can be meaningfully represented as a range of scale scores within some interval. Further, there should exist some type of ordering between the states or conditions that should be reflected by the values. For instance, if measuring some aspect of quality of life, those with relatively high quality of life should have higher scale scores than those with lower quality of life. Generally, scale scores are derived from item responses that are individually scored in some manner, resulting in a summary score that reflects the relative state or condition within the construct.

Once a collection of survey items for a particular health construct has been developed, a scoring scheme must be in place for responses. This can be built in, such as by using Likert scales, with responses being associated with numerical values (e.g., "1" is "poor,"... ,"5" is "excellent"). Scale scores generally represent a summary of the item responses, such as total sum of item scores. Certainly, there can be more complex scoring schemes, like those used in advanced psychometric methods such as Item Response Theory, where item response scores are differentially weighted when estimating a score value. Once items and a scoring scheme have been developed for a scale, it then becomes essential to validate important psychometric properties of this instrument. These include establishing whether the scores are stable across administrations of the scale given that the condition or state of the subject has not changed, verifying that the underlying construct is actually being measured by the scale, and determining whether the scale is sensitive enough to reflect that a subject's state or condition has changed. These key properties are respectively referred to as reliability, construct, and discriminant validity. Once a first version of a scale is developed, the next step in formal validation will be to administer it to individuals, and analyze response data to assess its psychometric properties. This process may be iterative (repeated several times), with items and/or scoring schemes adjusted to improve psychometric aspects of the scale. These properties can be assessed as follows.

Reliability involves studying the measurement variability associated with the scale. For instance, when the state or condition associated with a construct is stable, it is desirable for similar scores to arise from measurement. This would indicate that the measurement score does not have large within-subject variability. To establish this, the associated survey is administered on at least two occasions to the same people within an appropriate time frame, keeping all sources of variability to a minimum, such as ensuring that a participant's state is stable and making the environment is similar during both occasions. One can then determine the reliability of the scale by gauging the variability between these same subject measurements. Given a same construct being measured, larger number of items administered should lead to more reliable measurement.

Construct validity relates to the degree to which a scale measures the target construct (Does the scale measure what it is supposed to measure?). There are various possible approaches in establishing this. One approach is to link scores to an observable variable that is hypothesized to be related to the construct. Higher (or lower) values of the variable are expected for those at higher levels of the construct. A common variable for comparison is a legacy measure (a measure that has already been developed and used) that was designed to measure a related construct. Also, clinically available information may be useful when studying populations affected by particular health conditions. For instance, an assumption can be made for a quality of life measure that the greater the severity of a particular disease the more diminished the individual's level of quality of life. It will be of interest to establish this statistically by examining the relationship between scale scores and clinical indicators of disease severity. If the expected relationship appears to exist, construct validity for the scale is supported.

Internal consistency is the extent to which a collection of items measures a same construct. A high level of internal consistency, expressed statistically, for instance, by a statistic called Cronbach's Alpha or correlations, is anticipated when all the items comprising the scale measure a single, unidimensional construct. Establishing high internal consistency is an indirect form of construct validity, in that it gives indication that a scale is measuring a single construct. Groupings of items to be associated with a particular construct can be identified through exploratory factor analysis or by expert opinion.

The responsiveness of a scale is a property that refers to its ability to detect changes in a state or condition that are clinically important. Again, a measure is administered on two occasions at an appropriate time frame, so that a number of subjects will undergo a change in state or condition. It becomes very much of interest to see if respective scale scores change as well, particularly in relation to the variability of within subject measurements. If a scale is to be used as a primary outcome measure in clinical studies, then determining a minimally significant difference in scores that reflects meaningful clinical change is useful. For example, this value can be used in identifying a target effect size for power analyses.

A potentially important application in scale validation for immigrant health research is the translation of an existing measure into another language. In these situations, the same validation issues as discussed previously arise. Further, one may also want to equate the scores on a translated measure to those of the original measure. An area of psychometrics called equating deals with understanding how to convert scores on one measure to psychometrically equivalent scores for another measure. As a final note, the scope of validity of a scale should be recognized, and this relates to the understanding the population characteristics from which responses were sampled. For instance, if item responses and scale scores from participants with a particular health condition are used in validation, then the scale's validity is established for that particular population and may not hold more generally.

Schizophrenia

Frederick W. Hickling
Caribbean Institute of Mental Health and Substance Abuse (CARIMENSA), University of the West Indies, Mona, Kingston, Jamaica

Schizophrenia is a chronic enduring mental illness falling under the psychiatric classification of the *psychoses*. Psychoses are mental illnesses in which the person's organization of his or her thoughts and the person's ability to recognize reality are severely impaired. Schizophrenia is characterized by disturbances in perception, thought, and behavior, with features of hallucinations (false sensory perceptions), delusions (fixed, false beliefs), bizarre thought and behavior. Schizophrenia begins most commonly in adolescence or early adulthood. Without appropriate treatment it often progresses into a chronic enduring condition characterized by significant social and cognitive impairment. The pioneering scientific study linking the increased occurrence of schizophrenia in White Norwegian migrants to Minneapolis in the USA was published in 1932. The dramatic increase of migration to First World countries in the past century has catalyzed the plethora of studies of migration and mental illness. A review in 1987 of the findings of more than 100 studies of migration and psychopathology identified an increased rate of schizophrenia in migrants by a factor of 2, over the native population of the host country. (The annual incidence of schizophrenia ranges from 0.5 to 5 per 10,000.)

Significant resources have been invested in the research study of schizophrenia in migrant populations particularly in Europe. A recent review of the studies reported the excess incidence of psychosis in African-Caribbean migrants to the United Kingdom, confirming the reported risk ratios of 2–18 times the rate of schizophrenia of these Black immigrants and their second and third generation offsprings. Unlike the initial study of White migrants to a White country, the risk ratio for schizophrenia in second and third generation African-Caribbean migrants to Britain was increased rather than decreased. A meta-analysis in 2005 of 12 studies from the UK, three from Holland, one from Sweden, and one from Denmark estimated the relative risk of schizophrenia associated with immigration to be 2.7 (95% CI: 2.3–3.2) for first generation immigrants and 4.5 (95% CI: 1.5–13.1) for second generation immigrants compared with the native-born population. Another meta-analysis in 2010 also suggested that immigrants had an increased risk for schizophrenia in countries of longstanding immigration, but with lower risk for those of recent immigration. This study suggested that the risk was higher in Black immigrants and in the Black population living in the United States.

The elevated risk ratios of schizophrenia in Black immigrants to the UK were reported in the 1980s and 1990s, with the wide-ranging speculation as to the cause of this finding leading to the watershed study of the incidence of schizophrenia in Jamaica. Hickling & Rodgers-Johnson demonstrated an age-corrected schizophrenia incidence rate for Jamaicans of 2.09 per 10,000 and suggested that the findings of the British studies for Blacks in the UK are either a methodological artifact or are due to major etiological factors specific to African-Caribbean people living in the UK. The 2010 meta-analysis indicated that the three studies in the English-speaking Caribbean countries of Jamaica, Trinidad, and Barbados, using the same methodology as that used in the British studies, found similar rates to those observed in native White British in the UK. This meta-analysis also reported that the two studies in the Dutch-speaking Netherlands Antilles identified rates comparable to those observed in native Holland.

A study in 1996 in Jamaica compared the psychiatric diagnoses of White mentally ill immigrants to that country with the diagnoses of a sample of Jamaicans matched for age, sex, and social class, who had never migrated. This study reported that White mentally ill immigrants to Jamaica did not develop schizophrenia at a higher rate than the native-born. This result runs contrary to the consistent finding of increased rates of schizophrenia in immigrant populations. This study also showed that for this cohort of White immigrants, migration created a condition of immediate and marked upward social mobility in the host country, Jamaica, a factor which rarely if ever occurs for immigrants, whether Black or White, to White First World countries.

All of the meta-analytic studies that have emerged from White European or North American countries have suggested a hidden epidemic of schizophrenia in the immigrant populations of Europe and North America. These studies have given rise to a plethora of possible etiologic reasons for this putative epidemic. McGrath, in a guest editorial, agreed that migration is a stressful event, and that stigma and racism can contribute to adverse health. The editorial also supported the suggestion that the possible etiologic cause of this acknowledged epidemic of schizophrenia in Black immigrants in predominantly White countries perhaps lies in the neurodevelopment deficiency of vitamin D for Blacks living in predominantly White countries. It was suggested that it is time to examine through clinical trials the efficacy of vitamin D supplements in the prevention of schizophrenia.

The hypothesis advanced following the only study of White immigration to a predominantly Black country was alternatively linked to socio-political stress as the more favored etiologic factor. This study suggested that political/economic system in predominantly Black post-colonial countries like Jamaica protects White immigrants from the social stress of migration, which is associated with schizophrenia in migrant groups in predominantly White societies. It was suggested that the converse may also be true, namely, that the socio-economic and political structure of White First World countries may contain built-in conditions which predispose both Black and White migrants to downward social mobility, creating a psychosocial stress factor which is predisposing to the development of schizophrenia.

Screening

Ecaterina Mariana Enache
Department of Microbiology, University of Medicine and Pharmacy “Gr. T. Popa”, Iasi, Romania

Screening refers to a test that identifies factors associated with a certain medical condition or predisposition to diseases or that can lead to diseases for offspring. Basically it is done in order to determine whether a condition exists even before any symptoms begin.

Screening in the Clinical Context

In the context of clinical care, it is often conducted to assess the risk of breast cancer and cervical cancer, prostate cancer, colorectal cancer, high blood pressure, metabolic diseases such as diabetes and high cholesterol, and genetically transmitted diseases. Screening will be increased if the screening test is valid, easy, accessible, and noninvasive and if it is not costly.

Screening will distinguish between persons who have a specified disease, those who have a possibility to have it in the future, and those who are healthy carriers of a gene that they may pass to their children, who may then be at elevated risk of developing that disease. Screening can also be utilized to establish the prevalence of a certain condition in general population.

The screening process can be divided into three phases: preparing the patient or participant for the test, sample analysis, and interpretation of test results and information management. The patient will receive information regarding the disease (*How serious is it? What is the mode of transmission* (*autosomal dominant or recessive*)*? What are the complications? What is the significance of carrier status? What are the possibilities of treatment, if any?*; test procedures; issues related to the test (the test validity, sensitivity, and predictive value); and information on the implications of a positive or negative result. The patient will also receive information about the likelihood of correct predictions, the individual and family implications of test results, the availability of alternative tests, the potential risks and benefits of tests, and potential implications of the tests for insurance.

Analysis of the test samples depends on the type of disease for which the test is being conducted. The samples to be collected vary depending on the disease. For example, blood is taken for genetic tests and metabolic disorders and biopsies are conducted for cancer. The interpretation of test results and information management is done by a specialist in the particular medical specialty. Depending upon the particular situation, the specialist may discuss with the patient the possibility of treatment, only monitoring the patient, or pregnancy or abortion. Sometimes genetic counseling may be necessary as well.

Screening programs have many advantages and disadvantages. Many are very expensive and require significant resources, such as medical staff and laboratory technology, but they are clearly necessary. This is particularly true when the disease can be diagnosed before birth, the disease occurs frequently and is severe, and when there is the possibility of effective and acceptable treatment. Disadvantages also include the possibility of false-positive and false-negative results and the costs associated with their use by large numbers of individuals who may not be at risk for the particular disease and who will not need treatment. Additional concerns include the adverse effects associated with undergoing screening procedures, such as stress, anxiety, discomfort, radiation exposure, and chemical exposure.

The greatest advantage of screening may be the detection of medical conditions at an early stage before symptoms occur while treatment is more effective or when preventive measures can be applied. Screening can detect medical conditions of parents that can be transmitted to their children. In this case, future parents can make informed decisions regarding their procreative actions. In some cases, screening results can influence decisions about marriage for some communities, for example, Tay Sachs disease in the case of Askenazic Jews.

Screening may be recommended at varying points in time. It can be prenatal, as in pregnant women over the age of 35 years to detect neural tube defects or Down syndrome in the fetus; neonatal for phenylketonuria, congenital hypothyroidism, and galactosemia; and in adults, for multifactorial diseases such as osteoporosis and cancer. Screening for diseases such as Down syndrome, phenylketonuria, and galactosemia is not mandatory in most of the countries.

Screening in the Immigration Context

Many countries have implemented screening procedures in the immigration context to screen prospective immigrants for specified diseases. Most frequently, such screening is conducted for syphilis, tuberculosis, and HIV. As an example, the USA, Canada, and the UK screen individuals seeking permanent resident status for tuberculosis and syphilis. At one time, the USA also screened prospective immigrants for HIV. Depending upon the particular country to which someone intends to immigrate, the individual may also be screened for a variety of other infectious diseases, including schistosomiasis, filariasis, and strongyloidiasis.

Many countries are also concerned about whether an illness may impact a prospective immigrant's ability to earn a living and support himself or herself. For example, New Zealand's immigration forms include the question: "*Do you have any physical/mental/communication/developmental/intellectual disabilities which may affect your ability to earn a living or take full care of yourself?*" The USA asks a similar question of individuals intending to immigrate to the country.

Secondary Data Analysis

Curtis Tatsuoka
Neurological Outcomes Center, Case Western Reserve University, Cleveland, OH, USA

Secondary data analysis involves the reanalysis of existing data to study research questions that were not necessarily foreseen when the data was collected. In contrast, obtaining primary data involves the researcher collecting data directly from subjects. Secondary data is available in many forms, and offers an important way to advance research and knowledge. A major example of a data set that has been used for secondary analysis is the US Census. Other important data sets are collected at the US Federal government level. For instance, through the National Council on Health Statistics, publicly available data are collected on vital records, and surveys are collected on a range of important health and health care policy issues. With the advent and importance placed on electronic data collection, electronic medical records have become another source of large-scale data. A constraint in immigrant health research using secondary data is whether or not immigration status can be ascertained.

There are several attractive aspects to secondary data analysis. First, extensive and rich data can be readily available, at little or no cost. Also, sample sizes may be very large, so that important patterns of specialized interest such as ethnic minorities may be detectable. In contrast, primary data collection usually involves careful design, exhaustive and time-consuming effort, and is often expensive. Sample sizes are generally not large, due to financial constraints, and access to subjects that satisfy specific inclusion criteria and are agreeable to participate in a study can be limited as well.

There are also possible drawbacks and pitfalls to secondary data analysis. For instance, specific types or precision levels of data that may be important for an analysis may not be available. While proxy variables may be identified, this may require accepting compromises in terms of preferred exactness. A related issue is the identification of the scope of sampling that was conducted for the data. It must be determined if populations of interest are included in a data set, and can be identified. Also, sampling schemes may be complicated, with data collected from the same families or through community networks. Data records from subjects may thus not be statistically independent, but rather a correlated cluster structure exists. Ignoring this type of correlation could have serious consequences for the validity of the statistical inferences, so they must be identified, if it all possible from the secondary data set. Further, some subgroups may be oversampled relative to their population frequency, so that the data are not representative of the target population of interest. Weighting schemes for the samples may need to be implemented.

Advantages for primary data collection include being able to implement measurement approaches specifically tailored for the research questions of interest. Data can be collected in a range of manners considered best suited for the study, such as through surveys, structured interviews, or careful review of medical records. Specific variables of interest can be targeted, and issues in dealing with immigrant populations, such as language barriers, can be addressed. Sampling designs can be carefully considered, and correlated cluster structures easily identified and accounted for in analyses. Also, careful safeguards can be put in place to monitor data quality, and overseen firsthand. For secondary data, it may be unclear how rigorously data checking mechanisms were implemented, or how missing data arose.

In sum, secondary analysis can be a useful approach to answering research questions and may be a particularly useful way of evaluating health outcomes among immigrant or ethnic minority groups who are represented in large databases. It may be especially useful for allowing exploratory analysis of hypotheses before primary data collection is conducted. It also can be used for comparison with analyses based on primary data.

Secondary Education

Sara Hirschfeld Lee[1], Rina Lazebnik[2]
[1]Department of Pediatrics and Adolescent Medicine, Rainbow Babies and Children's Hospital, Cleveland, OH, USA
[2]Division of General Pediatrics and Adolescent Medicine, Rainbow Babies and Children's Hospital, Cleveland, OH, USA

Immigrant students are among the fastest growing population in public schools in the United States. If current immigration patterns continue, it is estimated that immigrant youth will make up 30% of the nation's school population by 2015.

Immigrant youth face a number of developmental and health challenges during their secondary education. In the United States, a number of immunizations are required for school entry, including diphtheria, tetanus, pertussis, measles, mumps, rubella, and polio. Obtaining these immunizations, or proof of these immunizations, may be difficult for newly arrived families with limited access to health care and language difficulties. Schools also usually require a general physical examination, as well as vision and hearing screening, which again could be difficult for families to obtain.

Immigrant youth have higher rates of poverty – over a third of immigrant families have difficulty affording food. Hungry students have difficulty concentrating. Immigrant adolescents may have higher rates of sleep disorders, anxiety, and depression – all of which can interfere with learning. Depending on the quality of medical care and education services in their country of origin, immigrant youth may arrive at secondary schools with undiagnosed learning disabilities.

Even before arriving at school, immigrant youth face challenges to their education. Many immigrant youth arrive with significant gaps in their formal schooling. They may have been out of school because of war, natural disasters, or time spent in refugee camps. Female youth may be from countries where girls were not provided with an education. These students may not be literate in their native language, making English literacy even more difficult.

Cognitively, younger adolescents are initially capable of mainly concrete thought and are unable to perceive the long-range consequences of their decisions. As their brains develop, they establish abstract thought processes and become more focused on the future. Immigrant youth must accomplish this developmental task while learning a new language. Becoming proficient in English – the biggest education challenge – can take 5–7 years. Studies show that immigrant youth who perceive themselves as not speaking English well are more likely to drop out of school. Immigrant adolescents must not only learn English, but they are also expected to master more complex academic content to keep up with their peers. Immigrant youth who live in homes with limited English proficiency are less likely to develop proficiency themselves and are more likely to leave school, to be behind a grade or more, or to never have been enrolled in school at all.

Despite these disadvantages, one strong advantage immigrant youth have is the high educational goals immigrant parents tend to have for their children and the high value they place on the educational opportunities offered to their children in the United States. However, parents themselves may have little formal education and may have difficulty helping with schoolwork. Parents also may place less value on the theoretical ideas learned in high school and question why more practical skills are not being taught. They also can be intimidated by the school system; that intimidation, combined with language difficulties and a work schedule that may not allow them to participate in parent–teacher conferences, can make advocating for their child difficult.

Immigrant youth must often be their own advocates. Adolescence is a time of physical and psychosocial maturation, and as youth become adults they begin to develop independence. Immigrant adolescents must adjust to a new culture and acquire a new language. In doing so, they begin the separation from their parents and their original culture. Achieving independence and a coherent sense of self can be more challenging for immigrant adolescents because they feel like they are leaving behind their old world as they enter a new one.

Immigrant youth also use school to develop peer groups. In early and middle adolescence, peer groups appear to take precedence over family as adolescents look to friends to help with self-image and behavioral codes. For immigrant youth, peer groups offer a sense of belonging. Those who do not find friends feel excluded and are vulnerable to bullying. Many immigrant parents do not understand the importance of peer groups or of extracurricular activities. They expect their adolescents to be working at jobs or to be home taking care of the smaller children.

Many alternative programs exist to address the unique challenges in educating immigrant youth. Typical ESL (English as a Second Language) programs can alienate immigrant youth and increase the likelihood of discrimination. Newcomer centers, flexible schooling, and transitional high schools are some of the more recent options that exist for secondary education of immigrant youth.

Segregation

Yolisha Singh
Manakau City, New Zealand

Humankind's phenomenal progress over the last 50 years has literally made the world a smaller place – technological advancement and accessibility as well as political momentum and change have played a large role in the development of global communities. This migration has resulted in a surge of large ethnically diverse migrant communities in most metropolitan cities. This in turn has placed a burden on government services and the ability of governments to adapt and cater to the needs of a much more diverse population.

With this ethnic and cultural diversity are intertwined the associated issues of segregation and acculturation. Segregation is defined as the separation of people based on race, religion, ethnic group, sex, or social class. Acculturation is the assimilation of one culture into a dominant culture. It has been considered that such acculturation may have certain benefits for society by minimizing inherent differences and a first step to consistent service provision methodology and policy. However, the acculturation of migrants to domestic culture has proven to be a slow and costly process and within certain xenophobic cultures the problem is exacerbated. This results in disparity of service provision to these communities across the service spectrum either as a result of lack of understanding, and improper access mediums.

Focusing on the health sector, a synopsis of current health segregation research makes it clear that there are various segregation dimensions to be considered, among them: residential segregation, income segregation, and racial/ethnic segregation. Dolores and colleagues explain residential segregation as being segregation in regard to the composition and spatial distribution of an entire metropolitan area.

Racial or ethnic segregation means that based on race (or alleged race), persons are restricted to either separate institutions/facilities or residences. This practice has historically occurred in Asia, Africa, and America, and works to maintain the many advantages of the race in power. Two former well-known systems of racial segregation include: South Africa's Apartheid system which sanctioned discrimination against non-Whites (including not only Blacks but also Indians and others) as well as the Southern American states after the American Civil War.

These contributory factors impact on: medical service access, patient expectations, and health outcomes. This is illustrated by a number of studies in various parts of the world. For example, in New Zealand, these have been concentrated on the Pacific Island and Asian populations. In New Zealand, the Asian population is 9.5% of the total population making them a significant portion of population. They show across the board a low level of health access with Asian-born Kiwis showing the lowest level of access. It was found that access, mental health, and levels of physical activity are major concerns that need to be addressed in order to provide the correct health service to this sector of the population. The NZASIA study on lack of cervical screening in Asian women also highlighted the impact of segregation and cultural differences on health care access. Another study by Gilbert et al. demonstrated a negative association between reports of discrimination and mental health status, among Black and Latino immigrants.

The New Zealand health system is largely community-focused, and many of the health sectors encourage in-community treatment in order to facilitate reintegration. However, with the influx of migrants and the development of migrant communities, there is now a larger need to understand the space and the community. Residential segregation has been considered as one dimension that contributes to the differentials in access and health outcomes. However, a conceptual framework considering segregation and health outcomes is imperative. A multilevel approach for research designs will allow the study of the impact of individual, neighborhood, and metropolitan area factors on health outcomes.

The following recommendations have been made to curb segregation negativities to service provision access and outcomes: inclusion of mental health measures in NZ Settlement research, collaborations between service providers, researchers and members of migrant communities, and dissemination of research to all key stakeholders.

It becomes evident that segregation has an impact on health outcomes, patient expectations as well as service access. However, the impact may indeed be positive. Some speculate on the potential positive impact of cultural differences. The example of the Pacific Island population is used to emphasize this. If socioeconomic factors were the only drivers of ethnic differences in mortality rates, then the Pacific Island population should have the highest mortality rate – however, they show a rate intermediate between that of Maori and non-Maori non-Pacific people in New Zealand. This could be a result of their cultural protection from the full impact of their socioeconomic position, and acculturation could increase the "culture capital" of the community. This will be useful in policy options for service provision within these communities.

Lorent et al. wrote that "although segregation is generally considered to be detrimental, some studies have shown that ethnic concentration provides advantages such as nurturing social contacts, improved job opportunities and integration of newly arrived immigrants." The Roseto effect, from the name of an Italian community in the United States, indicates that collective social functioning may influence health. Thus, some communities may be protected against surges in disease related to their social cohesion.

The extant literature recognizes the impact of segregation in the health sector, the potential for both positive and negative influences that need to be researched further, the need for a broader conceptual framework, and the inclusion of all stakeholders as part of the research and implementation process. There is therefore a clear need for further research on specific migrant communities to assess, first their inherent access traits and service expectations. Second, these need to be considered on several segregation dimensions in order to assess the positive and negative impacts that these factors may have. Finally, based on these findings, well-informed policy may then be developed to improve medical access levels, and overall health outcomes.

Self-Concept

Krystle J. Rivera, Amy Kerivan Marks
Department of Psychology, Suffolk University, Boston, MA, USA

The formation and preservation of self-concept is a fundamental aspect of human development that can present unique challenges for immigrants. The nature of the self and how individuals behave depends to a large extent on the patterns of action and interaction in the society in which they live. Children, adolescents, and adults each face different obstacles in the establishment of the sense of self, particularly when moving from one culture to another. Self-concept has been found to be correlated with mental and physical health, and as a result of the struggles many immigrants face, negative self-concept can sometimes develop, decreasing their quality of life. There are a number of ways to cope with this effect on both an individual and a systemic level. When providing education, social services, or medical and mental health treatment, an understanding of basic trends in self-concept and the ways in which people's views of themselves change throughout the acculturation process can be extremely valuable.

Definitions and Theories of Self-Concept

Self-concept can be defined as a complex, learned, multidimensional system of beliefs, attitudes, and opinions that each person holds about him or herself. This construct is a culmination of cognitions, feelings, and observations about one's self, assessments of the way others perceive and act toward the individual, judgments of other people's behaviors, and evaluations of personal historical narratives and ambitions for the future. Self-worth, self-efficacy, ethnic identity, and metacognition can all be aspects of an individual's self-concept. A variety of traits, characteristics, and likes and dislikes make up the self-concept, including gender roles and sexuality, cultural identity, romantic relationships, family expectations, academic achievement, career goals, and hobbies. Self-concept can evolve over time, particularly when undergoing extreme stress.

Theorists throughout history have had different ways of conceptualizing the self. William James described self-concept as being made up of a material or physical self, a social self, and a spiritual self, and wrote that people have as many social selves as there are individuals to recognize them. George Mead hypothesized that self-concept arises through social interactions as an outgrowth of the individual's concern about others' reactions, and also that there are as many selves as there are social roles. Some of these roles are thought to be of considerable significance for the individual across multiple domains, while others are specific to particular situations and settings. Carl Rogers' theory places the self as the central ingredient in personality and adjustment, and is based on a belief that there is a basic human need for positive regard from both oneself and others. Harry S. Sullivan further postulated that it is the interaction between a child and caregiver, particularly the mother, that is of utmost importance, as children internalize the values and prohibitions that receive approval from significant others. At the core, most theorists see self-concept as a learned, socially influenced way of seeing one's self in terms of values, roles, interests, goals, and relationships that influence behavior and life choices.

Formation and Transformation of Self-Concept

Over the course of one's life, individuals go through a process of consolidating and reintegrating the different components that make up their self and world view. During transitional periods, a person's awareness of the social and historical context of his or her life, aspirations for the future, character traits, struggles, and successes are all important in facilitating the capacity to deal with the developmental tasks specific to that particular stage. Two of the aspects of the self that help people organize, coordinate, examine, and understand their experiences are unity, the degree to which the person's experiences are interrelated and have meaning, and continuity, the degree to which the individual experiences oneself as the same person during these transitions. Related to these factors is the capacity to represent and reflect on thoughts and feelings in both the self and in others, and to show empathic understanding of one's experiences.

At the start of the lifespan, children's perceptions of their abilities affect their values, self-regard, and beliefs about their competence to achieve personal and academic goals. These beliefs are derived from interactions with the environment and significant others, and is shaped by both cultural and biological factors. As individuals transition through adolescence and into adulthood, the self-concept becomes more complex, due to the need to continuously reorganize the self to cope with change and increased demands, responsibilities, and role expectations. In stressful, anxiety-provoking situations, an individual's personality functioning and the stability of his or her psychic organization is put to the test. Once a crisis is resolved, emotional growth can occur; however, if conflicts are not resolved successfully, stagnation or psychopathology can occur. Throughout different developmental stages, the task is to reintegrate the internal world and reshape the self-concept based on interaction with new environments and new experiences.

The Impact of Self-Concept on Health

A number of physical and mental health factors have been associated with self-concept. Adults with positive self-concept tend to see themselves as healthier and more productive, with more control over their fitness, compared to their peers with negative self-concepts. These adults may be more likely to make healthy choices congruent with their views of themselves. For adolescents, positive self-concept has been associated with strong communication skills, academic success, and respect for authority. Adolescents with negative self-concepts have been found to have a higher risk for delinquency, depression, smoking and substance use, physical inactivity, and obesity. In general, people with a strong self-concept are more likely to be active, engage in self-care, and avoid risky behavior, all of which improve health and well-being.

Specific Challenges for Adolescent and Young Adult Immigrants

Much like the process of emerging adulthood, immigration has been described as a time of psychological flux demanding a need to reorganize the self. Historical perspectives held that immigration could be seen as a trauma that leads to “culture shock,” or a state of mourning the loss of a variety of love objects in the abandoned culture coupled with changes in identity that occur in the face of a new culture. A splitting of the self would occur in which immigrants are caught between their old selves and their attempts to adapt to the huge changes experienced in the transition to a new culture. The “sense of coherence” of the self is confidence that internal and external environments are predictable and that one has the inner resources needed to meet environmental demands, which can be threatened by immigration. The stressors following immigration can be particularly difficult for adolescents simultaneously trying to cope with a complex developmental phase. Learning a new language and cultural norms, dealing with new stimuli, confronting reactions of the host population, and coping with the myriad of emotions awaken by this process demand physical and emotional energy and time. Contemporary scholars see adolescence as a chance for immigrant youth to incorporate the values of cultural and family traditions, as well as those of the school, community, and workplace into their self-concept.

The values of collectivism and individualism vary across cultures, and can have a significant impact on the sense of self in young immigrants. In individualistic cultures, a high value is placed on sovereignty, self-sufficiency, personal goals and achievements, and having control over one’s own life. The quest for independence from parents is thought to be a typical adolescent developmental process, and pursuing one’s own dreams is emphasized. In more collectivistic cultures, personal meaning is derived from the coexistence of others, the needs of the group come before the individual, and connection to one’s family is an essential part of self-concept. In these cultures, striving for independence may not be a central focus, and if transitioning to a more individualistic society, the values placed on the self versus others can come into direct conflict. Despite this conflict, collectivism can be an asset and protective factor for ethnic minority families, especially under conditions of racism, immigration, or poverty. An alternative view of collectivism and individualism is that these are not two mutually exclusive constructs, but rather interacting qualities that work together in both individual and relational development. When working with immigrant populations, it is essential to have an understanding of and respect for the values of the culture from which they came, and to avoid imposing one’s own views on what is considered optimal development. At the same time, it is also important to be cognizant of the specific pressures placed on individuals in the host culture, and to be aware of the difficulties immigrants may face in the maintenance of self-concept.

Navigating the Process of Change in the Self-Concept of Emerging Adults

A loss of feelings of belonging and competence can be particularly damaging to young people trying to assert themselves as competent and masterful. Especially in individualistic societies, with adulthood comes an expectation of becoming responsible for attaining goals and relinquishing childish dependence upon parents. Developing a personal authority that reflects a young person's growing responsibility for their life improves the ability to make goals and commitments. Some degree of independence from parents combined with parental support is necessary to accomplish the developmental tasks of this stage. However, the nature of relationships between children and parents can take on different patterns in immigrant families.

Along with individual developmental tasks of adolescents, young immigrants often have responsibilities and obligations including helping the family financially, advising and translating for parents, and taking care of siblings. Greater expectations for assistance, support, and respect for the family can lead to a less consolidated and coherent sense of self compared to nonimmigrant peers, because keeping responsibilities to the family in mind can make it challenging for young adults to incorporate all of the different roles they play into their self-concept. Adolescent immigrants tend to be both more autonomous from their parents, taking on increased individual and family responsibilities, and simultaneously more connected to their parents, due to family obligations and needs. For immigrants, experiencing high levels of chronic stress and daily hassles impacts the sense of self, as it can be confusing to navigate expectations of multiple roles when personal values and desires are highly dependent on the needs of others. In order to maintain a healthy, adaptive self-concept, the tasks of emerging adulthood may need to be negotiated within a context of closeness with the family that has less emphasis on independence.

Catherine R. Cooper's Individuality and Connectedness model has been used to explore ways to bridge the multiple worlds that adolescents inhabit in order to strengthen their self-concept and motivation to succeed. Within this model, it is predicted that with enough support, adolescents can move toward achievement on behalf of both themselves and their families and communities. Self-concept can be built by examining the many worlds the individual inhabits in terms of expectations, experiences, behaviors, relationships, desires, and how each world overlaps or contrasts with the others. Educators can help these students find ways to pursue ideal lives and individual goals for themselves that include a sense of morals related to collectivistic values of family, community, and culture, as opposed to treating these adolescents as simply passive reactors to social, economic, and cultural forces.

Themes of Adjustment in Self-Concept

Individuals who migrate at later stages of development undergo more subtle and complex changes in self-concept compared to children and adolescents. Moving to a new country in adulthood with a sense of self that is closely linked to the culture of origin can lead to a number of different splits and reintegrations of the self. One theme that is often seen is moving from love or hate to ambivalence. Immigrants may hold "all-good" or "all-bad" conceptions of either the former country or the new culture, and idealizations and devaluations must be synthesized for healthy adjustment to occur and for both countries to be seen as multidimensional with positive and negative elements. A second theme is feelings of being "too close" or "too far" from either the old or the new culture, and a process of consolidating experiences can lead to a more optimal distance from each. A third split and reintegration is moving from a focus on the past or future to concentrating on the present. In these cases, there may initially be idealizations of the old country combined with longings to return in the future, and a resolution of this conflict can occur if the individuals can be mindful of the present and see a meaningful future in the new country. Finally, when transitioning to a new country, perceiving the new culture and customs as part of a "mine versus yours or us versus them" split can eventually be integrated into a "we and our" framework. During this process, new immigrants move from identifying totally with one culture and rejecting the other to feeling as if both cultures have become a part of who they are.

Adult immigrants may have a tendency for nostalgia and a need to mourn the loss of the old culture. In some cases, "ethnocentric withdrawal," clinging to an idealized view of one's earlier culture, or "counterphobic assimilation," a complete renouncement of the earlier culture, can occur. Nostalgia can lead to depression and a wish to return to something that was never there in the first place, and can block development and growth. In some circumstances, this can be a healthy, adaptive defense to protect the self from overwhelming anxiety, but in other cases, these defenses become pathological, preventing acculturation. Mourning the mental image of the lost culture may be necessary to move forward. Although this process may be painful in the moment, it is important and essential in the long run to better adapt to the new society.

Social Identity Theory and Strategies for Dealing with Negative Self-Concept

According to Tajfel and Turner's social identity theory, self-concept is largely shaped by group identification, and positive social identities are formed through favorable comparison of the individual's in-group against an out-group. Social identity theory is based on the assumption that there is a basic human need to belong, and people will strive to maintain a positive view of themselves and their own reference group. Being an immigrant can play a very important role in the conception of the self, as discrimination often works to shape and strengthen social identity. Negative self-concept is likely to develop through intergroup comparisons that result in feelings of deprivation and disadvantage, and when destructive stereotypes are internalized.

To ward off damaging effects of a negative self-concept and increase feelings of control, people may try to strengthen their self-concept through a variety of means, including individual mobility, social creativity, and social competition. The first coping mechanism, individual mobility, involves personal attempts to leave or dissociate from one's in-group. If their group is devalued, immigrants may try to distance themselves through acculturation and assimilation. Through upward social mobility, individuals attempt to move from a lower status to higher status group. Through social creativity, an individual may attempt to alter their perceptions instead of actions. There are a number of ways individuals use social creativity, including seeking new elements for intergroup evaluations, redefining existing elements, or selecting a lower-status reference group for comparison. Upward comparison within one's own group can be identity-enhancing, because it makes the group identity seem more positive and attractive. Conversely, the "black sheep effect" refers to the tendency for unlikable in-group members to be more negatively evaluated than unlikable out-group members. Changing the comparison group is another alternative. Instead of comparing to the dominant majority, an individual may make comparisons to other minorities or to other marginalized groups from the past.

The final coping mechanism, social competition, may be the most difficult to utilize, as it requires engagement in social action to promote changes in the status quo. These group actions, usually performed by people who have been living in the host culture for many years, may be used to gain acceptance from the majority culture. In these cases, social competition can be used to reject social inequality and promote collective actions to improve the condition of the group. Social action can influence in-group members to reduce behaviors that reinforce negative stereotypes. Attempting to change deviant behaviors of in-group members who impact the perceptions of the majority group can improve social status within the host culture.

Conclusion

Self-concept is complex, constantly evolving, and vulnerable to the experiences of immigration, acculturation, and assimilation for people of all ages. Although a number of different theories attempt to define and explain self-concept, one thing that remains consistent is the belief that self-concept can impact adjustment, psychological and physical health, quality of life, and important life decisions. The process of immigration can naturally bring about changes and re-integrations of the self and these transformations can be either adaptive or destructive. There are a number of ways in which immigrants can work toward modifying the old self into an integrated conceptualization that both respects and honors the culture of the past and incorporates new world values in a way that enables a successful, healthy transition.

Self-Medication

Jen Pylypa
Department of Sociology and Anthropology, Carleton University, Ottawa, ON, Canada

Globally, the majority of care in illness involves self-care, including self-medication without resort to a medical professional. Self-medication includes self-treatment with over-the-counter medications, herbal medicines and other "traditional" remedies, and – commonly in less-regulated contexts – prescription medications. In many immigrant source countries, "prescription" drugs such as antibiotics are easily obtainable without a prescription from pharmacies and community shops; informal medicine vendors may also sell imported prescription pharmaceuticals in countries with stricter vendor controls. Thus, immigrants may be accustomed to a wide range of self-medication practices. Self-medication is influenced by cultural knowledge, preferences, and familiarity with medicines and ailments; economics and access to health services, drugs, and sources of medicine knowledge; social relationships with family, friends, medicine vendors, and physicians who influence ideas about medicines and their uses; and other sources of information including advertising and health education.

Cultural practices guide medication use the world over, resulting in self-medication patterns among immigrants that may be different from the native-born population of a given nation and unfamiliar to local health providers. For example, in many parts of the world certain forms of medications are preferred, such as injections, which may be perceived to be stronger or faster-acting than pills and carry the potential infection risks of needle-sharing. Antibiotics may be perceived as appropriate for a broad range of ailments independent of bacterial infection; certain antibiotics may be associated with particular organs or symptoms, for example. Medication choices may be guided also by other cultural perceptions of medication efficacy. For example, humoral (hot-cold) theory is widespread globally, and may result in a preference for medications that are perceived as "hot" for "cold" ailments and vice versa, and a rejection of medications that are viewed as humorally inappropriate. For example, a "hot" medication such as penicillin might be seen as inappropriate for a "hot" illness such as a rash. Concerns about side effects may also be culture-specific and affect medication choices and uses. For example, Mexican immigrants in the USA describe vitamins and iron pills as inducing hunger, a side effect that may be desired (e.g., to make children eat) or avoided (e.g., to prevent weight gain) depending on the circumstances. Cultural and habitual guidelines for medication use also may determine the timing and dosage of medication consumption – for example, people may be accustomed to following "rules of thumb" such as taking medications in the morning, in the afternoon, and at night rather than every X number of hours.

A preference for certain familiar or trusted medications, or certain medication types or forms, may influence immigrants to import medications informally from their home countries for use in self-medication, including "prescription" medications obtained without consulting a physician. For example, in the United States, Mexican immigrants may border-cross into Mexico in order to buy Mexican oral antibiotics and other medications, or injectable medicines including antibiotics and vitamins. Even those whose countries of origin are more distant may import familiar medications from abroad, or they may have friends and family import medications. Such medications may also be sold "under the counter" in local shops owned by immigrants. Researchers in developed countries have expressed concerns about the quality, safety, and unregulated availability of some medications obtained from less-developed nations.

The practice of obtaining medications from abroad is encouraged by familiarity, cultural preferences, and experiences of efficacy associated with drugs from "back home." The practice is influenced also by the fact that immigrants may find it difficult to select, read, or interpret the proper use of unfamiliar over-the-counter medications in their new countries, especially given language barriers experienced by recent or elderly immigrants. Medications purchased abroad also may be less costly, as well as conveniently available without a prescription. Lack of health insurance and other barriers to health services use may encourage greater self-medication among immigrants than the general population, whether with pharmaceuticals purchased locally or abroad. In contrast, some recent immigrants lacking the necessary language skills, familiarity, and income to effectively select, purchase, and read the instructions on locally available over-the-counter medications may lack access to the ability to self-medicate easily for everyday ailments, impeding their use of appropriate self-care. Borrowing or reusing leftover prescription medications may be additional strategies used to compensate for a lack of familiarity with, or access to, locally available medications.

Herbal and other "traditional" remedies may be used in self-medication as well. While generational differences may occur, younger second-generation immigrants may also learn from their elders, resulting in intergenerational continuity in self-medication practices. Forms of traditional medicine employed by immigrants may include oral and topical preparations, self-prepared herbal medicines and commercial herbal products, as well as other treatment practices such as massage, other forms of physical manipulation, and spiritual healing. Home remedies may be used for ailments ranging from colds to severe and chronic conditions, and may be employed in combination with prescribed or over-the-counter pharmaceuticals. Informal practitioners from immigrant communities may be consulted also as sources of medicines and advice; these practitioners range from herbal experts to lay "injectionists" who inject medicines sometimes obtained from abroad. While "natural" home remedies may in some cases be preferred as a less toxic or dangerous alternative to pharmaceuticals, it is important to note that cosmopolitan medicines are extremely popular globally, and are commonly accompanied by expectations of the availability of a "pill for every ill" such that a wide range of drugs may be sought even for minor or self-limiting ailments.

Serologic Tests

Ecaterina Mariana Enache
Department of Microbiology, University of Medicine and Pharmacy "Gr. T. Popa", Iasi, Romania

Serologic tests refer to detection on antibodies present in serum using an antigen–antibody reaction.

Antibodies are formed in response to an infection (against a given microorganism), against other foreign proteins (mismatched blood transfusion), or to one's own proteins (autoimmune disease). The first use of the term "antibody" was in an article by Paul Ehrlich, "Experimental Studies on Immunity," published in October 1891. Antibodies (known as immunoglobulins) are gamma globulin proteins that are found in blood or other bodily fluids and are used by the immune system to identify and neutralize foreign substances entered into the body known as antigens, such as bacteria and viruses. Antibodies are produced by a kind of white blood cell called a plasma cell.

There are many categories of antibodies but, classically, IgM antibodies are specific for an acute phase of a disease, while IgG antibodies are specific for a chronic form or for exposure in the past to a certain antigen.

An antigen is generally any foreign substance (for example, whole bacterium or parts of it) that enters into the body, induces forming of antibody, and reacts specifically with it.

Serological tests are useful for the diagnosis of infections with bacteria that cannot be cultivated, on culture media (*Treponema pallidum*, *Mycobacterium leprae*) or can be cultivated with difficulty (*Chlamydia trachomatis*) when the site of infection cannot be reached in order to collect samples to perform direct diagnosis. These serologic tests have several advantages including the following: the test results are not influenced by therapy with antibiotics, the tests are easy to be performed (agglutination test, precipitation tests), are relatively cheap, and can be used both as diagnosis tests and confirmatory tests.

Disadvantages of this test include the time lag between onset of infection and the development of antibodies to the infecting microorganism resulting in the possibility for false negative results.

Methods used for serological tests that are commonly used in immigrant populations are: agglutinations tests, precipitation tests, complement fixation tests, hemmaglutinations tests, inhibition of hemaglutination tests, immunoflorescе, ELISA (Enzyme Linked Immunosorbent Assay), RIBA (Recombinant Immunobinding Assay)-Hepatitis C or WESTERN BLOT (HIV infection).

Sex Work and Sex Workers

Luciano Nigro
Department of Clinical and Molecular Biomedicine,
Parasitology Clinic, University of Catania, Catania,
Sicily, Italy

Sex work consists of engaging in sexual intercourse or performing other sex acts in exchange for money or favors. Sex work can be voluntary or forced through coercion or sex-trafficking. It can be empowering for those who make the active choice to engage in these activities, disempowering for those forced into this type of work against their will. Sex work can be a strategy for survival and in some cases for self-determination.

A sex worker is a person who works in the sex industry, such as prostitution or pornography among others. Some sex workers are paid to engage in sexually explicit behavior which involves varying degrees of physical contact with clients. A sex worker may be any combination of sex (male/female), gender (masculine/feminine/trans), and sexual identity (straight, bisexual, lesbian/gay.)

“Sex,” in contrast with “gender” underlines the social and cultural dimensions of masculine and feminine, and distinguishes between biology for the former, and society for the latter, and similarly between nature and culture.

“Trans” could mean many things: trans(s)exual, transgender, trans-amorous, trans-man, trans-woman, transfag, transdyke, male to female, female to male, genderqueer, intersex, pre-op, post-op, non-op, drag king, drag queen, gender-neutral, two-spirit, poly-gendered, boi, trans-partner, man, woman, or others.

Sex workers can and have been categorized using a number of methods.

The means of procuring clients: market sex workers (at the lowest rung of the earnings ladder); streetwalker (low, medium, high income worker); employed commercial such as massage parlor, bar, nightclub workers (low, medium, high income worker); freelancers and escort (medium, high income worker); phone sex operators (have sexually oriented conversations with clients, and do auditive sexual role play); web cam sex and performers in live sex shows; performers of erotic dances and other acts for an audience (striptease, go-go dancing, burlesque, peep shows).

The mode of employment: those working in the primitive labor market (persons who solicit in the street any time); those in the enterprise labor market (massage parlor and establishments); and those in self-employment (call-girls-boys-trans and social escorts).

Their pick-up mode: selected by clients viewing a group of women, along the streets, at entertainment or health center, through intermediaries such as pimps, procurers, or agents.

Their employment status: primary (with no other employment) or secondary (full time or occasional part time).

The sex of the customers and the sexual behavior that a sex worker engages in may not correspond to his/her sexual orientation.

In most countries, sex workers are stigmatized, discriminated, prosecuted, and harassed. Sex workers are commonly perceived as belonging to a social group which may engage in high-risk behavior for acquiring or transmitting HIV and other STIs. But in many parts of the world the reality may be quite different. It is difficult to determine precisely the incidence of HIV infection among sex workers, or the prevalence of safer sex practices during commercial sex transactions. Some limited studies have been carried out around the world over more than two decades of the HIV pandemic, and the results do not seem to confirm that sex work in itself significantly contributes to the spread of the infection. Like other marginalized populations, sex workers often receive scant attention from both public health officials and researchers. The stigma and the risk of criminal sanctions attached to sex work make reliable data hard to come by, and even more so for male and trans sex workers. According to research, the most common pathogens found in sex workers correspond to those that are highly prevalent in the general population. These were human immunodeficiency virus, *Neisseria gonorrhea*, *Chlamydia trachomatis*, *Treponema pallidum*, *Trichomonas vaginalis*, and Human papillomavirus.

Research has shown that in many developing regions of Africa and Asia, sexual relations with a greater number of partners and population mobility feature as principal factors for spread, transmission, and acquirement of STIs. This is especially relevant for sex workers who are often forced to leave their own country to work abroad. According to international data, most sex workers are illegal immigrants who find themselves living in very poor socio-hygienic conditions, which greatly limit their ability to seek access to information on available health services, prevention practices, and their legal rights. Consequently any access to healthcare services they may have is usually woefully inadequate. Language differences, the culture gap, and isolation from the local population make health-seeking behavior more difficult. To make matters worse, sex workers are not generally provided with targeted up-to-date information about prevention practices such as protected intercourse or safer sex.

Sexually Transmitted Diseases

LAURA GHEUCA SOLOVASTRU
Department of Dermatology, University of Medicine and Pharmacy "Gr. T. Popa", Iaşi, Romania

Sexually transmitted diseases (STDs) are one of the most common causes of illness among population of young age. They have major negative consequences on the health of affected individuals, on their reproductive potential, and on the communities which they come from. In this context it is true that each individual's choices are private matters, but one's sexual behavior may have significant implications for public health.

STDs have important social and economic implications. Every year, millions of young people reach the "reproductive age." Many do so in a safe, controlled way, being able to establish a balance between their goals, education, and sexual maturity, as essential, secure, and stable elements of human life. Nevertheless, instability and migration expose especially young people to an increased risk of unprotected sexual practices and STDs, such as HIV infection. In particular, the poor and uneducated people get to be involved in sexual activities without access to proper information and protection methods. Beyond socioeconomics, there are also various cultural and moral reasons for their lack of information. Throughout the world, there is evidence that informed people behave much more cautious than uninformed ones.

Historically, migration has been a major way in which diseases have spread. Infectious diseases usually spread farther and faster as transportation infrastructure is improved. The transmission pattern follows major routes and passes through international airports and seaports.

The more the people move, the faster the STDs are transmitted, just like other infectious diseases can spread. For instance, mobility itself has been considered an independent risk factor for HIV infection. While research results on the prevalence of STDs among migrant groups in different countries are still unclear and contradictory, classic studies show that the spread of HIV often coincides with migration patterns. Usually, HIV infection appears first in urban areas and then diffuses to rural areas along major road networks. A study in Kenya found that men who migrated between urban areas were more than twice as likely as nonmigrants to engage in high-risk sexual behavior – that is, to have more than one sex partner and to have sexual relations without using condoms. It was not clear whether their behavior was more risky because they moved or whether those who moved were prone to more risky sexual behavior than others.

Other factors may also increase risk for STDs in migrants and refugees. STDs spread most quickly in conditions of poverty, powerlessness, and social instability. Such conditions are often found in illegal immigrant communities, and even in legal ones. These people are underinsured at best, most of them having no financial resources for any health care plan at all. Also, immigrants often settle in areas with high prevalence of HIV infection, are exposed to intravenous drug use, and may be in poor health. The disruption of social ties and family life that occurs during migration, especially in situations of poverty and crisis, increases the risk of STDs, as immigrants could find new sex partners. Sometimes people have no choice but to sell sex for protection, money, food, and other goods.

During the last 30 years, population mobility both within and across national boundaries has increased dramatically all over the world. All mobile populations that are sexually active are at increased risk of acquiring STDs. The risk of acquiring an STD may be enhanced by poor understanding of the global epidemiology of these infections and the means available to mitigate risk. Rates of STDs may be elevated among migrant and marginalized populations (e.g., refugees, internally displaced, street youth). These populations may be overrepresented among commercial sex workers in many countries.

STDs are among the most frequent transmitted infections worldwide, the rates of the STDs being particularly high in developing areas. In 1990, the World Health Organization estimated the global burden of curable STDs at more than 250 million cases (syphilis, gonorrhea, chlamydia, and trichomonas). Estimates rose to 340 million new cases of STDs in 1999 and they included 151 million cases in South/Southeast Asia, 38 million cases in Latin America, and 69 million cases in Africa. In many countries, these increasing figures have been fueled by the economic and societal disruption of the HIV pandemic. In sub-Saharan Africa, in particular, there has been an explosive growth in the number of children who have lost one or both parents to AIDS (about 14–20 million in 2000). Many of these children have been driven to trade sex for food in order to survive.

More than 20 different infectious agents can be acquired and/or spread by various types of sexual contact (e.g., vaginal, anal, oral-genital/oral-anal). *Chlamydia trachomatis* is the most prevalent bacterial STD worldwide but prevalence rates for many of these infectious agents still vary widely by geographic region, for example, *lymphogranuloma venereum* is common in Southeast Asia, Africa, Central America, and the Caribbean, accounting for 2–10% of genital ulcers in India and Africa; chancroid is also common in many of the world's poorest regions such as areas of Africa, Asia, and the Caribbean, while rarely reported in the United States. Yet, changes in migration, immigration, and travel patterns during the last 50 years have ensured that almost any STD can be acquired anywhere in the world.

Many of the people who move frequently, including truck drivers and other transportation workers, sex workers, and seasonal agricultural workers and other temporary immigrants have a high risk of STDs. Although not considered temporary immigrants, long-distance truck drivers are of particular concern to disease-control programs because they are often at high risk and can spread STDs over long distances. They travel frequently, often to areas with high levels of STDs and, because they are away from home for long periods of time, they may have many different sex partners.

For example, in a survey among 400 West Bengal long-distance truck drivers, more than 60% reported having visited sex workers, 36% had never heard of AIDS, and only 22% were regular users of condoms. About one-half of truck drivers arriving in Kigali, Rwanda, from Mombassa and Nairobi, Kenya, were HIV-positive, according to a 1994 study. In a study of 200 adolescents who frequented truck stops in Kenya, half the boys and almost one-third of the girls reported having had at least one STD.

Many sex workers move from place to place, whether voluntarily or involuntarily. For example, women from Cambodia, Laos, Myanmar, and Vietnam work in brothels in Thailand. Sex workers from Thailand and the Philippines work in Japan. Thai women become sex workers in Singapore, and Nepalese women work in India, where 35% or more of sex workers are HIV-infected. Sex workers may spread HIV from cities to rural areas when they return home. In Ghana, many rural women who left for Côte d'Ivoire and became sex workers brought HIV infection back home to their villages, which now have a high prevalence of HIV infection.

Often, boom towns and tourist centers that attract temporary immigrants and visitors also attract many sex workers, to whom people away from their spouses or usual partners may turn. Immigrants who have sex with sex workers suffering from an STD can transmit the disease to other sex workers and also to their spouses or other partners at home if they do not use condoms.

HIV/AIDS has spread even to remote countries with conservative norms about sex. For example, in the Pacific Island nation of Kiribati some men who leave the country to work on foreign ships have become infected with HIV and have spread the virus upon returning home.

Some countries have charged international immigrants and foreign visitors with introducing HIV. China has held foreign tourists responsible for bringing the virus inside the country, although many HIV cases in China have involved returning emigrants who had had contact with sex workers elsewhere. In Ethiopia, refugees along with sailors and sex workers have been blamed both for the introduction into and for the transmission of HIV within the country. Mexico's Health Minister recently pointed to Mexicans returning home from the United States as the reason why the incidence of HIV/AIDS was increasing in rural areas of Mexico, especially where there is substantial migration to and then back from the USA. An estimated 25% of HIV/AIDS cases in Mexico occur in individuals who have been temporary immigrant workers in the United States.

A few countries such as India, the Gulf States, South Africa, Cuba, and Iraq have tried to stop the spread of HIV/AIDS by preventing people suspected of being infected with HIV from entering the country. However, border controls are ineffective and only create a false sense of security and detract attention from the need to reduce high-risk sexual behavior within the country. The World Health Organization (WHO) has also taken a stand against mandatory HIV testing in refugee situations, arguing that the tests can be inaccurate and do not prevent the spread of the disease. Mandatory testing may even increase the spread of HIV, if unsterile needles are used for drawing blood for tests, by infecting the people being tested.

The emergence and subsequent expansion of HIV infection and AIDS has had a major impact on preventing and controlling STDs and has also complicated the health care provided to such patients. It is advisable to perform syphilis serological tests and counseling and voluntary testing for HIV in all patients seeking consultation for any STD. In all cases, it is advisable to inform the patient about STDs issues (including HIV infection) and to present possible ways of preventing such infections.

Antibiotic resistance of some of the pathogens which cause STDs is increasing and further complicating the management of these cases. Providing adequate medical care in cases of STDs remains the most important element in controlling their spread, since it prevents complications and sequelae, and reduces transmission in the community.

Prevention has a very important role in STDs management, due to the absence of any possibility for vaccination against some diseases (syphilis, gonorrhea) on the one hand, and to the absence of any curative therapy for viral diseases such as hepatitis B and C or HIV infection, on the other. But yet, we know exactly how to prevent such infections.

The need to ensure a more effective prophylaxis in this area becomes a social obligation. Sexually transmitted diseases, with their gravity and their impact on social life, cannot be placed at the same level with other infectious and contagious diseases, because they are perfectly and completely preventable. All sexually active individuals must be properly informed, appropriately counseled, and encouraged by health authorities and by the media to modify sexual behaviors that are known to favor the transmission of infections.

Prevention methods in STDs vary according to efficiency and moral acceptability: information, education, behavioral changes, and use of condoms. While the use of condoms reduces the transmission of various sexual infections, the true preventive measures aim at modifying sexual behavior through information. But even in this context of radical prophylaxis concrete proposals are different. Some physicians reduce the level of information to a simple data communication, particularly about the transmission of sexual diseases and about condom protection, which means education for “safer sex.” Further, modifying sexual behavior includes a reduction in the number of sexual partners.

Public health authorities must identify the most suitable methods to decrease the number of cases of STDs among immigrants through information and sexual behavior modification, but also to educate young people, in particular about respect for human sexuality.

Contact tracing is the process by which sexual partners or other persons exposed to sexually transmitted infections are identified, located, evaluated, tested, and treated, as well as counseled about prevention. (This process may be known as partner notification in some countries; in the U.S. partner notification is a procedure that is distinct from contact tracing.) All sexual partners, parents of the infected newborns, intravenous drug users who share the same syringe and needle, or individuals who might be involved in cases of sexual abuse are possibly exposed to STD. Informing partners, treating and counseling them are mandatory in all cases of STDs. These measures have a positive impact not only on public health (surveillance and fight against the disease), but also significantly contribute in reducing the risk of patient re-infection.

Health authorities must carry out epidemiological investigations to determine the risk of an STD epidemic and to identify infected people (ill or carriers) and their contacts. Systematically identifying infected individuals is of great importance as the spread of STDs is heavily related to their behavior. In order to interrupt the chain of transmission, it is critical that the infected individuals be recognized, treated, and educated regarding sexual behavior changes.

Epidemiological investigation in venereology starts from the person asking for medical care and subsequently aims at the identification of the infection source. Both partners will be treated and they will discontinue sexual activity until certification of healing through laboratory tests. Sometimes there is a certain resistance from the patients in achieving the epidemiological investigation, due to the specific mode of transmission of these infections.

Immigrants as a group are already subject to discrimination, rejection, and social marginalization, because of their cultural and socioeconomic status. Specific illness beliefs may sometimes alter their own perception toward STDs, and language barriers can discourage them from seeking medical care. These could be the reasons why patients often refuse to provide history data which are useful to epidemiological investigation, leading to misdiagnoses or mistreatments.

The patients mostly assess the impact of the STDs on their personal life rather than on their health or on the other's health. Because of poor education and low exposure to media or to the world outside community, many infected immigrants may not be aware that some of the STDs are actually easily diagnosed and treated. As a consequence, strategies are needed to encourage testing for curable and non-curable STDs. In order to be effective, the strategies must consider the individuals' attitudes and beliefs about the influence of STDs on sexual relationships, as well as the public perception about existing methods of prevention, diagnosis, and treatment.

Relatively little attention has been paid by humanitarian agencies to the treatment of refugees and immigrants suffering from STDs. Among eight refugee camps in the Great Lakes Region of East Africa, only the two oldest camps provided comprehensive treatment for STDs at separate clinics; these served mostly men who were reluctant to bring in their wives or other partners for treatment. If attention is to be paid to STDs and especially HIV/AIDS, it is on a case-by-case basis. Such diseases are identified, for example, during pregnancy or childbirth rather than as part of a screening effort. For this reason little attention is given to treatment of partners and to follow up.

Yet, for public health reasons, some countries have established health care programs that enable any person suspected of suffering from an STD to access care. Such programs offer diagnostic methods, counseling, treatment, and follow-up for free, no matter the age, nationality, employment status, or medical insurance of the patient.

Shame

Laura Janine Mintz
Department of Epidemiology and Biostatistics,
Case Western Reserve University School of Medicine,
Cleveland, OH, USA

Shame is the painful feeling arising from the awareness of something dishonorable, improper or ridiculous, done by oneself or another. Shame is a complicated feeling that can have many origins. Any person can feel ashamed, but it can have wide ranging and complex implications for the health of immigrant persons. Shame can come from the dominant culture, for example, shaming immigrants based on their language, accents, practices, and customs. This can lead to immigrants being less likely to access needed services in their new homes because they fear, often correctly, that they will experience the shaming feeling directly from the dominant culture. As an example, a study in the *UCLA Law Journal* noted that police receiving phone calls about immigrant women being battered "were not taken seriously or responded to appropriately." This inappropriate police response mirrored a dominant attitude about immigrant women, particularly Latina immigrants, in Los Angeles. Members of immigrant communities are well aware of the attitudes of the culture around them and modify their behaviors to defend themselves from shaming from the dominant culture. In this case, an immigrant woman's response to shaming from the external culture may initially be seen as not self-protective, but understanding the full context of the response from authorities can reframe this response as protecting oneself and community from shaming.

Immigrants also experience shame based on things that may be stigmatized in their cultures of origin, but not necessarily the culture where they live. For example, immigrants may have different explanations for the causes and outcomes of illnesses and may see illness as a physical mark of shame. Ultimately, this belief may lead immigrants to be more reluctant to seek health care, because either they do not want to acknowledge or address an issue that they believe is shameful or they do not want others thinking that they have a shameful condition.

Immigrants can also feel ashamed because of conditions that may be seen as shameful in their cultures of origin and in their new cultures. Though infection with HIV is less stigmatized in many places around the world than it originally was, it still causes many people shame and is treated as shameful in many places. Immigrants that are infected with HIV may be less likely to seek care for their illness, because they are afraid of being shamed both by health authorities and by their own communities. In addition, feeling shamed for a condition like HIV may lead people to be exposed to violence, and immigrants are more vulnerable to violence because of the stigma and shame they may receive from people in their host country. Occupations can also be a source of stigma for immigrant persons – such as undocumented labor or sex work. Immigrants who earn money in these ways, or in other parts of the underground economies, may feel shame about their source of income, if their language or immigration status does not allow them to be employed in other ways.

Ways that immigrants may be shamed are interlocking and overlapping – people may feel them from many different angles. Any experience of shaming may lead persons to internalize that shame, and that internalization may leads not only to the changes in behavior discussed above, but also to larger psychological disturbances. A person that feels deeply ashamed of any of his/her circumstances may experience depression, or feelings of suicide, or other psychological difficulties. In immigrants, this may lead to even more serious problems, because they may not be able to access therapeutic services due to lack of money or other concerns. In addition, there may be a lack of therapeutic professionals that are linguistically or culturally competent with the particular community, or the person affected may be unfamiliar with the country of residence's health care system. Traditional healers and other therapeutic professionals within the immigrant's community may also be inaccessible because of the shame related to the issue that the particular immigrant is facing. Shame is complex, interlocking, and can have significant effects on the health and well-being of all peoples and is of particular interest in immigrants because of their unique circumstances.

Shenkui

Kristi Ninnemann
Department of Anthropology, Case Western Reserve University, Cleveland, OH, USA

Shenkui is a Chinese culture-bound syndrome attributed to excessive semen loss. Similar to the more widely studied *dhat* found most frequently in India, sufferers of *shenkui* endorse both physical and psychological symptoms which are ascribed to an imbalance in Yin and Yang. Semen is an essential component of Yang, or male energy, and disharmony, or an excess of Yin, can result from semen deficiency and loss. It is believed that excessive semen can be lost through repeated sexual intercourse, masturbation, nocturnal emissions, or through the perceived passing of semen in white or turbid urine. Physical symptoms of *shenkui* include general weakness and malaise, musculoskeletal pain often in the back or kidney region, dizziness, and sexual dysfunction. Males presenting with the disorder often report high levels of anxiety and panic, as well as fear that the loss of Yang through semen loss will result in death.

Shenkui is classified as a culture-bound syndrome in the DSM IV-TR and the ICD-10 Classification of Mental and Behavioral Disorders.

Shin-Byung

Kristi Ninnemann
Department of Anthropology, Case Western Reserve University, Cleveland, OH, USA

Shin-Byung translates into English as "God" or "divine illness." Often referred to as a Korean "folk illness," it is characterized by physical and psychological symptoms that manifest in an individual who has been called to be a *Mudang*, or Korean shaman. Reported most frequently in women, *shin-byung* consists of three distinct phases. The initial phase of *shin-byung* is characterized by physical complaints such as general weakness and malaise, lack of appetite, gastrointestinal upset, musculoskeletal pain, and dizziness. Psychological symptomotology may also be present in the forms of insomnia, depression, or anxiety, and individuals may report increased levels of fear and confusion. The duration of the initial stage varies greatly between cases, from days to decades. Further, individuals in this stage are often unaware they have *shin-byung*, and as such may seek medical treatment for that which they view to be purely somatic difficulties. During the second phase of *shin-byung*, an afflicted individual becomes aware that she or he has received a divine call to become a *Mudang*. This call, as well as the diagnosis of *shin-byung*, is revealed through dreams, periods of dissociation/depersonalization, and/or hallucinatory experiences. Previous somatic symptomotologies come to be understood as the beginnings of possession by ancestral spirits. Individuals in the second stage of *shin-byung* have been characterized in the literature as resembling persons with Western mood, dissociation, and/or psychotic disorders. The final phase of *shin-byung* is marked by full possession of the sufferer and the assumption of the shaman role. This phase is often reached through participation in a shamanic initiation ceremony. Once initiation is complete, the somatic and psychological symptoms initially experienced in phases one and two of *shin-byung* largely dissipate, and the individual emerges a *Mudang*.

Shin-Byung is classified as a culture-bound syndrome in the DSM IV-TR; however, it does not appear in the ICD-10 Classification of Mental and Behavioral Disorders.

Situational Ethnic Identity

Sarah Nagle-Yang
Department of Psychiatry, University Hospitals Case Medical Center, Cleveland, OH, USA

Ethnic identity classically has been defined as the component of one's social identity that is derived from membership in a certain ethnic group. This fundamental definition has been expanded in recent years to address the complexities of modern society. Recent literature has moved beyond the view of ethnic identity as an entirely stable entity and toward a definition that encompasses a more dynamic and fluid aspect of the self. These studies support the notion that one's ethnic identity is comprised of both stable and context-specific features which interact on a daily basis.

Certain contextual "cues" have been identified as sources of fluctuation. One is the presence of others from the same ethnic group. A group of Asian immigrant children living in Scotland reported stronger Asian cultural values when the interviewer was Asian than they did when the interviewer was English. In a group of Greek- and Italian-Australian youths, subjects were more strongly identified with their ethnic heritage in the company of family or at immigrant gatherings while they reported feeling more "Australian" when surrounded by their Australian peers. Paradoxically, research also suggests that minority status tends to strengthen one's identification with a particular ethnic group. African-American students on a predominantly White campus, when interviewed by survey, felt that they "represent all African-Americans."

Another setting in which ethnic salience tends to increase is in the presence of cultural symbols, such as language, ethnic media, and cultural traditions. Chinese-American college students reported an increased prominence of their "Chinese" identity when exposed to Chinese language. Paradoxically, in a study of bilingual individuals living in China, participants were actually more likely to endorse Chinese values when a questionnaire was offered in English as compared to the same questionnaire offered in Chinese. In these examples, it appears not to be the language itself that increases ethnic salience but an effect of contrast to the cultural background out of which a person normally operates.

In addition to these situational factors, recent literature has identified more stable elements of identity that contribute to greater ethnic salience. People who hold their ethnic identity as more central to their overall view of themselves are more likely to experience varying situations through the lens of their ethnicity. For example, students with higher ethnic centrality are more likely to see race as an explanation for negative feedback from a supervisor. It is also hypothesized that ethnic salience occurs more frequently in individuals who see their ethnic group as honorable or esteemed.

This fluidity of ethnic identity can move beyond the more abstract ideas of self-concept and play a measurable role in one's behaviors, performance, and psychological well-being. In a study involving Asian-American women, the participants were given a mathematics test after answering a questionnaire focused on aspects of either their gender or their ethnicity. When their ethnic identity was activated, they performed significantly better on the test. The difference in their performance was thought to be due to a self-application of common cultural stereotypes that Asians have superior mathematics skills as compared to other ethnic groups and that women have inferior mathematics skills as compared to men. This effect has been well studied among African-American students, who consistently show worse performance on tests which are presented to them as a way to measure intelligence or specific abilities as opposed to a test which measures such things as hand–eye coordination or "psychological factors involved in solving verbal problems." This may be explained by the fact that, for African-American students, tests which diagnose intelligence make salient a negative cultural stereotype of decreased academic ability.

The expression of ethnic identity can also directly affect one's psychological well-being. A sense of belonging to an esteemed group can have important psychological benefits. In a diary study of Chinese- and Mexican-American high-school students, those with a higher regard for their ethnic group were happier and generally less anxious over a 14-day period. These adolescents were also less likely to be negatively affected by daily stressors, indicating that ethnic regard may serve as a buffer against normative stress. This is consistent with previous studies that indicated that among African-American adolescents, those with positive connections to their ethnic group were protected from the deleterious metal health effects of racial discrimination.

The way in which one navigates multiple cultural identities can also affect mental health. Specifically, the degree to which one views his identities as compatible affects his emotional reaction to different settings. A person who has attained a compatible identity can respond in a contextually specific manner while maintaining a coherent sense of self. Alternatively, others experience internal conflict while navigating different environments, often feeling pressure to regulate their behavior to adapt to the given situation. These individuals, termed "cultural chameleons," tend to have a more compartmentalized self-image, have shown significantly decreased psychological well-being, and show increased sensitivity to rejection in daily social interactions.

Slavery

Brittany Daugherty
Department of Psychology, John Carroll University, Cleveland, OH, USA

Slavery is an aged concept that has been used across many different civilizations to justify harsh living conditions and the absence of human rights and freedoms. It is a life of confinement and forced labor ruled by fear and profit, a strategically constructed institution of bondage and servitude which is cheap and expendable. This type of violent control over another person considered to be property is driven by economic gain. Most often, slaves are native indigenous people, minority ethnic groups, and individuals living in poverty or of low socioeconomic status or social class. Slavery dates back to ancient civilization when slavery was thought to be natural and that some people were predestined to be slaves. The forms of slavery include prisoners of war, child abandonment, punishment for crime, repayment of debt, and birth slave children.

The term “slavery” is often equated with historical episodes such as the Arab Slave Trade and the TransAtlantic Slave Trade. Although these occurrences of slavery are dated, the conditions are still pertinent. Slavery is a disturbing truth that continues to be prevalent in many areas of the world. The conditions of slavery can include debt bondage, indentured servitude, and serfdom. Debt bondage, one of the oldest forms of slavery, is a hereditary repayment of debt in exchange for labor, adopted from the medieval peonage system where one is obliged to servitude until debts are paid off. Indentured servitude is the provision of labor for a predetermined time in exchange for goods or services. Serfdom is a condition of bondage where one is lower class and unable to abscond bondage.

Many countries in South Asia, South America, Africa, and even Europe and the USA presently struggle with the ongoing issue of modern day slavery. More than 4,100 bonded workers in India are subject to a historical tradition of discrimination and bondage, which stems from a traditional Hindu hierarchal caste system. South Asia currently has the largest number of slaves working in debt bondage, many of whom are illiterate, impoverished, and subjected to systemic discrimination. The slaves’ acquired debt is impossible to repay; therefore their debts are passed to the next generation, perpetuating a cycle of generational slaves. Even though the nations that make up South Asia have officially banned slavery practices, the growing issue of slavery has yet to be aggressively addressed.

As the leading sugar exporter in the world and with a growing cattle and logging industry, Brazil has an increasing need for workers. These workers are usually impoverished men who are enticed from city slums and villages. Despite promises of honest wages, they are coerced away to remote plantations where they remain indefinitely in debt bondage. An estimated of 100,000 individuals are involved in farming as slave labor. The government has made efforts to fight slavery by implementing the 2003 National Plan for the Eradication of Slavery, which includes severe penalties for slaveholders.

In Africa, slavery mostly affects women and children. In countries such as Togo, Benin, Sudan, and Swaziland, shrine slavery is heavily prevalent. Shrine slavery is the usage of women and girls as sex slaves. With a lack of rights and major dependence on males, African women are highly susceptible to abuse and sexual manipulation. This type of sexual violence gives insight into how the African women suffer disproportionately from the deprivation of human rights. African slave children are often used to work in agriculture, manufacturing, and the sex trade. These child laborers make up the highest percentage in the world, with nearly 80 million children forced to work as slaves.

The United Nations (UN) has been working relentlessly to eliminate slavery in its entirety; the 1956 UN Supplementary Convention on the Abolition of Slavery was established to eradicate slavery, enhance human worth, and express the importance of human rights.

The UN has also created the Working Group on Slavery, whose primary focus is to prevent the selling of children, child prostitution, child labor, and the exploitation of children. Most recently, the UN has instituted what is referred to as the Trafficking Protocol, a set of guidelines established in 2003 to encourage anti-trafficking policies, increase awareness, and encourage proactive involvement. Many of these policies have been adopted by countries worldwide, but despite their efforts, nearly 12.3 million people suffer from forced labor. Slavery is still practiced in many countries in isolated areas away from the view of the public and the mass media.

A significant issue in contemporary slavery is human trafficking, a growing $32 billion industry that endangers the lives of mostly women and children. This modern day form of slavery promotes the illegitimate trade of people for the use of mostly bonded labor and sex labor. It is an international crime responsible for the degradation of millions of human beings. With an estimated 800,000 victims trafficked across international borders every year and 161 countries affected by human trafficking, there is an urgent need for an international plan to eradicate human trafficking. The USA is a target country for trafficked persons, with an estimated 50,000 slaves in the country. Nearly 17,500 foreign nationals are trafficked into the USA every year; the most highly concentrated areas for human trafficking are New York, California, Florida, and Washington DC. Due to this alarming statistic, the USA has implemented the Victims of Trafficking and Violence Act, which provides services and protection for those victims of trafficking.

New immigrants can face circumstances of poverty and other difficult conditions. Immigrant women and children can also be at greater risk for exploitation, harassment, and mistreatment. Immigrants may face a lack of protection, may be fearful of or not know how to report they are being abused, making them targets for ongoing abuse and manipulation. Consequently, the need for stronger UN policies, governmental acts, and laws are essential to protect the livelihood of immigrants and others. As immigrants are affected by the many push-pull causes of migration, it is important for them to understand and recognize the dangers of slavery and trafficking as well as their newly acquired citizenship rights.

Smoking

Edith Balbach[1], Jocelyn Chu[2]
[1]Community Health Program, Tufts University, Medford, MA, USA
[2]Institute for Community Health, Cambridge, MA, USA

Globally, six million people die prematurely due to tobacco use each year; 72% of those live in developing countries. The male smoking rate is about 35% in developed countries and 50% in developing countries, while the comparable US number is 23.1%. For women in developing countries the smoking rate is 9% and 22% in developed countries, while the US women's rate was 18.3%. The global tobacco epidemic affects smoking prevalence in the United States, because the majority of immigrants to the United States come from less-developed Latin American and Asian countries where tobacco use is common for men and increasing in social acceptability for men and women.

This entry discusses smoking prevalence among immigrant populations, secondhand smoke exposure issues affecting these populations, and interventions to prevent or reduce smoking among immigrants. What are the immigrant smoking rates? What can be done to reduce these rates or to keep them low? What implications do these rates hold for US tobacco policy? This discussion will focus primarily on Asian Americans and Hispanics, giving breakdowns within these broad categories when they are available. Unfortunately, published research provides little insight into migrants from other regions.

For first generation immigrants (living in the United States but foreign-born), the male smoking rate is lower than the 35–50% noted above. The rate is 14.4%, and the women's smoking rate is 7.6%, also slightly lower than the 9–22% figure. The reasons for this lower smoking rate are unknown, although it is possible that those who migrate are healthier than those who do not, so are less likely to smoke. In addition, the regulatory environment in the United States, which restricts where people smoke and imposes excise taxes on cigarettes, may help to discourage smoking initiation. Further, in the United States, smoking is increasingly concentrated among poorer populations. By contrast, smoking in developing countries from which people migrate may still be spread across social classes. Thus, the high rates in the country of origin may reflect higher smoking rates among those of higher socioeconomic status, who may be less likely to migrate.

Research on acculturation, traditionally measured by indicators such as length of time in the United States or language spoken at home, has found that immigrants' health behaviors mirror that of the rest of the population as those immigrants acculturate. Smoking follows this trend; the more acculturated immigrants are, the more likely their smoking rates will mirror those of the overall United States population. Being born in the United States to two foreign-born parents has a protective effect for both men and women, with smoking rates of 11% and 8%. But, if either parent is born in the United States, the smoking rates for both genders begin to approach those of the rest of the US-born population. If the mother is foreign-born and the father not, men have a smoking rate of 18.1% and women 15.7%. If the father is foreign-born and the mother not, men have a smoking rate of 16.3% and women 16.1%.

Hispanic Smoking Prevalence and Immigrant Status

The overall rate of smoking prevalence for Hispanics in the United States is 15.8%, including 20.7% of men and 10.7% of women. By comparison, the prevalence rates for non-Hispanic Whites were 22.0% overall, 23.5% for men, and 20.6% for women. Immigrants who identify themselves as "Mexican," as opposed to "Mexican-American," had an overall smoking prevalence of 15.5% compared to 18.3% for Mexican-Americans.

For women, Mexican-Americans who spoke English were more than twice as likely to smoke than those who identified as Mexican, and being born in the United States also doubled the rate of smoking prevalence. Acculturation, though, has only consistently shown an effect on women's smoking among Hispanic populations; acculturation increases Hispanic women's smoking rates. For example, Hispanic women in California who spoke mainly English had a smoking prevalence of 14.7%, while those who spoke mainly another language had a rate of 6.1%. In Houston, for women of Mexican heritage, the smoking prevalence for those born in the United States was 15.2% compared to 7.2% for those born in Mexico.

Mexican-American youth in Southern California who reported a US orientation, while they perceived their parents had a Hispanic one, were at increased risk for smoking. By contrast, youth with a Hispanic orientation were less likely to smoke.

Asian American/Pacific Islander Smoking Prevalence and Immigrant Status

In 2008, Asian Americans had an overall smoking rate of 9.9%, 15.7% among men and 4.7% among women. But, while the overall smoking prevalence for Asian Americans is low compared to other populations, this is based on highly aggregated data that does not differentiate among different ethnicities or by level of acculturation. For Asian immigrants, more acculturated men smoke at lower rates than less acculturated men, whereas the reverse is true for women.

Disaggregated data on immigrants from Asian countries reveal some important differences based on country of origin. In California, men's smoking rates were uniformly higher than those of women, and the highest male rates were seen among Korean (36.7%), Vietnamese (32.4%), and Filipino (24.5%) populations. For women, the highest rates were among Japanese (13.2%), Korean (9.0%), and Filipina (7.7%) populations. Immigrants from India had a smoking rate of 4.6% compared to a rate of 21.4% of those from Japan. Tobacco control advocates will need this kind of disaggregated data in order to plan culturally specific interventions on tobacco cessation and tobacco use prevention.

Prevalence surveys conducted in English, however, may be missing data from Asian populations who are not English-proficient, thus missing high prevalence rates in non-English–proficient populations, which represent over 60% of Asian Americans. Regional surveys conducted in Chinese, Korean, Cambodian, and Vietnamese have found an overall smoking prevalence of 29%, with men at 42% and women at 14%.

Although the effects of acculturation on smoking status are well documented, attention has been paid to other factors as well. For example, Asian Americans who reported "unfair treatment" had 2.62 times the odds of being a smoker as did those who did not. Those who reported racial/ethnic discrimination were 3.06 times as likely to be smokers as those who did not. Smoking may be a way to cope with stress for some immigrants.

Youth have often been studied separately. Asian American adolescents start smoking later than non-Asian American youth, have a lower smoking prevalence than non-Asians, and are more likely to smoke if they are more acculturated. In California in the 1990s, Asian American youth had a 30-day smoking rate of 6.9% compared to the 14.2% rate of non-Asian American youth. Youth of Chinese heritage reported the lowest rate, 2.8%, while Filipino youth were highest at 8.6%. Acculturated adolescents may be twice as likely to smoke as their non-acculturated peers. For example, those whose native language was English were significantly more likely to smoke than those for whom it was not, 7.9% compared to 4.5%. Acculturation was sometimes based on self-report and sometimes on specific behaviors, such as language spoken, language read, and diet.

Secondhand Smoke Exposure

In 2004, 38.3% of Asian Americans reported being exposed to secondhand smoke at home, although there were differences by subpopulation. The levels were highest in Vietnamese homes (44.9%), followed by Cambodians (43.8%), Koreans (42.0%), and Chinese (29.7%). Among the variables that predicted higher rates of smoking in the home were living in the United States less than 5 years, less acculturation, and being foreign-born. The overall US data for this time period indicate that 27.3% of households allowed smoking in the home.

Boston residents of Vietnamese and Chinese heritage indicated that they were interested in smoke-free environments and understood some of the health risks of secondhand smoke but were reluctant to confront smokers directly. They were thus supportive of strict laws and indicated that media messages urging mutual respect would be helpful in creating smoke-free environments.

US residents who are foreign-born are more likely to support smoke-free policies in bars, restaurants, indoor worksites, malls, sporting events, and hospitals than are those who were born in the United States to foreign-born parents. 75.7% of the former supported smoke-free policies in 4 of the 6 venues, while 65.7% of the latter did. Third generation residents, those who were born in United States to US-born parents, were less likely than the first two groups to support smoke-free policies; they supported smoke-free policies in 4 of the 6 venues 59.1% of the time. The latter group's support levels begin to mirror the attitudes of other

US-born individuals. Thus, policy preferences, like smoking prevalence, begin to resemble those of non-immigrants over time.

Interventions to Reduce Tobacco Prevalence

Interventions to encourage smoking cessation can be effectively targeted to reach immigrant populations. For example, a targeted social marketing program that was conducted over a 2-year period in New York in conjunction with citywide policy changes, including tax increases and smoke-free air laws, resulted in a drop in smoking prevalence among Chinese-Americans from 17.7% to 13.6% and among men specifically from 30.3% to 22.9%. But more high-quality research needs to be done on cessation and prevention programs among immigrant populations.

The tendency of immigrants as they acculturate to mirror the smoking prevalence of other US residents has important implications for prevention programs. In addition to programs targeted at immigrants, it is also important to continue work to bring down the overall US smoking rate. That is, if immigrants are conforming to a larger societal norm, then it is important to change that norm. A California study focused on Chinese and Korean immigrants who smoked found that Chinese immigrants quit smoking at seven times the rate that smokers in China quit and Korean immigrants quit at three times the rate of Korean smokers. The multi-lingual California tobacco control program mattered – over 80% of the sample recalled seeing an anti-smoking message in the previous month – and the social norms of California created an environment that encouraged quitting. In addition, for those living in ethnic enclaves that lack a social norm against tobacco use, some effort needs to be made to build these norms. Certainly, one way to influence the social norms of ethnic enclaves is through smoke-free policies and culturally appropriate, community-based prevention and cessation efforts.

In addition, monitoring industry targeting of immigrant populations and working with other countries on their tobacco-control efforts are important pathways toward mitigating tobacco use in immigrant communities. The tobacco industry has developed strategies for targeting Asian and Hispanic immigrants through marketing campaigns and geographically focused promotions. In addition, industry campaigns have been designed to target immigrants based on assimilation status.

Conclusion

Smoking-prevention efforts in immigrant communities thus have some unique challenges and opportunities. One, because immigrants come from countries that likely have more tax policy environments than many states in the United States, tobacco-control advocates should be concerned about policy development in these countries. Two, advocates should work with communities to interrupt the trend in which women begin to smoke more as they become acculturated. More community-based participatory approaches are needed to design interventions and understand the impact of those interventions. Three, advocates should be concerned about the degree to which aggregated data may obscure important elements of the tobacco epidemic among immigrant populations. This entry has illustrated the nuances that exist when populations are disaggregated. In addition, little is known about immigrant populations from regions other than Latin America and Asia/Pacific Islands. For all of these populations, we may need to look beyond measures of acculturation to understand smoking uptake and cessation. And finally, advocates need to monitor tobacco industry targeting efforts both inside the United States and in countries from which people are emigrating.

Social Capital

Diwakar Vadapalli
Center on Urban Poverty and Community Development, Mandel School of Applied Social Sciences, Case Western Reserve University, Cleveland, OH, USA

Social capital as an interdisciplinary concept in social and behavioral sciences came to widespread prominence during the late 1990s and is currently among the most widely researched topics. This article briefly discusses the concept and associated theory, and its relevance to immigrant health.

Most commonly stated, it is the “glue” that binds individuals and communities together for efficient social life. Robert Putnam, a political scientist, used the concept to explain the difference in performance of regional governments between northern and southern Italy. Putnam later published “Bowling Alone: America’s declining social capital” in 1995, claiming that social capital in the country has been in decline for the last few decades and that this explained the reduced political participation of its citizens among several other indicators of civic engagement. Although Putnam’s work brought the concept into popular imagination, John Field, in his 2002 book “Social Capital,” explains that Pierre Bourdieu, a French sociologist studying the hierarchical French upper class society, and James Coleman, an American sociologist studying the differences between educational outcomes of Chicago schools, defined and used the concept prior to Putnam’s work. In the last decade or so, social capital has been used to explain a number of social phenomena such as individual employment, social mobility, immigration and assimilation, educational outcomes, family structure, criminality, organizational effectiveness, urban revitalization projects, neighborhood stability, lower loan default rates, and general health, among others.

In spite of the accumulating empirical literature over the last three decades from a wide variety of fields of study, and several theoretical expositions, relations between constituent elements such as trust, norms, and social networks are still disputed as are the measurement instruments and techniques. Considerable efforts advanced the techniques of measuring social capital at an individual level and at group/community level with organizations such as the World Bank adapting this concept for comparisons across countries.

Varying definitions and measures add to its conceptual richness as well as its practical unwieldiness. Most definitions of social capital include three elements: trust, trustworthiness, and networks. The networks people belong to are hypothesized to yield several benefits to them ranging from increased material or emotional support due to higher levels of trust and trustworthiness within that network. According to Bourdieu, social capital is the "aggregate of actual and potential resources which are linked to the possession of a durable network of more or less institutionalized relationships of mutual acquaintance and recognition." He clearly separates the network from the actual resources realized through the network, which he terms "social capital." Coleman, on the other hand, defines social capital by ". . .its function. It is not a single entity, but a variety of different entities having two characteristics in common: They all consist of some aspect of social structure, and they facilitate certain actions of individuals who are within the structure." The strongest criticism of this definition points to the all-encompassing nature of the concept, opening the door to social capital being all things at the same time. Putnam's definition of social capital as "features of social organization such as networks, norms, and social trust that facilitate coordination and cooperation for mutual benefit" is similar to Coleman's, but clearly identifies networks, norms, and trust as three major components of social capital. Following this definition, memberships in groups and networks formed a major part of subsequent measures of social capital. Bourdieu's conceptualization is at an individual level while Putnam's is at a community level. In contrast, Coleman argued that "social capital is embedded in the social relationships between individuals but is available to rational actors as a means of achieving their goals." Notwithstanding these more fundamental differences in definition and measurement, the concept appealed to researchers in a variety of fields and was promoted as a potential bridge between several fields within social sciences.

Three types – bonding, bridging, and linking social capital – are generally identified in the literature. Bonding social capital refers to the close-knit ties, familial or otherwise, among members of a group. Bridging social capital refers to the lose ties between individuals at different levels of the power hierarchy of the group. Linking social capital also refers to loose ties but between individuals from different political and/or social groups. Linking social capital is often invoked to represent access to external resources. Although social capital was generally seen as a beneficial asset to individuals and communities, scholars also acknowledge it as an exclusionary mechanism for groups to restrict their membership and thus the associated benefits.

Social capital was identified as a contributing factor to better outcomes on a number of measures, including health, for members of immigrant groups. Tight-knit relationships within immigrant groups are shown to contribute to several positive outcomes in education, employment, health, and access to other resources. Several studies, starting with Roseta (in the state of Pennsylvania, USA) in the 1950s, show that first generations of immigrants have better health outcomes than descendants of immigrants. These better outcomes were attributed to the strong social cohesion and associated norms within the immigrant groups, which were absent in comparison groups. Descendants are less likely to maintain such close ties and follow the norms of older generations from another land. Although the concept needs to be developed on several counts, social capital is useful as a metaphor in explaining several phenomena such as health status, particularly among immigrant populations.

Social Integration

Cătălin Jan Iov
University of Medicine and Pharmacy “Gr. T. Popa”,
Iasi, Romania

Introduction

It is in our human nature to initiate, maintain, and develop relationships with other humans. Any kind of relationship connecting at least two persons is based on common interests, common beliefs, and common actions. In other words, it connects peers. It is important to note the term “common.” The globalization process that initiated increased immigration, along with annual increases over the past three decades, expanded this term to mean a common geographic place, the same country.

In the context of globalization, adaptation to a new world is a must for the immigrants that want to be part of it. The adaptation process is strongly dependent on factors such as the immigrant’s culture, host language proficiency, and time spent in the host country. All immigrants’ social interactions with the new populations they are trying to integrate into can be called “social integration.” The wider concept of adaptation includes cultural integration, structural integration, economical integration, and social integration.

In contrast to social integration, social marginalization excludes individuals from the host society, and isolates them. Examples of marginalized groups are homeless people, long-term unemployed, delinquents, difficult teenagers, immigrants, disabled persons, and substance abusers. Vulnerable populations can also include individuals with serious medical conditions, obese individuals, the elderly, prisoners, etc. What they have in common are difficulties at some time in the life span with adapting to and accessing the broader social setting.

Research and Social Integration

Social integration as a field of research reveals approaches to smoothly integrate the newly arrived into local society. Similar cultures, similar languages, and similar habits facilitate the social integration process. Critical challenges occur where there are differences in key factors, for example, ethnicity. A proven means to facilitate social integration is ethnic intermarriage. Weaker ties between ethnic groups are casual contacts or friendships, while intermarriage is based on similarities in language and habits, but not necessarily culture-based habits. Sharing the same family model and life view not only support ethnic intermarriage, but also marriage between peoples of the same ethnicity. Another key factor is language. A minimal level of proficiency in the host country language is required unless the broader host population knows the language of the immigrant group. Since verbal communication is the fastest and simplest way to share thoughts, language is the strongest tie between individuals either from the same ethnic group or from different groups. While ethnic intermarriage can be found either vertically (e.g., between immigrants and the local population) or horizontally (e.g., between minority groups), the vertical path allows immigrant minorities more rapid access to local society and local values, and facilitates faster intercultural exchanges and cohesion.

All types of contact, ethnic intermarriage, casual contact, or friendship have been demonstrated to be based on factors such as race or cultural background. For instance, race is the most important factor in cross-group interactions in the United States, while in Europe cultural differences are more important than race.

Integration involves a larger host group and at least one smaller group, always a minority and almost always a group with special needs which classify the members as vulnerable against the host group. Social meaning includes all social interactions between the vulnerable population group and the host. Taking it together with integration, the concept of social integration is defined as all social actions with the aim to allow small groups of vulnerable populations to access and use social resources such as communication and common values.

Models of Social Integration

Social integration models are based on multicultural societies, such as the United States, the Netherlands, Germany, Canada, Italy, among others. All have a history of immigration, but there are differences in the models used in each country. The models in Canada and the United States recognize the rights of minorities but do not necessarily promote management of relations between different ethnic groups or races. An integration model supposes an acceptance of any culture with all its specific elements. Moreover, this model supports and empowers different ethnic communities. The most important ethnic minorities are confirmed by the State and the opinions from their advisory bodies have to be taken into account by the State. The State allows media (e.g., radio, TV, print) to promote minority cultures and allows religious schools to be established. This model is used by the Netherlands and was based on the historical foundation of the Dutch State. The State structure has different cultural, religious, and political groups. This model promotes coexistence as tolerance of difference, civil dialog, collaboration as participatory development planning, and cohesion as the result of shared meaning and values.

Other models of integration were implemented in France, based on assimilation of the migrated population into the majority, and in Germany, based on integration of immigrants into the local job market where immigrants took low paid and "dirty" jobs that the mainstream German population would not have accepted. The German model may be found in Denmark, Italy, Austria, and Greece, and while immigrants gained access to the labor market they were excluded from civic and political participation, resulting in insecure legal status. During the 1990s there was an anti-immigration sentiment in Germany, with exclusionary and xenophobic attacks on ethnic minorities. However, the anti-immigration sentiment in Germany has changed, and recently an integration model has been implemented. It offers education and job training for young immigrants to develop careers or even more, start families.

Past experiences with new immigrants facing language and cultural barriers when arriving in the host country, resulting in high unemployment rates, low income, and poverty, caused some host countries to change their immigration policy. For instance, a minimal level of host language proficiency is today required for those who seek permanent residency in Canada and the Netherlands.

Facilitating Factors for Social Integration

Studies reveal that the younger the immigrant, the easier the social integration process. Immigrant children 15 years of age and older face many integration issues, while those younger than 15 years of age learn the host language faster and more easily integrate into the host educational system. Some studies show that the younger immigrant populations gain faster access to social resources, and vertical ethnic intermarriages are more often found. However, those who migrate over 15 years of age tend to marry within their ethnic community and have fewer peers from the mainstream host population.

Therefore, elements that facilitate social integration include open dialog with other groups, horizontally with other minorities or vertically with the majority population, period of time spent in the host country, host language proficiency, age at migration, and ethnic intermarriage. Social integration indicators vary from model to model. A common indicator of integration is socioeconomical status of the immigrant group. This is a major indicator of equality and cohesion with proportional participation in the labor market, education, health, and housing. Another indicator is public attitudes and perceptions regarding the immigrant group, although this indicator would depend on the context and method of measurement. Other indicators may be the ethnic intermarriage rate, accommodation of religious needs of the immigrant group in public life, and participation in social tasks and discourse.

Social Learning Theory

Brittany Daugherty
Department of Psychology, John Carroll University,
Cleveland, OH, USA

Learning is a phenomenon that is interconnected with our daily living. Social learning theory illustrates the impact of modeling and observation on behavior and attitudes. It is considered observational learning, in which behaviors are first observed then imitated; also known as modeling. There are three kinds of observational learning: live, verbal, and symbolic. Live learning is when a behavior is actually demonstrated, verbal learning is when an explanation of a behavior is given, and symbolic learning is when behaviors are derived from books, films, and/or the mass media. All are thought to be important in the outcome of behaviors.

This theory incorporates both behaviorism and cognitive learning in its premise, two prominent forms of psychological thought. Behaviorism, the objective science of studying observational behavior, interprets how the environment influences human behavior. Cognitive learning is the field of studying internal thought processes that help encode, store, and retrieve information. Therefore, it interprets how psychological processes influence human behavior. Social learning theory essentially uses both environmental and psychological factors to explain modeling of human behavior.

Albert Bandura, a renowned mid-twentieth century psychologist, expanded on work done by earlier researchers, while trying to explain learned aggression in adolescents. He believed that behaviors were not inherited; they were simply learned by observing others. According to Bandura, there are four steps to the learning and modeling process: (1) *Attention*, precisely paying close attention to the behavior as it is occurring. (2) *Retention*, able to recall what one has derived from the behavior. In other words, the individual is coding, rehearsing, and essentially preserving information. (3) *Reproduction*, performance of the modeled behavior. (4) *Motivation*, the reason behind imitating the behavior. Continued imitation of behaviors is due to some rationale to mimic the behavior. Motivations can be either external or internal, or positive or negative, therefore affecting how a learned behavior is demonstrated and the likelihood of reoccurrence.

Replicated behaviors can either be positively motivated, used to strengthen the behavior, or negatively motivated, used to weaken the behavior. These can include direct reinforcement/punishment, vicarious reinforcement/punishment, and self-regulation (reinforcement/punishment). Direct reinforcement/punishment would be when a replicated behavior is either praised or criticized by someone else. Vicarious reinforcement/punishment is when the behavior is observed and recalled as being reinforced or punished, allowing the behavior to be seen as either acceptable and encouraged, or unacceptable and shunned. Self-regulation is when satisfaction or displeasure is experienced for meeting or failing one's own standards for fulfilling the behavior. Bandura faulted behaviorism for its overly simplistic view on human behavior being primarily influenced by the environment. He believed in "reciprocal determinism" meaning that human behavior, the person, and the environment heavily influence each other. These three variables illustrate the interconnectedness of the two disciplines of behaviorism and cognitive learning and reflect the multifaceted factors incorporated in the system of learning.

Of the many behaviors that can be learned through modeling, aggression is one of the most researched. Bandura's famous and most talked about studies illustrate how modeling is highly effective in learning aggression. The "Bobo doll experiment" was created by Bandura and his colleagues to demonstrate how exposure to aggressive models would be replicated in the same manner by child observers. Results showed that children who witnessed aggressive acts committed against the Bobo doll replicated the acts in much the same manner and exerted much more aggression than other children who had not witnessed aggression against the Bobo doll. Bandura's study, the most influential study of social learning theory, was an empirical investigation of the many different factors that play a significant role in learning.

As it applies to immigrants, social learning can occur and produce a state of compliance and adaptation. Social learning can permit immigrants to learn new customs and lifestyles of their new home. It can provide them with the opportunity to contribute to their new communities; adopt modern day skills, customs, and expectations; and improve their current skills and education. Social learning plays a significant part in assimilation. It is evident that not all social learning is positive; negative aspects of social learning can expose immigrants to crime and other deviant behaviors.

Social Network

► Social networking

Social Networking

Rosalyn Negrón
Department of Anthropology, University of
Massachusetts Boston, Boston, MA, USA

Social networking is the practice of building and mobilizing social relationships. It connotes an active process whereby individuals identify, seek, forge, and maintain connections with others. Today, social networking is often associated with online services like Facebook and MySpace, which facilitate the cultivation of relationships and the building of online, sometimes virtual, communities of shared interest. The focus here, however, is more generally on the ways that people assemble and maintain networks of social relationships with kin, friends, coworkers, and others through varied means of communication. While this may include computer-mediated forms, social networking is clearly also done through face-to-face, telephone, and written means.

According to social network theory, people and their actions are embedded in a web of relational ties that both enable and constrain. The structure of this web can be a factor of the overall structural and environmental conditions in which social relationships are embedded. As important, the structure of a person's network – for example, how interconnected network members are – can be a factor of the active efforts, strategies, interests, and attributes of the social networking individual. As with social network structure, the attributes of a person's network – like the proportion of contacts who are smokers – also enable and constrain behavior. Such network dynamics help explain, for example, the spread of health conditions like HIV/AIDS and obesity.

Social networking is important for understanding various dimensions of immigrants' experiences. Drawing on social network theory, immigration researchers have examined the role social networks play before, during, and after migration. The networks that emerge from the migratory process consist of sets of interpersonal ties that connect prospective migrants and former migrants in a migratory chain. This chain involves the mobilization of key relationships, information, and material resources. Immigration policies, such as those in the United States and Canada, where immigrant visas are allocated on the basis of family ties, reinforce and formalize the operation of chain migration networks. These ties are thought to increase the likelihood of emigration by lowering the costs, raising the benefits, and mitigating the risks of international movement. Besides reunifying family members, chain migration creates portals between migrant destinations and hometowns. Through social networking, prospective migrants in hometowns secure assistance from fellow townsmen and women already settled abroad and who have – often by virtue of their own network connections – access to employment leads, housing information, legal advice, and other resources. Such valued resources available through relationships are known as social capital. Upon arrival, ties to earlier migrants continue to play an important role in immigrant adjustment and well-being. Co-ethnic organizations and ethnic enclaves in the host society provide a base from which to further accumulate and mobilize social capital in times of need.

Immigrants' ability to enhance their social capital after migration can depend on the mode and degree of their incorporation into the host society. In turn, this can depend on, among other things, language proficiency and immigration status. An immigrant's lack of proficiency in the official host country language could limit her/his ability to build interethnic relationships or navigate formal institutional channels. Undocumented immigration status can have a similar effect, as immigrants fearing discovery or exploitation may limit interactions to those they trust. Such constraints have been shown to have important health consequences. Language discordance between healthcare provider and patient hinders comprehension of a patient's complaints or a doctor's treatment. Undocumented immigrants are less likely to be insured, less likely to seek preventative medical services, and more likely to delay seeking treatment. Drawing on informal community- and trust-based networks can help to overcome such barriers to immigrant health. Bilingual relatives can serve as interpreters, a fellow church member can recommend a trusted doctor, and a friend may know a friend who works for a health insurance company and can help in navigating bureaucratic hurdles.

As the preceding examples suggest, both strong ties (close relatives) and weak ties (acquaintances or friends of a friend) provide valued resources with significant health outcomes. However, the literature on immigrant health has emphasized the role of strong social support networks in overcoming barriers to healthcare and relieving the effects of stress. But it is clear that weak ties are a crucial source of social capital. In fact, the strength of weak ties, as proposed by Mark Granovetter in his influential study, lies in their ability to provide access to new information. While true that strong ties in densely knit networks can mobilize help more quickly and intensely, they can also result in the network circulation of redundant information. Additionally, people with dense and homogeneous networks may find themselves subject to the normative expectations and practices dominant in their network. This can impact health if, for example, poor health habits – from smoking to sexual risk taking – characterize a person's network. Weak ties, on the other hand, can add diversity (of ideas, attitudes, backgrounds, goods, services) to a person's network. Not only does such diversity provide access to novel health information and healthcare options, but also presents alternative models of health behavior for comparison and adoption. Thus, social networking serves as a way for individuals to broaden the quantity, quality, and diversity of contacts available for ready assistance. Social networking highlights the ways that social connectedness is important for immigrants' healthy adjustment to life in a new land.

Social Security Disability Insurance

Bum Jung Kim
Department of Social Welfare, University of California
Los Angeles (UCLA), Los Angeles, CA, USA

Social Security Disability Insurance (SSDI) is a payroll tax-funded, federal insurance program in the USA. SSDI is managed by the Social Security Administration, and it is designed to provide income to people who are unable to work due to a disability. SSDI offers a wide range of benefits to family members when a primary wage earner in the family becomes disabled or dies. To finance SSDI, Social Security taxes are paid by workers, employers, and self-employed persons. SSDI benefits are payable to widowers, widows, and disabled children or adults. Since SSDI is a social insurance program, benefits are only granted after a lengthy determination process, whereby the applicant must prove that he or she is disabled.

Qualifications

To qualify for benefits, a person must have a mental or physical condition that prohibits him or her from being involved in any "substantial gainful activity (SGA)." SGA refers to any significant activity, physical or mental, which is performed for remuneration or profit over a reasonable period of time. To qualify, an individual's monthly earned income must be less than $1,000. Additionally, the condition is expected to last at least 12 months or result in death. Also, a person must be under the age of 65. Finally, a person must have worked 5 out of the last 10 years as of the determined date of onset of disability. In general, benefits continue until beneficiaries are able to work again on a regular basis. There are also a number of special rules, called "work incentives," that provide continued benefits and health care coverage to help the person make the transition back to work.

Benefits

The monthly amount of disability benefit is based on the Social Security earnings record of the insured worker. Eligibility for monthly SSDI benefits begins 5 months after Social Security determines the onset of disability. Payments are started 1 month in arrears (behind payment date). For instance, the disability benefit for January's payment will be paid in early February. Benefits may continue while the individual remains disabled and meets work or other eligibility requirements. Benefits can discontinue for specific activities, reasons, or events. SSDI beneficiaries are periodically reviewed by Social Security officers to determine whether there is any medical improvement in an individual's condition and to assess continuing eligibility. These reviews are either a medical Continuing Disability Review (CDR) or a work Continuing Disability Review (CDR).

When beneficiaries start receiving disability benefits, certain members of their family also may qualify for benefits. Benefits may be paid to children, spouse, and divorced spouse. Each family member may be eligible for a monthly benefit of up to 50% of disability rate. However, there is a limit to the amount that Social Security can pay the family members. If the sum of the benefits payable on their account is greater than the family limit, the benefits to the family members will be reduced proportionately.

Social Service Needs

Amy N. Sharpton
Department of Veterans Affairs, Louis Stokes DVA Medical Center Cleveland, Brecksville, OH, USA

Introduction

Since the Immigration and Nationality Act of 1965, the number of first-generation immigrants living in the United States has quadrupled to more than 38 million in 2007. Emerging trends in immigration have included steady growth, varied and frequent changes in ethnic composition, and declining socioeconomic levels. It is little wonder that upon arrival immigrants are faced frequently with urgent social service needs. This is true especially of refugees and those less likely to have a support network in place, either in the United States or in their country of origin. Affordable housing, jobs, and access to health services consistently are reported as chief among immigrants' needs.

Federal Policy on Social Services for Immigrants

Social workers and others concerned are tasked with designing programs that comply with federal policy and support immigrants in their social and economic integration. The Personal Responsibility and Work Opportunity Reconciliation Act (PRWORA) of 1996, reformed dramatically the nation's welfare system, but served also to restrict severely immigrants' eligibility for social services. In addition to income, eligibility for major federal benefits was linked to immigration status and whether the applicant arrived before August 22, 1996, the date the law was enacted. The Act's passage was met immediately by bipartisan calls for restoration of social services to legal immigrants. Consequently, in 1998, the Agriculture Research, Extension, and Education Reform Act restored eligibility to legal noncitizen children, elders, and disabled individuals who entered the United States before PRWORA's enactment on August 22, 1996. Then in 2002, the Farm Bill broadly restored eligibility for legal noncitizens who fell into one of three categories: disabled, regardless of date of entry; residing in the United States at least 5 years; or a child age 18 and under, regardless of date of entry.

The food stamp restorations to legal immigrants has had great significance in terms of policy, as the provisions were expected to become the most expensive portion of the $6.4 billion in nutrition assistance authorized by the Farm Bill. Equally notable, for the first time since welfare reform, the Farm Bill extended a federal benefit to legal noncitizen children who had lived in the United States for fewer than 5 years. The 5-year waiting period still applies to most legal immigrant adults for the Food Stamp Program (FSP) – and to most legal noncitizen adults and children for welfare and Medicaid.

How best to meet the social service needs of US immigrants is a complex issue, with public opinion varying greatly. The debate has been renewed with proposed reform in areas of both immigration and healthcare. The topic is made even more complex by other concerns such as the state of the economy, frequent budget cuts, and a growing number of US citizens lacking healthcare coverage.

Areas for Further Research

Social workers have called for additional research into the "chilling effect" phenomenon, in which previous eligibility restrictions have been correlated with barriers to current program participation, even long after the restrictions have been lifted. Additional topics that have been suggested for continued research include institutional challenges to reversing eligibility restrictions; the effects of restrictions on different populations; the degree to which the restoration brought new immigrant households to the FSP, versus extending more benefits to households already receiving benefits but with some legal immigrant members; the potential impacts of sponsor deeming and liability policies that might lead to reduced participation among newly eligible noncitizens; and the need for strategic investments in outreach and other efforts to improve access and boost participation among targeted populations.

Social Stress

Elaine Hsieh
Department of Communication, University of Oklahoma, Norman, OK, USA

International migration constitutes a significant life event, during which immigrants often face drastic differences in social norms, cultural beliefs, and language proficiency in the host society. Many use the term "acculturative stress" (i.e., the psychological, somatic, and social difficulties that may accompany acculturation processes) to describe stress experienced by immigrants as they adapt to the host society; however, some researchers have argued that (a) acculturation is not necessarily a stressful experience and (b) immigrants' experience of stress may or may not be related to the acculturation process.

Recent research has highlighted that stress is a socially constructed experience and is dependent on individuals' interpretation of their experiences. The interpretative nature explains the inconsistent findings in which some found an elation period for new immigrants and others found that emotional distress is highest during initial resettlement (particularly the first few to 18 months). Whereas some immigrants may find the challenges in the host society refreshing and exciting, others may view it as undesirable obstacles. Alternatively, an immigrant may consider some challenges stimulating and others agonizing. Differences at life stages may also influence individuals' interpretation. For example, young parents may feel proud and satisfied that their children are well assimilated, indistinguishable from native others in the host society; in contrast, elderly immigrants may experience a significant sense of loss and guilt recognizing that their native culture will be permanently lost to their future generations.

By situating stress in social contexts, researchers highlight individuals' experiences of stress as (a) consequences of their social circumstances and (b) a determinant for specific outcomes (e.g., psychological distress). Immigrants experience specific stress factors that are unique to their backgrounds and life experiences. Migration circumstances (e.g., asylum seekers versus economic-motivated settlers), socioeconomic status (e.g., professionals versus migrant farm workers), legal status (e.g., legal versus illegal immigrants), expected duration of stay (e.g., temporary versus permanent residence), ethnic group (e.g., ethnic majority versus ethnic minority), language proficiency, and host culture receptivity influence immigrants' adaptation process. For example, most of the immigrants who arrived to the United States after 1970 were from countries in Latin America and Asia. They often experience more entrenched prejudice and discrimination and fewer opportunities for economic advancement in comparison to those in earlier waves of

European immigration. Length of time in the host society is also an important factor. Generally speaking there is initial euphoria when first arriving the host society; however, immigrants soon experience increased disenchantment and demoralization during the acculturation process, which often is accompanied by stress. The experience of stress may taper off as immigrants develop strategies to meet the challenges of the host society. Although there appears to be a U-shape trajectory of elation to depression to recovery, recent studies have suggested that duration of stay is a moderator, rather than a predictor, of immigrants' experience of stress, which can fluctuate over time due to immigration demands and their ability to meet those demands. Another factor is the location of settlement, which may have implications for the availability of social support and other resources (e.g., financial resources). Moving to a different country often entails a loss of one's support network, resulting in difficulties in meeting challenges in everyday life. On the other hand, if individuals are able to reunite with family members or to live in ethnic enclaves in the host society, they may adapt better and experience less stress due to the increased social support. Some researchers also have noted that pre-migration stress (e.g., exposure to violence) may also increase individuals' susceptibility to post-migration stress.

Immigrants' experience of stress may be reflected in their experience of depression and cardiovascular diseases, both of which are known to be sensitive to prolonged exposure to stress. Stress also is found to negatively influence the immune system and to be correlated to various medical conditions, including chronic pain, asthma, arthritis, hypertension, gastrointestinal disorders, and preterm labor, among others. Due, in part, to the self-selection of healthy people to immigrant, immigrants generally have better health status than average native-born residents in the United States. Some researchers also have argued that foreign-born immigrants may experience less stress and better health because their cultural values (e.g., strong family network and aversion to risky behaviors) and practices (e.g., healthy diet and physical activity) provide a buffering effect to their immigration demands and challenges; however, the cultural buffering effect tends to subside over time and across generations. For example, researchers have found that the stronger a Japanese immigrant adheres to the original Japanese culture, both during childhood and retention during adulthood, the lower the risks of coronary heart disease. First generation Hispanic women are less likely to have adolescent pregnancy or low birth weight children than the second generation. From these perspectives, it is important to recognize that first generation immigrants do not necessarily experience the highest level or amount of stress; rather, different generations of immigrants experience different stressors at fluctuating levels and at different stages of life as they meet their distinctive immigration demands in their adaption and acculturation processes.

Finally, it is important to note that the host society as a whole also experiences stress in its socio-structural systems as it attempts to accommodate and assimilate new immigrants. The influx of immigrants, along with their cultural values and social norms, can create significant pressure for the host society. These "stressful" events in the host society are subject to interpretation as well. Some host societies may view the demographic changes as an exciting inflow of resources to rejuvenate, strengthen, and/or diversify its international competitiveness. Others, however, may consider these changes as threats to contaminate their original cultural components and design policies to moderate or even prohibit the fusion and infusion of "foreign" cultures.

Socialized Medicine

Maria-Theresa C. Okafor
Division of Gerontology, Department of Epidemiology and Public Health, University of Maryland School of Medicine, Baltimore, MD, USA

Socialized medicine (sometimes equated with universal health care) refers to a system of publicly funded health care, whose primary objective is to provide accessible, affordable, and quality health care services to all eligible members of the population. Benefits of socialized medicine include increased life expectancy, improved general health, and decreased infant and maternal mortality, to name a few. Socialized medicine is financed in a variety of ways, including taxation and contributions from workers and the government. Many countries have some form of socialized medicine, including industrialized nations (i.e., United Kingdom, Canada, and Australia) and developing countries (i.e., Ghana, Cuba). The United States is the only industrialized nation which does not have a universal health care system. However, in recent years some areas of the United States have moved toward implementation of state-wide, near-universal health care systems that mandate health insurance for all residents. Such systems may allow exceptions to be made for individuals meeting certain poverty-level criteria.

In recent times, there has been increasing controversy regarding whether immigrants (documented and undocumented) are entitled to any benefits of socialized medicine. Proponents for immigrant rights argue that from an ethical standpoint health care is a fundamental human right (supported by international human rights treaties), and therefore immigrants are entitled to benefits, regardless of whether they are legal or permanent residents. Such proponents view socialized medicine as a means of mitigating the racial and class inequalities in a given population. Opponents of immigrant rights argue that socialized medicine should be a privilege reserved for citizens and that any coverage of noncitizens will increase economic costs and diminish the quality of health care received (i.e., longer waiting lists, overworked physicians).

In some countries, there are regulations in place that allow immigrants access to socialized medicine under specific circumstances. For example, in the United Kingdom, refugees (displaced persons granted asylum in a foreign country as a result of war, violence, or fear of persecution taking place in their native country of residence), asylum seekers (persons who have formally applied for refugee status in a foreign country), and other overseas visitors who have had “lawful residence” in the country for at least 12 months prior to their need for health care are allowed to utilize the National Health Service, the United Kingdom’s socialized medicine system. However, this still does not account for the health care needs of undocumented (illegal) immigrants and failed asylum seekers.

In countries such as the United States, that do not have a formalized system of universal health care, legal immigrants are restricted (or prohibited entirely) from receiving benefits from social insurance programs such as Medicaid and Medicare; illegal immigrants are not eligible for Medicaid or Medicare services. Such restrictions may inevitably result in an increased dependence on emergency room visits as a source of primary care or deter immigrants from attempting to access any health care services, for fear of deportation or financial repercussions. Immigrant children and immigrant elders are perhaps the most affected by such decisions, given that they already represent particularly vulnerable subgroups across the world.

As a group, immigrants often arrive in their host countries with a health advantage over the general population. However, they undergo various environmental and lifestyle changes that place them at higher risk for disease. The process of adapting to a new culture (acculturation) can be very stressful, particularly for those who left their country under adverse circumstances such as refugees, asylum seekers, and illegal immigrants. Furthermore, many immigrants live below the poverty level, and those who are noncitizens have higher poverty rates than naturalized citizens. This means, that in addition to the stressors of acculturation, immigrants may be forced to deal with less than desirable living conditions, malnutrition, and extreme financial hardships. Such factors may severely compromise their health and undermine any preexisting health advantage that they might have had. Chronic diseases such as obesity, diabetes, hypertension, and cancer are on the rise among immigrants. In addition, untreated infectious and parasitic diseases among immigrants remain a problem.

Currently, socialized medicine has had varying degrees of success in addressing the health care needs of immigrants. For those able to receive care, socialized medicine has been largely beneficial. However, the system is not without limitations. Language barriers and unavailability of interpreters impede necessary communication between immigrants and health care workers. This can be frustrating for immigrants who may perceive such barriers as culturally insensitive, while health care workers are frustrated by their inability to get information necessary for proper diagnosis and treatment. In addition, by the time immigrants come forward to receive care, their ailments are in advanced stages and treatment options may be limited. Also, conditions in an immigrant's native country (or sheer distance) often make it difficult for health care workers to access traceable history of disease or treatment; immigrants may not even be able to provide self-report information on such history. Finally, because of the ambiguity regarding entitlement to socialized medicine benefits, providers are unsure who is eligible, what care they can provide, and what penalties exist for providing care to ineligible individuals.

From a population health perspective, it would seem that granting immigrants access to socialized medicine would not only improve the overall health of communities, but also be more cost effective in the long run (i.e., preventive care can reduce long-term costs for untreated conditions).

Somatic Symptoms

Holly C. Sienkiewicz
Department of Public Health Education, The University of North Carolina at Greensboro, Greensboro, NC, USA

Somatic symptoms are body-related symptoms that are experienced by an individual. Sometimes individuals experiencing such symptoms may undergo numerous medical tests that yield negative results prior to receiving a psychological diagnosis. In psychiatry and psychology, the terms “somatic,” “somaticize,” and “somatizing” are often used when patients presenting physical complaints lack apparent biological or medical underpinnings and the symptoms are deemed to be brought on by mental distress. Unlike malingering, patients who somaticize are not thought to feign their symptoms. Studies suggest that patients who somaticize have often experienced physical pain, discomfort, or trauma prior to the onset of symptoms.

Immigrants and refugees sometimes display symptoms of somatization during the initial stages of acculturation. If a physician suspects that an immigrant or refugee is somatic, he or she cannot consider a psychological cause of disease until physical conditions have been ruled out. This process may involve multiple visits and costly tests. Somatic symptoms vary between cultures. Worldwide, somatic complaints manifest most commonly in the form of gastrointestinal pain, abnormal skin sensations, numbness, chest pain, headaches, palpitations, and shortness of breath. The most common somatic symptoms in the USA include gynecological, gastrointestinal, and cardiovascular complaints. Somatization is a common result of psychological trauma. Studies suggest that exposure to war is a significant predictor of somatic complaints. The presence of psychological trauma, including exposure to war, should alert clinicians to the possibility of the presence of posttraumatic stress disorder (PTSD).

Individuals in many different cultures unintentionally convert personal or social distress into somatic ailments. Such conversion symptoms are allegedly reported more frequently in non-Western societies. Displaying a degree of somatic symptoms may be customary in some cultures and is not necessarily indicative of a mental disorder. In some cultures, the display of somatic symptoms tends to be less stigmatizing than other psychological symptoms, and therefore, more socially acceptable.

South Asians

FARAH AHMAD
School of Health Policy and Management,
York University, Toronto, ON, Canada

South Asians are culturally diverse people who trace their origin in the Indus Valley of the Indian subcontinent. The civilization has existed here since 2500 B.C. From 1858 to 1947, the majority of this region was colonized by the British. The end of British rule culminated in partition of India into two nations, India and Pakistan (East and West), in 1947, and the ensuing conflict over Kashmir. In 1948, Sri Lanka (formerly Ceylon) became an independent state. In 1971, East Pakistan separated from West Pakistan and became Bangladesh. Today, South Asia encompasses the countries of India, Pakistan, Bangladesh, Sri Lanka, Nepal, and Bhutan. The latter two were previously monarchies and became democratic states in 2008 and 2007 respectively. According to the United Nations’ data presented in the World Population Prospects (2008 Revision), South Asia occupies 3.8% of the world’s land and 24% of the world’s population. Not surprisingly, several subcultures exist in South Asia with diverse languages and religions. The major religions of South Asia are Hinduism, Islam, Sikhism, Buddhism followed by Jainism and Christianity.

South Asian Immigrants

Most South Asian immigrants have migrated directly from aforementioned countries. However, a minority belong to the South Asian diaspora. The word diaspora comes from Greek and refers to “a scattering of seeds.” South Asian diaspora refers to people whose ancestors were from the subcontinent of India but migrated to other colonized communities established by British and French in the nineteenth century. Some of these countries are Guyana, Trinidad and Tobago, East and South Africa, Fiji, and Mauritius. More recently, they have also been identified from countries like the United Kingdom, the United States, Australia, and New Zealand. South Asian diaspora invokes a concept of community with multiple locations and movements or “twice migrants.”

In the last few decades, the number of South Asian immigrants has increased dramatically in various nations throughout the world. This could be explained by the “push–pull” phenomenon. Pushing forces are those negative circumstances which exist in the countries of origin (e.g., political instability and ethnic or religious conflicts) leading to emigration. Pulling forces are the attractive features (e.g., safety and economic opportunity) in the countries adopted by migrants. Some scholars link the increased emigration of South Asians to the post-colonial aftermath with a breakdown of local culture and the political system, suspension of economic progression, and the rise of structural hierarchies and social stratification (e.g., gender and caste). This is possibly compounded by increasing economic divide between countries.

North American Settlement

South Asians comprise one of the fastest growing immigrant groups in North America. However, their immigration trends have changed over time.

In the USA, immigration from South Asia has occurred in three waves. The *first wave* lasted from 1907 to 1924 and comprised almost exclusively a few thousand men from Punjab who arrived as farm laborers or migrant workers and settled in California. Most of them married Hispanic women due to the US immigration law which discouraged returning to South Asia for marital purposes. After World War II, the immigration policies started to relax. The Luce-Celler Bill of 1946 established a small quota for immigration from regions of India and Pakistan and permitted their naturalization. In 1952, the McCarran-Walter Act removed all race restrictions on immigration, supplanting the 1790 Naturalization Law which only accepted “free, White persons” as citizens.

The *second wave* of South Asian immigration began with the Immigration and Nationality Reform Act of 1965 and continued until the mid-1970s. In 1965, the annual quota of immigrants was raised to 20,000 per country and allowed family reunification. This policy shift, amidst the civil rights movements, came as a response to criticism from the United Nations and the need for skilled professionals. The policy favored high-skilled workers such as medical doctors, engineers, and scientists. This led to a large proportion of South Asian immigrants securing white collar jobs in the USA and their labeling as “model minority” (for other Asian groups).

The *third* wave of South Asian immigration began in 1976 when stricter regulations started to emerge for skilled workers. The recent immigrants are generally less educated and often arrive to join their predecessors. They are often in low paid jobs or self-employed running grocery stores, gas stations, restaurants, or taxies. With lesser economic stability, many family members may live together under poor conditions which contradict the previous “model minority” status. According to the 2000 census, 1,678,765 Americans identified themselves as Asian Indian regardless of the country of birth. The largest proportions are found in California and New York.

In Canada, South Asian immigrants have arrived in two dominant waves. The *first wave* of South Asian immigrants came from Punjab in the early 1900s as industrial workers. During this era, family members of non-European migrants were not permitted. It is estimated that in 1908, there were 5,000 South Asians in Canada. In 1909, Canadian government limited immigration to only people who came by continuous travel from their country of birth. This regulation effectively halted South Asian immigration, and between 1909 and 1943, only 878 South Asians were permitted to enter Canada. During this period, unlike the US policy, South Asian men were permitted to return to their native countries. Thus, many visited their homeland to marry or bring their wives and any children less than 18 years of age. After the World War II, immigration restrictions were gradually removed. By the 1950s, immigration rules eased with an annual immigration quota for various countries. In 1967, immigration policy moved toward a point-system based on qualifications and, hence, eliminated preferential support to Caucasian immigrants.

The *second wave* of skilled South Asian immigrants and their families began in the 1970s and continues to date. Currently, Canada selects economic immigrants on the basis of attributes such as education, needed professions, language skills, and age – all of which are grouped under the rubric of human capital – along with pre-migration health screening. In 2006, South Asian immigrants became the top visible minority group in Canada. The number of South Asian immigrants in Canada rose by 37% between 1996 and 2002. According to 2006 Canadian census, 1,316,770 people are self-identified South Asians regardless of the country of birth. The largest numbers reside in Toronto, Vancouver, and Montreal.

Settlement Challenges

Migration is not without challenges for South Asians arriving in countries like Canada and the USA where most of the population is of European or Caucasian descent. Immigrant South Asians may experience multiple oppressions not only from their own community (i.e., gender and class-based norms) but the dominant society as well. Several studies report that immigrants encounter settlement challenges due to systemic, informational, cultural, and linguistic barriers. Compared to European immigrants, the intensity of these settlement barriers is often higher for South Asian immigrants due to their visible minority status leading to experiences of being different, also called "minoritization." Studies with South Asians report experiences of overt or subtle discrimination or racism. In the USA, South Asian immigrants are also likely to be influenced by negative stereotypes of African Americans. Recent South Asian immigrants also encounter the expectation to be a "model minority" like their predecessors though they may lack the socioeconomic advantage enjoyed by their predecessors. Post 9/11 discrimination is another stressor for South Asian immigrants.

Transnationalism

In the modern world of technology, migration is not a unidirectional experience. With the availability of affordable, rapid transportation and communication technologies, immigrants are able to travel frequently between their countries of origin and settlement, and retain close contacts with families and friends left behind. Scholars have documented the value given to maintaining attachment and close ties among South Asian first- and second-generation immigrants. This mitigates their ability to maintain their original cultural norms and health beliefs while assimilating and acculturating with dominant norms of the settlement society. As described by Portes and DeWind transnationalism represents "the obverse of the canonical notion of assimilation, sustained as the image of a gradual but irreversible process of acculturation and integration of migrants to the host society. Instead, transnationalism evokes the alternative image of a ceaseless back-and-forth movement, enabling migrants to sustain a presence in two societies and cultures." This adds urgency to the need to understand the social, historical, economic, and political context for immigrants in pre- and post-migration countries.

Cultural Norms, Values, and Beliefs

Cultures norms, values, and beliefs are formed by social organization and activities of families and communities. To understand the transformation of norms, values, and beliefs, it is important to examine the family structure and community orientation from a cross-cultural perspective.

In South Asia, a traditional family structure has extended kinship and a shared household where several married brothers live under the same roof with parents and unmarried sisters. Senior members of the family, such as parents or grandparents, control the social activities of younger family members. Thus, elders hold the authority to make decisions about employment, education, matrimonial selection, and age of marriage for younger family members. A traditional marriage is arranged by parents often at young age, because economic independence of a man prior to marriage is not viewed as necessary in the context of a shared household.

The meaning of marriage is to build relationships between families, instead of two individuals, and this in turn signifies family honor and obligations. Men are given higher status in the family due to their expected role in economic contributions, limiting women's power in decision-making. In contrast, the Western family structure is nuclear and a typical household has only one married couple while unmarried adult children often live separately. This encourages children's independence in Western families but necessitates financial viability before marriage, leading to marriages at a later age.

The organization of family units contributes to orienting the respective community. One such example is the collectivist and individualist orientation of cultures. South Asian culture is collectivist in nature where self is interdependent; personal goals and communal goals are closely aligned; social behavior is guided by obligations, duties, and communal goals; and emphasis is placed on maintenance of relationship even when disadvantageous. The Western culture is individualistic where self is independent; personal goals have priority over group goals; social behavior is guided by attitudes, personal needs, rights, and contracts; and relationship maintenance is critically analyzed for advantages and disadvantages. Thus, autonomy and uniqueness are valued in the West while sharing of resources and conformity are desirable in the South Asian culture. In this light, desire for group harmony encourages self-sacrifice, obedience, elders' respect, and filial piety among South Asians. Strong patriarchy in South Asian culture can lead to exploitation of collectivist values and norms. For example, women are held responsible for maintaining the family unit which leads to their higher self-sacrifice than men. Women are also expected to be obedient in their roles as daughters, mothers, and wives, also referred to as "three obediences." This often leads to their subordination in a family and community.

Cultures are not static and also have individual variations. Yet, cultural transformation is rapid for individuals who migrate to a region with different cultural patterns. This also raises the possibility of intergenerational tensions. For example, migration of South Asians to Western culture may mean loss of extended kinships and shared households which can lead to decreasing bonding. At the same time, their next generation aspires for independence contrary to the values of parents and grandparents leading to stress at the both ends.

Health and Determinants of Health

Although large-scale studies with adequate number of South Asian immigrants are limited, three health issues frequently emerge in the published literature. These include their low use of preventive services (e.g., cervical and breast cancer screening), high risk of cardiovascular diseases, and domestic violence. Please see relevant sections for these issues.

There is dearth of knowledge about the health determinants specific to South Asian immigrants. Some small scale community studies generate important insights but the findings are not necessarily generalizeable. In this light, it is important to explore various conceptual frameworks to set direction for future research, programs and policies.

One such framework is presented by Bierman et al. to understand the pathways through which multiple factors determine the health of immigrants, in particular at the intersection of gender and ethnicity. First, the geo-political environment constitutes the overarching context, creating forces that determine who migrates, where they migrate from, and their resulting migration settlement. Thus, the health and wellness of South Asian immigrants is the product of macro-level or national factors, such as the economy, labor market conditions, and immigration policies. Second, the meso- or community-level factors determine health such as neighborhood characteristic, social networks and discrimination. Finally, the micro-level factors related to individuals and families (income, education, and family structures in countries of origin and in the adopted nation) contribute in immigrant health. Socially constructed gender roles and its shifts in the countries of origin and settlement mediate at the macro, meso, and micro levels, resulting in different health outcomes for men and women.

Future research is needed to improve understanding on the population-specific determinants of health to tailor health, social and economic policies aimed at optimizing health and well-being of immigrants, including South Asians.

Southeast Asia

Background

For the purpose of this entry, Southeast Asia consists of members of the Association of Southeast Asian Nations (ASEAN). These nations include Brunei, Myanmar (formerly known as Burma), Cambodia, Indonesia, Laos, Malaysia, Philippines, Singapore, Thailand, and Vietnam. East Timor is generally recognized to be in Southeast Asia but is not a member of ASEAN. For historical and cultural reasons Papua New Guinea is considered to be part of Oceania.

Few other regions on earth have experienced and been defined by the impact of continuous conflict, famine, and external forces of control as Southeast Asia. In order to approach the questions of health policy and the individual care of Southeast Asian immigrants, it is critical to recognize the devastating impact of war and genocide in the twentieth century. Geographically the region is divided into two distinct areas. Mainland Southeast Asia stretches from Myanmar southeast to Vietnam. The countries to the south are grouped under maritime Southeast Asia, including Singapore, Brunei, the Philippines, and Indonesia; the latter of which is spread across 17,508 islands. The entire region is geologically very active with frequent earthquakes and volcanic eruptions. The Boxing Day Tsunami of 2004 originated in Indonesia, and much of the destruction was within the Southeast Asian region. The tsunami was caused by one of the largest earthquakes ever recorded and killed 230,000 people across 14 countries.

The region contains many extremes: The population of Brunei is estimated to be 400,000 with a GDP per capita of US$36,700 whereas the population of Indonesia was reported at 240,271,522 with a GDP per capita of US$4,000, still surpassing the region's lowest GDP per capita – Myanmar, at US$1,200.

Another extreme is religion. Today Indonesia is home to the world's largest population of Muslims whereas Thailand is almost 95% Buddhist. In the region overall, Islam and Buddhism are dominant, but there are large populations of Christians as well as enclaves of Hinduism and remote areas that practice animism.

Outside Influences

Before the 1500s, the first known nation-states in the region were sophisticated Buddhist and Hindu empires with strong Indian influences. They existed for at least a thousand years prior to the thirteenth century, and many left extraordinary religious structures such as the Hindu Angkor Wat in Cambodia and the Buddhist temple Borobudur in Indonesia.

During the thirteenth century, two major events occurred in different areas of Southeast Asia. In mainland Southeast Asia, Kublai Khan's Mongol forces swept into Myanmar and overthrew the reigning Bagan kingdom. The Mongols were followed by the Tai-Shan people from Yunnan, China, who would fan out to Myanmar, Thailand, and Laos. In maritime Southeast Asia, Muslim traders arrived, and Islam began to take hold. One of these traders was thought to be a Chinese merchant named Zeng He, who arrived in the fifteenth century with Muslim Chinese crews. The ties he established across Southeast Asia during his voyages paved the way for one of the first waves of Chinese migration to Southeast Asia and the formation of Chinese communities across the region.

Early European Influence

In the 1500s Europeans began to arrive. Eventually the Portuguese claimed Timor, and the Spanish ruled the Philippines. The Dutch established the Dutch East Indies (modern day Indonesia), the French established control in mainland Southeast Asia and called it Indochina (including modern day Cambodia, Laos, and Vietnam), and the British Straits Settlements included modern day Singapore, and Malacca, and Penang in Malaysia. The British also expanded into Myanmar from their colonial outposts in India. Along with European trade and outposts came missionaries and Christianity. The European presence in the nineteenth century led to a second wave of Chinese migration to the area, as developing and exploiting local resources resulted in an insatiable demand for labor. This wave is sometimes referred to as the great "Chinese Diaspora." The migration led to a strengthening of ties between China and Chinese communities that had been established hundreds of years previously by traders in the fourteenth to seventeenth centuries.

World War II

The 1940s brought World War II and the Japanese occupation of much of Southeast Asia. Japan invaded Cambodia, Laos, and Vietnam but left the French colonial authorities in place until 1945. In a last ditch effort to gain support of the Asian population as their new empire crumbled, the Japanese jailed the French authorities. This led to disruptions in production and contributed to a famine in Indochina that killed one million people in 1945. The Japanese did not occupy Thailand, as it aligned with Japan and declared war on the USA and the UK. However Thailand generally did not act on the war declaration, and more than 50,000 armed Thais supported the Allied war effort. Myanmar was an active battle ground while the British fought to keep the Japanese out of India.

Many Indonesians initially greeted the Japanese occupation of Indonesia as freedom from Dutch oppression. Although Indonesian nationalists cooperated with the Japanese, thousands of Indonesians were conscripted for slave-labor military projects such as the Burma–Siam Railway and died as a result of poor treatment and starvation. Japanese troops committed sex slavery on a broad scale. The United Nations estimated that during this period four million Indonesians died as a result of forced labor and famine.

In Singapore the British forces suffered a crushing defeat resulting in Japanese purges of ethnic Chinese in Singapore, systematic massacres in which 25,000–50,000 people died. After the war ended in 1945, the effects of the Japanese occupation and failure of the British defense of Singapore sparked a political awakening that led to the eventual independence of Singapore through peaceful means.

Revolution and Anti-Colonial Struggles

After the Japanese surrender and the end of World War II, the Philippines gained independence peacefully in 1946 and Myanmar in 1948. Indonesian independence fighters gained independence in 1949 after 4 years of conflict with the Dutch. In the territories that would form the nation of Malaysia in 1957, the British fought and suppressed a communist insurgency from 1948 to 1960. This was the forerunner of an ideological conflict that would spread throughout Southeast Asia over the next 30 years as the USA and the West developed a policy of "containment" against communist expansion in the region. Nowhere was the conflict more devastating than in the former French colonies, Vietnam and Cambodia, where it had consequences on immigrant health that continue today.

First Indochina War

The war began after World War II when the French returned to resume colonial control of Vietnam. The Viet Minh, a communist movement, fought the French with support from the People's Republic of China and later from the Soviet Union. After defeating the French in 1953, negotiations resulted in Vietnam being split in half with the North going to communist Viet Minh control and the South to an American-backed regime. Negotiated plans for an election were never followed through, and this led to renewed conflict.

Second Indochina War: Vietnam, Cambodia, and Laos

The 1954 division led to the Second Indochina War (referred to in the USA as the Vietnam War) from 1960 to 1975. It began with indirect American support in the 1960s and escalated to years of continuous bombing campaigns and massive commitments of troops and resources from the USA and its allies. Due to massive public opposition and lack of political will, USA signed the Paris peace accords and withdrew in 1973. Two years later South Vietnam fell to the forces of the Communist north. By the end of the war more than 3.1 million Vietnamese had been killed and 2.6 million injured. The end of the war marked the end of 116 years of foreign control of Vietnam and 30 years of continuous warfare by the leaders of the Communist party in Vietnam.

Cambodia gained independence from France in 1953 and remained a constitutional monarchy until open conflict with the communist (Maoist) Khmer Rouge began in 1970. Fighting continued until the Khmer Rouge gained control of the country in 1975, the same year the North Vietnamese gained control of South Vietnam and unified their country. Within days of capturing the capital, Phnom Penh, the Khmer Rouge led by Pol Pot began a campaign of genocide that killed 20% of the population or approximately two million people from 1975 to 1979. Cambodia was invaded by Vietnam in 1978, and despite a limited Chinese invasion of Vietnam in 1979 to support their Cambodian allies, the capital Phnom Penh fell to the Vietnamese. Stability did not come to Cambodia until an agreement in 1991 that was policed by 20,000 U.N. Peacekeepers.

The Laotian Civil War (1953–1975) occurred between the Pathet Lao communists and the French colonialists and later the Royal Laotian Army. Despite American, Thai, and South Vietnamese intervention, efforts by the North Vietnamese supporting Pathet Lao communists were ultimately successful, and the Pathet Lao overthrew the Royal Laotian government in 1975.

Legacy of War: Unexploded Bombs, Land Mines, and Refugees

Laos has the unfortunate distinction of being the most heavily bombed country, excepting the atomic bombs dropped on Japan. In their attempts to interdict North Vietnamese supply convoys to the guerillas in the south, the US Air Force is thought to have dropped one bomb load every 8 minutes, from 1964 to 1973. More bombs are reported to have been dropped on Laos in these 9 years than the combined ordinance used in World War II. It is thought that in some areas almost one third of the bombs did not explode, a legacy which still causes death and maiming today.

Thirty-five years later, residual effects from the Indochina war in Cambodia include land mines and unexploded military ordinance that the warring forces (US, Vietnamese, Royal Cambodian, Thai, Khmer Rouge, and other military forces) left. Cambodia is one of the most heavily mined areas in the world, and it is estimated that two to four million mines remain. Cambodia has one amputee for every 290 people; UNICEF estimates that children sustained half of land mine casualties in Cambodia, many of whom will not have access to modern prosthetics. These victims also have unmet mental health needs and commonly express symptoms of posttraumatic stress disorder (PTSD) and chronic depression.

Between 1975 and 1995, more than three million people are thought to have fled Vietnam, Laos, and Cambodia, many as "boat people" who ended up across the globe. Some estimates suggest that as many as 250,000 boat people died on their journey. The ones who survived did so in extremely harsh conditions, often languishing in refugee camps for years with the constant threat of return to the country they had fled.

Emigration to Other Countries

Because of American military and political involvement in Indochina, almost 1.4 million refugees from Southeast Asia were relocated to the USA; 1.1 million of them are thought to be Vietnamese, the majority living in California and Texas. A significant percentage of Vietnamese refugees are the progeny of Vietnamese women and the more than three million male American personnel stationed in Vietnam during the war. These children often experienced ridicule and abuse in Vietnam.

From 1975 to 1993 more than 500,000 Cambodians fled into Thailand, and another 100,000 entered Vietnam. At least 300,000 of those Cambodians permanently fled the region, with more than 179,000 migrating to the USA, 50,000 to France, and 45,000 to Australia.

The American resettlement of more than a million refugees from the Indochina war was influenced by the experience of Miami, Florida, in coping with the Cuban refugee crisis. In the 1960s, Miami received hundreds of thousands of refugees, and its social service system was overwhelmed. Therefore, the government dispersed Southeast Asians widely throughout the USA. It was a failed social experiment, as the refugees were isolated by differences in language, food, lack of community, and religious or spiritual support. Refugees migrated within the USA toward locations where family and community leaders had settled, primarily in areas where there was infrastructure established by Asian-American populations.

Myanmar

The conflict in Myanmar has generally been an internal one. Myanmar maintains trade and relations with its neighboring states and China but is otherwise isolated from the international community. The conflicts began when a 1962 coup d'état led to military rule. Since that time, inefficient central control of production and other economic policies have changed Myanmar from "the ricebowl of Asia" to one of the world's most impoverished nations. Over half the Burmese population consists of diverse ethnic groups. There has been a long history of government offensives against a variety of ethnic insurgent groups resulting in hundreds of thousands of refugees and internally displaced persons. Burmese refugees in Thailand include the Karen, Karenni, Shan, Tavoyan, and Mon ethnic groups. The U.N. estimates that at least 150,000 Burmese refugees have gone to Thailand, 125,000 to Bangladesh, and 20,000 to Malaysia.

Human Trafficking

Approximately 200,000–225,000 women and children are trafficked annually in Southeast Asia alone. The majority of these women are trafficked to countries within southeast and eastern Asia, but at least 30,000 are transported to the USA each year as unwilling prostitutes and domestic labor. Additional tens of thousands end up in Australia and Europe. Human trafficking is a form of exploitation that involves controlling and transporting people through the use of force, deception, or coercion. It is reported to be the third most profitable criminal activity in the world after drug and gun smuggling and resulted in estimated worldwide profits of US$31 billion in 2008.

The classic pattern of trafficking occurs when a woman is lured by a placement agency to leave her rural village to come work in a city as a maid or receptionist at a hotel or spa. Traffickers then isolate the woman and often rape her and threaten to maim or hurt her or her family if she does not work as a prostitute for them. There are numerous variations on this theme: Traffickers target children with promises of a school program and turn them into beggars or flower sellers; men are promised well-paying construction jobs and find themselves as indentured slaves in mines or other work in unsafe conditions for little pay. The traffickers are reportedly organized crime syndicates, parents, relatives, friends, intimate partners, and neighbors. Trafficked women are at high risk of sexually transmitted diseases and often have their access to health care and testing restricted by their employer; they may be banned from using condoms if clients pay extra or insist.

Young girls who are virgins are highly sought after by traffickers, as they are free from HIV or STDs. They are also thought to convey increased vigor to their male clients. Healthcare workers who see victims of trafficking may not realize their patient's history or may mistakenly screen them for domestic violence. Trafficked immigrants are usually under severe threats not to discuss their status with healthcare workers or have been told that healthcare workers will notify the police and throw them in jail if they find out that they are illegal immigrants. Most countries in Southeast Asia are primarily source countries for victims. Thailand is a significant source country for women sent to Japan, Taiwan, Europe, North America, South Africa, and Australia. Thailand is also a significant destination for women from Myanmar, Laos, Cambodia, and southern China who are brought there for the domestic sex industry.

Narcotic Trafficking

The "Golden Triangle" of opium production across northern Thailand, northern and eastern Myanmar, and western Laos has been the center of poppy cultivation (the source of opium and heroin) since the nineteenth century. In the 1990s, Thailand drastically reduced poppy cultivation and narcotics traffic to the point where it is no longer a significant producer. In 2000 Myanmar produced 60% of the world's heroin and Laos was the third leading producer. This contributes to regional instability but also significant health problems including drug addiction and HIV. Overland heroin trafficking takes drugs into China and across Myanmar to India where the drugs can be distributed internationally. Along the more common routes, heroin trafficking has been demonstrated to cause epidemic outbreaks of HIV; the HIV prevalence along these routes ranges from a low of 30% to as high as 80% among injection drug users.

Culture and Communication

The following section primarily applies to first generation immigrants being treated by Western healthcare workers and is meant to be a general guideline. Cultural practices vary widely across Southeast Asia. More importantly, expectations and knowledge vary widely within cultural groups and among patients and families.

In many Southeast Asian cultures, importance is placed on the family over the individual. Elder family members are given significant weight in decision-making, and families are expected to care for elders. The oldest male is often given the role of speaking for the family, and this can be difficult for Western healthcare workers who may not understand why a female or younger patient is deferring or refusing to make a decision if the spokesperson is not present or disagrees. Because there is a cultural norm to show deference and avoid conflict with authority figures, Southeast Asian families may appear to be passive or ignorant when they do not respond to cognitive reasoning by doctors and nurses. Younger members of the family or women may also avoid eye contact.

Many Southeast Asian cultures do not see a clear hierarchy of knowledge with science playing a primary role. Instead there is often an attempt to seek a balance between modalities of spiritualism, alternative medications, and Western therapies. This can lead to mixing and matching of therapies that may be bewildering to Western caregivers who are focused solely on interpreting illness from a pathophysiologic standpoint. Some Southeast Asian traditions have very strong practices about restoring the balance of "humors" and will identify many foods and therapies as either cold or hot. Healthcare workers who do not understand or ignore these belief schemas may find themselves alienating the person or family they are trying to help. Because complicated cognitive explanations may not be effective across language barriers, other techniques may be necessary. Two successful approaches that have been employed are engaging spiritual or community leaders as advocates and integrating Western treatments with alternative practices such as spiritual and complementary medicine. It is often much more acceptable if a Western treatment is seen as bringing harmony and balance, rather than replacing existing practices. Practitioners may also find that while many Southeast Asian cultures deeply respect the role of the doctor, it does not mean they will blindly follow along. The building of rapport through listening and establishing mutual respect can be time consuming and challenging; however, it will be very rewarding in terms of establishing a basis for trust and adherence to therapeutic recommendations.

As a broad generalization, many people from Southeast Asia will come to a practitioner focused on symptoms rather than a particular disease. Patients in Western cultures tend to expect a doctor to translate their symptoms into a diagnosis; significant anxiety may occur if the doctor is unable to give a diagnosis, even if the symptoms are relieved. Many Asian cultures place an emphasis on alleviating the symptoms first. Southeast Asian patients may not be impressed by a practitioner who provides a clever diagnosis but does not offer a prescription or therapy to alleviate their chief complaint. It is crucial in these encounters to listen carefully to the patient or family as to why they are presenting; if the presenting symptom is not addressed, it may be impossible to engage the patient or family later in therapy.

Paradoxically, some (but not all) Southeast Asian patients come from cultures where they expect the doctor to make a pronouncement of a definitive diagnosis and prescribe a treatment plan in a paternalistic (rather than collaborative) manner, often based on a few vague symptoms. This relates to traditional expectations that healthcare providers have "supernatural" powers to make various predictions. Also, similar expectations can lead to consternation among patients and families when well-meaning practitioners attempt to engage the patient and family in decision-making in an ethically sensitive manner. This is not to imply that clinicians should be paternalistic. However, the manner of the communication needs to be sensitive to their expectations. When there is doubt, cultural expectations and norms should be inquired about and understood, rather than insisting on an individualistic approach.

Mental Illness

Nowhere are these cultural and communication issues more of a concern than in mental health evaluations. With the tremendous history of violence, bombings, starvation, torture, rape, and forced migration, many immigrants are at risk for mental illness or distress, particularly posttraumatic stress disorder (PTSD), and clinical depression. Immigrants to Western countries in particular may describe isolation, harassment (verbal, sexual, or physical), stigma, and loss of status. It is very difficult for Southeast Asians to discuss mental illness, and practitioners should be alert for psychosomatic presentations of PTSD and depression when vague symptoms are reported that do not respond to any treatment. Investigations of functions like sleep, appetite, and motor activity may be more useful than inquiry about mood and guilt. Prior direct or indirect exposure to trauma is normal in Southeast Asian immigrants. While many people are resilient and able to cope with their traumatic past, others suffer chronic sleep disturbance and survival guilt. For some, PTSD symptoms may surface after many years of apparent good mental health, either because of role transitions (e.g., a father who no longer needs to provide for his family after he retires) or during times of new social stressors. Functional status such as changes from social roles (e.g., caring for grandchild by grandmother, job performance of husband) should also be inquired about to help elucidate the severity of depression and PTSD.

While most clinicians strive for a good rapport with patients, a strong alliance and validation is crucial before introducing the idea of psychiatric care or referral. This may take several visits and even then should be introduced slowly and sometimes indirectly, to "save face" and to avoid shame on the part of the patient, since psychiatric disorders are associated with "weakness." Except in the most extreme circumstances, family members or friends should be rarely used as interpreters when completing mental health evaluations. While this is an awkward and potentially inappropriate practice in almost any culture, for Southeast Asian patients, it could be truly intolerable for elders to place this burden on their children or to share this distress. Use of inappropriate interpreters will often result in incomplete information and minimization or denial of symptoms. In the USA, phone-based medical translation services and interpreter services have been instituted and even mandated in many settings. Sufficient time should be allocated in each visit to account for the time needed for translation.

End-of-Life Care

In the USA, many patients of Southeast Asian ancestry will respond well to palliative care when it is characterized as comforting, peaceful, and engages the entire family. This is particularly true of patients coming from Buddhist traditions. However, hospice workers need to recognize that families of these patients may attempt to undertake care even when it is draining and exhausting, as they may see asking for assistance as a failure of their obligation to their elders or family. By the same token, Western medical teams can be confused when Asian palliative care patients are brought to the emergency room even though nothing medically urgent has occurred; this can be due to misunderstandings about the role of the hospital or the family feeling overwhelmed. A serious issue of ethical conflict described by caregivers of Asian patients is that they may be requested by the family not to inform a patient that they are dying. This can be out of an instinctive fear not to upset their loved one, but also may come from a sense that it will expedite death. This apparent clash between Western and Eastern values can often be resolved by directly asking the patient or responsible person about their preferences for information sharing, prior to the disclosure of the information to any particular party.

Osteoporosis

Southeast Asian women may be at higher risk for osteoporosis after menopause. At least one study has shown that bone density reference values may be lower for elderly women born in Southeast Asia. Among premenopausal women, there appears to be higher bone mineral density in association with earlier age of menarche, years of education, lower height, and coastal birth (due to seafood consumption).

Culture-Specific Syndromes

These are unique patterns of symptoms that occur in many cultures around the world. They include symptom clusters or behaviors that occur within cultures without clear relationships to Western pathophysiologic understanding of human disease. There are many within Southeast Asian cultures and they are discussed in the medical literature. Some of the more famous examples are given below:

- *Amok*: a dissociative episode characterized by a period of brooding followed by an outburst of violent, aggressive, destructive, or homicidal behavior.
- *Koro*: an episode of sudden and intense anxiety that the penis (or in the rare female cases, the vulva and nipples) will recede into the body and possibly cause death, known as “rok-joo” in Thailand.
- *Latah*: hypersensitivity to sudden fright, often with echopraxia, echolalia, command obedience, and dissociative or trancelike behavior. The Malaysian syndrome is more frequent in middle-aged women. Known as “bah-tschi,” “bah-tsi,” and “baah-ji” in Thailand and “mali-mali” or “silok” in the Philippines.
- *Koucharang*: (Cambodia) or “thinking too much illness” is associated with past trauma and symptoms of headaches, behavioral changes, and other somatic complaints.
- *Khyol*: “wind illness,” may also refer to dizziness and fever, but commonly describes a disturbance of balance that can be due to a variety of illnesses.

Infectious Diseases

The prevalence of HIV in Southeast Asia ranges from 0.2% in Laos to 1.4% in Thailand. In 2007 the epidemics in Thailand, Myanmar, and Cambodia were declining while in Vietnam and Indonesia HIV rates were increasing. Routes of transmission are both injection drug use and sex, often but not exclusively through prostitution. Other infections seen in refugees and Southeast Asian immigrants include: amebiasis, angiostrongyliasis, anthrax, capillariasis, chikungunya, cholera, cryptococcosis, cyrptosporidiosis, cysticercosis, dengue, Japenese encephalitis, filariasis, gnathostomiasis, helminthiasis, hepatitis B (15% of the population in some studies), leishmaniasis, leprosy, leptospirosis, malaria, medliodosis, mycetoma, strongylodiasis, trenatodes, tropical sprue, typhus, and yaws.

Health Promotion and Healthcare Maintenance

Research has consistently demonstrated that Southeast Asian immigrant populations are less likely to use routine cancer screening services. In addition, the risk of hepatitis A and B is higher for Asians and routine screening and vaccination is recommended, especially in those with comorbidities. *Helicobacter pylori* is highly prevalent and should be part of the work-up for gastro-esophageal disease. Finally, a system of care should be in place to screen for and provide follow-up treatment for depression and PTSD. A number of PTSD support groups, especially tailored to particular Southeast Asian groups (e.g., Vietnamese from a particular region, Hmong, etc.), may be helpful though more systematic research is needed. Given the community orientation of many Southeast Asian groups, healthcare practitioners should routinely ask about preferences for religion or spirituality, minority group affiliations, language spoken (with particular attention to dialects, which is informative about a person's geographic and ethnic origin), use of herbal medications, traditional healing practices, and view of Western medicine and psychotherapy for those receiving mental health services.

Spanglish

Bettina Rausa
Salk Institute for Biological Studies, La Jolla, CA, USA

Spanglish is the use of both Spanish and English in a manner linguistically defined as code-switching. Code-switching occurs when speakers of two languages use the languages interchangeably. Spanglish is spoken by an estimated 35 million people in the USA, although Spanish is spoken by about 250 million people worldwide, while English is spoken by roughly 350 million.

Spanglish is commonly referred to as the language of Chicanos, that is, Americans of Mexican descent. However, Spanglish, and different varieties of it, are also spoken among other groups of Latinos in the USA, including Puerto Ricans. In fact, code-switching occurs in many instances where people are bilingual in other languages besides Spanish and English, such as Maltese and English, French and German, Spanish and Catalan, and English and French. Typically where there are linguistic borders (i.e., USA and Mexico), or when a country has more than one official language (i.e., Malta), instances of code-switching are found.

The 1990 US census indicated that the Spanish language was lost in the US Southwest after one or at most two generations. A comparison of subsequent censuses revealed that Spanish is maintained only in those regions where recent immigration from Spanish-speaking countries is intense. Distance from the Mexican border is a key parameter for Spanish language retention, intimately linked to opportunities for using Spanish on a daily basis at home and in the workplace.

Examples of Spanglish include sentences or expressions such as "I'm going back to work *pasado mañana*" (I'm going back to work the day after tomorrow); "*La blusa me costó* forty dollars" (The blouse cost me forty dollars); "I bought a new computer today. *Me lo compró mi hermana*" (I bought a new computer today. My sister bought it for me). Although there is no strict or universally agreed upon definition of both Spanglish and code-switching, in general, code-switching in Spanglish follows two rules, one being that the switching from one language to the other consists of unchanged Spanish or English words, and the pronunciation of the words is not altered but remains as pronounced by native speakers of each language. One exception to this, however, is when what is referred to as linguistic borrowing occurs and particular words have both a Spanish and English part. For example, the word *carro* for car and *puchando* for push, as in "*no puchen el carro*" (don't push the car). If Spanish and English are mixed in such a way that does not follow code-switching rules, it is not commonly comprehensible. In other words, Spanglish is not just a matter of using two languages simultaneously to communicate, but rather it follows a set of grammatical and pronunciation rules. According to most linguists, Spanglish follows the three primary code-switching rules: (1) code-switching can take place only between full word boundaries (free morpheme constraint), (2) monolingual constructs within the sentence will follow the grammatical rules of the monolingual fragment, and (3) permissible switch points are those that do not violate the order of adjacent constituents on both sides of the switch point of either of the languages (also called equivalence constraint).

As with many other forms of communication that are not the predominant and strictly enforced communication styles of the predominate culture in any society, Spanglish does not exist without its critics. Some language purists, scholars, and writers are very critical of Spanglish, defining it as using both poor Spanish and poor English language skills. Some see Spanglish as a degradation and deterioration of the Spanish language and fear that its legitimization will eventually eradicate the Spanish language. However, for many people who speak it, Spanglish is culturally significant because it reflects an identity for groups of individuals of Latino origins living in the USA. People tend to speak Spanglish to those whom they feel emotionally or culturally connected. In fact, it has become deeply rooted in Chicano culture. Spanglish is now used by contemporary writers, radio personalities, musicians, and even politicians on the campaign trail to connect to their audiences. It is commonly used in media and advertising. Some hypothesize Spanglish will continue to become more widely used and eventually fully accepted in the American English vernacular, similar to Yiddish (a combination of Hebrew, German, Russian, Polish, and other Slavic languages which, when it was first used, was referred to as "gibberish" for women and children).

Since Spanglish can be used to convey familiarity and solidarity between speakers, Spanglish used in health care settings could be quite important. Health care providers who are fluent in both English and Spanish can use Spanglish with their Spanglish-speaking patients to break down cultural, racial, and socioeconomic barriers that may exist between patients and medical professionals. Spanglish can create a cultural affinity and show empathy, understanding, and acceptance in an area of human exchange that could otherwise be wrought with miscommunications and misunderstandings, and a social hierarchy that may preclude a patient from seeking medical help in the first place, from being as forthcoming as necessary for a medical professional to properly treat a health issue, or from following valuable medical advice. Speaking Spanglish, or accepting it as a legitimate language among patients, can open up communication in such a way that it may lead to better health outcomes for patients.

Sterilization

Patricia Moran
Veterans Administration, Louis Stokes Cleveland Division, Cleveland, OH, USA

Permanent sterilization is the most common method of contraception worldwide; an estimated 180,000,000 tubal ligations are performed each year worldwide on reproductive aged women. In the USA, more than 600,000 tubal ligations are performed yearly. Researchers interviewing women about reasons they voluntarily chose to have a tubal ligation found over 98% cited “completed family,” while 31% said they “could not cope with or afford more children.” Nearly two-thirds reported they viewed a tubal ligation as the safest, most reliable, or most acceptable contraceptive method.

Interestingly, permanent sterilizations chosen by males versus females show converse demographic and socioeconomic profiles. Data from the 2002 National Survey of Family Growth found women who had tubal ligations tended to be less educated (lacking a high school diploma or equivalent), poorer, Hispanic/Latino or Black/African, while men who opted for vasectomies tended to be well-educated, married, relatively affluent, and White. While it is well known that vasectomy is simpler, cheaper, safer, and equally effective as female sterilization, it remains one of the least utilized methods of contraception. Of married women aged 15–49 years, fewer than 5% in developed countries and 3% worldwide rely on their partner’s vasectomy as their method of contraception. An exception to the above is in the sub-Saharan African countries, where for the past decade vasectomy prevalence rarely has exceeded 0.1%; researchers have suggested that vasectomy is unacceptable to most African men. The most common reasons men reported for choosing to undergo a vasectomy were: not wanting more children, viewing a vasectomy as the most secure family planning method, wanting to take responsibility for pregnancy prevention, their or their partner’s dislike for alternative birth control methods, and – among married or cohabitating couples – vasectomy was chosen over tubal ligation because it is safer, simpler, and had a shorter recovery time.

It is well established that in developed countries voluntary permanent sterilization is available to men and women. In the USA, while most men who underwent voluntary vasectomy held private health insurance, being poor does not exclude one from being able to choose permanent sterilization. The federal government and the states jointly finance Medicaid, a health care fund for the needy. Generally, sterilization is covered as a family planning service and receives a 90% match, with 36 states and Washington DC always covering tubal ligations and vasectomies under the family planning benefit.

The USA is known internationally for protecting individual rights and freedoms. While statistics for countries that participate in forced sterilization are not reliable and mostly anecdotal, well documented by the media has been the Chinese government's implementation of its 1979 "one-child family policy." The Chinese government denies claims of authorizing forced sterilizations; however, in 1996 the US Congress enacted a law to grant asylum to victims of forced sterilization, forced abortions, and other compulsory population control.

Charles Darwin's "theory of evolution" may be blamed for the institution of worldwide eugenic programs. In 1865, Sir Francis Galton, a British physician and a relative of Darwin, extrapolated from Darwin's theory that mental illness was hereditary and mentally ill persons were a hazard to society. Galton introduced the term "eugenics" to the European and American public, defining the practice as "reducing the numbers of unfit persons in society."

There was never a federal sterilization statute, but in 1927 the Supreme Court case *Buck v. Bell* legitimized the forced sterilization of mentally retarded persons. Over the next few decades, compulsory sterilization of the mentally ill and retarded was instituted, and some states extended coverage to persons who were deaf, blind, or considered to be physically deformed. With public awareness of Adolph Hitler's genocide policy, sentiments toward eugenics grew less favorable post-World War II. Also, in 1942 the Supreme Court decision in *Skinner v. Oklahoma* weakened the legality of forced sterilization, resulting in fewer being carried out. Despite the *Skinner* case, the routine sterilization of persons in institutions for the mentally ill and mentally retarded continued through the mid-1970s. Today, involuntary sterilization of mentally incompetent persons does occur, but not without following state mandated statutory guidelines and obtaining court ordered consent. The process varies from state to state; however, the goal remains to protect the interest of the patient and the physician.

Stigma

James T. Walkup
Graduate School of Applied and Professional Psychology, Institute for Health, Health Care Policy, and Aging Research, Rutgers, The State University of New Jersey, Piscataway, NJ, USA

The concept of stigma is a member of a family of related notions signifying social devaluation, including prejudice, discrimination, racism, sexism, and the like. The modern understanding of "stigma" is often dated to sociologist Erving Goffman's 1963 *Stigma: Notes on Management of a Spoiled Identity*. Goffman based his use of the term on the practice, in ancient Greece, of relying on a tattoo or brand to mark a person as socially subordinate or an outcast (e.g., criminal, traitor, slave). He used the term "stigma" to refer to a personal attribute that may discredit or "spoil" an identity because people respond with negative expectations and discrimination. Already present in Goffman's initial formulation are themes relevant to immigrant health. Goffman elaborated three types of stigma attributes: the body, which includes health conditions such as obesity or disfiguring skin conditions; deviant traits, which include health conditions such as mental illness or addiction (but also legal status, such as being undocumented); or what he labeled "the tribe," referring to racial/ethnic identities that are devalued as "different" in a given context.

Since Goffman's introduction of the term, it has been developed in several directions by psychologists, sociologists, and advocacy groups. Psychologists have tended to rely on experimental methods to examine cognitive and emotional processes associated with viewing someone as possessing a stigma, such as the types and characteristics most likely to evoke this response, and, to a lesser extent, the processes involved in being viewed in this way, such as the factors that might influence loss of (or preservation of) self-regard. Sociologists have largely relied on large attitude surveys, measuring the nature and extent of the stigma assigned to an attribute that "spoils" an identity, how these attitudes vary across groups and over time, and how these attitudes influence various social processes, such as care-seeking, housing, and dating. A partial exception to this pattern is an effort to combine experimental and survey methods by the General Social Survey. Different versions of a vignette were created. For example, one described a person as having psychotic symptoms. Another instead described the person as having personal problems. By randomly assigning respondents to one condition or another, researchers were able to see how people responded to the characteristic described, and to explore whether these differences might be related to characteristics of the respondent. Advocacy groups, particularly those associated with health conditions, such as HIV/AIDS or psychiatric illness, have drawn on empirical work, particularly to document the harmful impact of stigma on its targets, but have primarily treated it as a wrongful, discriminatory attitude, based on ignorance or unreflective emotional responses.

Developments in this area of greatest relevance to immigrant health are efforts to embed well-understood aspects of stigma in broader social context, and integrate multiple levels of influence. In one influential contemporary model, Link and Phelan analyze stigma in terms of the convergence of four processes: the labeling of human variations, cultural beliefs tying certain of those labeled to negative attributes, a social separation of "us" and "them" that sets apart those labeled, and the associated experience of status loss, discrimination, and restriction of life chances by those labeled. This model also stresses the importance of a context of social, economic, and political power. While attitudes and actions of those who hold power can effectively stigmatize those who have little power, those who are relatively powerless cannot do the same for those with more power, however much they might hold negative attitudes toward identity characteristics of the powerful. The Framework Integrating Normative Influences on Stigma (FINIS), developed by Pescosolido and colleagues, draws together multiple different types of data relevant to three levels of influence: the micro, including both characteristics of the target of stigma and influences on the stigmatizer; the macro, including both cultural messages (e.g., linking mental illness and violence) and larger societal structures (e.g., those producing or countering disparities in wealth and power such as universal health care); and the meso, including social networks influences on the nature and extent of "exposure" to individuals with target attributes.

New policy directions may come from better use of empirical data by advocacy groups. (For example, anti-stigma efforts to identify mental illness as a brain disease may have backfired in some respects, by making people more pessimistic about treatment.) Also important may be efforts to make sense of the clustering of stigmatized traits. A sex worker may also be addicted to drugs or have a criminal record. Little is known about how stigma responses are affected. A related need is better understanding of how, when (and whether) to distinguish stigma effects from effects associated with the other conceptualizations of devaluation (e.g., prejudice, discrimination).

Stockholm Syndrome

Susan Hatters Friedman
Departments of Psychiatry and Pediatrics, Case
Western Reserve University School of Medicine,
Cleveland, OH, USA

In late August of 1973, four employees of a bank in Stockholm, Sweden were taken hostage by an escaped convict and his prison cellmate. The six were together in the bank for over 131 h (over 5 full days and nights). The hostages not only became attached to the bank robbers, but even defended their actions after the standoff ended. The term "Stockholm Syndrome" was coined subsequently, to describe the attachment and positive regard developed by the hostages toward their captors.

Several more recent American cases have been reported to have similarities to the Stockholm Syndrome, including the Patty Hearst, Elizabeth Smart, and Shawn Hornbeck cases. In each case, the victim was taken hostage or kidnapped, yet reportedly developed psychological bonds with the captor. These may be self-protective during the acute crisis or may persist even after release.

Research expectedly shows that hostage victims experience a powerful helplessness. The hostages may start to feel sympathetic toward their captor, and also try to convince themselves that they will not be harmed physically by the captor. The captor may be seen as giving life purely by not taking away life.

Another theory about the development of Stockholm Syndrome is "identification with the aggressor." Identification with the aggressor is also used in understanding childhood abuse and posits that a child victim may grow up to become an adult aggressor. In addition to kidnapping and childhood abuse, other scenarios in which Stockholm Syndrome has been implicated include dating violence, domestic violence, and prison gangs.

Graham and colleagues have suggested several precursors to the development of Stockholm Syndrome, including: a direct threat to survival, an inability to escape, and the victim's perception of both kindness and terror.

Formal study of Stockholm Syndrome is difficult for several reasons, including not only the obvious difficulties in obtaining research samples, but also the difficulties inherent in the lack of formal classification in a psychiatric handbook (the DSM-IV or any international classification system) and need for validation of symptom criteria. Studies about prognosis and appropriate treatment are thus absent.

While there has similarly been a lack of significant formal study, there are special situations in which immigrants may be at risk for developing Stockholm Syndrome. Both child and adult victims of human trafficking may experience traumatic bonding, experiencing terror toward their captors, but also gratitude for supposed favors and indeed their own lives. Those forced into prostitution may form a desperate relationship which could convince others that they are "choosing" to stay. Apparent attempts for escape may even be missed.

Similarly, the self-perception of those in a camp toward their captors may approximate that described originally in Stockholm Syndrome. Narratives about Holocaust victims indicate that they often peaceably went to their own deaths. The situational characteristics enumerated above certainly would apply to concentration camp victims. Too, persons who have lived in a war-torn country may have been placed in situations ripe for the development of the syndrome. Though much is not known about the individual psychological factors which lead one victim to develop Stockholm Syndrome but not another, it is something which health professionals may consider and be sensitive to when they are treating refugees and trafficking victims.

Stress

Stephanie M. Keller
Department of Psychology, Case Western Reserve University, Cleveland, OH, USA

Over 100 million immigrants and 13 million refugees have moved across borders in the past several decades. While this experience can foster personal growth as well as offer new opportunities, many deem the experience as extremely stressful. A number of factors can influence the ease or difficulty of this transition including reason for the move (e.g., war/torture vs. potential educational opportunities), financial stability, discrimination, empathy, social support, emotions, and family dynamics. For many immigrants, reducing external stress is not an option. Rather, effective coping styles must be developed. In addition, increasing resources such as culturally sensitive workshops within the community may help to reduce stress for recent immigrants.

Common Stressors

Stressful experiences are often associated with the immigration process itself, but can certainly extend far before (e.g., planning stages pre-immigration) and beyond (e.g., employment search post-immigration) this time period; the current entry will focus primarily on post-immigration factors (e.g., job and acculturation stressors). Often, voluntary migration, optimistic expectations, and high levels of available social support are shown to be associated with positive outcomes for immigrants. However, even if the perception of the immigration is positive, there are a whole host of uncontrollable stressors that come along with the move. For example, language barriers, acculturation stress, insecure job and/or legal status, actual and perceived discrimination, and financial restraint are obstacles that are faced by immigrants.

First, job stressors are often reported as one of the largest concerns by new immigrants. One can imagine that moving to a new country and trying to find a job in a brand new, unfamiliar environment would be extremely difficult. Additional barriers such as language differences within the workplace can increase stress as well. Immigrant workers often face discrimination from employers due to race, ethnicity, and immigration status. This discrimination is linked to work-related injuries and illnesses. For example, immigrant workers have been reported to perform heavier, more dangerous job duties without proper safety training or equipment. In addition, they often receive lower wages and poorer health benefits compared to nonimmigrant workers.

A second, rather common stressor that immigrants face is the process of acculturation, which can be generally defined as adjusting to culture change. This process can be stressful, especially when the new culture is very different from one's original culture. Some experiences that may induce acculturative stress include forming friendships with peers in the new culture, forming or altering family traditions, finding a church, and even grocery shopping for ethnic foods. Sometimes, immigrants can feel a sense of "push-pull" meaning that they can feel as though adjusting to or embracing the new culture means abandoning or pushing away from their native culture; this can lead to an increased sense of stress. In addition, the levels of acculturation can differ between members of a family, causing tension and potential conflicts within the household. Overall, post-immigration factors such as finding and maintaining a new job as well as adapting to a new culture can be extremely stressful for recent immigrants.

Effects of Stress on Mental and Physical Health

There are many ways in which immigration-related stress such as finding a new job or familiarizing with a new culture can affect one's health: (1) physiological changes within the body, (2) worsened judgment causing less effective coping strategies to be used, and (3) an over- or underutilization of the healthcare system. First, stress can increase the likelihood of developing mental or physical illness. For example, immigrant adults relative to nonimmigrant adults living in the USA tend to display higher levels of depression, anxiety, substance use, cardiovascular conditions, and other health problems.

Second, stress can take the form of worsening one's judgment and lead a person to choose maladaptive or ineffective coping strategies. For many immigrants, reducing stress is not an option (e.g., a person cannot change the discrimination that they face in the workplace); instead, effective coping strategies need to be developed. Coping can be defined as the conscious effort to control one's response to stress and adapt. For example, one way of coping may be to distract oneself from the situation and take a walk. In general, there are four types of coping – including active coping, avoidant coping, cognitive-emotional coping, and instrumental support coping. Research shows that avoidance-based coping (e.g., denial, substance use) leads to increased perceptions of stress and lower health functioning. On the other hand, active coping and a support network tends to mitigate the effects of stress on health.

The third way stress that stress can affect immigrant health is by causing a change or increase in symptoms of an existing illness, resulting in overuse or underuse of the healthcare system. Overall, stress worsens previous medical conditions and this results in an increased use of the healthcare system. However, among immigrants, there tends to be an underutilization of the healthcare system. For example, immigrants (compared to native-born individuals) report lower rates of visiting a primary care physician, are less satisfied with the care they receive, and report lower rates of health promotion discussions (e.g., exercise or smoking cessation) during doctor visits. There may be a wide variety of reasons for the underutilization of health care including: differential beliefs of illness (particularly mental illness), use of natural remedies for illness, limited access to health care, and language barriers. Overall, stress can affect immigrants in a variety of ways. Unfortunately, external stress reduction is not always feasible; therefore, the development of effective coping strategies may improve functioning. Additionally, increasing community resources for immigrants may prove to be influential in decreasing their levels of stress.

Increasing Resources to Cope Effectively with Stress

Although reducing external stressors to improve health may not be an easy option for many immigrants, there are potential ways to increase resources for immigrants dealing with uncontrollable stressors. Both internal and external resources are necessary for coping with stressors effectively. For example, a sense of internal control over one's situation can reduce feelings of stress. On the other hand, developing culturally sensitive workshops in the workplace and providing equal training opportunities would help to reduce discrimination and stress externally. Recently, community health education and improving social functioning have been highlighted as potential ways to improve the health of immigrants. First, some suggest that education about symptoms of common illnesses and disorders that many immigrants face could be helpful; clinics may even deliver workshops taught in other languages to decrease the number of barriers for those who do not speak the native language. For example, recent estimates suggest that there has been a large increase in the number of Latinos immigrating into the Southeastern portion of the USA. Thus, local hospitals in these areas could offer public educational workshops on symptoms and treatment options for depression in both English and Spanish.

Second, others highlight the role of a strong social support network in helping to ease the transition and influence better mental and physical health. Many times, due to immigration, social bonds and relationships are challenged, and may disintegrate. Strong social support has consistently been related to better mental health and this relationship is especially apparent in the face of stress. Social support can come in a wide variety of forms from a variety of sources. For example, the number of social contacts as well as satisfaction with number of contacts, emotional support (e.g., provided a "shoulder to lean on"), informational support (e.g., helped find a phone number for a doctor), religious support (e.g., prayed), or tangible aid (e.g., provided with money to pay for a bus ride to work). The role of social support in immigrant health may operate through a variety of pathways. For example, social support may serve as a gateway to learning about resources (e.g., health services, education, nutrition). Stronger support networks may also facilitate a sense of belonging and nurturance, such that the newly immigrated individuals do not have to feel as though they are transitioning alone; support may also facilitate integration into the community through religious ceremonies. Finally, support may act as a buffer, suggesting that support safeguards against behaviors that may promote negative health consequences. For example, those with stronger support networks may be less likely to engage in avoidance-based coping such as substance abuse to handle stressors.

Summary

In conclusion, immigrants face many unique stressors that extend both before and beyond the immigration process itself such as job difficulties and acculturation stress. Increased stressors can lead to poor physical and mental health; while reducing immigration stressors is not always possible, coping effectively may help to reduce the effects of stress. Effectively helping to alleviate the effects of stress and provide aid to immigrants, begins with supplying culturally appropriate, and accessible resources. Moreover, providing immigrants with community-based health workshops in many languages can provide them with the necessary information to gain access to health services or understand common health problems faced by immigrants. Moreover, these workshops may also provide a location for recent immigrants to meet and potentially form social bonds.

Stroke

Richard S. Jung
Neurological Institute, Stroke and Cerebrovascular Center, University Hospitals Case Medical Center, Case Western Reserve University, Cleveland, OH, USA

Stroke is the third leading cause of death in the world. It is preceded only by heart disease and cancer as the top killers of men and women and accounts for about one in every 18 deaths. Approximately, two to three in every 1,000 persons will have a new or recurrent stroke every year. According to the American Heart Association's latest statistical release, a stroke occurs every 40 sec in the USA, while someone dies every 4 min from this disease. Stroke leads as a cause of severe disability and consumes significant medical and financial resources of the health care system in the short and, especially, the long term. The total cost for stroke in the USA for 2010 is a projected estimate of $73.7 billion.

A stroke occurs when a blood vessel that supplies part of the brain or spinal cord is disrupted either by a clot or by rupture. This interruption of blood flow and oxygen to the targeted brain tissue, if prolonged and not reversed quickly, can lead to permanent injury within minutes to hours. Strokes are typically categorized into two types: ischemic and hemorrhagic. Ischemic strokes occur when an artery carrying blood from the heart to the brain becomes occluded usually by a clot. Hemorrhagic strokes occur when small arteries in the brain rupture and cause bleeding in the brain. This is known as intracerebral hemorrhage. A serious subset of hemorrhagic stroke, called subarachnoid hemorrhage, occurs when an outpouching of a weakened artery wall, known as an aneurysm, ruptures and results in bleeding around the brain. In the USA, 87% of strokes are ischemic, 10% are due to intracerebral hemorrhage, and 3% are from subarachnoid hemorrhage. Although the vast majority of all strokes are ischemic, 30% of all stroke death is due to hemorrhage.

Stroke incidence and risk factors also differ between racial and ethnic groups. Blacks and Hispanics (including Mexican and Latin Americans) have almost twice the first-ever stroke risk compared to non-Hispanic Whites and Asians. African, Latin, and Native Americans as well as Asians have higher incidences of intracerebral hemorrhage as compared to Whites. Non-Hispanic Whites have a higher incidence of narrowing of major arteries, atherosclerosis, in the neck compared to Blacks, Hispanics, and Asians who carry a higher risk of artery narrowing in the head. Major risk factors that contribute to the recurrence risk of stroke include elderly age, previous stroke or transient stroke warning, race, poorly controlled blood pressure and cholesterol, heart rhythm disturbances, blood sugar problems, smoking, female gender, pregnancy, physical inactivity, and clinical depression.

People who are suffering a stroke can present with a variety of symptoms depending on the area of brain injury and the type of stroke. Sudden onset of slurred speech, one-sided face or limb weakness and numbness, disturbances in comprehension and language expression, and abnormalities of vision are common presenting signs of ischemic and hemorrhagic strokes. Hemorrhagic strokes tend to elicit headaches more so than their ischemic counterparts. The sudden onset of the "worst headache of my life" in a drowsy person is highly alarming for an aneurysm rupture and subarachnoid hemorrhage. Any of these symptoms should prompt emergent evaluation at the nearest medical facility by activating the emergency medical response system. Infrequently, stroke symptoms can last for a short period of time (in the order of several minutes to a few hours) with full recovery to normal function. This is known as a transient ischemic attack or TIA. People who experience a TIA should also seek immediate medical attention as the risk of having a stroke in the next 3 months is about 10–15%, with half occurring in the following 48 h.

In 1996, the US Food and Drug Administration approved the use of a medicine called recombinant tissue plasminogen activator (r-tPA) for treatment of acute ischemic stroke. This medicine is administered within 3 hours of the onset of symptoms through a vein as an injection and works to accelerate the breakdown of the clot that is causing the obstruction. Those who are not eligible for r-tPA are usually treated with medicines that can modulate blood clotting such as aspirin, clopidogrel, warfarin, and others. Other, more aggressive therapies are also available at larger academic medical centers for treatment of moderate to severe ischemic strokes including mechanical disruption and local breakdown of the clot from within the blood vessel, opening of narrowed blood vessels in the neck or head with or without the placement of a stent to keep it open. Intracerebral hemorrhage is treated by optimal blood pressure control and investigations to determine the cause of bleeding. Subarachnoid hemorrhages are treated quickly and aggressively in a critical care setting by isolation of the ruptured brain aneurysm by placement of small platinum coils from within the artery or by neurosurgical clipping from the outside of the vessel.

Stroke is a deadly and expensive disease. People of all backgrounds are at some risk of having any stroke in a lifetime. Focuses on primary prevention, risk reduction, and life style modification are more important now than ever to prevent strokes in our constantly changing and aging society.

Student Visa

Kathrin Mautino
Mautino & Mautino, San Diego, CA, USA

Foreign citizens wishing to study in the United States must obtain the appropriate visa that will permit them to do so. The F visa is a classification that allows foreign citizens to study in the United States, primarily at the university level. Children can receive F visas to attend private elementary or secondary schools, or public high school.

Schools or school systems that wish to accept F visa students must go through a certification process with the United States Citizenship and Immigration Services (CIS). Public elementary schools, home schools, and adult education programs are not eligible to enroll F students. The school or school system is then registered in the Student and Exchange Visitor Information System (SEVIS). An official is designated as the designated student officer and authorized to submit student visa applications to the government.

The potential student first applies for admission to a school. If accepted, the designated student officer certifies that the student is admissible and issues a SEVIS form I-20. The student then presents that document to an American Consulate or Embassy for the issuance of a visa. Unlike virtually every other visa category, no application need be made to the CIS. In effect, the CIS outsources its authority to the authorized schools.

Student visas are nonimmigrant intent visas. In other words, in order to qualify for a student visa, the individual must convince an American consular officer that he or she intends to return to the home country at the end of the study program. Individuals who have pending immigrant visa petitions generally will not be issued a student visa. Students who have violated the terms of a different visa status or who have been in the United States illegally are also unlikely to obtain a student visa.

Unlike most other categories of visa, an individual entering on a student visa will not have a firm expiration date placed on his or her stay. Instead, students are admitted "D/S" that stands for "duration of status." In other words, as long as the student is pursuing a full course of study, the student will be allowed to remain in the United States. However, public high school students are limited to 12 months in F visa status. School vacation times are considered to be time in status for students. Students can change educational levels, such as transferring from a junior college to a 4-year university, or going from a baccalaureate program to a doctorate program. Transfers between programs or schools require that appropriate forms be filed by each school with CIS.

In the past, the federal government was fairly forgiving if a student dropped out of school for a limited amount of time and applied for readmission. However, schools are now required to report to CIS and to the Immigration and Customs Enforcement (ICE) any student who fails to attend the school or maintain a full course of study. ICE officers have been known to visit student apartments to arrest individuals who are no longer attending classes. Schools can in some circumstances authorize a student to take less than a full course of study.

Students who become ill during the school year and must reduce or temporarily suspend their studies must receive authorization from the Designated Student Officer (DSO) first. A student may miss a maximum of 12 months of school and still be authorized to remain in the United States in F-1 status.

F-1 students can work on-campus pursuant to the terms of a fellowship scholarship or other financial aid. In addition, at the end of their program of study, most students are eligible for 1 year of practical training. During this year, the student receives an employment authorization document with which the student can seek a job. Such employment is supposed to be related to the field of study, but no restrictions appear on the document itself. Students on practical training who travel overseas and return to the United States are often questioned by Customs and Border Protection (CBP) officers at the airports about their employment. Those not working at a job related to their field of study risk being returned to their home country.

Those who violate the terms of their student status are inadmissible to the United States until they have remained outside the United States for a 5-year period.

Substance Use

Laura Janine Mintz
Department of Epidemiology and Biostatistics,
Case Western Reserve University School of Medicine,
Cleveland, OH, USA

Substance use is a term used to describe the use of mind altering or psychoactive substances in a way that does not cause physical or psychological dependence or addiction. Substance use in immigrants is complicated by differing laws, customs, mores, and traditions between the culture of origin and the nation where immigrants reside, and this can cause legal and personal difficulties when immigrants use substances that may not be accepted in their new homes. Individuals' usage of these chemicals may have diverse and complicated impacts, which may be additionally complicated by the immigrants' socioeconomic and legal status in the new nation, as well as the immigrant's ability to acculturate outside of the home. The following is a short discussion of some substances used in immigrant communities, and their implications for health in the context of immigration.

Alcohol

Alcohol use varies widely around the world, and attitudes about appropriate use of alcohol vary significantly. Much of the complication between what is substance use and substance abuse is culturally bound, such that use that is considered average, typical, or normal, in one place may be considered deviant in another. Immigrants from cultures where, for example, drinking during the day is seen as healthy activity may be surprised if they immigrate somewhere where drinking alcohol at all is frowned upon or illegal (Saudi Arabia), or where drinking during the day is often seen as socially negative (USA). Similarly, immigrants may be confronted with different habits about drinking – as in the USA, where daytime drinking is often frowned upon, but binge drinking is a common habit of young people, whereas in other cultures (France), moderate drinking is taught and encouraged by family members, and binge drinking is rare. Additionally, research suggests that immigrants moving from cultures that abstain from alcohol to cultures where alcohol use is more common tend to drink more, and may be more vulnerable to alcohol abuse.

Tobacco

Tobacco is one of the most commonly used substances (behind alcohol) worldwide, and mores and cultural norms about tobacco use vary widely. In industrialized nations, where public health campaigns about the impact of tobacco use and public restrictions against tobacco use are common, smoking has been steadily declining. In developing nations, this social situation is often different, with tobacco being more acceptable in public places. Immigrants moving between cultures may have to negotiate disapproval of smoking or pressure to quit smoking where they have not previously experienced it.

Cannabis/Marijuana/Hashish

Drugs derived from cannabis are used worldwide in a variety of ways. In the late nineteenth/early twentieth century, many modern governments began outlawing cannabis products. Since then, several of those countries have decriminalized or otherwise altered their legal code to accommodate personal use of cannabis products. Trafficking of cannabis products often follows patterns of immigration, and often immigrants are implicated, frequently incorrectly, in use or trafficking of cannabis.

Khat/Qat

Khat is a plant with mild psychoactive properties chewed or brewed as a tea by many persons throughout East Africa and the Arabian Peninsula. At one point, the plant was only a concern in the immediate area in which it was cultivated. However, widespread immigration of people from the countries where qat is traditionally grown to other parts of the world has led to different legal status in different countries throughout the world. This is most notable in Britain, where it was ruled illegal, and a large public campaign against khat chewing and use was begun.

Ayahuasca/Peyote/Psilocybin/Peyote/Other Psychoactive Plants and Plant Preparations

These plants and plant preparations are used, in different forms, in many places around the world for their hallucinogenic properties. Often, they are used as a part of coming of age rituals, or for spiritual or religious communion. Typically, they are used by indigenous persons for specific rituals, and are not used recreationally. Many of these plants and fungi have been described by foreigners and exported for recreational or other uses. The compound ibogaine, for example, is touted as a natural substance to allow for withdrawal from opiate drugs, and other plant compounds (ayahuasca) have drawn immigrants and tourists to the cultures where they are used to experience their effects.

Supplemental Medical Insurance

Beth E. Quill
Children's Defense Fund - Texas, Bellaire, TX, USA

Medicare or "Health Insurance for the Aged and Disabled" became law under the Title XVIII of the Social Security Act of 1965 and was created to increase access to care and reduce the financial burden of care for the elderly, particularly for minorities and the poor. All persons over age 65 who worked at least 10 years in Medicare-covered employment (and their spouses) are eligible to receive Medicare benefits as are certain other disabled groups such as kidney dialysis and disabled workers.

Originally, Medicare was comprised of two parts: Part A (Health Insurance) and Part B (Supplemental Medical Insurance, SMI). Part A covers hospitalizations, home health care, skilled nursing facilities, nursing home, and hospice care and is provided without premiums to most beneficiaries. Part B (Supplemental Medical Insurance) pays for physician, outpatient, home health, and other services. Enrollees must pay a monthly premium for these benefits. Most beneficiaries are enrolled in part A and B. In 1997, Medicare was expanded by the Balanced Budget (Pub. L. 105-33) and created Part C. This was established as the Medicare-Choice program offering options for participating in private health insurance plans. A further expansion in 2003 with the Medicare Prescription Drug, Improvement and Modernization Act established Part D, the fourth part of Medicare. Part D was designed to assist with the cost of prescriptions drugs not covered by Part A or B at a reduced cost to enrollees. The program provides subsidized access to prescription drug insurance on a voluntary basis upon payment of a premium, with premium and cost share provisions for low income enrollees. Currently, Medicare covers 95% of the elderly population in the USA and many persons who are on Social Security because of disability.

In 2008, 45 million were enrolled in one or both of parts A and B and Part D provided coverage for 31 million people.

Supplemental Medical Insurance

Historically, SMI was referred to as Part B. SMI now however, includes both Part B and D as two separate accounts in the SMI fund.

Part B

Part B provides benefits for medically necessary services and preventive services. Original Medicare enrollees generally have to pay for the doctor's visit. If a Part B deductible applies, then enrollees pay all costs until the deductible and then 20% of amount and Medicare pays the balance.

Medically necessary examples include: ambulance services, defibrillation, doctor services, emergency room and urgent care services, eyeglasses, primary care, foot treatment, home health services, nutrition therapy, occupational and physical therapy, surgical dressings, x-rays, radiation, medical supplies, and selected prescriptions. Covered services are commonly delivered in doctors' offices, community health clinics, outpatient, ambulatory surgical centers, or provided in the home.

Preventive service examples include: bone mass density, cardiovascular screenings, colorectal screening, diabetes screening, vaccines, mammograms, glaucoma tests, prostate cancer, screening, Pap tests, and smoking cessation. Preventive services are usually provided in conjunction with medical authorization and in accordance with accepted medical standards of practice. Services may expand as the merits of particular tests, treatments, and procedures are evidenced.

Part D

Since 2006, Part D coverage has offered subsidized prescription drug coverage for everyone with Medicare on a voluntary basis upon payment of a premium and with cost-sharing subsidies for low income individuals. To enroll for Part D, beneficiaries must enroll in either a stand-alone (PDP) prescription drug plan that adds coverage to an original Medicare plan or an integrated Medicare Advantage Plan (like an HMO or PPO) that offers Medicare prescription drug coverage. Both of these are called Medicare drug plans. Plans vary in cost and drugs covered but all plans must provide at least a standard level of coverage set by Medicare. Most prescription plans charge a monthly premium fee in addition to the Part B payment. Many plans also have an annual deductible or an amount that the individual must pay before the plan pays. Co-payments, a common feature, are a share of the cost of the prescription by the enrollee and the plan pays their share. Further, most Medicare plans have a coverage gap when, after a certain amount has been spent by the beneficiary and the plan, the beneficiary pays out of pocket up to a limit. Part D coverage includes most FDA approved prescriptions and biological. Plans, however, set up formularies to determine what they will cover.

Medicare is largely unavailable to immigrants. While a limited number of legal aliens might meet the criteria, benefits of medical care, preventive care, and prescriptions coverage are generally inaccessible to immigrants. Significant gains have been made with aligning the needs of elderly and disabled under SMI as evidenced with the expanded Part D. Yet, many elderly continue to expend out of pocket for care or do not seek care. Immigrant elderly not covered by Medicare will be paying out of pocket for most or all of necessary care, or go without essential services.

Support Services

Amy N. Sharpton
Department of Veterans Affairs, Louis Stokes DVA Medical Center Cleveland, Brecksville, OH, USA

Introduction

Support services to immigrants to the United States (US) come in a variety of forms, from broad-scale state and federal programs to private organizations, nonprofits, and grassroots efforts. Those involved with the support services programs agree that the need is at an all-time high for services that support immigrants as they integrate into US society. The benefits of such programs are enjoyed by immigrants and the larger society as a whole – from a richer and more diverse culture to a stronger and more talented workforce that is better equipped to participate meaningfully in the globalized job market.

Immigrants make up a large portion of all US workers, especially those with lower skills and earnings. In 2005, for example, immigrants comprised 15% of the US workforce; while greater than two out of every ten immigrants were earning below twice the minimum wage, and 45% of all immigrant workers had less than a high school education. In 2000, greater than 46% of immigrant workers had a limited English proficiency, nearly three-quarters of whom spoke Spanish. While there is great variation in immigrants' educational attainment and ability to speak English, they are overrepresented among the lowest skilled workers. In particular, limited English-speaking immigrants have fewer options in the workplace; research shows limited English skills are the single factor most closely associated with low wages and poverty in immigrant families.

With the passage of Executive Order 13166 (EO 13166) – Improving Access to Services for Persons with Limited English Proficiency – each federal agency is tasked with taking steps to provide access to its federally conducted activities. EO 13166 was designed to provide persons who have limited English proficiency (LEP) with greater access to federal programs and activities. As agencies have adopted strategies to comply with the federal mandate, the need persists at all levels for support services to immigrants.

Frequently significant achievements are realized at the local level, where relationships can be formed on an individual basis and outreach programs can be tailored to meet the unique needs of the local immigrant population. These programs are funded frequently by the private donations of individuals and the community. Local programs focus especially on working to promote and improve the self-reliance and dignity of diverse populations.

Need persists across institutions for support services to immigrants. Especially critical to successful immigration are housing, health and human services, education, and the workplace. From the local to federal levels, successful support services provide information and connect immigrants to much needed resources. Past meeting the immediate needs of immigrants – such as housing and food – support services connect individuals to each other and the local community.

Survey Development

Katherine Crow
WebMD Health Foundation, Rancho Santa Fe, CA, USA

There are several factors to consider in the development of a survey instrument. Once the goals and objectives of the study have been defined, the researcher will need to determine the best means for collecting the survey data (mail, telephone, or in-person).

There are also several elements of survey design to consider. First, the survey designer must decide on whether to use open-ended, closed-ended questions, or a mixture of the two types of questions. Open-ended questions require the respondents to answer in their own words, whereas closed-ended questions call for the respondent to choose a response from those provided in the survey. There are advantages and disadvantages to both types of questions. Open-ended questions can provide the researcher with a vast amount of information from the respondent, but these types of questions require more work for the respondent to answer and for the researcher to interpret and analyze. Closed-ended questions are easier to quantify, but good closed-ended questions can be challenging to develop.

The survey designer should be aware of bias in the way the survey questions are worded. Two common problems include asking leading questions or double-barreled questions. A leading question suggests a possible answer or makes one response seem more acceptable than another (e.g., “Most Americans prefer to purchase products manufactured in the United States. Do you prefer to purchase products manufactured in the United States?”). A double-barreled question is one in which two separate ideas are presented in one question. In this situation, the respondent may agree with one part of the question and disagree with the other, but he/she is unable to convey that through the response choices (e.g., “What factors contributed to your decision to marry and have children?”). Questions should be simply stated and specific; general questions may result in respondents interpreting the meaning of the question in different ways, resulting in unreliable data.

The survey should be pretested with a small number of people that are similar to the target group of respondents. The pretest responses will show problems with the survey instrument such as low response rate for sensitive questions or confusion about the way a question is worded. Questions should be simple and straightforward and make sense to the target population. The survey developer should also ask the individuals who participated in the survey pretest if the questions were clear and easily understood, if the response options made sense and if any options were missing, and if the amount of time the survey took to complete was acceptable.

The introduction to the survey should name the entity conducting the study, describe the purpose of the study, and how the survey respondents were chosen. It should state that the respondent's time is valuable, ensure confidentiality (names of respondents are not associated with results) or anonymity (identities of respondents are not known), and give an estimate of the amount of time it will take to complete the survey.

If the goal is to use the same survey with different immigrant groups, it is important to work closely with the design team, translators, and review panel during the process of survey development. This will help to ensure the development of culturally appropriate survey instruments. One way to ensure correct translation into different languages is to use a technique called "back translation." The English version of the survey is translated into the language of the target population and then translated back into English by a different translator. The two English versions are then compared to identify inconsistencies. It is very important to pretest the survey instrument to ensure that the translation is appropriate for the survey target group.

In order to ensure proper procedures of survey completion, supervisors should spend time observing the field staff interviewing respondents during in-person interviews or listen to interviewers administer the survey over the telephone. In addition, supervisors can validate surveys by re-interviewing a random sample of each interviewer's completed surveys or by reassigning a percentage of surveys to another interviewer for validation. The respondent, however, must be willing to complete the survey twice.

In summary, a survey can be an effective means to systematically collect data which can then be used for planning health or social services and evaluating programs. The data can also help program planners understand whether certain beliefs and practices are widely held, and by whom. However, the survey instrument must be carefully developed in order to collect accurate and reliable information.

Survivor Syndrome

CATHLEEN A. CERNY
University Hospitals Case Medical Center, Cleveland, OH, USA

Survivor Syndrome is a group of symptoms that may be experienced by survivors of a catastrophe. Although Vietnam and other wars, cancer, HIV/AIDS, natural disasters, abortion, suicide, corporate lay-offs, and the September 11, 2001, terrorist attacks have all been associated with survivor syndrome, it is most frequently discussed within the context of the Holocaust. There is a huge body of literature on Holocaust survivors, their children, and survivor syndrome. The symptoms of survivor syndrome generally fall into the anxious-depressive spectrum. It is theorized that these symptoms result from the survivor's traumatization and perception, conscious or unconscious, that he or she has done something wrong by not succumbing to tragic events as others did.

Dr. William G. Niederland, a psychiatrist and psychoanalyst, first described survivor syndrome in his 1961 book *The Problems of the Survivor-Part I.* Niederland was himself an immigrant who left his home country of East Prussia and came to New York City in order to escape fascism. During the course of his impressive career, Niederland worked with hundreds of Holocaust survivors and concluded that their traumatization had been of such a severe magnitude that it produced a clinical entity distinct from other forms of psychopathology. Some of these observations took place when Dr. Niederland served as a consultant to German courts ruling on indemnification claims from Holocaust survivors. Dr. Niederland was a prolific writer and authored several important papers and books on the topic of survivor syndrome over the course of four decades.

In his 1968 paper, "Clinical Observations on the Survivor Syndrome," Dr. Niederland listed the following major manifestations of survivor syndrome:

- Anxiety
- Disturbances of cognition and memory
- Chronic depressive states
- Tendency to isolation, withdrawal, and brooding seclusion
- Psychotic and psychosis-like action
- Alterations of personal identity
- Psychosomatic conditions (preoccupation with medical complaints that are believed to be attributable entirely or in part to psychological factors)
- Appearance as a "living corpse"

Many of these symptoms overlap with the symptoms of posttraumatic stress disorder (PTSD) as delineated in the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision.* Niederland published "The survivor syndrome: Further observations and dimensions" in 1981. In this article, he stated that survivor syndrome is chronic, many times as severe and can have a frequent and notable influence on the offspring of survivors.

Yael Danieli created a typology of post-war adaptation in which she classified post-Holocaust survivor families into four categories: victim families, fighter families, those who made it, and numb families. Victim families are dominated by depression, worry, mistrust, and preoccupation with continued survival. Fighter families have an intense drive to achieve. They believe in self-sufficiency. Numb families are marked by shock and resignation. Numb parents protect each other to the exclusion of their children. "Those who made it" are similar to the "fighters" in that they have great ambition to make a big name for themselves. "Those who made it", however, use their success to gain commemoration of the Jewish experience during the Holocaust. As you may imagine, these family adaptive types had a strong impact on assimilation into a new country and on offspring.

Some individuals have theorized about a "Second Generation Survivor Syndrome" found in children of Holocaust survivors. Researchers talk about intergenerational transmission of trauma. Psychologist and second generation member Eva Fogelman suggests that instead of a syndrome, there is a "Second Generation Complex" that affects identity, esteem, interpersonal relationships, and worldview. For example, Holocaust survivors may be overprotective of their children and over-involved in their lives. It can be difficult for the children to navigate Erickson's separation-individuation stage of development. This is the stage when adolescents are striving to form their own unique identities. In order to deal with the unique issues faced by Holocaust survivors and their offspring, Dr. Fogelman has helped to form trauma support groups.

The Pulitzer Prize winning novel *The Amazing Adventures of Kavalier and Clay* by Michael Chabon provides an excellent example of survivor syndrome. Josef Kavalier, a Jew, escapes from Prague during the build-up to World War II, leaving his entire family behind. With the help of his cousin Sammy Clay, Josef reinvents himself as comic book artist Joe Kavalier. He has yet another identity as bar mitzvah magician, The Amazing Cavalieri. This is all for the sake of earning money to buy his family's freedom in

America. Joe works almost ceaselessly and forbids himself the pleasures of his success while his family is still being persecuted. When Joe falls in love with the enigmatic Rosa Saks and is able to arrange for his brother Thomas' voyage to New York, he at last allows himself to dream of a bright future. His hope is destroyed when Thomas' ship is sunk by a German U-boat. Joe cuts all ties with those he loves in America and goes into self-imposed exile by joining the US Navy. Determined to kill Germans, Joe nearly dies while posted in Antarctica. The road back to Sammy and Rosa is a difficult one and Joe's deceased family haunts him every step of the way. The character of Joe Kavalier illustrates the majority of Niederland's eight survivor syndrome manifestations listed above.

As indicated earlier, much of the literature on survivor syndrome focuses on Holocaust survivors and their children, but there are many other contexts that have the potential to produce this syndrome and affect immigrants. For example, the 2004 Indonesian Tsunami killed over 270,000 people in 11 African and Asian countries. There have been studies examining rates of PTSD in subsets of tsunami survivors, but it is likely too soon to tell if survivor syndrome will also emerge. As a result of the tsunami, there were changes in both migration and immigration patterns. Countries such as Canada and Australia made changes in visa and immigration policies to help people affected by the devastation. In light of that tragedy, the 2010 earthquakes in Haiti and Chile and the 2011 earthquakes in Japan, mental health professionals the world over need to be prepared to treat traumatized immigrants.

In summary, survivor syndrome can result from traumatic life events. In most cases discussed in the literature, corporate lay-offs being an exception, the trauma is of a horrific extreme with extensive loss of human life and unbelievable human suffering. Symptoms of survivor syndrome do have some overlap with posttraumatic stress disorder (PTSD), such as anxiety and withdrawal. Survivor syndrome differs from PTSD in that there is cross-generational transmission of the trauma with significant impacts on children and even grand-children. For that reason, adjustment to life in a new country can be very challenging for immigrant survivors and their families. That is most apparent and most studied in Holocaust survivor immigrants.

Sweatshop

Valeria Velazquez
UC Berkeley Labor Occupational Health Program,
University of California at Berkeley, Berkeley, CA, USA

From an occupational health and safety perspective, a "healthy job" is one that protects against workplace hazards, provides living wages and benefits, respects human dignity on the job, limits excessive stress and workload, offers job security, and supports healthy lifestyles, family life, and communities. While some companies offer many of these elements, others fail to meet the most basic health needs of their workers and, worse, expose them to hazardous and even deadly conditions in what are often referred to as "sweatshops."

The United States Government Accountability Office officially defines a sweatshop as any workplace that is not in compliance with more than one labor law (federal or state) governing minimum wage and overtime, child labor, industrial homework, occupational safety and health, workers' compensation, or industry registration. The term originally referred to garment factories, but has come to generally describe workplaces with abysmal conditions. These conditions include exposure to hazardous materials, repetitive job tasks, and extreme temperatures, often accompanied by long hours, low wages, child labor, forced labor, lack of freedom of association and the right to collective bargaining, and abusive management. Industries that commonly utilize sweatshops are apparel, shoe, electronics, toy, and other textile manufacturing plants/factories. One of the most significant historical incidents that exposed the dangers of such worksites, and subsequently led to increased regulation, was the Triangle Shirtwaist Factory fire of 1911 in New York in which 146 workers (mainly immigrant women) died as a result of being trapped inside or jumping to escape. Over 80 years later, history repeated itself in the Kader Industrial Toy Company, Thailand. More than 200 workers were killed and 469 injured in a fire where doors were locked and workers leaped to their deaths to avoid burning alive. Arnold and Bowie in 2003 noted that US companies including Hasbro, Toys “R” Us, J.C. Penny, and Fischer Price had been contracting with this factory to produce toys. Chan in 2001 discusses a gruesome account of the tragedy given by a witness of the disaster. He described how the piles of bodies of victims who had been trying to open the doors from the inside tumbled out after outsiders were finally able to open the exits.

Although sweatshops still exist in the USA, the majority are in developing countries in Asia and Latin America. Beginning in the 1970s, global capitalism saw a growth in multinational corporations, manufacturing in poorer countries, contingent work, and displacement of workers from their home countries or regions seeking employment. In order to maximize profit, multinational corporations outsourced production to countries where there are fewer or ineffective labor, wage, and health and safety protections for workers. Poor people within these countries flocked to the cities to find work. Developing nations, encouraged by international organizations such as the World Bank and the International Monetary Fund, established “Free Trade Zones” (also known as Export Processing Zones) to promote foreign investment using tax incentives and lax regulations. Employers set up factories in these zones that frequently exhibit inferior “sweatshop” conditions. For example, they employ large numbers of migrant workers (hundreds to thousands), and provide housing, although often under substandard health conditions. The multinational corporation normally divests itself of any legal responsibility by subcontracting to local outfits. Workers often have little legal recourse to challenge questionable labor practices.

Sweatshops impact immigrant health both directly and indirectly in various ways. Common workplace hazards that directly impact health include harsh physical conditions (e.g., toxic chemical exposures, repetitive motions, airborne pollutants, malfunctioning machinery, fire hazards). Workers experience high injury and illness rates due to dangerous working conditions. For example, Chan in 2001 describes how in the Shenzhen region alone in China, 90% of some 12,000 hospital-certified industrial injuries in 1998 involved maiming. A striking example of such conditions as presented by Arnold et al. is a Nike factory located in Vietnam which exposed 10,000 workers to toluene (a toxic chemical used as a solvent) at amounts 6–177 times that allowed by Vietnamese law.

In addition to the more traditional workplace hazards, the sweatshop economy creates indirect health impacts. Workers’ health declines as a result of substandard wages, lack of access to healthcare, forced migration, environmental degradation, stress, and lack of dignity and respect. Stressful circumstances, like poor wages or lack of decision making control over work, can expose workers to multiple psychosocial risks, including anxiety, insecurity, and worry. These psychosocial risks or stressors can increase risks of infections, diabetes, high blood pressure, heart attacks, strokes, and depression. Obligatory overtime, which is rarely paid in such sweatshops, threatens worker health by increasing exposure to worksite hazards, increasing stress by making fulfillment of family obligations difficult, and often causing sleep deprivation. If workers are required to work while sick, they are more likely to spread contagion to other workers. Insufficient rest can cause chronic fatigue, decreased vitality, depression, inattentiveness, and even serious mental illness. In addition these workers often have no outlet to complain or seek help. Workers have limited rights to associate or to collective bargaining. These facilities commonly draw workers from rural areas to more urban centers, which often removes family and legal support, and limits access to education.

Sweatshops also have significant impacts on global public health. They often do not pay for the public services they use for production and distribution and do not contribute the country’s tax revenue. The prevalence of sweatshops can be detrimental to overall societal public health resources if they are not contributing to infrastructure such as health care access via taxes as are local businesses. Local economies disrupted by the arrival of multinational corporations, which often fail to provide a livable wage, have experienced increased displacement levels due to workers seeking a means of survival elsewhere.

In order to promote accountability among sweatshop employers, international standards such as the Worldwide Responsible Apparel Production (WRAP), the Fair Labor Association Standard (FLA), and SA8000 have been established. In addition to the International Labour Organization, which established a set of conventions and recommendations on safety and health that provides a template for minimum safety standards, a number of global and local organizations exist that have led the struggle against sweatshops.

Sweden

► Immigration in the global context

Switzerland

Amy N. Sharpton
Department of Veterans Affairs, Louis Stokes DVA Medical Center Cleveland, Brecksville, OH, USA

History

The land now known as *Switzerland*, called *Helvetia* in ancient times, was a league of cantons, or boroughs, in the Holy Roman Empire. In 1291, as a defensive alliance among three cantons, the Swiss Confederation was founded around the core of three German forest districts: Schwyz, Uri, and Unterwalden. Although in 1499 the Swiss victory against the Swabian League of Emperor Maximilian I amounted to de facto independence within the Holy Roman Empire, it was not until 1648, under the Treaty of Westphalia, that European countries recognized Switzerland's independence from the Holy Roman Empire. A constitution of 1848, modified in 1874, replaced the confederation with a centralized federal government.

Geography

Switzerland extends across the north and south side of the Alps; the country's 41,285 km^2 covers a diverse landscape and climate. The population is about 7.8 million, with an average population density of 190 people/km^2. With its mountains, the southern half of the country is populated more sparsely than the northern half. Switzerland lies between latitudes 45°N and 48°N, and longitudes 5°E and 11°E. It contains three basic topographical areas: the Swiss Alps on the south, which comprise about 60% of the total land area; the Central Plateau or middleland; and the Jura mountains on the north. Many glaciers are found within the Swiss Alps, totaling an area of 1,063 km^2. From these glaciers originate several major rivers that flow to all of Europe; these include: the Rhine, Inn, Ticino, and Rhone. Switzerland has more than 1,500 lakes and contains 6% of Europe's fresh water.

Although the Swiss climate is temperate generally, it can vary greatly – from glacial conditions on the mountaintops to the near-Mediterranean climate at Switzerland's southern tip. Summers tend to be warm and humid, with periodic rainfall; they are ideal for pastures and grazing. In the mountains, the less humid winters may have week-long periods of stable conditions, while the lower lands tend to suffer the opposite, sometimes seeing little sun for weeks. The wettest conditions persist in the high Alps and in the Ticino canton which have much sun yet heavy bursts of rain periodically. Precipitation tends to be spread moderately throughout the year with a peak in summer. Autumn is the driest season; winter receives less precipitation than summer. Notably, the weather patterns are unstable with few predictable patterns.

Economy

Switzerland's economy is based on a highly qualified labor force performing highly skilled work. The main areas include microtechnology, technology, biotechnology, pharmaceuticals, banking, and insurance. The service sector employs the greatest number of people. Most employees are employed by small and medium-sized enterprises; these enterprises play a critical role in the Swiss economy. The Swiss strive to limit as much as possible the impact that economic activity has on the environment; this is reflected in Switzerland's energy and transport policies. Apprehension over unemployment has been one of the main concerns of the Swiss for several years.

Switzerland has a restricted surface area and virtually no mineral resources. Its economy depends heavily on foreign trade. With a total population of just over 7,500,000, it has a relatively small domestic market, another factor which has encouraged Swiss manufacturers to look abroad. They depend on foreign markets in order to make worthwhile investment in research and development. Switzerland imports raw materials and exports high-quality goods. In 2003 the value of 1 ton of exported goods was 225% more than that of the same amount of imports.

Politics

Switzerland is comprised of 26 cantons; the most recently created canton is the Canton of Jura, which separated from the Canton of Bern in 1979. Swiss citizens are subject to three legal jurisdictions at the commune, canton, and federal levels. The 1848 Federal Constitution provides for a system of direct democracy. Because it is aided by the more commonplace institutions of a parliamentary democracy, at times it is referred to as a half-direct or representative-direct democracy. The instruments of Swiss direct democracy at the federal level, known as civic rights, include the right to submit a constitutional initiative and a referendum – both of which may overturn parliamentary decisions. Via a federal referendum, a group of citizens may challenge a law that has been passed by Parliament if, within 100 days of passage, they can gather 50,000 signatures against it. In this case, during a national vote, voters decide by simple majority whether to accept or reject the law. Eight cantons together can also call a referendum on a federal law.

Switzerland is active in many UN and international organizations; however, it possesses a strong commitment to neutrality. The country's sovereignty and neutrality have been long honored by the European powers. The country was not involved in either of the two World Wars, and its political and economic integration has strengthened ties with its neighbors.

Health

The Swiss population is expected to peak at 8.2 million in 2036 before falling to 8.1 in 2050. The number of people aged 65 and over will increase by 90% in the same period to 2.2 million people; that will be 27% of the population. In 2005 average life expectancy for men was 78.7 years and 83.9 years for women; this represents a slight increase from previous years. The Swiss birth rate in 2005 was 9.77/1,000, down from 10.4 in 2000.

There is a high standard of care in Switzerland and a relatively high health care cost, as they spend the 2nd highest proportion of GDP on health care than any other country. The cost is high particularly for hospital treatment. As one outcome of a major health reform in 1996, health insurance is mandatory in Switzerland; everyone is individually insured, including children. Individuals are able to choose their insurer from a number of authorized operators, who cannot refuse to provide coverage. Those on low incomes and families with children receive a subsidy to their insurance contribution. Accounting for 25% of expenditure, federal, cantonal, and local tax revenue is a key source of health care financing.

Health care provision is a mixture of public, subsidized, private, and fully private. Most GPs are individual practitioners, paid on a fee-for-service basis by insurance companies. Hospitals may be publicly operated, for example by the cantons or local government, or private (for profit or nonprofit). Fees are set by each canton. Patients are free to choose their providers and specialists. Despite efforts to reduce health insurance premiums, the fast growth in health care costs remains a major domestic political concern. Further cost cutting in health care is likely to remain on the political agenda.

Immigration

Switzerland is positioned at the crossroads of Northern and Southern Europe. It is known for its neutrality, a decentralized government, and its ethnic and linguistic diversity – German, French, Italian, and Romansch are all national languages. Today, decisions are made at the local level, as each canton is responsible for certain aspects of migration and integration-related policies.

Switzerland has one of the highest immigration rates on the continent; according to the 2000 Census, 22.4% of the total population of 7.4 million is foreign born. Historically, Switzerland was primarily a destination for employment-seeking French, Germans, and Italians; however, in the latter half of the twentieth century it became home to Eastern European dissidents, Yugoslavian refugees, and asylum seekers from the Middle East, Asia, and Africa.

Although it is not part of the European Union, since the 1990s, Switzerland has forged closer ties with its member countries, thereby making it easier for EU citizens to live and work in Switzerland and vice versa. Switzerland has had to face many of the same issues as its neighboring countries, including growing numbers of asylum applications, integration problems, and rising antiforeigner sentiments. Like the rest of Europe, Switzerland's immigration policy will have to reconcile these concerns with the immigration needed to compensate for the aging population and to ensure future economic growth.

Syphilis

Christopher A. Kenedi
Auckland District Health Board, Auckland,
New Zealand

Syphilis is a sexually transmitted disease that begins on the genitals, but if untreated can spread to the body and brain and eventually result in disfigurement, organ failure, mental illness, and death. Syphilis can also spread from mother to infant during pregnancy (known as congenital syphilis).

Syphilis was first described clearly in 1494 as an outbreak among French troops besieging Naples. Since then syphilis has been the target of many public health campaigns to control its spread and attempt eradication. Syphilis in the brain is referred to as neurosyphilis and has been blamed speculatively for the disfigurement and insanity of a variety of historical figures, including Henry VIII and Adolf Hitler. Since the advent of treatment with penicillin in 1947, it has become an easily treatable disease when diagnosed in the early stages. However, it is also referred to in medical literature as "the great pretender" because in later stages it can mimic many other diseases.

Primary syphilis involves a painless lesion, called a chancre, which can occur on the penis, vulva/vagina, oral or anal regions. It typically lasts for 4–6 weeks, and then heals, giving the false impression that the disease has been cured. The next stage, secondary syphilis, occurs 2–8 weeks later. Symptoms are varied, but it is often associated with a rash that includes the palms and flu-like symptoms. Although patients are contagious when the chancre is expressed, the highest rate of infectiousness is during the secondary syphilis period. The final stage of syphilis (tertiary syphilis) can occur 1–50 years later and can involve any organ in the body.

Congenital syphilis can be devastating when it is untreated. At clinics in Mwanza, Tanzania, syphilis was responsible for 50% of stillbirths. Congenital syphilis is also an important cause of mortality in live infants; in one study 52% of infants with congenital syphilis died during their first year in Haiti.

Epidemiology

Syphilis is present on every continent and tends, like most sexually transmitted infections, to have a higher percentage of cases in urban settings. With the exception of some regions of the United States, syphilis is less common in industrialized nations. It is a particular problem in sub-Saharan Africa, South and Central America, and the developing nations of Southeast Asia.

In Western Europe, the World Health Organization (WHO) estimates that the incidence of new cases is approximately 5 per 100,000 people. This is in contrast to the former Soviet Union where the incidence was estimated at 5–15 per 100,000 in 1990 but in the Russian Federation had risen to more than 250 per 100,000 by 1996. This is partially associated with the loss of free diagnosis and mandatory treatment after the fall of the Soviet Union.

The WHO has global estimates on syphilis only through 1999 when 12.22 million cases were reported worldwide. WHO data from 1999 showed overall syphilis rates of 8% in the South Pacific, 4% in Cambodia, 3.1% in Djibouti, 3% in Morocco, and 2.4% in Sudan. Rates of syphilis in pregnant women were 17.4% in Cameroon and 8.4% in South Africa.

There are very few studies estimating the rate of syphilis infection in immigrants. One looked at Canadian immigrants. From 2000 to 2004, there were 2,001,417 immigration applicants to Canada, which requires syphilis testing for all applicants 15 years or older. Of these, 2,209 (0.001%) were found to have positive syphilis serology. Rates from refugees who have their syphilis testing done in Canada were 50% higher than from “family class” applicants and 4 times the rate of syphilis found in “economic class” immigrants, who often have their syphilis testing performed abroad.

Another study retrospectively examined manual laborers in Thailand who were tested to receive clearance to work abroad. 221,093 workers aged 20–60 were tested at a hospital in Bangkok (59% were men). Of these, 1832 (0.83%) tested positive for the RPR (non-treponemal syphilis test). All had denied previous infection with syphilis and were reported to be “generally healthy in appearance” on exam. Workers who tested positive were referred to clinics for additional diagnosis and treatment. 1426 (77.8% with a positive RPR) were confirmed to have syphilis.

HIV is clearly associated with the international resurgence of syphilis. After declines in syphilis rates in the late 1980s, the late 1990s saw dramatic increases in the spread of syphilis. HIV infection makes people more susceptible to syphilis, and syphilitic lesions make people more susceptible to HIV infection.

Testing

Syphilis testing is almost a universal requirement for immigrants and guest workers. An immigration medical exam should include both blood tests and a physical exam (including genitalia and a neurological exam) to effectively rule out a syphilis infection. Primary syphilis often will be accompanied by negative blood tests and can only be identified by visualizing the chancre on the genitals, anus, or mouth. Patients with very longstanding syphilis infection (tertiary syphilis or neurosyphilis) may have negative blood tests on laboratory screening but will often show signs of organ dysfunction or neurological disturbance on a clinical exam.

The bacterial agent that causes syphilis, *Treponema pallidum pallidum,* cannot be routinely cultured in a laboratory. The tests commonly used to identify patients exposed to syphilis are called non-treponemal tests because they rely on indirect methods for diagnosis, detecting byproducts of the infectious organism. In the United States, the two most common non-treponemal tests are called the Rapid Plasma Reagin (RPR) and the Venereal Diseases Research Laboratory (VDRL) test. Because these tests do not identify the organism that causes syphilis directly, they are both susceptible to false positive results from non-syphilitic conditions. Approximately 1–2% of the general population will test with a false positive result on these tests. Historically there have been numerous reports of people being told they have syphilis during routine testing for marriage licenses or immigration medicals when in fact they had medical conditions such as systemic lupus erythematosus, malaria, Lyme disease, viral infections (including HIV), pregnancy, or other non-syphilitic conditions.

In all situations where a patient has a positive non-treponemal screening test, the result should be followed by a more specific test such as the Fluorescent Treponemal Absorption test (FTA-ABS) or *Treponema pallidum* particle agglutination assay (TPPA), which are highly specific for antibodies to treponemal organisms. However not all patients with positive direct-treponemal tests have had syphilis. These tests can be falsely positive if the patient has another type of (much rarer) treponemal infection such as Yaws, Bejel, or Pinta. There are no routine blood tests to distinguish among the treponemal infections, so the distinction is made by clinical exam and exposure history. In general, anyone who tests positive for syphilis should also be tested for HIV, gonorrhea, and chlamydia.

Treatment

The treatment of syphilis involves injections or infusions of penicillin. In early stages of the disease, this usually requires 1–3 shots. In later stages, such as syphilis involving the central nervous system, it can require weeks of intravenous penicillin.

Syphilis remains a persistent challenge for clinicians and public health practitioners around the world. Although it is usually relatively easy to treat when diagnosed, it remains a disease of particular concern for authorities monitoring immigrant health. This is due to the easy spread of the disease, the possibility of congenital malformation, and the long-term deleterious consequences of untreated syphilis for the health of individuals.

T

T Visa

Noël Bridget Busch-Armendariz
School of Social Work, Center for Social Work Research, The University of Texas at Austin, Austin, TX, USA

In the past decade, human trafficking (the exploitation of human beings for the purposes of sex or labor) has emerged as a major global human rights issue. In response to this growing crime, the US Congress passed the Trafficking Victim's Protection Act (TVPA) in 2000 and reauthorized it through the Trafficking Victim's Protection Reauthorization Acts (TVPRA) in 2003, 2005, and 2008. The majority of states now have also passed antihuman trafficking statutes. The TVPA focuses on prevention strategies, prosecution of traffickers, and the protection of victim.

Included in the legislation were two new nonimmigrant visa categories: T and U Visas. To qualify for a T Visa, an adult victim must be certified by a law enforcement agent as having suffered from a severe form of trafficking and must cooperate, or be willing to cooperate, with law enforcement in the of the criminal case. Victims under the age of 18 years are not required to cooperate with law enforcement. A victim who is granted a T Visa may remain in the USA for 4 years from the date of its approval, although the 4 years may be extended if the investigation and prosecution of the case is ongoing, and may request legal permanent residency after 3 years. T Visas are limited to 5,000 per year. The T Visa is accompanied with an automatic employment authorization document and holders are eligible for assistance through the refugee programs administered by Human and Human Services and the Office of Refugee Resettlement.

Tajikistan

Gary Edmunds
Center for Minority Public Health, Case Western Reserve University, Cleveland, OH, USA

Tajikistan is one of the 15 Newly Independent States that were constituted following the disintegration of the USSR and one of the 12 of those Newly Independent

Sana Loue & Martha Sajatovic (eds.), *Encyclopedia of Immigrant Health*, DOI 10.1007/978-1-4419-5659-0,

States that form the Commonwealth of Independent States. Tajikistan was plunged into a civil war following its independence. The cause of that war, which lasted from 1992 to 1997, remains controversial to this day, with some scholar attributing it to ethnic and religious tensions and animosities and others to the lack of economic and military capacity that resulted from the Soviet withdrawal. Regardless of the cause, Tajikistan continues to be viewed as one of the economically and politically weakest states in the post-Soviet sphere.

The poverty that ensued following the civil war continues to this day. Tajik society and government depend heavily on the remittances from Tajik labor migrants who have secured employment outside of the country. Indeed, the remittances from Tajik labor migrants back to their country almost equal the country's GDP, approximately $6–8 billion. It has been estimated that almost every Tajik household relies to some degree on these remittances from family members overseas and that the Tajik government relies on the remittances to fill the gap in social welfare that the government cannot fill.

Experts estimate that between 600,000 and over 1 million Tajik migrants work in the Russian Federation and to a lesser extent in Kazakhstan. Common jobs include public transport drivers, construction workers, retailers, and street sweepers. These are low-skilled, low-paying jobs, and often exist within the informal economy. Despite high unemployment, the local Russian populations often refuse low paid jobs; thus, migrants compete mostly among themselves rather than with Russian citizens.

During times of economic crisis, groups in host or receiving countries may perceive competition for jobs from immigrants. Migrant workers and their families thus become victims of discrimination, exploitation, violence, and xenophobia. According to news reports in December 2008, a group of teenage skinheads killed at least 20 migrants in Moscow. The Moscow Human Rights Bureau, a Russian nongovernmental organization, reported that more than 100 migrants were murdered between January and October 2008, double the number of the previous year.

The poverty that characterizes many Tajik families and the difficulties faced by Tajik migrants who seek employment in other countries has led to some migrants' participation in drug trafficking and commercial sex work. Although the consumption of heroin in Tajikistan has remained relatively low to date, research suggests that a growing number of individuals, and migrants in particular, may be forced by organized criminal networks to carry heroin that reaches Tajikistan from Afghanistan into Russia and the Baltic states for distribution there. Women seeking employment outside of Tajikistan may be forced to work in the sex trade. The vast majority of women interviewed in the International Organization of Migration (IOM) return projects in Tajikistan 2001 say they were deceived about what work they would undertake, or recruited in other illegal, coercive, or deceptive ways.

Migrants returning to Tajikistan from the Russian Federation and other countries may unwittingly bring diseases home to their families. Tajikistan currently has the highest rate of tuberculosis of all countries in Central Asia. Researchers conducting a study of individuals' access to care for tuberculosis in Tajikistan found that 10% of all patients who received treatment in the study area had developed active TB while they were temporary migrant workers in Russia. They were required to return to Tajikistan to seek treatment there, potentially resulting in the exposure and infection of persons with whom they had contact on buses, trains, and airplanes. Additional research suggests that male migrant workers returning to their homes in Tajikistan may expose their wives to sexually transmitted infections that they contracted during unprotected intercourse with commercial sex workers and other sexual partners in the receiving country.

Tajikistan, like all of the CIS countries, is losing many of its most active and qualified urban working force due to the widespread poverty and relative lack of professional opportunities. The emigration to other countries of highly skilled specialists and business people ultimately leads to an exhaustion of the country's potential. The brain drain from countries like Tajikistan has become a national catastrophe.

Tamils

LAURA SIMICH
Social Equity and Health Research, Centre for Addiction and Mental Health, Toronto, ON, Canada

Tamils are a group of immigrants mainly living in the Indian State of Tamil Nadu and the Northeastern Province of Sri Lanka. Tamil immigrant health must be considered in the historical context of forced migration and the social context of the diaspora, which maintains strong ties to the homeland. Sinhalese majority governments that came to power after Sri Lanka attained independence in 1948 settled Sinhalese in Tamil home lands, enacted discriminatory legislation, and threatened Tamil cultural heritage. Hostilities erupted in series of violent confrontations in 1983, characterized by mob attacks on Tamil civilians and Tamil counter attacks on Sinhalese soldiers. Since then, tens of thousands have died and acts of terrorism, reprisals, detentions, and torture have continued. In the late 1980s, massacres in the North and East of Sri Lanka accounted for 5,000 civilian and militant deaths and forced many Tamils to migrate. According to the U.N. Working Group on Enforced and Involuntary Disappearances, there were 11,513 disappearances between 1980 and 1996.

A mediated peace process initiated in 2002 raised hopes for achieving peace in Sri Lanka. In 2009, however, the Sri Lankan government defeated Tamil militants and placed hundreds of thousands of Tamil civilians in detention camps. With more than one million internally displaced people and more than 900,000 who have sought refuge abroad, Sri Lanka has become one of the world's leading sources of refugees. About one quarter of the world population of Sri Lankan Tamils now live in the diaspora. Although population estimates vary, the greatest numbers (about 250,000) are in Canada, followed by India (150,000), the United Kingdom (110,000), the European Union (110,000), and Australia (30,000).

Among refugees, the predominant health consideration is often psychological distress due to witnessing or experiencing torture, violent conflict, and loss of home and family members. High rates of trauma are reported frequently in refugee populations, and the Tamils are no exception: research shows a prevalence of posttraumatic stress disorder of 12% in the Tamil population in Canada. However, the disease model offers a limited means of understanding Tamil health and well-being. In the Tamil refugee diaspora, mental health outcomes are influenced by complex pre-displacement, displacement, resettlement factors, and systemic factors. Social determinants of Tamil health include deleterious experiences of asylum seekers with detention and legal systems in countries of exile, economic hardship and underemployment, loss of social support networks, as well as demands of existing networks, family conflict, perceived racial and workplace discrimination, and lack of access to culturally appropriate medical services. Social scientists also report that Tamil health, adaptation, and social integration in the diaspora are positively affected by sense of identity, spirituality, and the role of social networks, which demonstrate that, in general, Tamils are proactive and resilient in responding to resettlement stress.

According to one Canadian study, Tamil help seeking for health problems is affected by several intrinsic and extrinsic factors: beliefs that ailments will go away by themselves, and that help is unnecessary or ineffective; mistrust of the formal health care system; linguistic and practical barriers; and the distinction between physical and mental problems, with respondents reporting the likelihood of seeking help for physical symptoms, but not for feelings of sadness, fears, or suicidal thoughts.

There is a paucity of evidence in English on physical health among Tamils, who are usually subsumed in population statistics for South Asians in general. Given the concern that South Asian populations experience a higher risk of heart disease, more sophisticated studies of subpopulation differences and a focus on social and health disparities are needed to determine rates of chronic disease and prevention strategies. For both mental and physical health problems, there are currently inadequate resources in the formal health care systems of countries of resettlement for Tamil communities.

Strong ties to the homeland suggest that Tamil immigrant health is also influenced by the well-being of Sri Lankan Tamils affected by disaster. In December 2004, a massive tsunami struck Asia, including parts of Sri Lanka from which Tamils originate. The loss of life and devastation of entire Tamil villages impacted an estimated one quarter of disapora families. In response, a global outpouring of disaster aid was notable, but in some ways surpassed by Tamil diaspora communities that raised money and delivered aid directly, establishing health clinics and challenging Western assumptions about the best way to deliver culturally appropriate disaster relief. The acute trauma inflicted on the Sri Lankan Tamil population by the tsunami, in addition to the chronic trauma of decades of warfare, was generally observed by scientists and medical practitioners to subside after several months, suggesting that the impact of traumatic events is not irreversible and that Tamil health is promoted by restoring and strengthening psychosocial support within communities.

TANF

► Temporary Assistance for Needy Families

Telephone Interpretation Services

Brandy L. Johnson
Rynearson, Suess, Schnurbusch & Champion, L.L.C., St. Louis, MO, USA

Telephone interpretation allows human interpreters to utilize a telephone to facilitate communication between individuals who want to speak to each other but do not speak the same language. Telephone interpretation is typically conducted in a consecutive mode wherein, rather than speaking simultaneously, the interpreter listens to each utterance and then translates it to the other language. Telephone interpretation is often seen in business transactions, governmental functions, and in the healthcare arena.

As the world becomes more global, there is an increasing need to communicate with individuals who speak a different language. The ability to travel with ease and move away from an individual's home country allows interaction with populations that speak a language in which the traveler or immigrant has little or no proficiency. According to the United States 2000 Census, for example, 1 in 30 residents, or 17.5 million adults and 3.4 million children, were limited in their ability to speak English.

The inability to speak and understand the language of the area where one resides often results in an inability to fully participate in society. These individuals may not be fully aware of the governmental programs, societal programs, and activities from which they could benefit. A limited language proficiency also often results in a reduced access to health care, insurance, and assistance with other financial matters. Telephone interpretation services have developed to help address these problems.

Telephone interpretation services provide expedient access to numerous languages, including less common languages such as Farsi and Tagalog, at any time of day or night. The ability to have access to many languages twenty-four hours a day is especially an asset in rural areas where the business or healthcare provider may not have on-site interpreters fluent in the language being spoken.

In the healthcare arena, telephone interpretation may be a good alternative for patients who value their privacy. Depending on the patient's cultural, religious, and social background, he or she may place a high value on their privacy when being examined or discussing health issues. This is especially true when the visit involves the sexual health of the patient. The use of a telephone interpretation service allows for translation without the need to have a third person, usually a member of the same community, in the room while the patient is being examined and discussing his or her health. The utilization of telephone interpretation also permits the patient, especially one who speaks a less common language, to communicate with a healthcare professional without having to rely on a family member to act as a translator. The use of a family member as an interpreter may cause the patient to be less forthcoming about topics like their symptoms or the mechanism of injury. The patient may not feel comfortable requesting specific types of treatment, such as birth control, or reporting abuse if they are forced to use their husband or children as a translator.

There are some circumstances when telephone interpretation is discouraged in a healthcare setting. For example, face-to-face interpretation is optimal when the patient is receiving mental health care. Face-to-face interpretation is also more beneficial when the patient is hard of hearing or a child. Telephone interpretation is also discouraged when the patient is being educated with visual components (i.e., instructing the patient in wound care, blood sugar testing, or equipment use).

Telephone interpretation is provided by for-profit groups, non-for-profit groups, and, in some countries, the government. Countries such as Australia, New Zealand, and South Africa have established telephone interpreting services. In other countries, telephone interpretation services are mainly provided by for-profit companies. The United States is one of the countries where the majority of the telephone interpretation services are provided by for-profit companies that are external to the healthcare provider or organization. However, some hospitals and healthcare systems do provide telephone interpretation services.

Telephone interpretation can be expensive. Insurance companies usually do not pay for telephone interpreters. Likewise, the governments of many countries do not pay for interpretation. In most states in the United States, for instance, Medicare and Medicaid do not reimburse telephone interpretation services. A lack of access to qualified professional interpreters leaves individuals with limited language proficiency with a reduced access to care, a diminished quality of care, and an inability to form a bond with the healthcare provider. A 2002 survey of uninsured Limited English Proficiency patients in the United States found that 32% of those who needed an interpreter but did not get one stated they would not return to the facility if they ever became insured.

Effective communication cannot be had between two parties that are unable to understand each other. In a global world where travel and immigration is common, the need to communicate effectively is growing. Telephone interpretation services provide a quick and efficient means of allowing individuals speaking different languages to communicate with one another.

Temporary Assistance for Needy Families

Tambra K. Cain
Barrett, Twomey, Broom, Hughes & Hoke, LLP,
Carbondale, IL, USA

Temporary Assistance for Needy Families, or TANF, was created by the enactment of the Personal Responsibility and Work Opportunity Reconciliation Act of 1996, Public Law 104–193, and became effective as of July 1, 1997. The TANF program replaced the Aid to Families with Dependant Children program. At the time of the enactment of TANF, Congress made the specific finding that the number of individuals receiving aid to families with dependent children (referred to as "AFDC") had more than tripled since 1965. More than two-thirds of the recipients were children.

Congress enacted TANF to: (1) provide assistance to needy families so that children may be cared for in their own homes or in the homes of relatives; (2) end the dependence of needy parents on government benefits by promoting job preparation, work, and marriage; (3) prevent and reduce the incidence of out-of-wedlock pregnancies and establish annual numerical goals for preventing and reducing the incidence of these pregnancies; and (4) encourage the formation and maintenance of two-parent families. TANF provides parents with job preparation, work, and support services to enable them to leave the program and become self-sufficient.

The Federal TANF program is operated by the Administration for Children and Family division of the US Department of Health and Human Services. However, the Personal Responsibility and Work Opportunity Reconciliation Act of 1996 also provides that states shall be given block grants to administer TANF programs on a state level. Each state will then administer its own TANF program and report to the federal government for oversight. Not only are TANF block grants available to the 50 states of USA, but also to the US territories such as Puerto Rico, Guam, the Virgin Islands, and the District of Columbia. TANF block grants are also provided to certain federally recognized tribes and tribal organizations.

On average, in the fiscal year 2009, there were 4,027,329 recipients of TANF services. California was the state with the most recipients in 2009, with a total of 1,307,832. Wyoming was the state with the least recipients with only 577. The 2009 annual TANF recipients have declined from the number of TANF recipients for the fiscal year 1997, the year that the Personal Responsibility and Work Opportunity Reconciliation Act of 1996 went into effect. The TANF recipient rate for fiscal year 1997 was 10,935,125. For fiscal year 1997, Guam had the lowest TANF recipient rate, at 4,528.

States may not use TANF funds to provide assistance to a family – unless the family includes a minor child who resides with a custodial parent or other adult caretaker relative of the child or a pregnant individual. States may require that families receiving TANF assign certain support rights, such as child support payments, to the state, but only while receiving TANF benefits. Parents enrolled in a TANF program may also be required to attend high school or other equivalent training program, if they do not already have a high school education.

There is a 60 month limitation on the length that a family may receive federal assistance services. This 60 month time limitation applies regardless of whether the federal assistance services were consecutive or not, excluding any time that a person was a minor child and not the head of a household or married to the head of a household. The state may grant an exception to the 60 month limitation if the family can show that there is a hardship situation or if the family includes an individual who has been battered or subjected to extreme cruelty. A state shall disregard any month of TANF assistance received by adult while living on an Indian reservation or in an Alaskan native village with 50% unemployment and at least 1,000 individuals were living on the reservation or in the village at that time.

In order to be eligible for benefits, persons applying for federal public benefits, with some exceptions, are required to prove that they are either citizens or a qualified alien. For purposes of TANF, a qualified alien means an alien who, at the time the alien applies for, receives, or attempts to receive a Federal public benefit, is an alien who is lawfully admitted for permanent residence under the Immigration and Nationality Act. There are a number of exceptions to that policy; specifically, the prohibition against non-qualified aliens receiving TANF shall not apply to an alien until 5 years after the date that an alien is admitted to the USA as a refugee under section 207 of the Immigration and Nationality Act, an alien is granted asylum under section 208 of such Act; or an alien's deportation is withheld under section 243(h) of such Act. Additionally, the prohibition against non-qualified aliens receiving TANF shall not apply to an alien who is lawfully admitted to the USA for permanent residence under the Immigration and Nationality Act, and has worked 40 qualifying quarters of coverage as defined under title II of the Social Security Act or can be credited with such qualifying quarters, and did not receive any Federal means-tested public benefit during any such period. Finally, the prohibition against non-qualified aliens receiving TANF shall not apply to an alien who is lawfully residing in any state and is a veteran with a discharge characterized as an honorable discharge and not on account of alienage, is on active duty (other than active duty for training) in the Armed Forces of the USA, or the spouse or unmarried dependent child of such a qualifying veteran.

Terrorism

Ryan C. W. Hall
Department of Psychiatry, University of South Florida, Tampa, FL, USA

Terrorism is the premeditated, politically or socially motivated use of violence against civilians or noncombatants by national or subnational groups (e.g., Al-Qaeda, FARC, IRA, Sea Shepherd) or clandestine agents with the intention of influencing a population socially and politically. In general, acts of terrorism are designed to induce fear, terror, anger, or panic in a population, thus leading to a societal change. The change is usually achieved by causing casualties, economic damage, destruction of infrastructure, and/or by creating the impression that the government cannot protect its citizens.

Usually, the terrorist acts committed by immigrants are perceived as being based upon radical religious beliefs, be they Christian in Northern Ireland; Zionist in Palestine after World War II; Islamic, as in Al-Qaeda; or cult-like religions/beliefs, such as occurred with Aum Shinrikyo in Japan. The reality is that even those terroristic attacks claimed in the name of religion are also carried out for political purposes, even if the public, media, and politicians do not focus on those reasons. Native or "homegrown" terrorist acts are committed primarily by a single individual or small group that is usually motivated by political/cultural causes or beliefs rather than religious ideology (e.g., Oklahoma City federal building bombing in 1994; attack on Austin, Texas, IRS building in 2010; Basque separatists). Native terrorists (excluding paramilitary groups such as the IRA or FARC) are often perceived by the public as being less of a "long-term threat or danger" compared to foreign terrorists. Many times homegrown terrorists are seen as fringe members of society that are defective in some way (e.g., Maj. Nidal Malik Hasan, aka the Fort Hood Shooter, mental state has been frequently questioned in the media) which may explain why the general public is less fearful of them compared to international terrorists who follow an "outside ideology". However, recently "homegrown" terrorists are beginning to claim radical religious beliefs as seen with the arrest of "Jihad Jane" who was a Pennsylvania suburban house wife who converted to Islam and was arrested for planning domestic and international terroristic acts.

The motivation, success, and acceptability of terrorist groups whether imported or homegrown is a matter of perspective (i.e., one man's terrorist is another man's freedom fighter). Two of the Middle East's now-revered leaders, Menachem Began and Anwar Sadat, both began their political careers as "terrorist/freedom fighters."

Acts of terrorism are designed to create a national psyche of "us versus them," which often negatively affects attitudes toward legal immigration. Acts of terrorism often result in anti-immigration political movements, which potentially alienate and prevent the successful incorporation of immigrants into a society (e.g., Swiss People's Party, "SVP," which used posters depicting minarets as missiles on a Swiss flag to support a referendum to ban construction of minarets). This anti-immigrant sentiment furthers terrorists' goals by creating political tension, alienating, and potentially disfranchising new immigrant populations, which creates opportunities for new member recruitment and further strife.

New and already-established immigrants are targeted for recruitment by terrorist networks. Recruitment is made easier by some immigrants' disenchantment with the new host country and their resultant desire to maintain their cultural identity with their homeland. Data suggest this is particularly true in disaffected second- and third-generation immigrants. Disenchantment may be born from a perceived lack of acceptance/opportunity in the new country, romanticization of their homeland and exigencies associated with a siege mentality developed in the immigrant community based on feelings of religious, linguistic, cultural, and financial isolation. The sense that their children are being isolated and deprived of opportunity can further radicalize immigrants and make them more likely to act out their frustrations in violent or antisocial ways. Legal immigrants are valuable recruits because they have legal status in a country; have passports; can travel freely; learn the infrastructure of the host country; understand its customs and culture; often speak the language; have jobs and access to information; can be placed in potentially critical positions; have ties to two countries, which may make it easier to transmit information overseas or visit abroad; and can supply informational and physical support (e.g., money, safe houses) in the new country.

As well as being the targets of recruitment for terrorists, immigrants are often also the victims of terroristic acts as well. People from 79 different countries died in the World Trade Center attack on September 11, 2001.

Terrorism has impacted global immigration policies. New restrictions on travel and immigration have been implemented by the United States, the European Union, Japan, Australia, New Zealand, and several Middle Eastern and Asian nations, all of whom have expressed concern about the potential for travelers and new immigrants, particularly Muslims, to commit or participate in terrorist acts. For the United States, approximately 50% of new terrorists will attempt to obtain some form of immigration benefits (e.g., student or work visa), while another 40% will attempt to become US citizens through the naturalization process or sham marriage. In addition, approximately two-thirds of individuals, who committed or were planning to commit a terrorist act, had committed some form of immigration fraud. Although the vast majority of legal immigrants are not involved with terrorism, the acts of a few have created a global political environment where there is less tolerance and lenience for the violation of immigration laws.

The primary focus of many countries' terrorism policies is to stop foreign-born terrorists from committing acts of terror in their country and to prevent them from gaining access to legitimate travel documentation and citizenship in other, more friendly and democratic nations (e.g., individuals from Yemen traveling on a European passport are less likely to raise suspicion when traveling to the United States than when traveling on a Yemenese passport). Governmental attempts to control the movement of terrorists across national boundaries results in more detailed visa and travel applications (e.g., fingerprinting) and background checks for immigrants, more time spent processing applications, more expense and application time for the applicant, and more formal bureaucracy for immigrants to contend with when obtaining and renewing their immigrant status. A concrete example of how terrorism has directly affected immigration is the Naturalization Services Passenger Accelerated Service System used by both the United States and Canada, which relies, in part, on fingerprints as a form of biometric identification. This change was mandated by The Patriot Act passed in response to the September 11, 2001 terrorist attacks. Billions of unproductive dollars are now spent annually on airport security as a direct result of the 9/11 attacks and other bombing plots enacted by terrorists.

Recent information about immigrants who have committed terroristic acts will further complicate the lives and penalize nonviolent immigrants, who were once actively sought and encouraged to immigrate. Many terrorists who have committed acts in other countries were well educated (e.g., the doctors who carried out the Glasgow airport attack on June 20, 2007, and the engineer who attempted the December 25, 2009, aircraft bombing from Nigeria). Recent studies found that 62% of international terrorists are college educated. In addition, many terrorists enter their target country on educational visas and blend into university student populations. Approximately 25% of individuals who committed terrorist acts in the United States from 1990 to 2004 had applied for or received a student visa.

The impact of terrorism on immigrants often results in immigrants feeling unwelcome in their new country; requires them to spend more time, energy, and financial resources to obtain immigrant status and to maintain it; and results in them being at risk for being directly involved in terroristic activities through attempts to recruit them into terrorist networks. They may become the victim of violence or discrimination. The recent trend of terrorist organizations to infiltrate countries and attack using educated professionals to carry out specific well-planned attacks produces a backlash and further limits the ability of peaceful immigrants to access jobs and other opportunities, hence increasing their bitterness, resentment, isolation, and potential to be radicalized. As stated by the then-Secretary General of the United Nations, Kofi Annan, after the terrorist attacks on September 11, 2001, "Terrorism affects every society. As the world takes action against it, we have all been reminded of the need to address the conditions that permit the growth of such hatred and depravity."

Tetanus

Kayleene E. Pagan Correa
Division of Pediatric Emergency Medicine, Rainbow Babies and Children's Hospital, Cleveland, OH, USA

Tetanus is a nervous system disorder characterized by the prolonged contraction of skeletal muscle fibers caused by a gram positive anaerobic bacillus named *Clostridium tetani*. This bacterium, discovered by Arthur Nicolaier in 1884, produces the tetanospasmin molecule (tetanus toxin). This molecule travels to the spinal cord, causing painful muscular spasms and rigidity that can be triggered by loud noises, light, or other sensory stimuli. The bacterium is usually acquired through a penetrating injury or puncture wound in a person who has not been immunized or has an incomplete immunization. Other patients that can be affected are those with burns, ulcers, or intravenous drug users. Newborns can also be affected, especially those whose umbilical stump were cut under non-sterile conditions or whose mother had never been immunized. Tetanus is not transmitted from person to person. The incubation period ranges from 2 days to several months, with most cases occurring during the first 2 weeks. For newborns, the period of incubation is usually 5–14 days. Largely contaminated wounds are associated with a shorter incubation period, worse prognosis, and more severe disease.

Tetanus can present in four different ways: generalized, localized, cephalic, and neonatal. The most common type of presentation is the generalized tetanus, seen in approximately 80% of cases. One of the most common presenting signs is trismus (lock jaw); it is produced by spasms of the jaw muscle named the masseter. Other muscles of the body can be affected causing risus sardonicus (facial muscle spasms that produce grinning), stiff neck, difficulty swallowing, respiratory deterioration, and opisthotonus, which is a severe spasm that causes arching of the back with the head bending back and heels flexed toward the back. Patients can also have symptoms of autonomic overactivity such as a rapid heart rate, elevated blood pressure, fever, and profuse sweating. Localized tetanus has a milder presentation with muscle contractions in the same body region where the injury or wound occurred. It can eventually progress to the generalized type. Cephalic tetanus is usually seen in patients with head, neck, or face injuries or otitis media (ear infection). Signs and symptoms include difficulty swallowing, trismus, or focal cranial neuropathies with the facial nerve being the most commonly affected. Cephalic tetanus may progress to the generalized type. Neonatal tetanus is a form of generalized tetanus exhibited in newborns that can cause poor sucking and seizures in addition to the muscle spasms.

Tetanus occurs worldwide but is more common in warmer climates. In 1924, P. Descombey developed the tetanus toxoid vaccine, used in World War II, but it was not until the 1940s when immunizations became universal for children in developed countries, leading to a dramatic decrease in the incidence of tetanus. In the USA, the incidence is approximately 0.08–0.16 cases per million population (22–44 cases on average per year). A higher incidence is seen in underdeveloped countries. As per the World Health Organization (WHO) report in 2009, the highest incidence of tetanus occurred in the Democratic Republic of Congo (1,368 cases), Uganda (1,304 cases), and the Philippines (1,022 cases). China also had a markedly high incidence in 2008, with 1,786 cases; all reported cases were of neonatal tetanus. Mortality from generalized tetanus in the USA is approximately 10–30%, but it is higher in patients older than age 60. Neonatal tetanus has the highest mortality, being 25–90% in developing countries.

The treatment of tetanus should be accomplished in an intensive care unit whenever possible, because patients may require mechanical ventilation. Wound cleansing and debridement should be performed and antibiotics such as penicillin G (2–4 million units IV every 4–6 h for adults; 100,000 units/kg/day for children) or metronidazole (500 mg IV every 6–8 h for adults; 30 mg/kg/day for children) should be administered for 7–10 days. Benzodiazepines such as diazepam (10–30 mg starting dose) can be used to control the muscle spasms, and in severe cases, neuromuscular blocking agents such as vecuronium and pancuronium can also be administered. Other drugs such as labetalol, morphine, and clonidine can be used to treat autonomic symptoms. A single dose of Human Tetanus Immune Globulin (TIG) 3,000–6,000 units intramuscularly is recommended. In countries where TIG is not available, equine tetanus antitoxin 1,500–3,000 units intramuscularly can be administered after appropriate sensitivity testing and desensitization, if necessary, is performed. All patients with tetanus should be immunized with three doses of tetanus and diphtheria toxoid vaccine spaced at least 2 weeks apart. Tetanus disease does not confer immunity following recovery. As a preventive measure, all children should be immunized and receive five doses of the tetanus and diphtheria toxoid vaccine prior to school entry with a booster dose given every 10 years as adults. Tetanus prophylaxis should also be administered in routine wound or burn management depending on the patient's immunization status and the quality of the wound.

Thailand

Christopher A. Kenedi
Auckland District Health Board, Auckland,
New Zealand

In the heart of Southeast Asia, Thailand is the modern form of Siam that was established in the mid-fourteenth century. It is the only nation in Southeast Asia never to have been occupied by a European power. With a Gross Domestic Product of US$273.2 billion, Thailand is bordered by poorer neighbors to the north – Burma (Myanmar) ($27.2 billion) and Laos ($5.2 billion) and to the east-Cambodia ($9.2 billion). China is 125 km north of the Thai border across Laos. Thai culture and traditions are strongly influenced by Chinese historical practices and, to a lesser degree, by Indian culture, along with influences from Burma, Laos, and Cambodia.

The country is a kingdom, a constitutional monarchy with King Bhumibol Adulyadej, who has reigned since 1946, making him the world's longest-serving current head of state and the longest-reigning monarch in Thai history. However, during his reign, there have been a number of military coups and political upheavals, the most recent in 2006–2008. Theravada Buddhism is practiced by more than 94.7% of all Thais. Muslims make up 4.6% of the population, primarily in the south. Since 2004, there has been escalating conflict between a separatist Muslim movement and the Buddhist Thai community in southern Thailand, resulting in the deaths of thousands, the burning of more than 300 schools and militarization of the area.

Thailand is the world's 50th largest country in terms of surface area (approximately 513,000 km^2 [198,000 mi^2]), but it is the 21st most-populous country, with approximately 64 million people. About 75% of the population is ethnically Thai, 14% is of Chinese origin, and 3% is ethnically Malay; the rest belong to minority groups including Mons, Khmers, and various hill tribes – many of whom live in very isolated conditions and without ownership of their lands or access to legal systems. One-third of the population lives in urban areas with the majority of those in Bangkok. The overall literacy rate approaches 92%.

Thailand is a newly industrialized country with exports – mostly machinery and electronic components, agricultural commodities, and jewelry – continuing to drive the economy, accounting for as much as three-quarters of GDP. It also has a strong tourism base due to well-known tourist destinations such as Pattaya, Bangkok, and Phuket. It experienced rapid economic growth between 1985 and 1995 and then from 2000 to 2008. Agriculture accounts for 43% of the country's labor force but 12% of GDP. Industry represents 44% of GDP and 20% of its labor pool, with the balance in services. Ten percent of the country lives below the poverty line.

Thailand does have universal health coverage, although there is a strong system of private hospitals and privately funded practitioners as well. A major problem for Thailand is HIV/AIDS and they have had 58,000 people die from AIDS related illnesses since 1984. The prevalence rate is now estimated to be 1.4% of the population. There has been an 83% reduction in new infections from 142,819 in 1991 to 21,260 in 2003. In 2006, at least 80,000 people were receiving drugs to keep HIV under control – approximately 88% of the HIV+ population. A new challenge is coping with H5N1 Avian flu which has infected poultry and people in Thailand.

It is estimated that at any time, 2.2 million legal and illegal immigrants live in Thailand. This population is a mix of Burmese men supplying labor for the construction and seafood industry, women from Cambodia and Vietnam who are performing domestic labor, textile work, and sex work, as well as refugees from regional conflicts. At least 116,000 were Karen, Hmong, and other asylum seekers from Burma alone. There is also a large expatriate community in Thailand of Westerns from the USA and Europe. Recently, the unemployment rate has increased and the Thai government has threatened to deport almost 500,000 Burmese immigrants who did not register by a deadline. There is some fear that they may "go underground" to avoid deportation for political or safety reasons as well as economic ones. This also means they will be reluctant to seek medical attention.

Human trafficking is a serious issue in Thailand which is the only nation dually listed by the UN Office on Drugs and Crime as being one of the top eight importers of human trafficking as well as one of the top eight exporters of exploited human capital. Women and sometimes children are brought to Thailand from China, Laos, and Cambodia for the sex industry or for domestic labor and forced to remain by force or coercion. They are often forced to engage in unsafe sexual practices and their wages as well as their freedom may be stolen from them. Buramese men are brought to Thailand and sold in indentured servitude to work in unsafe conditions, particularly in the seafood industry and construction jobs. Thai women are also trafficked abroad to Europe, the USA, and Australia among others to work in the sex and service industry. A recent United States Senate investigation looked at the trafficking of Burmese refugees through Malaysia into Southern Thailand and found evidence that it is occurring on a systematic basis with women and men who are unable to pay off extortion demands being sold to brothels or fishing boats.

A particular issue for Thai patients is the role of the family and gender roles. Men are expected to support their families while daughters may be seen as relatively transient as they will eventually leave. Despite the fact that men hold much of the outward power, women will often remain strong behind-the-scenes, and it is women who often hold the deeds to property in Thailand. This means that decisions, including treatment decisions, will often be made after consultation in private and sometimes with family elders or religious figures. Thai patients may find the urgency of western health care workers confusing and distressing.

Another issue in Thai culture is *kun na* or saving face. *Mai pen rai* is a very common expression that loosely translates as "it doesn't matter," but really is an attempt to constructively address conflict by implying that the issue at hand is less important than the stress it will cause. Thai place an enormous value on *chai yen* – avoiding the expression of strong feelings; and the expression of strong emotion, especially negative ones is a cause for significant "loss of face" and humiliation. This can be extremely difficult for medical practitioners who are attempting to counsel a choice that is not in line with a family elder or religious figure as patients may disengage from treatment to avoid confrontation or a loss of face for a senior family figure. Treatment discussions are often best held in a calm and controlled setting using open-ended questions and involving as much of the family or respected religious figures as they would like to have present.

Although 95% of Thais identify themselves as Buddhists, in reality there is a high degree of operational syncretism where Hindu Brahmanism, animism, and other spiritual practices are seen as complementary. Many, if not most, businesses and homes will have decorated spirit houses for offerings of incense, flowers, and candles. Thais approach health care with similar views; they may place a Western diagnostic evaluation on a sliding scale with religious or complementary medicine opinions. This can be difficult for science-based health practitioners who have a distinct view of health and illness.

The health experience of Thai immigrants and workers abroad has not been evaluated in a systematic fashion. A Thai postdoctoral student working in Washington DC conducted a series of interviews and a survey of Thai health care experiences. He found that Thais in the USA liked many things about the US healthcare system, but were frustrated by its complexity, cost, and the lack of decisiveness in doctor's recommendations; many voiced confusion and disconnectedness when an American doctor offered them a variety of choices. Thai immigrants reported that they sought care preferentially with Thai doctors or self-medicated using over-the-counter drugs, Chinese medications/therapies such as acupuncture, or familiar medications from Thailand. They went to American hospitals when they felt they needed "technology" or for life-threatening problems.

A second study of Thai women in Brisbane, Australia, found similar results; that the high cost and complexity of health care in Australia compared to the perceived "efficiency and efficacy of Thai practitioners" resulted in women delaying medical attention until they returned to Thailand. They also found that language and cultural barriers led to low participation in preventive health programs for Thai women in Australia.

Thai workers abroad are at risk of being misdiagnosed if they bring health problems with them that are rare in their host country. A hospital in Israel reported 30 Thai agricultural workers who experienced an outbreak of trichinosis (associated with infected pork), a disease that is not well known in the Jewish state.

Another study looked at the health of Thai migrant workers while abroad and found that 32% reported adverse effects on their psychological health and 19% to their physical health, but overall their Thai communities improved due to the workers' contributions sent home. The report concludes that the effects of migration on health were transient and that overseas migration provided indirect health benefits to larger communities (e.g., villages) through economic gain and improvement of infrastructure.

Thailand has a number of local and regional diseases that may impact Thai emigrants who are residing in other areas of the world. Health care providers should consider these issues which may be otherwise unfamiliar to them when evaluating Thai patients. Fevers in Thai patients abroad or in immigrants who have moved to Thailand should be evaluated for dengue, malaria, and chikungunya in the differential diagnosis.

Dengue fever is a viral infection from infected mosquitoes that is the most common cause of fever in travelers returning from South Central Asia. It can occur anywhere in Thailand, but more infections are associated with urban settings. In Thailand, it seems to have an endemic pattern as well as epidemic spikes in outbreaks. When thousands can be affected, it is associated with fever, severe headaches, joint and muscle pain, "bone break fever," rashes, nausea, and vomiting and bleeding. It is potentially fatal in severe cases.

Chikungunya fever is also caused by a virus from infected mosquitoes. Symptoms include sudden fever, joint pain, chills, headache, nausea and vomiting, lower back pain, and a rash. After resolution of the initial infection, Chikungunya survivors may experience a prolonged course (months) of arthralgia or arthritis which can lead to extensive workups for rheumatic disease. The disease is particularly prevalent in the southern region. More than 49,000 cases were documented in 2009.

Malaria is resistant to mefloquine (a common anti-malarial medication) along the eastern (Cambodian and southern Laos) and western (Burmese) border of Thailand. Malaria generally occurs in rural areas of Thailand and is characterized by influenza-like symptoms in intervals. It is often accompanied by anemia and jaundice. Malaria can occur between 7 days and many months after exposure.

Other diseases that can be found in Thailand and the region include: Japanese encephalitis, filariasis, and plague. Fresh water (such as agricultural work) can bring exposure to schistosomiasis and leptospirosis. Measles persists in Thailand, although vaccination coverage has improved. H5N1 avian influenza has been associated with wild and domesticated bird populations in Thailand on a sporadic basis.

Tobacco

Amanda Jane Reich
Community Health Program, Tufts University,
Medford, MA, USA

Tobacco use is the leading preventable cause of death in the USA. The Centers for Disease Control and Prevention (CDC) estimates that 443,000 deaths annually can be attributed to smoking and secondhand smoke in 2010. The smoking-related diseases that are associated with tobacco use include numerous cancers including cancers of the lung, esophagus, and pancreas; cardiovascular diseases such as heart attacks and strokes; and respiratory diseases like chronic airway obstruction.

Tobacco use in the USA has declined since 1964, when the Surgeon General's Advisory Committee on Smoking and Health published a report which concluded that cigarette smoking was a cause of lung and laryngeal cancer. Since then the proportion of US adult smokers declined from 42% in 1964 to 20.6% in 2009. Nonetheless, 45 million Americans continue to smoke. And while the first Surgeon General's report on smoking was published in 1964, it was not until 1998 that a similar report was published that included an analysis of racial and ethnic differences in tobacco utilization. To date, the Surgeon General's report has not looked specifically at the impact of tobacco use on immigrant populations. The 1998 report, Tobacco Use Among US Racial/Ethnic Minority Groups, did prompt researchers to consider how acculturation affects patterns of tobacco use among immigrants to the USA.

Immigrants and Tobacco Use

Smoking rates among immigrants differ from those of nonimmigrants. In general, immigrant assimilation is positively associated with tobacco use; however, there is a lack of large data sources available to illustrate the diversity of immigrant populations. When smoking prevalence is reported only by race or ethnic categories, the heterogeneity of immigrant groups is obscured. An analysis of National Health Interview Survey data revealed that while immigrants demonstrated significantly lower smoking rates than nonimmigrants, rates varied according to country of birth.

Acculturation is an important variable in assessing immigrant tobacco use. A recent analysis of electronic medical records found that prevalence of tobacco use increased considerably with acculturation among women, particularly Laotian/Hmong, and Mexican-born Spanish speakers, while changing little among men. Some of the disparity is related to gender differences in the native cultures, where female smoking rates may be much lower. A review of studies assessing acculturation and smoking among Hispanic women underscored the gender-specific nature of the relationship. Another analysis of female Hispanic smokers noted that while acculturation is associated with smoking, having a less cohesive family structure was an important component as well.

A related concept involves generational differences. Being foreign-born appears to have a protective effect against smoking. An analysis by Acevedo-Garcia (2005) found that the odds of being a smoker were highest among US-born individuals of US-born parents and lowest among foreign-born individuals. Again, the complexity of the relationship between immigrant status and tobacco use is revealed through a closer look at the data. The analysis also found that being foreign born and being second generation with two immigrant parents was especially protective against smoking for females as compared to males, racial and ethnic minorities compared to Whites, and low-income individuals compared to high income individuals.

This generation-specific gradient applies not only to use of tobacco, but also in regards to whether an individual supports smoke-free policies (e.g., banning smoking in a public place). Data from the Current Population Survey Tobacco Use Supplement indicated that immigrants exhibited stronger support for banning cigarettes in every venue (including malls, restaurants, indoor workplaces, bars, hospitals, and sporting events), although the support eroded with greater assimilation into the USA.

Unfortunately, any protective factor conferred to foreign-born immigrants may be at risk due to targeted marketing by the tobacco industry. While researchers lack detailed and specific large data sources, a review of tobacco industry documents revealed that three distinct strategies have been aimed at immigrant populations. These strategies included marketing geographically in immigrant communities, segmentation based on immigrants' assimilation status, and coordinated marketing focused on countries of origin. The industry used information on immigrant populations to tailor marketing strategies and increase tobacco use.

Tobacco Control

Simran Singh
Department of Veterans Affairs, Cleveland, OH, USA

Cigarette smoking is a major cause of disease worldwide. Approximately, 5.4 million deaths each year are caused by tobacco use. The World Health Organization (WHO) estimates that every 6.5 sec a current or former smoker dies. Tobacco use is the single most preventable cause of disease, disability, and death in the USA. Each year an estimated 443,000 deaths occur as a result of cigarette smoking, representing nearly one in every five deaths. Lung cancer, atherosclerotic cardiovascular disease, and chronic obstructive pulmonary disease are responsible for the majority of these deaths. Despite these risks, nearly 43.4 million US adults smoke cigarettes. Another 126 million nonsmoking Americans are exposed to secondhand smoke, resulting in an estimated 49,000 tobacco-related deaths. In addition, the economic burden of tobacco use in the USA exceeds $193 billion per year, with $96 billion in medical expenditures, and another $97 billion in lost productivity. Annually, secondhand smoke costs more than $10 billion in health care expenditures.

Health Effects of Smoking and Health Benefits of Smoking Cessation

The Center for Disease Control (CDC) estimates that due to smoking adult male smokers lose an average of 13.2 years of life, and female smokers lose an average of 14.5 years of life. Ceasing tobacco use has major and immediate health benefits for persons of all ages. Statistically, former smokers live longer than persons who continue smoking. As compared to those who continue to smoke, those who stop smoking before age 50 reduce their risk by one half of dying over the next 15 years. It is estimated that cigarette smoking accounts for at least 30% of cancer deaths and that tobacco is responsible for nearly 90% of lung cancer cases. Lung cancer is the leading cause of cancer death among both men and women, is one of the most difficult cancers to treat, and is hard to detect in the earliest, most treatable stage. From the point of cessation, the risk of lung cancer begins to reduce within 5 years. It may also reduce the risk of other cancers, such as cancers of the head, neck, esophagus, stomach, kidney, pancreas, colon, rectum, and bladder. Tobacco cessation is advantageous even after one cancer is diagnosed, as it reduces the risk of acquiring a second cancer and may improve survival from the first.

Cancers account for about 50% of the deaths related to smoking. Tobacco is a major cause also of atherosclerotic cardiovascular disease, including: heart disease, peripheral vascular disease, stroke, and abdominal aortic aneurysm. Tobacco use doubles the risk of developing heart disease. One year after quitting smoking, the risk of dying from heart disease is reduced by one half and continues to decline over time. Some studies have shown that within 2 years of stopping smoking, the risk of heart attack was reduced to the rate of nonsmokers.

Smoking increases the risk of long-term lung diseases such as chronic obstructive pulmonary disease (COPD). Most of the lung damage caused by smoking is not reversible, but quitting smoking can reduce further lung damage. Chronic cough and sputum (phlegm coughed up from the lungs) are reduced in most smokers within 1 year after tobacco cessation. Children exposed to secondhand smoke are more likely to develop asthma or sudden infant death syndrome (SIDS).

Additionally, smoking causes or worsens other conditions, increases the risk for osteoporosis, and increases the risk of hip fracture in women. Stopping smoking begins to reverse this risk in about 10 years. Pregnant smokers have an increased risk of miscarriage, early delivery, stillbirth, and delivering a low birth weight infant. Smoking causes premature skin wrinkling and increases the risk of sexual problems (e.g., infertility, impotence).

Nicotine Addiction

Smoking is recognized as a chronic, addictive disease. Addiction, characterized by the compulsive seeking or use of a substance despite harmful consequences, is accompanied frequently by adverse physical and psychological dependence. It is estimated that 85% of US smokers are addicted, while nicotine is the addictive drug in tobacco that produces dependence. Although it is reported that approximately 70% of smokers want to quit, and 35% attempt to quit each year, less than 5% succeed. The low rate of successful quitting and the high rate of relapse are related to the effect of nicotine addiction.

Discomforts of Tobacco Cessation

The health benefits of smoking cessation far exceed any adverse psychological or physical effects that may proceed quitting. Symptoms of withdrawal are common, peak in the first 3 days, and decrease over the next 3–4 weeks. Withdrawal symptoms may include irritability, anxiety, difficulty concentrating, increased appetite, difficulty sleeping, frustration, anger, and restlessness. Episodic cravings for cigarettes may persist for many months but will go away if ignored. Some people who stop smoking experience depression, which may be severe enough to require counseling or treatment. Weight gain can occur during the cessation process, because people tend to eat more after quitting. Typically, people gain 2–5 lb in the first 2 weeks, followed by an additional 4–7 lb over the next 4–5 months. The benefits of quitting smoking are much greater than the drawbacks presented with weight gain, and an exercise program and reasonable diet can minimize weight gain.

Preparing to Quit

After deciding to quit smoking, the first step is to set a quit date. Sometimes those who smoke fewer cigarettes are able to quit gradually, but stopping “cold turkey” is more successful in general. Other steps that may help in preparing to quit include telling family, friends, and colleagues of one’s plan to quit; eliciting support; reviewing previous attempts at cessation; preparing to deal with nicotine withdrawal symptoms; preparing to deal with things that trigger smoking (e.g., current smokers, stress, and alcohol); and talking to a health care provider.

Tobacco Cessation Interventions-Behavioral Modifications and Medications

Tobacco dependence is a chronic condition that often requires repeated interventions. The most effective interventions involve a combination of counseling and FDA-approved cessation medications. Health care providers play a pivotal role in encouraging smokers to quit and in providing or referring patients to appropriate counseling and treatment. Brief clinical interventions, even of 5 min or less, and counseling are effective cessation treatments. The first step in the process, identification and assessment of tobacco use status, separates patients into three treatment categories: patients willing to quit, patients unwilling to quit at this time, and patients who have quit using tobacco recently. Patients willing to quit should be treated with the “5 As”: Ask about tobacco use, Advise to quit, Assess willingness to quit, Assist in quit attempt, and Arrange adequate follow-up. The “5 Rs”: Relevance, Risks, Rewards, Roadblocks, and Repetition are designed to motivate smokers who are unwilling to quit at this time. Patients who have quit using tobacco recently should be provided relapse prevention treatment.

Approaching changes in behavior through problem solving, skills training, and social support increases one’s chances of successful cessation, and using behavioral changes in conjunction with a medication further increases rates of success. Pharmacological treatments to help with tobacco cessation include nicotine replacement therapies, buproprion (Zyban® and Wellbutrin®) and varenicline tartrate (Chantix®). Clonidine, an antihypertensive medication, and nortriptyline, a tricyclic antidepressant, are considered second-line smoking cessation drugs that have shown a modest benefit in increasing smoking cessation rates. However, use is limited by significant adverse side effects. Hypnosis and acupuncture are popular tobacco cessation methods; however, scientific support is weak for these methods.

Nicotine replacement therapy is designed to reduce the intensity of withdrawal symptoms. It is safe, even in people with known heart disease; however, using nicotine replacement therapy while smoking is not recommended. Nicotine is available in several forms: as a gum, lozenge, patch, nasal spray, or inhaler. None of these is significantly superior to another. Combinations of therapies are more effective generally than one form alone. Withdrawal symptoms are not prevented by nicotine replacement therapy, but the intensity of the symptoms can be reduced.

Varenicline tartrate is a prescription medication that works in the brain to reduce nicotine withdrawal symptoms and cigarette cravings. In several studies, it was more effective than buproprion and placebo. Common side effects of varenicline include nausea and abnormal dreams. In 2007, the FDA reported a small number of people who developed suicidal thoughts and aggressive and erratic behavior during treatment with varenicline. Although some of these suicidal thoughts and abnormal behavior may have been due to quitting smoking, the report states that not all such patients had discontinued smoking.

Bupropion is an antidepressant that is well tolerated usually, but may cause dry mouth and difficulty sleeping. The drug is not recommended for those who have a seizure disorder, head trauma, eating disorder, or who drink excessively.

Tobacco Control

Through a combination of economic, legal, educational, social, and clinical strategies, comprehensive tobacco control programs aim to reduce tobacco use and its associated diseases, disability, economic costs, and death. For example, increases in excise taxes, restrictions on smoking in public places, prevention and cessation programs, and effective antitobacco media campaigns have all been effective interventions to reduce tobacco use. Raising the price of cigarettes is effective in preventing tobacco use amongst adolescents and young adults and in increasing cessation amongst adults. Furthermore, revenue from excise taxes can be used by the government for tobacco control programs. Comprehensive smoke-free laws serve to reduce exposure to secondhand smoke, to reduce the social acceptability of smoking, and to encourage smokers to cut back or quit. The most effective smoking cessation interventions involve a combination of counseling and the use of FDA-approved cessation medications. Integrating population-wide cessation services into comprehensive tobacco control programs has shown great promise. Examples include toll-free telephone services such as the national service 1-800-QUITNOW and the American Cancer Society's Quitline® program 1-877-YES-QUIT. Effective antitobacco media campaigns have included messages that highlight the negative consequences of tobacco use, expose the industry's deceptive marketing tactics, and emphasize social norms that reduce the acceptability of smoking.

There is growing evidence that comprehensive tobacco control programs reduce smoking prevalence and negative health-related outcomes. To sustain the tremendous gains in reducing tobacco use in the USA, continued support of these programs is paramount, despite severe local, state, and national budget cuts.

Tobacco Use

Vera Nierkens
Department of Public Health, Academic Medical
Center, University of Amsterdam, Amsterdam,
The Netherlands

Tobacco is one of the most common preventable causes of death. It is estimated that tobacco use kills five million people each year worldwide. Most people use tobacco by smoking cigarettes, cigars, or pipes, but there are also several forms of smokeless tobacco, such as chewing tobacco, moist snuff, or dry snuff. In recent decades an increasing amount of information about tobacco use among immigrant populations and how this behavior changes became available. This information will, among other things, provide information relevant for prevention of future use of Tobacco.

Among immigrant populations in "Western countries," smoking rates vary largely. Most data are available from the USA and some European countries.

The US estimates for 2008 show that, compared to 22% of the non-Hispanic Whites and about 21.3% of the adult African Americans, 15.8% of the Hispanics smoke cigarettes. Among Asian populations smoking rates are about 10% although these figures differ largely between several subpopulations. One study from Canada found that 20.8% of Ethiopian immigrants smoke regularly. Figures about smoking rates in Europe reveal that among the largest immigrant populations, smoking rates vary between 15% among Moroccans in the Netherlands and 47% among Polish migrants in Ireland and about 44–50% among Turks in the Netherlands and Germany. These figures should be compared to the figures of the general populations, i.e., 23.6% in Ireland (above age 15) and 28% in the Netherlands (above age 15) and 27% and Germany, respectively. Figures about cigar smoking are less common. US estimates from 2005 show that 4.6% of the Hispanics and 1.8% of the Asian Americans smoke cigars compared to 5.8% of the general population.

Regarding smokeless tobacco the percentages of use seem to be lower than among the host population, except for the South Asian immigrants. While the prevalence is 0.6% among Asian Americans and 1.3% among the US Hispanics (compared to the US Whites (4.30%)), among South Asians in the UK 9% of men and 16% of women reported using chewing tobacco. This pattern can be explained by tobacco use habits in their countries of origin. Among US youth, percentages ranged from 2.0% among Asian American middle school students to 4.7% among Hispanic middle school students, compared to 10.3% among White high school students and 2.8% among middle school White students.

Historically, tobacco use is more prevalent among males than among females, and in many developing countries this is still the case. In line with these "historic trends," in some immigrant populations female tobacco smoking is still low. For example, among Indian, Pakistani, and Bangladeshi the prevalence of smoking is 5%, 5%, and 2%, respectively, while the smoking rates among men were 20%, 29%, and 40%. A similar pattern was found among Moroccan migrants in the Netherlands. In other groups, such as Turkish migrants in Europe, tobacco smoking is more or less similar to the host population in women and especially high among men; percentages between 40% and 60% were found. In the USA, gender differences are found among Asian Americans (6.1% vs 20.6%) and Hispanics (11.1% vs 21.1).

Although smoking rates are low in some female migrant populations, we can expect an increase in tobacco use in these groups. In recent decades there is increasing knowledge about changes in tobacco use of immigrants towards the tobacco use in the host population. Most knowledge about this topic concerns Hispanics in the USA, but also studies from other groups show similar associations. It appeared that immigrant women, who are more integrated into the host population, are more frequent smokers than those who are less integrated. Among men, however, these associations of smoking patterns with acculturation ("level of integration") are generally not found or are in the other direction, i.e., smoking rates are higher among less integrated men. This might be explained by the fact that smoking is already more prevalent for them in their home country than it was for women.

Changes in smoking prevalence are also found among the younger migrants or migrants' offspring. Among youth in the USA, smoking rates among the Hispanics are highest (16.7%) compared to 7.3% among Asian Americans. Generally it was found that among females born in the host population, the prevalence of tobacco use is higher than in migrants themselves. For example, a larger percentage of Turkish females born in the Netherlands smoke than their migrant peers born in the country of origin. However, in this particular study the percentages among males born in the Netherlands were lower than in those born in Turkey and seem to converge to the smoking rates among the host population. Similar trends were found among Turkish migrants in Germany.

As known among the Western majority population, tobacco use has been associated with socioeconomic status. It is well known from the general population that the prevalence of tobacco use of people in a lower socioeconomic position is higher than among those in a higher socioeconomic position. Also among immigrant populations, associations with education level or poverty have been found, though these associations vary among several groups and gender. For example, in the Turkish and Surinamese migrants in the Netherlands, smoking rates among males are similar to those in the host population and appeared to be higher in the lower education level groups. However, in some age groups, women, especially the higher educated, smoke cigarettes. This pattern seems to be in line with smoking patterns in countries of origin and can be understood in light of the tobacco epidemic, a model that described the smoking through populations across the world as going through four stages. According to this model, smoking increases rapidly from less than 15% among men in the first stage to a peak of 50–80% among men in the second stage. In these stages female prevalence lags behind that of men by one or two decades, but increases rapidly in the second stage. From the third stage onward, a decline in smoking prevalence occurs among men to a percentage of 40% by the end of this stage and also female smoking starts to decline at the end of this stage, reaching a maximum of 35–40%. The fourth stage is characterized by a slow decline in smoking prevalence for both sexes. In this phase an increasing number of prevention programs can be observed. While Western countries are in the last stage, implying that especially more lower educated people smoke, countries where migrants come from are in earlier stages in which a positive association of socioeconomic position with smoking among women have been found.

In conclusion, tobacco use among migrants varies between migrants from different countries and seems to change by influences from both the country of origin and the host population. This information provides insight into how to target those populations most at risk for smoking prevention or smoking cessation interventions.

Torture

NADEEN ALJIJAKLI
Duane Morris LLP, Washington, DC, USA

Torture is the deliberate infliction of severe physical or mental pain or suffering on a person for the purpose of intimidating, coercing, punishing, securing information or a confession, or for any reason based on discrimination. According to international law, torture relates to acts – other than pain or suffering resulting from lawful sanctions – that are performed by persons acting in an official capacity or with their awareness. However, torture occurs in other contexts also, such as crime, domestic violence, and ritual abuse. Examples of torture methods include severe beating, sexual abuse, sensory or sleep deprivation, restraint or being held in uncomfortable positions, extreme temperatures, deafening noises, solitary confinement, and other forms of physical and psychological abuse.

There are at least 400,000 survivors of torture living in the USA. Although torture is illegal under international law and under domestic laws of most countries, it is a standard practice still in more than 100 countries. The US government has documented that 5–35% of refugees arriving in the USA are victims of torture. Torture survivors come to the USA in numerous ways, some with and some without authorization from the US government. International law forbids states to return individuals to their home country if there is reason to believe they will be tortured. The USA offers protection and resettlement to refugees who are processed abroad, as well as asylum and other forms of relief to those already in the country. Generally, asylum seekers are required to apply for asylum within 1 year of their arrival.

Upon their arrival, persons may not suffer from physical scars and debilitating injuries only, but may also develop mental health disorders, including depression and posttraumatic stress disorder (PTSD) – an anxiety disorder that occurs as a result of experiencing a traumatic event. Common symptoms among torture survivors include difficulty concentrating, anxiety, depression, avoidance, emotional numbing, guilt, memories and nightmares of the torture, flashbacks, sleep problems, fatigue, irritability, hypersensitivity and exaggerated startle response, thoughts of suicide, chronic pain in muscles and joints, illness, and other long-term effects. These symptoms can be lifelong and irreparable if not treated by trained professionals.

Nevertheless, generally refugees and immigrants do not report themselves as survivors of torture, and frequently physical or mental health problems resulting from torture remain undetected. In addition to cultural attitudes regarding trauma, various emotions affect survivors' willingness to seek treatment – these include shame, humiliation, and fear of deportation to their home country. Although increasing in recent years, health care providers' knowledge of proper screening and methods to effectively treat torture survivors remains limited.

Often torture survivors have backgrounds as community leaders or grassroots activists; studies have shown that survivors tend to have earned high levels of education and public recognition in their country of origin. Treatment centers report that survivors come from a wide variety of occupations and professions including business, labor, religious, farm, and human rights leaders; attorneys and journalists; university professors and students; and physicians and nurses. The commonality is that they were targeted because of what they thought, said, did, or represented. Perpetrators of politically motivated torture seek to silence opposition by crushing their will and by discouraging others from engaging in public life. This affects the survivor's identity and sense of self profoundly, despite strong personality traits and leadership abilities. The trauma of torture may worsen through the process of escape as survivors may have to cope with the fear that they might be forced to return; potential separation from family members; and the overwhelming nature of adjusting to a new society, culture, and language. Additionally, they may face the challenges of limited finances; poor access to adequate housing, food, and health care; and, depending on their immigration status, no authorization to work from the US government.

Torture can affect all members of a survivor's family, as the survivor's vulnerable mental state and resulting behavior are likely to impact daily family life. Frequently, children of survivors experience learning and behavioral problems, mood swings, violent play or artwork, frequent complaints of pain or illness, fear and anxiety, or avoidance of anything reminding them of the traumatic event.

Mental health care, counseling, and treatment can assist survivors and their family to recover from the trauma, work through the bereavement process, rebuild trust in others, reconnect with family, build skills and confidence, and integrate into their communities. Numerous medical and human rights organizations and centers throughout the USA offer torture survivors specialized treatment and services. Recognizing that many refugees entering the USA have suffered torture, through the Torture Victims Relief Act of 1998 (TVRA), the US government provides funding for treatment and rehabilitative services to assist survivors. Treatment programs vary and may include services from physicians, nurses, psychiatrists, psychologists, counselors, social workers, and religious chaplains. In addition to receiving mental health treatment, these programs work with survivors to ensure that they have stable housing, adequate food and clothing, and access to legal services to help with the challenges of the immigration process.

Some survivors are victimized again or exploited as newcomers to the USA. For example, employers may seek to underpay or overwork them, or – knowing that immigrants may fear deportation if they involve the authorities – perpetrators may rob or abuse them. Treatment programs can assist survivors in avoiding or dealing with such predicaments.

Torture survivors have experienced unthinkable trauma that is likely to impact them psychologically; the effect is long-lasting for some. With proper attention and care, however, survivors can rise beyond their experience of suffering and become integral parts of society.

Traditional Chinese Medicine

Amy N. Sharpton
Department of Veterans Affairs, Louis Stokes DVA
Medical Center Cleveland, Brecksville, OH, USA

Introduction

Classical or traditional Chinese medicine (TCM) refers to the cumulative practices beginning in the first century BC that there were passed down by a small group of the literate minority in China. Since 1949, state-regulated medical practice has come gradually to be divided between biomedicine and a greatly modernized form of the classical art called TCM, and combinations of the two.

Dating back more than 5,000 years, traditional Chinese medicine is grounded in Taoism, which at turns has been defined as both a religion and a philosophy. Taoism was evolved by Lao-tzu and Chuang-tzu, who advocated a life of complete simplicity, naturalness, and of noninterference with the course of natural events. In many of China's medical facilities, TCM is practiced today alongside Western medicine.

Concepts

Traditional Chinese medicine holds a view of the world and the human body that is indicative of the ancient Chinese perception of humans as interconnected with nature and subject to its forces. The human body is regarded as an organic entity – with the various organs, tissues, and other parts having distinct functions, while maintaining a state of interdependence as well. As a consequence, health and disease are viewed relative to the degree that these functions are balanced.

The theoretical framework of TCM is comprised of three key concepts: the Yin-Yang theory, the life force qi, and the eight principles by which symptoms are analyzed and categorized. The Yin-Yang theory holds that all phenomena consist of two opposing yet complementary aspects, which can be defined in a variety of ways, for example, up and down, left and right, hot and cold, and stillness and movement. Furthermore, the theory posits that all developments derive from the movements of yin and yang; this interplay provides the origin of both birth and destruction. The theory, which is central to TCM, holds that the two forces shape the world and all of life.

TCM practitioners contend that within all living things is a vital energy or life force called qi (pronounced "chee"). They propose that qi, as it circulates through a system of bodily pathways called meridians, is influenced by the opposing forces of yin and yang, and that this qi is the life force that regulates one's spiritual, emotional, mental, and physical health. They view health as an ongoing process of maintaining balance and harmony in the circulation of qi.

The TCM approach to medicine employs eight principles by which to analyze and categorize symptoms. The eight principles can be viewed as opposing forces and include cold/heat, interior/exterior, excess/deficiency, and yin/yang. Traditional Chinese medicine employs also the theory of five elements – fire, earth, metal, water, and wood. The elements correspond to particular organs and bodily tissues and are used to explain bodily mechanisms.

Treatment

Practitioners of TCM, emphasizing individualized treatment, used four methods primarily to evaluate a patient's condition: (a) observing, paying particular attention to the tongue; (b) hearing/smelling; (c) asking/interviewing; and (d) touching/palpating, focusing especially on the pulse. Today's TCM practitioners use a variety of therapies to promote well-being and to treat disease; the most commonly used therapies are Chinese herbal medicine and acupuncture. A pharmacological reference book used by TCM practitioners, the *Chinese Materia Medica*, contains hundreds of medicinal substances, including plants, minerals, and animal products – all classified by their perceived action in the body. Herbs are combined usually in formulas and given as teas, capsules, tinctures, or powders. Acupuncture is used to stimulate specific points on the body. This is accomplished by inserting thin metal needles through the skin, as practitioners seek to remove blockages in the flow of qi. Other TCM therapies include moxibustion, burning a cone or stick of dried herb, flowers, leaves, bark, fruit, seeds, stems, or roots on or near the skin; cupping, applying a heated cup to the skin to create a slight suction; Chinese massage; mind–body therapies such as qi gong and tai chi; and dietary therapy.

Popularity

In the United States, TCM falls under the category of complementary and alternative medicine (CAM). While not considered at present to be part of conventional medicine, CAM is comprised of a variety of diverse medical and health care systems, practices, and products that appear to be gaining acceptance and use, if not by the medical community at large, than by the more than three million adults who turn to TCM-related therapies each year. It should be noted that complementary medicine is used in conjunction with conventional medicine, while alternative medicine is used in place of conventional medicine.

Although it is unknown the exact number of those in the United States who use TCM, in 1997 it was estimated that more than one million patients were served each year by approximately 10,000 practitioners who employed one or more TCM therapies. The 2007 National Health Interview Survey included questions on the use of various therapies related to TCM, and an estimated 3.1 million US adults reported that they had used acupuncture within the most recent 12 months. Furthermore, approximately 17% of adults reported using natural products, including herbs – giving it the distinction of being the most commonly used therapy.

Trafficking

Christopher A. Kenedi
Auckland District Health Board, Auckland,
New Zealand

Human trafficking is a form of exploitation that involves controlling and transporting people through the use of force, deception, or coercion. The end result is that people are moved, often by smuggling or under false pretences such as tourist visas, from one area or nation into another. The nature of the exploitation is often forced labor for little or no pay in unsafe conditions. Other reasons for trafficking include involuntary prostitution, forced marriage, recruiting child soldiers, and the trafficking of babies and children for adoption. It is reported to be the third most profitable criminal activity in the world after drug and gun smuggling and resulted in estimated profits of US$31 billion in 2008.

Credible estimates of the number of people moved by human traffickers each year ranges from 500,000 to 4 million depending on the definitions used. Most United Nations and United States government data suggest that the number is greater than 1.5 million people annually, although that figure may be heavily weighted to count only women and children, whereas the larger estimate of four million includes men trafficked primarily to be exploited for labor purposes.

Citizens of Albania, Belarus, Bulgaria, China, Moldova, Nigeria, Thailand, and Ukraine are reported as the most likely to be the victims of trafficking; the most common destinations for human trafficking operations are Belgium, Germany, Israel, Italy, Japan, the Netherlands, Thailand, Turkey, and the United States. Thailand is notably listed as both a source of victims and a destination; Thai women are primarily sent to Japan, Malaysia, Singapore, Taiwan, Hong Kong, Bahrain, Australia, South Africa, Europe, and the United States, chiefly for sexual exploitation, but also to some destinations for sweatshop labor. Men, especially migrant workers from Burma (Myanmar), are trafficked into Thailand to commercial fisheries, seafood processing plants, and for farm, industrial, and construction labor. This pattern shows how trafficking can mimic the supply and demand of a labor market in response to economic conditions.

However trafficking is more than a black market for unscrupulous suppliers and employers to obtain cheap labor; it also represents a form of control. This is demonstrated by the trafficking of women between Cambodia and Vietnam for exploitation as forced sex workers; both nations are relatively poor, but the flow of trafficked women goes both ways. There are two reasons for this. First, agents in both places act as way-stations to move the women on to industrialized nations. Second, within each local sex industry, the foreign women are perceived to be more compliant and less resistant when they are in a strange country with unfamiliar language, customs, and geography. In a foreign land, they are unaware of resources to help them escape and may be subject to prosecution as illegal immigrants if they approach the police. The victims feel isolated and may see their captors as their only hope for survival, putting the captor in a powerful situation both physically and psychologically. Even the victims' employers or customers, who do not speak their language, may not realize that they are unwilling participants.

Internationally, these activities are performed by a disparate collection of entities from individuals seeking personal gain to well-established organized crime and militaristic enterprises. Combating human trafficking is difficult due to discordant national laws, prosecutorial incentives, social-cultural practices, and economic conditions. Although trafficking is most intense when nations of disparate economic status are in close proximity (e.g., Italy and Albania, Burma and Thailand), the low costs associated with international travel mean that it has expanded well beyond being a border issue.

Who Are the Victims of Human Trafficking?

In most cases, victims of trafficking are distinguishable by their experience: Women describe being promised jobs in the hospitality industry, modelling, or domestic labor and find themselves forced to work as prostitutes. These women tell stories of various forms of coercion: being beaten, starved when they do not cooperate, raped, locked in brothels, having their families threatened, having their passports or money taken, threatened with police prosecution as illegal immigrants, and having the wages of their sex work confiscated. In some cases, they are required to service as many as 20–30 men each day. Other women find themselves sold to individuals as wives, sexual slaves, domestic laborers, or a combination of roles. Migrant workers (legal or otherwise) are reclassified as victims of trafficking when they are transported to a new area and forced to maintain their jobs against their will or when they unknowningly enter indentured servitude. Illegal immigrants are frequently caught in this predicament, as the smugglers who bring them into the country (for an up-front fee) announce upon arrival that the debt has ballooned upwards; this is usually accompanied by threats or violence.

Targets of human trafficking can be surprisingly varied. Many victims are poorly educated, impoverished, and desperate to support themselves or their families, or they are refugees fleeing persecution or conflict. There are numerous accounts of children and orphans being sold by families to traffickers; this sometimes occurs when a child is sold to a brothel procurer for a sum against the child's future earnings in the brothel. There is also outright kidnapping and transportation, primarily of women and children. However, some victims are tricked by sophisticated con artists into thinking they are seeking legitimate opportunities for immigration or employment.

Like all criminal activities, there are gray areas in trafficking; for example, some impoverished villages will take on a collective debt to send one or more of its members, often illegally, to a nation where there is perceived to be lucrative work. Knowing of the debt, the individuals may undertake work in unsafe conditions, suffer harassment or deprivation, or engage in sex work to pay back the original debt. The debt may be at usurious interest rates and owed to illegal lenders, the smuggling across borders may be illegal, and the work may be exploitive. But it is not clear that if the exploitation is not directly linked to the transport of people as a criminal enterprise as to whether or not it is human trafficking. Some would argue that there must be a combination of movement from one area to another by deception/coercion/force as well as ongoing pressure to maintain an exploitative position in order to be trafficking. Others argue that it is too narrow a definition. It is also crucial to realize that trafficking does not require transport across national borders; it can involve enterprises intra-nationally from one region to another, and this is noted to occur in Thailand, China, Russia, and other nations with a diverse range of cultures and large geographic expanse.

Children make almost 20% of human trafficking victims according to the United Nations Office on Drugs and Crime (UNODC). Children are trafficked for begging, prostitution, street vending, selling flowers, and cheap labor, as well as to be put up for adoption or to act as soldiers. The children frequently are placed into debt bondage to beg or sell, or they form parts of organized begging rings, and this happens even when there is no family debt or economic hardship. In Cambodia, a local nongovernmental agency study found that 76% of trafficked children sent to Thailand came from families who owned land, 93% of families owned their own house and had no debt on the land or house, and 47% stated that their mother was the facilitator. Primarily but not exclusively used in sub-Saharan Africa and Southeast Asia, child soldiers can be strongly indoctrinated in the military unit as family and are sometimes taught that their leaders have god-like powers. In these cases, the children are told they are fighting for a divine cause and can be used effectively as suicide squads and human shields. Men are primarily trafficked for exploitation in dangerous jobs such as mining and quarrying in areas with unsafe conditions but also for agriculture, light industry, household labor, and the sex industry.

Who Are Human Traffickers?

Like many criminal enterprises, the operators range from individual entrepreneurs (such as pimps and local drug dealers) to complex multinational organizations that systematically transport and exploit migrant workers (e.g., some subcontractors in the seafood and textile industry). According to the UN, almost 80% of the activity is centered around sex workers, and trade is commonly carried out by small to medium organized crime syndicates who specialize in target regions (e.g., Moldavia) and send their victims to specific distribution regions (e.g., particular brothels in Italy or the Netherlands). In Southeast Asia, this activity seems to be specialized work of its own, while in Europe many of the organizations involved are also smuggling and transporting drugs, and the trafficking is a sideline. It has been reported that women and men have been forced to act as drug smugglers (referred to as "drug mules") by either transporting or ingesting sealed packets of drugs to be excreted at their destination, where they are then pressed into service as sex workers.

In warzones, captives may be transported and sold by military forces. War seems to attract human traffickers, as they supply men for involuntary conscription and women for sex slavery, sometimes to both sides of a conflict, with little fear of authority. Narco-terrorist groups are reported to kidnap and coerce workers across borders to participate in drug harvest and production, using their armed forces to keep the workers under control. Recent natural disasters such as the 2005 Boxing Day tsunami and 2010 earthquake in Haiti have also shown that human traffickers see any chaotic circumstances as an opportunity to profit, particularly in terms of trafficking children.

Human trafficking is almost universally condemned, and most international organizations have a statement of position on trafficking, but there is little coordination in efforts to combat it. Involved in the fight are at least eight agencies and units of the United Nations – primarily the UNODC, the UN Inter-Agency Project on Human Trafficking (UNIAP – focusing on nations bordering the Mekong region), the UN High Commissioner on Refugees, and the UN Children's Fund (UNICEF). Also involved are the European Union, Interpol, the Association of Southeast Asian Nations, several agencies of the United States Government which offer international support, and many nongovernmental organizations which operate internationally to increase awareness and locally to help victims of trafficking. Unfortunately, the cumulative budgets of these agencies and organizations are less than 0.5% of the profit cleared by traffickers.

If human traffickers are prosecuted, it is commonly when the activity is discovered during drug raids rather than as a target of investigations into trafficking itself. Human trafficking is rarely a primary target for investigation and prosecution for many reasons: It is not recognized, the impact is not understood, the victims are seen as being "from somewhere else" or illegal immigrants, or the local authorities are under-resourced or corrupt. Human trafficking as an enterprise is illegal in most countries, and there are many bilateral and multilateral national agreements against it, but they have had limited practical effect.

The impact of trafficking can be devastating. In Africa and Asia, it is a major contributor to the spread of HIV; sex workers who are trafficked may be prohibited from using condoms or from being tested because the brothel owner can charge a higher fee for unprotected sex. Young girls may be trafficked specifically to sell their virginity or for violent sexual practices that result in permanent physical as well as psychological damage. Trafficking puts men, women, and children into occupational risk where injury or death is common due to unsafe conditions; because the immigration status of these workers is questionable, usually they are not eligible for local health care resources and end up destitute on the street. On a larger scale, human trafficking is disruptive to the efforts of organized labor and corporations that attempt to follow national standards and laws for occupational safety regulations or provide benefits for their employees. When competing with companies that use labor from human trafficking, legal enterprises will always be at a financial disadvantage. On a purely economic level, the same principle applies to brothel owners and explains why so much of human trafficking is associated with the sex industry; brothels with women who are victims of human trafficking provide worse conditions and allow unsafe practices, thus undercutting the fees of other sex workers.

Trafficking Victims Protection Act

Noël Bridget Busch-Armendariz
School of Social Work, Center for Social Work Research, The University of Texas at Austin, Austin, TX, USA

Overview

In the past decade, human trafficking has emerged as a major criminal and social justice issue, both in the United States and abroad. Largely due to the scarcity of empirical studies on human trafficking, there is some lack of agreement on statistics of human trafficking. However, the US Department of State's 2008 *Trafficking in Persons Report* (*TIP*) estimated that there are 800,000 victims of human trafficking worldwide, and the Polaris Project, one of the major US antihuman trafficking organizations, estimates 200,000 American minors are at risk for human trafficking. The attention paid to human trafficking in the 1990s, positioned the United States as a global leader in efforts to understand the human trafficking issue and ensure effective responses from human rights and victim-center perspectives.

Landmark acts such as the Trafficking Victims Protection Act (TVPA), signed by President Clinton in 2000, and the Trafficking Victims Protection Reauthorization Acts of 2003, 2005, and 2008 have set domestic and international standards for various aspects of human trafficking, including prevention, prosecution of traffickers, and protection of victims. Each reauthorization reflects our growing understanding of this crime and provides for new and enhanced mechanisms to address the new main types of trafficking: forced labor or sex trafficking. Mechanisms include the continued and additional allocation of resources to combat the issue, approaches for improvement in collaborative efforts between law enforcement and social services, the expansion and clarity of vulnerable groups and definitions of victims, a call for additional research and evaluation, and the assurance of assistance for all victims.

Relevance for Immigrant Communities

International victims of human trafficking fall into two broad categories: those trafficked for sex and those trafficked for labor. Women and children trafficked into sex industries are often forced into activities such as prostitution and pornography. Since female victims and male perpetrators are the foundation of the sex trafficking trade, the roles of victims and perpetrators merit gender-focused strategies to combat sex trafficking. Victims of labor trafficking may be forced into domestic servitude or industrial labor. One crucial component in labor trafficking is migration. Industries that demand cheap labor – agriculture, construction, fisheries, manufacturing, and construction – encourage migration of unskilled workers. Victims may also be trafficked to maintain panhandling operations. In the absence of standards to protect their human rights, migrants become particularly vulnerable to exploitation. While sex trafficking receives a great deal of attention, some believe that labor trafficking is actually in greater demand, and that law enforcement agencies in border states are more than twice as likely to have investigated human trafficking cases than non-border states. Victims that are certified by law enforcement are entitled to legal remedies including the T Visa.

Transcultural Psychiatry

Kristin L. Hicks
Department of Psychiatry, Mount Carmel Health Providers, Columbus, OH, USA

Transcultural psychiatry is a branch of psychiatry concerned with the cultural context of mental illness. Although there is a belief in the universality of major mental illnesses such as mood disorders and schizophrenia, cultural factors shape the manifestation and explanatory model of a given illness, as well as its diagnosis and treatment approach. For example, Caucasian Americans with depression commonly describe feelings of sadness and guilt, while Asian Americans may focus more on somatic symptoms, such as pain or fatigue. There are some syndromes that appear to manifest only in specific societies or cultural areas and do not clearly fit into the diagnostic categories of Western psychiatry. These are referred to as culture-bound, or culture-specific syndromes in Western psychiatry. One example is *Amok*, an illness described in Malaysia in which an individual, typically a male with no history of aggressive behavior, will acquire a weapon and attempt to kill or seriously injure anyone he encounters.

Transcultural psychiatry was first established as a distinct, yet interconnected discipline in 1956 when the departments of psychiatry and anthropology at McGill University published *Transcultural Research in Mental Health Problems* under the guidance of Eric Wittkower. Wittkower, a psychiatrist who served the British during World War II, observed the profound effects of culture and environment on individuals during the war. He and other psychiatrists began to see that much of the mental illness they encountered was related to the wider sociocultural context.

Over the next several decades, transcultural psychiatry societies began to form around the world. Members emphasized the role of culture in psychiatric assessment and promoted equal access to mental health care regardless of race, gender, or culture. There was also a movement toward uncovering racism in psychiatry and conducting culturally appropriate research. Until recently, the majority of research subjects in psychiatry have been Caucasian males. When Western psychiatry became more biologically oriented in the 1980s and attempted to establish universal mental illness categories in the American Psychiatric Association's *Diagnostic and Statistical Manual* (*DSM*), there was a shift away from the social sciences and a schism developed between psychiatry and anthropology. Anthropologists continued to emphasize the importance of understanding disease in terms of a patient's culture within the framework of cultural relativism, a concept introduced by Arthur Kleinman. Cultural relativism is the idea that culture not only shapes illness as an experience, it shapes the very way we conceive illness. Kleinman argued that Western psychiatry imposes Western categories of mental illness as if they were not culturally derived.

With the development of the fourth edition of the *Diagnostic and Statistical Manual* (DSM) in the 1990s, renewed attention was given to the role of culture in psychiatric assessment. Culture-bound syndromes were described in DSM-IV and several of the most common syndromes were listed. Today transcultural psychiatry encompasses ideas common to both Western, biologically oriented psychiatry and cultural relativism, and providers attempt to modify treatment in accordance with cultural variation. For example, transcultural psychiatrists recognize the potential for interethnic variation in response to drugs, and attempt to involve indigenous healers when appropriate. A belief in the universality of the major psychiatric illnesses is tempered with a need to understand illness in terms of local culture.

Translation Services

Amy N. Sharpton
Department of Veterans Affairs, Louis Stokes DVA Medical Center Cleveland, Brecksville, OH, USA

Introduction

Since the Immigration and Nationality Act of 1965, the number of first-generation immigrants living in the United States has quadrupled to more than 38 million in 2007. Greater than 17% of the US population speaks a language other than English at home, and these numbers are increasing. Affordable housing, jobs, and access to health services consistently are reported as chief among immigrants' needs. While there are a variety of social services aimed at meeting these, a primary barrier to access to these services, especially health care, is language. It is critical that the growing numbers of limited English proficient (LEP) residents be able to communicate with their health care providers.

Role of Translation Services

In no sector are translation services needed more than in the area of health care. Research has shown that compared to individuals who are proficient in English, individuals with limited English proficiency are more likely to go without needed medical care. All patients, immigrant and native-born alike, come to the health care setting with varying degrees of health literacy skills. For the immigrant, culture and language create the context in which he or she must acquire and apply health literacy skills. Given the growing proportion of US residents with limited English proficiency, it is crucial in health care settings that potential language barriers are addressed.

Translation Services and Quality of Experience

In terms of how non-Western immigrants assess the quality of their experience with Western medicine, recent studies have suggested that patients with limited English proficiency frequently wish to discuss the use of non-Western medical practices with their providers, but that they encounter significant barriers. Language and quality of translator services are two such obstacles. Studies indicate that patients place a high value on the quality of the interpreter services, preferring to use professional translators rather than family members, and preferring same gender translators.

Providing Translation Services

With the passage of Executive Order 13166 (EO 13166) – Improving Access to Services for Persons with Limited English Proficiency – each federal agency is tasked with taking steps to provide access to its federally conducted activities. EO 13166 was designed to provide persons who have limited English proficiency (LEP) with greater access to federal programs and activities. This order has had significant impact on health care organizations that are supported in whole or in part by federal dollars. They are required to provide at no cost to the patient/consumer with LEP, language assistance services – including bilingual staff and interpreter services at all points of contact during all hours of operation. The order further mandates that translator services: (1) must be provided to patients, in their preferred language, both verbal offers and written notices informing them of their right to receive language assistance services; (2) must assure the competence of language assistance provided to LEP patients by interpreters and bilingual staff; (3) must make available easily understood patient-related materials and post signage in the languages of the commonly encountered group and/or groups represented in the service area; and (4) must ensure that data on the individual patient's race, ethnicity, and spoken and written language are collected in health records, integrated into the organization's management information systems, and periodically updated.

Outcomes

Multiple studies document that quality of care is compromised when LEP patients need but do not receive interpreter services. Their quality of care is inferior, and more interpreter errors occur – often due to the use of untrained or ad hoc interpreters. Inadequate interpreter or translator services can have serious consequences for patients. Research has shown this is especially true for patients with mental disorders. Trained professional interpreters and bilingual health care providers positively affect LEP patients' satisfaction, quality of care, and health outcomes. Evidence suggests that optimal communication, patient satisfaction, and the fewest interpreter errors occur when LEP patients have access to trained professional interpreters or bilingual providers.

Transnational Community

Ken Crane
Department of History, Politics, Society, La Sierra University, Riverside, CA, USA

The social pathways by which international migrants move between countries are typically well worn, following previously established networks of relatives and friends. This commonly manifests in the creation of communities where substantial numbers of people are from a single "sending" community. For example, in Plymouth, Indiana most of the people of Mexican origin originated from the small town of Santiago Capitiro, in the Central Mexican state of Guanajuato. Since migration typically follows established social pathways, what started as a single individual temporarily leaving to work in the USA eventually led to over 1200 people from that one *pueblacito* (small town) who have settled permanently in Plymouth. However, while they have settled in Plymouth they maintain significant ties and involvements back in Capitiro. The end result illustrates the principle outlined by anthropologist Glick Schiller et al., that Capitiro and Plymouth have become intertwined within a larger "transnational social field" composed of family ties, social networks, clubs, and associations of co-nationals (paisanos), and participation in government programs of Mexico, all of which allow people to stay socially, politically, and economically involved in more than one community. What makes this situation "transnational" is that people maintain economic, political, and social involvements in both countries simultaneously.

Even when people are not physically present they can use other means, notably financial remittances, to stay involved in their home community. The Mexican government actually initiated a program to encourage investment back home. Known as "tres por uno" (3 for 1), it matches each dollar intended for community infrastructure projects with three dollars from the federal, state, and municipal government. Researchers in the Mexican Migration Project identified a common pattern among Mexican immigrants in the USA, who joined social clubs with co-nationals and invested their savings and remittances in a home, business, or community improvement, a practice that signified continued membership in their home community.

The increasingly common practice of living transnational lives has pushed the boundaries of understanding the meaning of community. Transnational migrants are in fact constituting multiple sites of what were originally specific, geographically bounded communities. The annual festivals in the "hometown" often become times when its citizens from transnational branch communities celebrate and reestablish their communal identity.

Transnational lives are also stretching our understanding of political loyalty. People in transnational communities claim to be able to make significant contributions to social and political institutions in both societies, not limited to one or the other. In fact both Haiti and Mexico consider their citizens who live in the USA to be important actors in the political and economic life of the nation.

Transnational migration creates different types of family configurations. Migration in general is challenging for families. Transnational communities often have families in which one or more parent is gone for significant amounts of time. It is not uncommon for children to be under the care of extended family, grandparents, or aunts, as parents seek to find means to secure the longer term well-being of the family through labor migration.

Transnational communities are not new, but the pace of migration, globalization, and means by which people can move and participate in multiple communities is unprecedented. More than ever, in the words of anthropologist Karen Richman, communities have become "intimately linked" through migration. Ultimately, the ability to understand the lives of immigrants is realized through understanding the transnational and "multi-sited" nature of their lives.

Trauma

DIANA BULGARU ILIESCU
Institute of Legal Medicine Iasi, Iasi, Romania

Trauma encompasses both physical trauma and emotional trauma. It can be caused by a natural disaster, by intentional acts of individuals, or as the result of an accident. Common causes of trauma include being present in a war area; being the victim of a terrorist act; being caught in a natural disaster such as a fire, hurricane, earthquake, tornado; undergoing a surgical procedure; and experiencing the divorce from or death of a loved one.

Trauma and traumatism have often been confused. Trauma is the wound made by an injury, whereas traumatism is its result. The term traumatology refers to the study of natural traumas and of traumas caused by people and of their psychobiological consequences. At one time, the term "trauma" was used in medicine, especially in surgery, to designate the lesion caused by an external aggression. Freud utilized this term in the psychoanalytical context and attributed its cause to three possible explanations: violent shock, burglary, and the negative effect of an external factor on the body. Some psychologists have defined trauma as an event of extremely large intensity that manifests in an individual's life and goes beyond the individual's power to adapt. Another definition refers to an influx of excessive excitation that goes beyond the tolerability level of the individual.

Immigrants are potentially vulnerable to trauma due to their increased exposure to social, economic, and professional instability. Immigrants' poverty, lack of employment opportunities, lack of health insurance and adequate health care, and discrimination by individuals of their receiving countries may result in their increased vulnerability to physical and psychological trauma.

Immigrants may experience psychological trauma from the first moment they come into contact with the new society, depending upon the level of risk factors mentioned above; untreated, the trauma can develop into a more or less disabling mental illness. According to the *Diagnostic and Statistical Manual* published by the American Psychiatric Association, psychoemotional trauma is known as posttraumatic stress disorder.

Psychological trauma is a very intense emotion that results in a permanent psychological change, often evidenced by the person's excessive sensitivity to subsequent emotions. A psychological trauma represents a disorder in the individual's psychological life, *generating long-term pathogenic effects*. The fourth edition of the *Diagnostic and Statistical Manual* and the tenth edition of the *International Classification of Disease*, both of which are used for diagnostic classification purposes, support the idea that a trauma relates to an event that has already passed when the symptoms of the disorder appear. A trauma is not just an external stress, nor is it a simple state of mind; rather, it appears when the new event meets the experience that the individual has undergone. When the traumatic conditions of the environment and the subjective meaning that the individual attributes to these conditions interact, we can talk about a traumatic situation. The shock reaction has three stages:

1. The shock stage occurs 1 h to one week following the event. After the event has passed, the individual becomes aware of the proportion of the event. This stage is characterized by: apparent sensitivity, negation, alteration of time perception.
2. The action stage, which appears after a period of time has passed since the event, lasts up to 2 weeks. The individual has the following reactions: anger, self-doubt, depression, feelings of helplessness, inability to see the positive side of things, sleep disorders, irritability, hypervigilance, and frequent flashbacks from the traumatic situation.
3. During the relief stage, some types of behavior from the action stage may still persist and help may be needed. Drugs and alcohol must be avoided during this period.

Posttraumatic stress syndrome symptoms can manifest in the following ways: nightmares or flashbacks from the trauma, meaning that the individual has the impression that the accident is happening again; avoidance of places and things that can stir memories; the so-called paralyzed trauma and lack of interest for certain things; shivering; a continuous feeling of dissatisfaction; insomnia; and lack of concentration. Some people may experience depression or feelings of guilt or anger. In the case of children, posttraumatic reactions take the form of repetitive actions. These symptoms can appear shortly after the trauma or they can disappear and then appear again.

The symptoms can last for months and sometimes they are so serious that they can affect the individual's personal and professional life. Initially, the individual may deny or be unaware of the loss (of psychosocial balance, persons, bodily integrity, etc.). It appears as a reaction to the initial shock when the individual's life is deeply affected. In most cases, survivors remain self-focused for a long period of time. Then, in order to be able to deal with questions such as "Who am I?" "Why did this happen to me?" "What is happening with my life?" "Will I be able to deal with my new life?" the individual denies his or her own feelings. In trying to hide his or her emotions from others, the individual may become depressed, work excessively, or consume excessive quantities of alcohol or drugs. The social support of friends and family members may be critical to the individual's recovery.

Psychological trauma situations may be classified based on the level of severity, the number of traumatic circumstances, and the manner of action of the event (direct or indirect). According to the gravity level of the traumatogenic factors, we can distinguish:

- Mild trauma situations, such as a change of school for children or moderate family fights in the case of adults
- Medium trauma situations, e.g., school expulsion or the birth of a sibling in the case of a child or the diagnosis of a chronic disease in the case of an adult
- Severe trauma situations, such as the separation, death, or divorce of one's parents, or an undesired pregnancy
- Extremely severe trauma situations, such as experiencing sexual abuse, bodily injury, or the death of a spouse
- Catastrophic trauma situations, such as the death of a child, a spouse's suicide or attempted suicide, or a natural disaster

Trauma can also be classified based on the accumulation of traumatizing events.

Monotrauma refers to a single, uncommon situation that the individual experiences. *Polytrauma* appears when there are multiple trauma circumstances that last in time. They can occur either simultaneously (coexistence of trauma events) or sequentially. When events occur sequentially, the effects may be cumulative, remaining at the subliminal level of the individual's mind, or sequential, so that there is a certain coherence in these sequential events. Each new event determines a chain reaction that is amplified when a new event occurs.

We can also distinguish between direct trauma, when the victim is the traumatized person; secondary trauma (indirect trauma), when persons from the victim's group are affected; tertiary trauma (indirect trauma), when future generations are affected; and vicarious trauma, affecting those who help those affected directly, such as firefighters and police officers. In some cases, the trauma may be both direct and vicarious, as in the case of emergency medical personnel who must tend to the traumatized victims of a disaster and who are traumatized themselves by the sight of what they must deal with.

Trauma is also classifiable based on the relationship between the perpetrator and the victim. Simple trauma situations involve an event in which the victim is unknown to the criminal. Complex trauma situations refer to situations in which the criminal is someone familiar to the victim.

Clinicians must also consider the possibility of an adaptation disorder. The predominant symptoms that characterize an adaptation disorder are feelings of depression, anxiety, behavioral disorders (battering, vandalism, reckless driving), or other maladaptive reactions (physical problems, academic or professional inhibition, social isolation). An adaptation disorder can last no more than 6 months, even though the triggering factors are still going on or have consequences that are still going on.

Individuals may respond to traumatic events using different trauma coping styles. These include:

- Instrumental coping, which is a defense mechanism that the person uses when he or she wants to solve the problem
- Expressive coping, that is, an attempt to communicate about the trauma
- Cognitive restructuring coping, which can be positive (the person's attempt to understand better what has happened, to explain the cause, to overcome the situation) or negative (negation or fragmentation)
- Resilient coping, or an attempt to repel the event

Other coping strategies that may be beneficial for some individuals include a regular eating, sleeping, and working schedule; allowing extra time to accomplish current duties; the mental repetition of the positive acts that the person would do in case "this happens again"; participating in recreational exercises such as nature walks or trips; understanding the psychological basis for physical symptoms (for example, shoulder pains can be interpreted as "carrying a burden which is too heavy"); having therapeutic massage for release of body tension; describing personal experiences in diaries or personal letters; avoiding the transformation of the event into an obsession, by reading about it in newspapers, magazines, or by watching television or listening to radio reports; becoming aware of the fact that people need various periods of time to recover after a trauma; learning relaxation techniques such as progressive muscle relaxation; joining a support group; and forgiving the person who caused the trauma. Unfortunately, many of these strategies are not often available to those immigrants who lack a stable social and financial situation that would allow them to have access to specialized services.

Trauma Exposure

Marjorie Nigar Edguer
Mandel School of Applied Social Sciences, Case Western Reserve University, Cleveland, OH, USA

Trauma exposure varies widely for immigrants. It is defined as witnessing or experiencing real or perceived life-threatening events. Traumatic events include war, acts of terrorism, torture, natural disasters, sexual violence, physical abuse, accidents, community violence, and political violence. Trauma exposure includes the death of friends and family, whether or not one witnessed the death. It can include traumatic separation and loss; some traumatic separations are related to uncertainty regarding a loved one's status. When natural disasters, wars, and other life disruptions occur, it may not be clear whether family members are alive or dead. This question will never be resolved for some, thus requiring immigrants to learn to live with the uncertainty.

Community violence is violence in the larger community, violence that one witnesses or experiences that is perpetrated by people who are not related intimately to the victim. Political violence is related to political goals; this includes people acting violently to change their government. However, for most immigrants and refugees it refers to governments using violence to control the populace. Trauma exposure may lead to a variety of mental and physical health problems. Previous trauma exposure may be exacerbated by experiences related to the migration process. Trauma exposure and individual migrant experiences are influenced by age, culture, and other life experiences. Assessment of the impact of trauma exposure is complicated by cultural and language differences.

Refugees in particular are likely to have trauma exposure, and often they experience multiple incidents of trauma exposure. Research identifies over 50% of refugee populations as experiencing some form of trauma prior to migration, with many refugees experiencing multiple traumas. Many refugees are coping well despite their trauma exposure; however, trauma exposure is an important predictor of mental health status. Approximately 10% of refugees will have a diagnosable mental disorder; the most common mental disorders diagnosed in refugees are posttraumatic stress disorder (PTSD), anxiety disorders, and depression. The most common mental disorders diagnosed in child and adolescent refugees include PTSD, anxiety, depression, attention deficit disorder, and behavior disorders. Non-refugee immigrants may have similar trauma exposure as refugees, but the exposure is less likely to be identified.

The migration process is a stressful experience for many immigrants. Even when the migration is voluntary, the process of leaving familiar surroundings and expectations can be stressful. Complications of previous trauma exposure can make adjustment more difficult. Refugees who are detained as part of their migration process experience high levels of mental health problems. Furthermore, prolonged uncertainty concerning immigration status increases the impact of previous trauma exposure. The long-term impact of trauma exposure is mediated by other factors at the individual, family, and community level.

Because children are in the developing stages, they are impacted by trauma differently than adults; they are particularly vulnerable to experiencing long-term effects. Children may experience changes in their biological stress systems, brain development, and language acquisition; they may show signs of trauma-related psychological problems including increased arousal, intrusion/reexperiencing, avoidance, dissociation, and difficulty with mood regulation. Children's abilities to meet the demands of new environments may be compromised; in these instances, additional services will be important to support their successful transition. All of these effects have implications for children who immigrate following trauma exposure. Children experience trauma differently also because of their lack of status and power – because they do not have access to the same options as adults and their coping options are more limited. Trauma exposure in childhood places one at greater risk for future problems. These children are at increased risk of anxiety, depression, trust issues, PTSD, and behavior problems (including problem behaviors that resemble Attention Deficit Disorder or Attention Deficit Hyperactivity Disorder).

An example of trauma exposure involves the *Lost Boys of Sudan*. Following civil war in Sudan, where they witnessed much violence, lost family members, and feared for their lives, many young children fled to Ethiopia. The migration was a stressful experience, with risk of death by starvation or attack by animals. After arriving in Ethiopia, the refugees were displaced again when the refugee camps were attacked by the Ethiopian government and rebels; people fled back to Sudan and ran the same risks in the return journey. Violence continued upon their return to Sudan. Many survivors were able to make it to a refugee camp in Kenya where they were able to begin focusing on the future, not just on survival. From Kenya, many of the young men immigrated to the United States where they have struggled to successfully transition into a new culture, with very different expectations and dynamics. The *Lost Boys of Sudan* illustrates well the resilience and stressors of many immigrants who have trauma exposure.

Assessing the impact of trauma exposure on immigrants is complicated by cultural, language, and literacy difficulties. People from different cultures may interpret and respond differently to standardized instruments, even when they are translated into their native language. Translation of psychological concepts can be difficult for languages that have no comparable concepts. Cultural norms regarding child development, adult roles, appropriate behavior, or expression of emotion may all impact how trauma exposure is viewed or how reactions to trauma exposure are expressed. Standardized instruments may not be normed on a particular cultural group. Immigrants may have difficulty communicating about their experiences. Government representatives with whom immigrants interact during migration may have limited understanding of trauma exposure and its repercussions. Complicating the dynamics surrounding government officials, prior to migration some immigrants have been traumatized by government officials in their country of origin, leading them to distrust people in official roles. It is important to train screeners who are working in official positions to be sensitive toward the possible experiences that people may be bringing with them.

Travel and Travel Health

Robert W. Stephens
Rynearson, Suess, Schnurbusch & Champion, L.L.C,
St. Louis, MO, USA

International travel is undertaken by a large, and ever increasing, number of people for wide ranging purposes. More people travel greater distances and at greater speeds than ever before. Travelers are exposed to a variety of health risks in unfamiliar environments. Most of these risks can be avoided if proper precautions are taken prior, during, and after travel.

The number of people traveling internationally is increasing every year. According to statistics from the World Tourism Organization (UNWTO), international tourist arrivals in the year 2008 reached 922 million. International arrivals are expected to reach one billion by 2010 and 1.6 billion by 2020. In 2008, more than half of all international arrivals were motivated by leisure, recreation, and holidays – a total of 467 million. Business travel accounted for some 15% of arrivals and travel for other purposes (visiting friends and relatives, religious reasons/pilgrimages, health treatment, etc.) for 27%. Slightly more than half of arrivals (52%) traveled by air transport in 2008 while the remainder arrived at their destinations by surface transport (48%) – road (39%), rail (3%) or over water (6%).

International travel can pose various risks to health, depending both on the characteristics of the traveler and on the type of travel. Travelers may encounter sudden and significant changes in altitude, humidity, temperature, and microbes, which can result in ill-health. In addition, serious health risks may arise in areas where accommodation is of poor quality, hygiene and sanitation are inadequate, medical services are not well developed, and clean water is unavailable. Accidents are the most common cause of morbidity and mortality in travelers, but it is also important to protect travelers against exposure to infectious diseases. All individuals planning travel should receive advice on the potential hazards in their chosen destinations and understand how best to protect their health and minimize the risk of acquiring disease. Forward planning, appropriate preventive measures, and careful precautions can substantially reduce the risk of accidents and illness. Although the medical profession and travel industry can provide extensive help and advice, it is the traveler's responsibility to ask for information, to understand the risks involved, and to take the necessary precautions for the journey.

According to the United Nations, international migration rose from 120 million in 1990 to more than 200 million in 2006. In many countries immigrants now constitute more than 20% of the population. Immigrants increasingly travel to their place of origin to visit friends and relatives. Travel to visit friends and relatives accounts for a major portion of the international journeys that take place annually. Generally this type of immigrant travel refers to citizens from a developing country who immigrate to an industrialized country, then subsequently return to their home countries for the purpose of visiting friends and relatives.

Compared with tourists to the same destinations, immigrants who travel to visit friends and relatives are at increased risk of travel-related diseases. These include malaria, hepatitis A and B, typhoid fever, rabies, tuberculosis, and diseases normally preventable by routine childhood immunization. It is estimated that immigrants who travel to visit friends and relatives account for more than half the total imported malaria cases in Europe and North America. The increased risk for immigrants is related to a number of factors, including higher risk of exposure and insufficient protective measures. Most immigrants returning home to visit family or friends are less likely to seek pre-travel advice or to be adequately vaccinated. Additionally, immigrants returning to their home countries are more likely to stay in remote rural areas, have close contact with local populations, consume high-risk food and beverages, undertake last-minute travel due to deaths or other family emergencies, and make trips of greater duration.

Because of familiarity with their place of origin, immigrants may perceive less risk, which may result in lower rates of pre-departure vaccinations and use of prophylactic measures such as antimalarial medications. The cost of pre-travel consultation, which is often not covered by health insurance programs, may be burdensome for immigrants. Also, access to travel medicine services may be hampered by cultural and linguistic limitations. Improving the access of immigrants to pre-travel health counseling is of increasing public health importance. Primary healthcare providers need to become more aware of the increased risks faced by immigrants. Strategies are needed to increase the awareness among immigrants of travel-related health risks and to facilitate uptake of pre-travel health advice regarding vaccinations and other preventive measures.

Tuberculosis

Oana C. Stîngă
University of Medicine and Pharmacy "Gr. T. Popa", Iasi, Romania

Tuberculosis is one of the oldest conditions caused by bacteria from Mycoacteriaceae group, order Actynomicetales, named *Mycobacterium tuberculosis*.

Under the microscope, *M. tuberculosis* is a rod-shaped, non-spore-forming, thin aerobic bacterium measuring 0.5 µm by 3 µm. *M. tuberculosis* is neutral on Gram's staining. However, once stained, the bacilli cannot be decolorized by acid alcohol.

The World Health Organization estimates that 9.27 million new cases of TB occurred in 2007 (139 per 100,000 population), compared with 9.24 million new cases (140 per 100,000 population) in 2006. Of these 9.27 million new cases, an estimated 44% or 4.1 million (61 per 100,000 population) were new smear positive cases. India, China, Indonesia, Nigeria, and South Africa are the top five regions affected by tuberculosis. The 2007 report indicated that 55% of the cases were spread across Asia (Southeast Asia and Western Pacific regions) and 31% were in the African Region. The other Americas and the European and Eastern Mediterranean regions are less affected by this disease. In Africa, the reported rates of tuberculosis infections are highly linked with HIV coinfection.

The spread of this condition was recognized mostly during the late 1980s and early 1990s in industrialized countries. The primary cause of disease transmission was emigration from regions with a high prevalence of tuberculosis. In United States, European descendents are likely to develop this disease due to rare exposure. In contrast, first-generation immigrants are at an increased risk of developing an active form of tuberculosis. In the United States and various other places, tuberculosis is a disease affecting disadvantaged/marginalized, sometimes HIV-infected and/or immigrant populations.

Economic disadvantages, poverty, and a weak health care infrastructure are strongly correlated with increased numbers of tuberculosis.

Organs Affected by Tuberculosis

In most cases, this condition affects the lungs, but theoretically it can affect all body organs (lymph-node, pleura, genitor urinary, skeleton, meninges, gastrointestinal tract, etc.). This disease is spread by air through droplet nuclei by patients with active lung tuberculosis.

Tuberculosis can be classified into primary and postprimary/secondary infection.

Primary Tuberculosis

Primary pulmonary tuberculosis occurs in individuals that were not previously exposed to *M. tuberculosis*.

The primary lesion is small size, round or polygonal, usually peripheral and in more than half the cases is accompanied by hilar or paratracheal lymphadenopathy. In most of the cases, the lesion heals spontaneously and may later be evident as a small calcified nodule (*Ghon lesion*). Although mostly described in children, the primary infection can be encountered in adults too.

The primary infection may be self-healing, may become a latent infection with a potential of reactivation, or, in children and persons with impaired immunity, may progress to clinical illness.

Secondary Tuberculosis

Postprimary infection is often called secondary or adult-type infection. It is a reactivation of a latent infection and it primarily affects the apical and posterior segments of the upper pulmonary lobes. The lesions are represented by pulmonary infiltrates, nodular opacities, cavities with liquefied necrotic contents that are ultimately discharged into the airways, resulting in satellite lesions within the lungs and calcifications.

Signs and Symptoms

Tuberculosis is a consumptive disease. Latent tuberculosis causes no symptoms and it is not contagious. The presence of an active tuberculosis infection is usually discovered due to a cough lasting 3 or more weeks accompanied by discolored or bloody sputum, unexplained weight loss, fatigue, slight fever, night sweats, chills, loss of appetite, and painful breathing or coughing. When it involves another organ like vertebrae, joints, muscles, urinary tract, lymphatic system, or bone marrow the symptoms are similar to other conditions affecting those body parts. Children in particular may not display all such symptoms.

Risk Factors

Risk factors include lowered immunity due to immunosuppressant conditions (i.e., recent infections, fibrotic lesions, HIV, diabetes, silicosis, hemodialysis or renal failure treatments, and others), contact with someone with active tuberculosis, substance abuse, malnutrition, and increased age. Added to these, immigrants from regions with high rates of TB – Africa, Asia, Latin America, multidrug-resistant tuberculosis regions, individuals coming from refugee camps and those who are experiencing a lack of medical care or extreme poverty are also at increased risk. Health care workers, personnel living and working in residential care facilities, and international travelers may also be exposed to greater risk.

Immigrants are often exposed to the above-mentioned risks, therefore the incidence of tuberculosis is increased among this group of population.

Prevention and Treatment

Preventive measures include educational programs to minimize the transmission risks as much as possible, vaccination (BCG vaccine) and screening tests (skin testing when Mantoux reaction is sought, X-rays).

Treatment

Untreated, active lung tuberculosis is contagious. With treatment, improvement in patients' health is expected within weeks and is evidenced by weight gain, defervescence, and decreased cough.

In the absence of treatment, the disease may cause death in 5 months in more than half of the infected individuals. Treatment of this condition consists of more than one anti-tuberculosis agent and must be administered for months. Periodic control is required.

Bacteriologic evaluation to monitor the response to tuberculosis treatment is the less invasive procedure. Negative sputum from previously confirmed tuberculosis-infected patients is sought.

Efficient treatment will result in a negative sputum test in more than 80% patients after the second month of drug administration. At the end of the third month, the remaining 20% of the treated patients will be expected to show test culture negative for sputum. If a case of positive cultures occurs after 3 months of treatment, drug resistance can be suspected and adjustment of the therapeutic scheme is required. At the end of the treatment, negative sputum must document the cure. After treatment, follow-up monitoring should be performed by sputum collection at 2, 5, and 6 months to determine if the cure is consistent or if there is a relapse.

For extrapulmonary tuberculosis, clinical exams and radiographic documentation are clear. At the end of the treatment, radiographic examination is useful only for comparative purposes.

HIV-associated tuberculosis requires precautions due to interactions with antiretroviral agents. According to Raviglione and O'Brien, Rifampin (one of the drugs used in the treatment of tuberculosis) is known to be a potent inducer of cytochrome P450 system's enzymes and lowers many HIV protease inhibitors. In HIV cases, Rifabutin interferes less with the treatment for HIV/AIDS.

Multidrug-resistant strains are challenging therapeutic regimens. Multidrug-resistant strains appear due to spontaneous point mutations that occur in mycobacterial genome. Although the danger of a strain being resistant to more than one drug is less, the danger exists and demands modified treatment schemes. This danger is reported to be increased in regions like Asia and the Soviet Union. In the United States, the rate was declining to 1% in the past decade. Resistance rates are higher among foreign-born and HIV-infected patients.

In conclusion, the treatment for this disease is not only long term, but also complex due to potential drug-associated toxicity. Treatment requires strict monitoring and patient adherence to the prescribed regimen. These restrictions are often difficult for immigrants confronted with extreme poverty, marginalization, and poor access to medical services due to lack of medical insurance.

► Trafficking Victims Protection Act

Typhoid

Ecaterina Mariana Enache
Department of Microbiology, University of Medicine and Pharmacy "Gr. T. Popa", Iasi, Romania

Typhoid fever has as an etiological agent *Salmonella enterica serovar typhi*. It is transmitted by the ingestion of food or water contaminated with the feces of an infected person. *S. enterica* serovar *typhi* is a Gram-negative short bacillus, part of the Enterobacteriacae family. This type of fever has been given several different names including gastric fever, the bends, abdominal typhus, infantile remittent fever, slow fever, and nervous fever. The name "typhoid" was first given by Louis in 1829, as a derivative from typhus.

Epidemiology

The World Health Organization identifies typhoid fever as a serious public health problem because of an estimated 16–33 million cases annually resulting in 216,000 deaths in endemic areas. Its incidence is highest in children and young adults between 5 and 19 years old.

Typhoid fever has disappeared from high-income countries, but it remains a public health problem in several Asian regions of the former USSR and in parts of South and Southeast Asia, Africa, and South America. In the last outbreak in the Democratic Republic of Congo, between September 27, 2004, and January 2005, approximately 42,564 cases of typhoid fever were reported, including 214 deaths and 696 cases of peritonitis and intestinal perforations. Incidence is up to 198 per 100,000 in the Mekong, Vietnam, and 980 per 100,000 in Delhi, India.

Persons infected with typhoid can become healthy carriers of the disease and responsible for spread of - disease. The most famous case was Typhoid Mary (Mary Mallon) who was an immigrant and a healthy carrier (in the urinary bladder) of *Salmonella typhi*. She spread the disease and infected 53 people, three of whom died.

Clinical Presentation

Typhoid fever has four stages, after an incubation period for 14 days:

1. In the first week, patients experience increased temperature, fever, headache (nonspecific symptoms). During this time, the bacteria go through gastric acid barriers (patients with low gastric acidity need less bacteria to develop an infection), spread to the intestine, then in lymph nodes where they multiply and spread through the bloodstream from where they reach targeted organs such as kidney, spleen, liver, and bone marrow.
2. During the second week, patients experience high fever, delirium (which results in the name “nervous fever” attached to this illness), hepatosplenomegaly, rose spots on the lower chest and abdomen in around one third of patients, diarrhea (approximately eight/day).
3. In the third week, complications such as intestinal hemorrhage or intestinal perforation emerge.
4. In the fourth week all symptoms decrease, the patient can be cured or can remain a chronic carrier (they suffer no symptoms, but they are capable of infecting others).

Laboratory Diagnosis

Specimen collection for direct diagnosis includes blood for blood culture, stool for stool culture, bone marrow for culture, and urine for urine culture. When the direct diagnosis is not possible, we can perform indirect diagnosis that consists of detecting antibodies against O somatic antigen and H flagella antigen.

Treatment and Prophylaxis

The first-line treatment is a fluoroquinolone; other choices are ampicillin, chloramphenicol, and trimethoprim-sulfametoxazole.

There are multiresistant strains of *S. typhi* increasing the risk for people living in regions with high endemic disease and to travelers. Strains resistant to chloramphenicol and other recommended antibiotics (ampicillin, cotrimoxazole, and even ciprofloxacin) have become prevalent in several areas of the world.

Prophylaxis is possible by avoiding drinking and eating contaminated food or water and through vaccination (the vaccines are not 100% efficient and other preventive measures are necessary).

There are two vaccines available:

1. Ty21a (Vivotif Berna, Swiss Serum and Vaccine Institute) live attenuated vaccine (oral). This vaccine is not indicated for children younger than 6 years of age. It has to be administrated in four doses, given 2 days apart. The last dose should be given at least 1 week before travel to allow the vaccine time to work. Another dose is needed every 5 years for people who remain at risk.
2. ViCPS (Typhim Vi, Pasteur Merieux) is a subcutaneous or an intramuscular injection. This is not indicated for children younger than 2 years old. For people who travel, one dose provides protection and it should be administered at least 2 weeks before travel to allow the vaccine time to work. Also, a booster dose is needed every 2 years for people who remain at risk. Vaccination is

recommended for travelers to parts of the world where typhoid is common, people in close contact with a typhoid carrier, and laboratory workers who work with *S. typhi*.

U

U Visa

Jamie R. Abrams
School of Law, Hofstra University, Hempstead, NY, USA

U visas are a nonimmigrant classification created under the Battered Immigrant Women Protection Act, enacted as part of the United States' Victims of Trafficking and Violence Act of 2000. Congress intended U visas to both aid law enforcement in detecting, investigating, and prosecuting certain criminal activity committed against undocumented immigrants, and to protect domestic violence victims consistent with the humanitarian interests of the USA. Congress created the U visa classification to protect certain categories of immigrants who were not covered under the Violence Against Women Act, including domestic violence victims abused by a lawful permanent resident or citizen in a dating relationship and immigrants' spouses, children, and intimate partners victimized by an undocumented perpetrator.

U visa petitioners must prove four threshold eligibility requirements. A petitioner must show (1) that she "suffered substantial physical or mental abuse" as a victim of certain qualifying criminal activity, a term that is defined broadly under the statute and includes domestic- violence-related offenses; (2) that she "possesses credible and reliable information" proving her knowledge of the relevant criminal activity; (3) that she "has been helpful, is being helpful, or is likely to be helpful" to the enumerated law enforcement, judicial, or service-providers with authority to investigate or prosecute the criminal activity; and (4) that the criminal activity violated a law of the USA. Successful U visa petitioners obtain temporary lawful status. Petitioners may also obtain derivative lawful status for qualifying family members (e.g., parents, children, spouses). Three years after the U visa holder obtains nonimmigrant status she may then petition for lawful permanent resident status if she meets eligibility requirements, most notably by proving that she has maintained a continuous presence in the USA for 3 years and that she has not "unreasonably refused to provide assistance" to investigating authorities. These primary legal benefits, in turn, support additional secondary benefits that petitioners can obtain with their lawful status, such as access to health care services, better wages, and housing.

While indeed the U visa classification is accessible to a wide range of petitioners, both male and female, it is perhaps most frequently used in the context of domestic violence. Abusers often use the victim's undocumented status as a further weapon of psychological or physical abuse, which jeopardizes many petitioners' ability to seek derivative lawful status under other statutes as a spouse or child of a citizen, for example. U visas are therefore powerful tools for domestic violence victims to seek lawful status without the abuser's assistance. Indeed Congress intended that U visas would position petitioners to report abuse without fear of negative immigration consequences – either from the government, law enforcement, or the abuser.

The "substantial physical or mental abuse" element reveals most directly the physical and psychological health implications involved for U visa petitioners. Petitioners can prove this element by presenting evidence of physical or mental abuse as statutorily defined to include injury or harm to the victim's body, or harm to or impairment of the emotional or psychological soundness of the victim. These terms are broadly interpreted by the US Citizenship Immigration Services (USCIS), the federal agency with U visa implementing authority, yet petitioners must meet the modifying requirement of "substantial" abuse. USCIS interprets "substantial" abuse to describe both

Sana Loue & Martha Sajatovic (eds.), *Encyclopedia of Immigrant Health*, DOI 10.1007/978-1-4419-5659-0,

the severity of the *injury* suffered by the victim and the severity of the *abuse* used by the perpetrator. USCIS weighs the substantial abuse requirement on a case-by-case basis, considering the following factors although no one factor is dispositive: the nature of the injury inflicted or suffered; the severity of the perpetrator's conduct; the severity of the harm suffered; the duration of the infliction of harm; and the extent of permanent or serious harm to the appearance, health, or physical or mental soundness of the victim. USCIS reviews the degree of harm suffered by the individual victim based on the individual victim's experience, allowing USCIS to consider the victim's preexisting physical or mental conditions and the extent to which existing medical conditions were aggravated by the abuse. USCIS considers the substantial physical or mental abuse requirement under a totality of the circumstances approach, allowing petitioners to cumulate a series of abusive acts to meet the substantial requirement, even where no single act of abuse on its own meets the test.

U visa petitioners must submit certain required documentation to prove these requirements, such as a signed detailed petitioner affidavit describing the basis for her petition, including the details substantiating her claim of substantial physical or mental abuse. Other materials are strongly encouraged, including health care provider records documenting the diagnosis and treatments of physical or psychological injury resulting from the criminal activity; affidavits from advocates, social workers, counselors, or mental health professionals that document any physical and mental abuse or injury that the applicant has suffered; copies of any police reports on domestic violence or sexual assault; affidavits from witnesses with knowledge of the harm or injury; and photographs showing injuries or damage from the criminal activity.

Unaccompanied Minors

Marjorie Nigar Edguer
Mandel School of Applied Social Sciences, Case Western Reserve University, Cleveland, OH, USA

In immigration, "unaccompanied minors" refers to a diverse population of migrant children who are noncitizens, under the age of adult legal status in their receiving country, and are not with a legally responsible adult. Unaccompanied minors may not have been seen as minors in their sending countries – they may have had adult status there. There are four general categories of unaccompanied minors: (1) refugees, (2) solo migrants, (3) those separated from family following migration, (4) trafficking victims. Regardless of the category to which they belong, unaccompanied minors have often overcome many hardships prior to their arrival in a new country. They may have fled persecution, human rights abuses, war, and other violence. Because unaccompanied minors do not have adult legal status, there are specific concerns since they are a very vulnerable population.

Historically, unaccompanied minors have been refugees who arrived in their new countries through planned resettlement programs. Many unaccompanied minors were relocated to new countries during and following World War II. Since then the practice has continued, usually where there is war or political unrest. For example, in the 1980s, unaccompanied refugee minors came from Southeast Asian countries to the United States, with their relocation supported by the US government and private aid groups. When a government identifies refugee children overseas and selects them for resettlement, there is a screening process and services are provided to help with the transition. In the United States, the government agency in charge of unaccompanied refugee minors is the Office of Refugee Resettlement (ORR), which works closely with two organizations, the Lutheran Immigration Refugee Service (LIRS) and the United States Conference of Catholic Bishops (USCCB). Other countries usually have similar arrangements to address the situations of unaccompanied refugee minors who are identified prior to migration. These unaccompanied minors who are participants in organized refugee programs will have access to support for long-term care: foster homes and other housing opportunities, food, clothing, medical care, education, language training, counseling, and other forms of support and necessities. Although these forms of support may be officially available to unaccompanied refugee minors, they are not always easy for the minors to access, and their availability is not uniform. The number of such refugees throughout the world has increased dramatically in recent years, and continues to grow; at least half of the world's refugees are estimated to be children below the age of 18.

Another group of unaccompanied minors are individual children who have traveled to a new country on their own to join family members who are already there, to escape the problems in their home country, or to take advantage of perceived economic opportunities. Children who are refugees but arrive without the support of an organized refugee program will find it difficult to navigate the legal systems surrounding asylum programs, and they will often lack the documentation to support their claims of refugee status. Children who are seeking to join family members who are already in the new country may be stopped at the international border, and detained and deported at that point. Even if they are able to cross the border successfully, they may not be able to navigate in the new country or find their family members. Some children believe that there are economic opportunities that will allow them to provide for their family, only to discover that the opportunities are nonexistent or are unavailable to them as minors. They may fall prey to criminals after they arrive.

Children may become unaccompanied minors following immigration. This usually occurs due to some form of separation from their family. If a family has entered the country without documentation, then some family members may be more vulnerable to detention, separation, and deportation. Depending on national laws regarding citizenship, children may be considered citizens while their parents are considered illegal immigrants, which means that children may be able to legally stay in the country but without their parents. If children are separated from their parents when their parents are detained or deported, they may or may not have other external supports in the community. Children are vulnerable following their parents' detention or deportation and may become homeless or victims of exploitation by adults or older children. Children have limited ability to access resources in the community. If children are themselves detained or processed for deportation, they are often separated from their family and may be held in juvenile facilities with children who have committed a variety of violent crimes, or even in adult criminal facilities. Children may be held for extended periods of time – months or years – in detention facilities.

Unaccompanied minors may be children who were trafficked and brought to a new country by adults who were intending to exploit them. Children are trafficked for profit all around the world, although it may take different forms in different places. International traffickers will bring a child into a country, and the child may subsequently escape or be abandoned by the trafficker, becoming an unaccompanied minor. Traffickers may lie to families about the opportunity that is being given to the child and children may be forced or coerced into accompanying the trafficker. Children who are trafficked may be sexually exploited or used in pornography; forced to labor in homes, farms or factories; or forced to beg. They are physically confined, starved, threatened, beaten, and abused. It is difficult to estimate the number of children who are trafficked. UNHCR (United Nations High Commissioner for Refugees) has protection guidelines regarding trafficking. The guidelines provide nations with policy recommendations for addressing these situations.

How countries deal with unaccompanied minors varies widely – some countries have specific policies regarding the disposition of unaccompanied minors that are based on immigration status; other countries uniformly detain all unaccompanied minors in jail-like facilities; other countries place them in foster homes following the same practices that would be applied for native children. The legal claims of unaccompanied minors usually follow the same guidelines that are followed for anyone seeking to immigrate. Unaccompanied minors may or may not be able to adequately use any legal counsel provided for them – they usually will not have any documentation to substantiate their identity, any claims for asylum, or their history. Language barriers can also limit unaccompanied minors' abilities to advocate for themselves or use the services available to them. United Nations policy stresses that it is important in making decisions regarding unaccompanied minors to keep the best interests of the child in mind. "No matter their status, children must be treated as children first and their best interests professionally identified and respected" (UNHCR 2008).

Undocumented

Mónica Ruiz-Casares
Division of Social and Cultural Psychiatry, McGill University/CSSS de la Montagne, Montreal, QC, Canada

Undocumented migrants are foreign citizens who enter or stay in a country without the appropriate documentation. They may have managed to cross borders undetected or entered into the receiving country using fraudulent documentation ("illegal entry"). Others, after entering using legal documentation, remain in the country beyond the period for which entry was granted or otherwise violate the terms of entry and stay without authorization (e.g., working in violation of some or all of the conditions attached to their immigration status) ("overstay"). They differ from those with pending applications, though failed asylum seekers or immigrants who have no further right to appeal may become undocumented if they do not leave the country when instructed. The status is temporary and may change over time, whether leading to regularization or the opposite. Alternative terms often used include *migrants in an irregular situation* or *irregular, unauthorized, unregistered, clandestine, noncompliant, semi-compliant,* or *illegal migrants, aliens, or nonnationals.* Despite a certain ambiguity of the term (i.e., it refers both to migrants who have not been documented and those without documents), "undocumented migrant" is often preferred over "illegal migrant" as, in most countries, residing without appropriate documentation is considered an administrative infraction rather than a criminal offense.

It is difficult to obtain accurate estimates on the number of undocumented migrants globally and by country. Existing estimates suggest that 30–40 million or 15–20% of all migrants are undocumented worldwide. In 2009, the CLANDESTINO project estimated that there were up to four million undocumented migrants across the European Union (EU), almost half of the level of irregular residence previously assumed. Depending on the source, estimates in the USA range between 7 and 15 million or more, with 12 million undocumented workers being a figure often used. Around 3.5 million children, many of whom are US-born citizens, live in families where at least one member is undocumented. In Canada, another major immigrant-receiving country, estimates of undocumented people are particularly vague, with 200,000 to half-a-million being the figures most frequently quoted. Unlike the USA, where undocumented migration is associated with clandestine border crossing, in Canada the majority of undocumented migrants initially entered through authorized legal channels.

Most undocumented migrants access health care through hospital emergency units and community organizations and health clinics. Undocumented migrants at landings or at public health centers run by Médecins Sans Frontières in several countries often present with problems related to their journey (e.g., trauma and dehydration), their living and working conditions, social exclusion (e.g., depression), and changes in eating habits (e.g., gastritis and duodenal ulcers). Research has shown pervasive feelings of fear and isolation among undocumented migrants linked to domestic violence (due to stress about papers), alcohol and substance abuse, depression, anxiety, and other mental health conditions. Children and youth, as well as smuggled and trafficked women, face significant physical and psychological health risks.

Lack of legal status and health insurance are major barriers of access to health care. Undocumented migrants will delay seeking care unless extremely sick for fear of exposure or deportation. Thus, victims of domestic violence rarely report it and children entitled to care do not always receive it due to their family's reluctance to approach the government if the head of the family or another family member is undocumented. Other barriers include inability to pay, long wait lists at centers that offer care, and lack of professionally trained interpreters and information on the system.

Research has shown that delayed care often aggravates minor health conditions, with particularly negative consequences for chronic conditions (e.g., hypertension and diabetes), infectious diseases, acute mental health problems (e.g., posttraumatic stress disorder and depression), and developmental problems in children (e.g., autism). Difficulties in accessing antenatal care in this population have led to serious complications of eclampsia and ectopic pregnancy, complicated labors and an increased rate of cesarean sections. Moreover, for undocumented women, pregnancy and birth render employment impossible, generate high health care costs, and disrupt precarious housing arrangements.

Exposure to hazardous living and working conditions and poor access to health care constitutes a public health challenge that transit and host countries increasingly have to deal with. Whereas some countries, such as Austria and Sweden, provide services to undocumented migrants on a payment basis only, others, such as Spain and Portugal, offer full access to healthcare. Generally, however, undocumented migrants are only entitled to emergency care or "immediately necessary" services.

Department of Epidemiology & Biostatistics,
Case Western Reserve University, Cleveland, OH, USA

Introduction

The UK has a publicly funded health care system that provides most medical services to citizens free of charge at the point of service. Free medical care is also provided to most legal residents, including immigrants and refugees. Certain services such as emergencies and treatment for certain communicable diseases are free regardless of citizenship. Despite this, immigrants and asylum seekers may face several barriers to accessing care in the UK. Calls for immigration reform have increased in recent years among members of the UK's major political parties, so changes may occur that improve or limit access to care for immigrants in the near future.

National Health Service

The National Health Service (NHS) is one of the oldest universal health care systems in the world. It was established after the World War II in 1948. The model was based on a system devised by social reformer William Beveridge, and implemented through the leadership of the minister of health, Nye Bevan. The system nationalized the hospitals, allowed general practioners (GPs) to remain independent, and made the government the payer for all fees. Private care and private insurance are allowed to coexist in the UK, but private care accounts for less than 3% of total health care services. Since its inception, health care services have been free at the point of service without co-payments, coinsurance, or deductibles. The exception is a small co-pay for vision correction and on prescription drugs. However, certain groups such as children, pregnant women, the chronically ill, and the elderly are exempt from co-pays on prescription drugs, and these users represent 85% of all prescription drug orders filled.

UK residents pay for the NHS through general taxation. A national sales tax in the UK runs from 15% to 17.5% and the marginal tax rates are higher in the UK than in the USA, a developed country that does not have universal health care.

The NHS is actually a collection of four health systems, run independently by England, Scotland, Wales, and Northern Ireland. However, many citizens are unaware of the distinction as there is great coordination between the systems and citizens of one area can usually seek care in another area.

Certain health services are provided to all persons, including immigrants, regardless of citizenship. These include treatment for accidents and emergencies, compulsory psychiatric treatment, treatment for certain communicable diseases, and family planning services.

Other NHS treatments are available to immigrants who meet certain criteria. If they are establishing permanent residence in the UK or have been living in the UK legally for 12 months then they are entitled to health care. Students, refugees, asylum seekers, and detained immigrants may also be eligible for free medical care from the NHS.

The National Institute for Health and Clinical Excellence, or NICE, is the government agency that provides recommendations of what services and drugs the NHS should pay for and which they should not. Since this is a form of rationing, in some cases persons are denied care that they or their physicians would like. Immigrants may find that certain treatments available in their native land are not available in the UK or require an out-of-pocket payment.

Immigrants may also have to deal with longer wait periods than they would in their country of origin for treatment of certain types of conditions. Acute conditions are treated immediately. Cardiac problems are usually addressed the same day, and cancer within a few weeks. However, treatment for certain chronic conditions and "elective" procedures may require the patient to wait for months.

Immigration to UK

The current political state known as the UK of Great Britain and Northern Ireland, which includes England, Wales, Scotland, and Northern Ireland, was created in 1922. This entry will focus on immigration policies from that date to the present.

Immigration during this period has been substantial with most immigrants originating from Ireland or former British colonies, including India, Bangladesh, Pakistan, the Carribbean, South Africa, Kenya, and Hong Kong. Until the British Nationality Act of 1981, citizens of commonwealth nations were deemed to be British subjects, but this is no longer the case.

Immigration is also heavy from countries in the European Union due to agreements with the other EU countries that require that citizens of any EU country have a right to work in other EU countries. Currently about 11% of the UK population is foreign-born.

In response to fears of rising immigration from eastern European countries, the conservative-liberal coalition has moved to cap the number of non-EU immigrants allowed to enter the UK each year. Some have expressed concern that this will negatively affect care for all UK citizens as the system is dependent on physicians originating from former British colonies such as India and Pakistan. A 2005 report found that in 2003, 29.4% of NHS doctors were foreign-born and that 43.5% of nurses recruited to the NHS after 1999 were born outside the UK.

Emigrants to the EU and Abroad

Citizens of the UK, who migrate to other countries, may still be eligible for health care under the National Health Service. However, because the NHS is paid for through the taxpayers, rules are in place to prevent people from “free-riding.” Persons who have been citizens of the UK for at least 10 years are eligible for care under the NHS, provided they have not lived abroad for more than 5 consecutive years. UK state pensioners living abroad seasonally are eligible for care, provided they do not spend more than half of the year outside of the UK.

Medical Care of Asylum Seekers and Refugees

Refugees seeking asylum in the UK have been a focus of policy-makers in recent decades, with both Conservative and Labour Party officials claiming that too many refugees are entering the country each year. The case they make is that refugees are choosing to migrate to the UK because it has some of the most generous health benefits. International law requires refugee migrants to seek asylum in the first country they enter that will grant asylum. Critics claim that refugees are taking advantage of this rule, by “shopping” for countries that offer generous benefits, such as the UK.

Asylum seekers have a right to access free physician visits and hospital care from the National Health Service while their applications are being processed. Additional support may be available through the UK Border Agency such as prescription drug benefits, dental care, and vision and eye care. Persons with HIV, tuberculosis, or severe mental health diseases may be eligible for additional care.

A systematic review of studies focusing on asylum seeker mental health found high levels of mental health problems reported among detainees in all studies. Suicide ideation, anxiety, depression, and posttraumatic stress disorder were commonly reported. Longer detention time was positively associated with severity of distress. Longitudinal results have shown that the negative impact of detention persists even after release.

A High Court ruling found that failed asylum seekers were still granted a right to NHS services provided they lived in the UK for more than 1 year. However, in March 2009, this decision was overturned by the Court of Appeals, and failed asylum seekers no longer have a right to NHS services free of charge, other than emergency services and certain other care that is offered to everyone.

Conclusion

The UK has one of the most comprehensive health care systems in the world in that it provides universal coverage and also operates most of the health care facilities. This system is favorable to documented immigrants and refugees in that it provides access to health care that they may not be able to afford out of pocket. The UK has strict immigration policies, so foreign-born persons may find it difficult to move to the UK unless they are deemed to be highly skilled workers sponsored by an employer, or students. Undocumented immigrants and failed asylum seekers still residing in the UK may have difficulty obtaining care under the NHS, but certain emergency services, mental health services, and treatment of communicable diseases can still be obtained free of charge. Immigration policies and immigration health policies in the UK are likely to change over the next several years as it continues to be a hot-button issue among policy-makers and voters. These changes may adversely affect immigrant access to the NHS.

United Nations Convention on the Rights of the Child

DEBRA PLEDGER-FONTE
The Institute for Palliative Medicine at San Diego Hospice, San Diego, CA, USA

People have rights that are extended to them whether they are in their native country or have immigrated to a new land. These rights are civil, political, economical, social, and cultural. They belong to all human beings including children and young people. Since children are particularly vulnerable, it is widely accepted that they need special attention and protection.

In the early twentieth century the United Nations (UN) recognized that children were living in exceptionally difficult conditions in all countries around the world and that international cooperation was needed to remedy this situation. The Declaration of the Rights of the Child of 1924 was one of the first documents that stemmed from this joint initiative. Since then the United Nations has put forth several provisions which include the Declaration of the Rights of the Child, adopted on November 20, 1959, as well as the Convention on the Rights of the Child, adopted on September 2, 1990. The Convention is the most widely ratified human rights treaty in history.

It took an international elected body of independent experts over 10 years to negotiate the Convention on the Rights of the Child ("the Convention"). The result is a document that takes into account the importance of tradition and cultural values for the protection and harmonious development of the child.

The Convention of the Rights of the Child became international law on September 2, 1990. As of April 2010, 194 states acknowledge this international law. The United Nations General Assembly added two optional protocols on May 25, 2000. Protocol One restricts the involvement of children in any military conflict and was adopted on July 12, 2002. As of April 2010, 132 states have acknowledged Protocol One. Protocol Two prohibits the sale of children, child pornography, and child prostitution and was adopted on January 18, 2002. As of April 2010, 137 states have acknowledged Protocol Two.

The Convention emphasizes that the best interests of the child shall be primary. The Convention spells out provisions, protection, and participation that should be considered. These considerations are the right to life and to a name, identity, family, and nationality; freedoms of thought, speech, conscience, and religion, and freedoms of privacy and assembly; the right to regulate activities pertaining to parenting and the care of a child which includes physical safety, foster care and adoption, mental and physical disability, health care, and social and economic security; education, participation in their culture, and play; and the right to be free from exploitation and abuse, including physical and sexual abuse, economic and sexual exploitation, exposure to addictive drugs, and warfare. These rights are extended to children no matter what their country of origin is or their color, language, race, religion, or sex.

The Convention defines a "child" as a person below the age of 18, unless State law recognizes a different age of majority. States can define appropriate ages for majority such as when a child can become employed and complete his/her education. The Convention has clearly defined that those under 18 years of age be prohibited from life imprisonment or capital punishment.

Compliance with the Convention is monitored through the UN Committee on the Rights of the Child. Governments that have ratified this Convention are required to submit regular reports on the status of children's rights in their country. The committee, which consists of internationally elected representatives, monitors and reviews the reports submitted by the governments.

The United States (US) government played an active role in the development of the Convention on the Rights of the Child and signed it on February 16, 1995. However, as of November 2009, the US has not ratified the Convention. There are several views on why this has not been done, but most feel it is partly due to the potential conflict with the US Constitution. In early 2009, there was an attempt by the State Department to review the Convention, but to date this has not been initiated. Because of this, the Convention has never been sent to the US Senate for ratification. The US has signed and ratified both optional protocols to the Convention.

Due to the Supremacy Clause in Article VI of the US Constitution, all treaties the US ratifies are considered the supreme law of the land. This would make any preexisting state and federal statutes null and void. This has created a conflict for ratifying the Convention. Parental rights groups feel the Convention would give the government a right to meddle in child rearing. Political and religious groups feel there is an issue of national control over domestic policies. The Obama administration has noted these objections constitute legitimate concerns. One answer could be addressed through the Reservations, Understandings, and Declarations (RUDs) process through which the US can sign a RUD that can hinder or negate responsibilities they would otherwise be bound to follow.

Most majority Muslim nations express reservations on some provisions of the Convention that are incompatible with Islamic Sharia law. This has been accomplished through the filing of RUDs which allows Islamic law to prevail.

Children will always be our future. They will be the future global leaders who set public policy and implement laws. Whether children are raised in the country of their birth or immigrants in another location, the rights of a child's health and well-being have been laid out by the Convention on the Rights of the Child.

United Nations High Commissioner for Refugees

Gary Edmunds
Center for Minority Public Health, Case Western Reserve University, Cleveland, OH, USA

The League of Nations was established in 1919 at the end of World War I. In 1921, it created the position of High Commissioner to deal with the large numbers of persons who had been displaced during World War I, the Russian Revolution, and the collapse of the Ottoman Empire. The Office of the High Commissioner was charged with the responsibility of defining the status of the refugee, helping refugees to find employment, and protecting refugees from continued expulsion. But persecution, political violence, natural disasters, armed conflict, and other catastrophic events continue to make it necessary for millions of people to flee their homes and seek protection in other countries.

In 1945, the League of Nations was replaced by its successor organization, the United Nations. The United Nations replaced the Office of the High Commissioner with the International Refugee Organization (IRO) in 1947. The International Refugee Organization only addressed the needs of refugees from Europe. Accordingly, in 1951, the United Nations High Commissioner for Refugees (UNHCR) was created and addressed refugee problems around the world. This office was established to give legal, social, economic, and political aid to refugees.

The definition of a refugee now follows the construction of the United Nations convention and is defined as a person who, "owing to a well founded fear of being persecuted for reasons of race, religion, nationality, membership in a particular social group or political opinion, is outside the country of his nationality and is unable or, owing to such a fear, is unwilling to avail himself of the protection of that country." Today the UNHCR provides refugees with material support such as food, shelter, healthcare, education, and other related social services and works in conjunction with other United Nations agencies, peacekeepers, military forces, regional agencies, human rights organizations, and other international and local organizations and agencies. As an example of the assistance provided to refugees, refugees living with HIV in Botswana are being provided with treatment under a special UNHCR program.

Yet, measures to relieve the plight of those experiencing forced migration, internal displacement or asylum have drastically diminished in relation to the growing scale of the problem. Although the annual budget of the United Nations High Commissioner for Refugees rose to $1 billion in 1997 through voluntary government contributions, the agency is increasingly unable to meet the present demand for food and shelter to support refugees, or to invest in rehabilitation or repatriation of these refugees.

More recently, the UNHCR has undergone some harsh charges that it is simply a pawn of state and capitalist interests. The UNHCR has also been the focus of charges that it has acted as an imperialistic opportunist and has betrayed its fundamental values in pursuit of institutional predominance in the international humanitarian field. As a result, the UNHCR is a conflicted organization, torn between its legal and human rights obligations and its need to appease the Western states that pay its bills.

The UNHCR's current emphasis appears in recent years to have broadened to include issues related to security of refugees: social security, economic security, and environmental security, and the all-inclusive "human security." This new emphasis reflects the UNHCR's continuing evolution from aid/development to legal protection to repatriation and, finally, to human security. The ability of the organization to undergo evolution had been envisioned for the UNHCR from the beginning. Because of its ability to adapt to changing circumstances and address the needs of refugees, the office was awarded the Nobel Prize for Peace in 1954 and again in 1981.

United States

Nicholas K. Schiltz
Division of Health Services Research & Policy,
Department of Epidemiology & Biostatistics,
Case Western Reserve University, Cleveland, OH, USA

Introduction

The United States is a country of immigrants. Nearly every person living in the United States is a descendent of immigrants that arrived in the past few centuries, or is an immigrant themselves. Despite this shared history of immigration among US residents, foreign-born persons in the United States face structural, cultural, and political barriers that impact their health and limit access to quality care. This entry will provide a profile of immigrants in the United States today, discuss the health of the immigrant population, and describe the US system of payers and providers and how it relates to immigrants' ability to access care. Finally, it will look at health care reform and other recent policy changes and its impact on immigrant health.

Profile of US Immigrants Today

As of 2008, there were approximately 39 million immigrants living in the United States, accounting for 13% of the total population. Among these foreign-born persons, 31% are naturalized citizens and 38% are lawfully residing noncitizens. An estimated 11.9 million persons are undocumented immigrants, representing 4% of the population and 5.4% of the workforce. The primary reason that persons immigrate to the United States is to find employment.

Naturalized citizens are immigrants who qualified for and passed a citizenship test. These may include children of US citizens born abroad, documented permanent residents who have lived in the US for 5 years, or spouses of US citizens. These people are considered US citizens and have the same rights and privileges as US-born citizens. Lawfully residing noncitizens, or "legal immigrants," include permanent residents that have a visa. These persons are not citizens, but do have access to many public programs. Refugees are also considered lawful noncitizen immigrants. Undocumented noncitizen immigrants are sometimes referred to as "illegal immigrants" or "illegal aliens" because they are often in the country illegally and subject to deportation. These citizens cannot access most public programs such as Medicaid and Medicare. Immigrants to the United States come from all over the globe. The majority of foreign-born persons living in the United States today have come from Latin America (54.6%), with Mexico alone accounting for 31.3% of the immigrant population. East/Southeast Asia (17.6%), Europe (12.5%), South Asia (5.5%), and the Middle East (3.5%) round out the top five regions of origin.

Fewer persons emigrate from the United States than immigrate to the country, and this has been true throughout the history of the nation. Even still, the State Department estimates over 5 million Americans currently live abroad. Additionally, many foreign-born persons in the United States will migrate back to their native countries at some point. Despite this, issues related to the emigration of US citizens from the United States are rarely studied including issues related to the health of these migrants. The focus of this entry will therefore be on the health of immigrants to the United States.

Immigrant Health and Hispanic/Immigrant Health Paradox

Health disparities exist in the United States, and low socioeconomic status is often associated with poorer health outcomes and reduced access to care. However, while immigrants, especially undocumented immigrants, tend to have a low socioeconomic status, they surprisingly score better on a variety of leading health indicators compared to domestic-born citizens. This phenomenon has been called the "immigrant paradox," or more commonly the "Hispanic paradox." One review study found foreign-born persons in general to have better outcomes than the US-born population in many health indicators including mortality, perinatal health, body-mass-index, heart disease, diabetes, cancers, mental health, injuries, and infectious disease.

Several theories have been offered to explain this paradox, including the "salmon bias," whereby immigrants return to their homeland before dying and hence are not included in US mortality statistics, and the healthy migrant hypotheses, which assert that the healthiest persons are the ones most likely to immigrate to a foreign country. Neither of these hypotheses has been able to fully explain the paradox. Cultural differences between immigrants and US-born citizens, as well as health behaviors before and immediately after migration, have been offered as an explanation. There is some evidence that the protective effects of immigration disappear over time as immigrants become more assimilated into American culture. This is especially true in the case of overweight and obesity.

Overview of Health Care in the United States

The health care system in the United States is not centralized at the payer or provider level. This is in contrast to most developed nations which have some sort of single-payer system (e.g., Canadian Medicare) or have a government-run health system (e.g., UK's National Health Service). In the United States most Americans receive coverage through private and not-for-profit insurance plans. Because the federal tax code allows health insurance premiums to be purchased as a pretax deduction, the majority of Americans receive their insurance as a benefit through their employers. Others purchase it as individuals on the open market. An estimated 46 million persons in the United States did not have health insurance coverage in 2009, and 22% of these uninsured were immigrants. According to the Kaiser Family Foundation, 47% of immigrants (legal and documented) are uninsured.

Naturalized citizens and lawful noncitizens generally have access to private and public health insurance similar to US-born citizens. That is, they can receive private health insurance as a benefit from their employer. They also qualify for Medicaid, a public program for low income individuals and families, if they meet the eligibility requirements, and can receive Medicare, a public program for individuals over 65 years or who meet other special criteria, provided they have been here at least 5 years and they or a spouse have paid at least 10 years into the system or pay a monthly premium. Since the passage of welfare reform laws in 1996, most lawful noncitizens must be in the country for 5 years before they are eligible for Medicaid and the Children's Health Insurance Program (CHIP). Some states allow legal noncitizens to enroll in Medicaid during their first 5 years in the country, but these programs do not receive federal matching funds.

Undocumented immigrants on the other hand do not qualify for public health insurance, and rarely receive employer-sponsored health insurance. Many of these immigrants work in low-wage industries that typically do not provide employer-sponsored insurance, or they are paid "under the table," meaning unofficially and not on the records of the employer, and not offered benefits. Their main option for having health coverage is purchasing it on the individual market. As this is one of the most expensive ways to buy insurance, and most undocumented immigrants have low incomes, very few can afford to purchase private insurance.

Most health care in the United States is provided by private health care providers, including private hospitals and private-practice physicians. Exceptions are the Veterans Affairs hospital system, which provides care for veterans of foreign wars, public hospitals that receive support from the federal, state, and local level, and not-for-profit community clinics which provide care for the poor and uninsured, including immigrants. Noncitizen immigrants, both undocumented and documented, have access to public and private health care providers, provided they have the means to pay. All persons who show up to emergency departments must be treated regardless of their ability to pay. For this reason, emergency departments have become a primary source of care for the uninsured, including immigrants.

Health Care Reform and Immigration

The Patient Protection and Affordable Care Act (PPACA) and Reconciliation Act of 2010, both signed into law in early 2010, made the largest reforms to health care in the United States since Medicare was passed in 1965. Among the changes in this law are provisions creating state-run insurance exchanges, where individuals and employees of small businesses may purchase private insurance plans. Persons purchasing insurance through this mechanism will receive income-dependent federal subsidies to help offset premium costs. The Medicaid program was expanded to cover all persons with income below 133% the federal poverty line (FPL), resulting in an increase in approximately 15 million enrollees when fully enacted. These reforms become fully enacted in 2014.

Naturalized citizens and lawful noncitizens will be able to purchase insurance on these exchanges and will be eligible to receive federal subsidies. Additionally, lawful noncitizens with incomes below 133% FPL will be eligible to enroll in Medicaid, provided they have continuously resided in the United States for at least 5 years. Naturalized citizens have the same access to Medicaid as US-born citizens.

Undocumented immigrants are not eligible for Medicaid or federal insurance subsidies. Furthermore, undocumented immigrants are banned from purchasing insurance policies on the exchange, even if they have the economic means to do so. This is concerning to undocumented immigrants that purchase individual private plans, as it is questionable whether this insurance market will exist after 2014. Many experts believe that insurance companies will offer all of their individual private plans through the exchanges. Undocumented immigrants wishing to purchase insurance, will in effect, become a niche market. This niche market may be too risky for insurance companies since they cannot deny coverage based on pre-existing conditions and undocumented immigrants are exempt from the individual coverage mandate. This would allow undocumented immigrants to purchase health insurance only at the time they needed it.

Border Health and the Recent Political Climate

Politicians and the public have taken an increased interest in recent years concerning the flow of undocumented immigrants into the United States along the US-Mexico border. The United States has increased border security through fences, surveillance equipment, and border patrol agents. Because border security is not one continuous system, but rather a patchwork, immigrants often try to cross in certain areas that may have less security, but may feature more inhospitable terrain. As a result, the act of migrating into the United States can pose a health risk as well. In 2009, 417 known deaths occurred among persons trying to cross the US-Mexico border. Many of them die in the deserts of Arizona or by drowning in the Rio Grande trying to enter through Texas.

The Development, Relief and Education for Alien Minors Act, or DREAM Act, is a bill first introduced in 2001 and reintroduced in 2010 in the 111th Congress that creates a pathway for persons who entered the country illegally as children to become citizens by completing 2 years of college, or 2 years of military service. Such a law would allow millions of undocumented immigrants in the United States to become citizens, and hence improving access to jobs, health insurance, and public insurance programs.

Most legislative efforts in recent years have moved toward restricting access to health care and public programs rather than expanding it for immigrants. Arizona passed a tough anti-immigration law in April 2010, causing many to fear that medical professionals will be required to report suspected undocumented immigrants who show up to their practice. The law may also have the effect of suppressing undocumented immigrants from utilizing health care services for fear of deportation. Opposition to the Arizona immigration law was widespread with many prominent voices calling for a boycott of the state. However, a Pew Research Poll showed public support for the law by a 59-32 margin. Given the popularity of such measures and budget shortfalls in most states, politicians may pass more laws designed to restrict lawful and undocumented immigrants' access to public resources and health care services.

Conclusion

Health disparities in terms of access and quality of care exist in the United States, and these disparities are often tied to low socioeconomic status. Immigrants, especially undocumented immigrants, tend to be of lower socioeconomic status than natural-born citizens. Despite the "Hispanic paradox" whereby many undocumented immigrants perform better in several leading health indicators, access to care remains a problem. Federal and state laws create barriers that prevent most undocumented immigrants from obtaining health insurance. Lack of universal health insurance and rising health care costs also prevent many lawful noncitizens from obtaining health coverage as well for financial reasons. Immigrant health is not only affected by laws pertaining to the health care system, but also the social, cultural, and political attitudes toward immigrants in the United States.

Universal Declaration of Human Rights

Elizabeth M. Valencia
Radiology Department, St. Joseph's Hospital & Medical Center, Phoenix, AZ, USA

The Universal Declaration of Human Rights (UDHR) is regarded as one of the most pivotal documents of the last half century. The Declaration deems all people are entitled to basic human rights regardless of civil, political, economic, social, or cultural status. Although not a treaty, the UDHR has served as a human rights template incorporated into international treaties. For instance, the International Covenant on Civil and Political Rights and the International Covenants on Economic, Social, and Cultural Rights were ratified in 1966 and established many of the protections delineated by the UDHR. Together these covenants and the UDHR comprise the International Bill of Rights.

History paved the road for the evolution of the UDHR and provides insight into its relevance and impact. By the mid-1940s, society had lived through the devastation of two world wars and a fervent vision for a postwar era of justice and peace evolved. As a result, the recently formed United Nations established the Commission on Human Rights, which was comprised of 18 states and chaired by the former first lady Mrs. Eleanor Roosevelt. The drafting subcommittee was comprised of representatives from Australia, Chile, China, France, Lebanon, United Kingdom, USSR, and the United States. The Declaration framework was structured on core principles of nondiscrimination, social and economic responsibility, and political civil responsibility. After a 2-year drafting process, on December 10, 1948, the UDHR was adopted by the United Nations.

The UDHR consists of 30 articles relating to civil, political, economic, social, and cultural rights. The first three articles define the rights of the individual. Specifically, articles 1–5 cover freedom, liberty, and security, and in addition, ban slavery and torture. Articles 6–9 ensure equal protection and nondiscrimination, and ban random seizure and confinement. Articles 10–11 establish a right to fair public hearing, due process by an impartial tribunal, and presumed innocence until proven guilty.

Articles 12–17 recognize the right of an individual in society. For example, articles 12–15 protect the right to nationality or change in citizenship, the free movement within a state or between states, and to seek asylum from persecution. Articles 16–17 involve the right to marriage, family, and sole or community property ownership.

Articles 18–21 emphasize civil and political freedoms. In particular, articles 18–21 address the right to freedom of religion and expression, peaceful assembly, and the right to vote. Finally, articles 22–27 delineate social, economic, and cultural rights.

In summary, the UDHR revolutionized the landscape of international law, by inspiring the development of several core treaties with UDHR origins: (1) Convention on the Rights of a Child; (2) United Nations Convention Against Torture; (3) Convention Against All Forms of Discrimination Against Women; and (4) Convention Against All Forms of Racial Discrimination. Equally impressive was the reaffirmation of the UDHR at the Second Human Rights World Conference by 171 countries in 1993. Continued public awareness regarding the UDHR is paramount, as evident with its translation into over 360 languages. In addition, human right violations can be reported via a 24-h United Nations facsimile hotline.

U.S.–Mexico Border

Tambra K. Cain
Barrett, Twomey, Broom, Hughes & Hoke, LLP,
Carbondale, IL, USA

The border between the United States and Mexico extends approximately 2,000 miles from the southern tip of Texas to California. On the United States side, it extends along the states of Texas, New Mexico, Arizona, and California; and on the Mexico side, the states of Baja California, Sonora, Chihuahua, Coahuila, Nuevo León, and Tamaulipas. In the United States, Texas has the longest stretch of the border, while California has the shortest. In Mexico, Chihuahua has the longest stretch of the border, while Nuevo León has the shortest.

On March 2, 1836, the Texas Declaration of Independence was signed, creating the Republic of Texas. The Republic of Texas lasted only until 1845 when, on March 1, 1845, United States President John Tyler signed a bill that authorized the United States to annex the Republic of Texas. The continuous conflicts in the Texas region in the mid 1800s and the US annexation of Texas eventually led to the Mexican-American War (1846–1848), which ended with the Treaty of Guadalupe Hidalgo.

The Treaty of Guadalupe Hidalgo gave the United States undisputed control of Texas, established the US–Mexican border as the Rio Grande River, and ceded to the United States the states of California, Nevada, Utah, and portions of the states of Colorado, Arizona, New Mexico, and Wyoming. From the Treaty, Mexico received $18,250,000 and the United States agreed to assume $3.25-million in debts the Mexican government owed to United States.

Five years later the Gadsden Purchase, named after James Gadsden, US Ambassador to Mexico at that time, completed the formation of the US–Mexico border. The Gadsden Purchase was signed by President Franklin Pierce on June 24, 1853, and ratified on April 25, 1854. It added southern Arizona and southwestern New Mexico to the United States and completed the US–Mexico border as we know it today.

Established in 1889, the International Boundary and Water Commission (IBWC) has responsibility for applying the boundary and water treaties between the United States and Mexico. The IBWC is an international body composed of the United States Section and the Mexican Section, each headed by an Engineer-Commissioner appointed by his/her respective president. Each Section is administered independently of the other. The United States Section of the International Boundary and Water Commission (USIBWC) is a federal government agency headquartered in El Paso, Texas. The USIBWC operates under the foreign policy guidance of the Department of State. The Mexican Section is under the administrative supervision of the Mexican Ministry of Foreign Affairs and is headquartered in Ciudad Juarez, Chihuahua, Mexico.

Trade Relations

Mexico is the third largest US trading partner, after Canada and China; and the United States is Mexico's largest trading partner. The United States bought more than 80% of all Mexican exports in 2008. The total trade between the two countries exceeded $367 billion in 2007. This stable trading relationship is due in part to the North American Free Trade Agreement (NAFTA), which is an agreement signed by the governments of the United States, Canada, and Mexico creating a trilateral trade bloc in North America. NAFTA went into effect on January 1, 1994. The Agreement gradually eliminates tariffs and dissolves many other trade barriers, for example quotas. NAFTA is structured to stimulate the border region's industrial growth. Such growth has historically brought about numerous environmental problems. Therefore, NAFTA established two agencies to help deal with the vast environmental concerns along the US–Mexican border. The first such program is the Border Environment Cooperation Commission (BECC), a binational organization that helps develop environmental infrastructure projects related to wastewater treatment, the prevention of water pollution, and the management of municipal solid waste. The other program is the NADBank, which was set up to work in conjunction with the BECC, guaranteeing loans for projects certified by the environmental commission. Both the United States and the Mexican governments supply the funds to the NADBank.

Immigration

Mexico accounts for approximately a third of all foreign-born residents living in the United States, and nearly two-thirds of all Hispanic immigrants to the United States. Of all people who leave Mexico to reside elsewhere, the United States is their principle destination. Recent data indicate there has been a substantial decrease in the number of new arrivals from Mexico to the United States. The flow of Mexican immigrants to the United States began to decrease in the mid-2000s, and has continued to do so through early 2009. This trend can also be found in data from the US Border Patrol, which tends to show that apprehensions of Mexicans attempting to cross illegally into the United States decreased by one-third between 2006 and 2008.

In 2008, an estimated 11.9 million unauthorized immigrants lived in the United States. The majority of these undocumented immigrants are from Mexico. The undocumented immigrant population grew rapidly from 1990 to 2006 but has now stabilized. There were approximately 8.3 million undocumented immigrants in the US labor force as of March 2008. Unauthorized immigrants make up approximately 4% of the nation's population and account for almost five and half percent of the US workforce. In 2005, over 1.2 million illegal immigrants were apprehended by the US Border Patrol, which apprehends about one out of every four illegal border crossers.

Tunnel passages across the US–Mexico border are another challenge as the smuggling of drugs, weapons, and immigrants also takes place through such tunnels. One tunnel running from San Diego to Tijuana was particularly advanced at one-half a mile long, 60–80 ft deep, and 8 ft tall with a concrete floor. That particular tunnel was wired for electricity and had drainage. The California entry was hidden in a very modern warehouse.

The Department of Homeland Security was established on November 25, 2002, by the Homeland Security Act of 2002. On March 1, 2003, the US Department of Homeland Security (DHS) took over the control of the Immigration and Naturalization Service (INS). Some of the agencies now under the Department of Homeland Security are: the United States Citizenship and Immigration Services, which processes citizenship, residency, and asylum requests; the US Customs and Border Protection, which staffs border checkpoints, collects tariffs, and patrols the border; and the US Immigration and Customs Enforcement, which conducts long-term investigations of border violations. The United States Border Patrol is a federal law enforcement agency within US Customs and Border Protection (CBP). The US Border Patrol has just over 20,000 agents and is primarily responsible for immigration and border law enforcement. There are 20 Border Patrol sectors; the Southern Border Sector covers the US–Mexico border, among others.

The US–Mexico border is guarded by over 17,000 border patrol agents. Yet, those agents only have effective control of less than 700 of the 2,000 miles of the border. In an effort to increase security of the US border and decrease illegal immigration into the United States, the Secure Fence Act of 2006 was enacted. The Secure Fence Act of 2006 is to establish operational control over the international land and maritime borders of the United States. The Secure Fence Act of 2006 authorized the systematic surveillance of the international land and maritime borders of the United States, including the use of unmanned aerial vehicles, ground-based sensors, satellites, radar coverage, and cameras; it also authorizes physical infrastructure enhancements to prevent unlawful entry by undocumented individuals into the United States and facilitates access to the international land and maritime borders by United States Customs and Border Protection, such as additional checkpoints, all-weather access roads, and vehicle barriers. The Act also allows for more than 700 miles of double-reinforced fence to be built along the US–Mexico border. Additional fencing was authorized for the states of California, Arizona, New Mexico, and Texas, which have experienced significant illegal drug trafficking and immigration.

A program called “Texas Virtual Border Watch” was created by the State of Texas to allow anyone with internet access to observe and report on the US–Mexico border via their computer. The program was funded by the Texas governor’s criminal justice office, at a cost of $2 million in its first year. The trial version of the Texas Virtual Border Watch received approximately 2,780 reports of suspicious activity by November 2008. The site has users around the world, including Australia. From November 2008 to February 2009, the program has been credited for four drug busts yielding 1,500 pounds of marijuana, and 30 incidents where illegal immigrants were repelled.

V

Vatican City

Andrew J. S. Howie
Mental Health and Drug and Alcohol Services, Far West Local Health Network, Broken Hill, NSW, Australia

Vatican City, officially titled *Stato Della Citta del Vaticano*, is a walled enclave within the city of Rome, with a surface area of approximately 44 ha and a population of approximately 800. Its significance as the center of Roman Catholicism; its architecture, art, museums, gardens, and historical significance; and its proximity to the center of Rome make it a popular tourist destination. Its importance for immigrant health has two main aspects, as a center of health for those residing within the state, and as a source of moral guidance for those of the Catholic faith elsewhere in the world.

Regarding the first aspect, primary care physicians and other health professionals within the Vatican provide care for residents of Vatican City only, under the Governance of the Department of Health and Welfare. Health needs of visitors are best met in the adjacent precincts of Rome. An exception is the Vatican Pharmacy (*Famacia Vaticana*). By virtue of being the only pharmacy in Vatican City, it provides its medicines duty-free (since the Vatican has no taxes). It caters to approximately 2,000 customers each day. The Pharmacy is located behind the central post office, which is also the Vatican supermarket. There are no contraceptives or abortifacients available within the pharmacy, since the Catholic Church opposes the use of both.

Regarding the second aspect, the leadership of the Church in various health domains is expressed in the work of various organizations. For example, The Pontifical Council for Health Pastoral Care has as its aim to "stimulate and promote the work of formation, study, and action carried out by the diverse Catholic International Organizations in the health care field as well as other groups and associations which work in this sector, on different levels and in different ways." The Pontifical Academies offer a lead for other Catholic Institutes worldwide on ethical issues. National organizations, for example, Catholic Health Australia, provide care and seek to influence policy decisions based on Catholic teaching.

Its special religious character notwithstanding, the Vatican has, through the dissemination of the Catholic faith through the Church, coordinated healthcare efforts throughout the world where there is need. Hence the influence of the Vatican for immigrant health extends well beyond the borders of the Vatican City itself.

Veil

Ahmed Afzal
Department of Anthropology, School of Natural and Social Sciences, Purchase College, State University of New York, Purchase, NY, USA

A veil is a garment or an item of clothing, worn mostly but not exclusively by women, that is intended to cover all or specific parts of the human body. The veil can refer to a headscarf (*hijab*), or a face veil (*lithma*) that women usually wear just under their eyes, or an all-enveloping cloak that covers the body from head to toe (*burka*). Veiling practices can be found in all major world religions – Judaism, Christianity, and Islam. Veiling practices in religious traditions are typically associated with formal prayer and ritual, where veiling symbolizes the piety, honor, modesty, and respectability of the person, their family, and the religiously marked space and/or ritual. Other religious interpretations and appropriations of the veil are less literal, characterizing the veil as the metaphysical separation between human beings or the world, and God.

Despite the existence of veiling practices in all contemporary religious communities, in recent decades, veiling practices among Muslim women have dominated public discourse and media attention globally, and especially in the West. Indeed, most of all of recent scholarship on the veil maintains a case study and analytic focus on veiling practices amongst Muslim women, and in constructing Islamic "otherness" and difference from the West. For example, according to Leila Ahmed, veiling signifies to many Westerners the oppression of women, the degradation of women by Islam, and the backwardness of Islam. Scholars have discussed the wearing of the veil in public among Muslim women to examine the social status and the subordinate position of women in contemporary Muslim societies and cultures. Such hegemonic understandings have contributed to a fetishizing of the veil and contributed to anti-Islamic sentiments in Europe and North America. The wearing of head scarves and especially face coverings by Muslim women has provoked controversy and raised volatile and contentious political debate over the assimilation of Muslims in France in an era of globalization and religious transnationalism. The recent debate over the use of headscarves in universities and government buildings in Turkey has similarly led to a reconsideration of the meanings of modernity and tradition in Turkey. Hate crimes directed against hijab-wearing women in major cities in the United States following 9/11 have contributed to a fetishizing of Muslim "otherness" (or un-Americanness) through dress and outward appearance.

Recent research has problematized such conventional and reductive understandings of the veil and veiling practices in contemporary Muslim communities that equate the veil solely with female oppression and subordination in patriarchical Muslim societies and cultures. Rather, these studies emphasize the need to view veiling within historical, sociocultural, and geopolitical contexts and specificities. Meanings and significance of the veil vary cross-culturally, such that any universalizing statement risks a reductive understanding of the veil, and veiling practices. One study of lower middle class women in Cairo, Egypt, found that for the majority of these hijab-wearing women, the hijab is a symbol of free will and agency. These women reject dominant, western understandings of the veil as a symbol of female subordination and subjugation, and as an expression of boundaries that restrict the freedom and mobility of women. As women enter the Egyptian work place in increasing numbers, the hijab creates the means for women's freedom from the space of the home, enabling them to move about in public, and enter occupations in mainstream economy. Veiling bridges the gap between tradition and modernity, and is more than just a simple revival of Islamic tradition or fundamentalism. For example, as hijabs become more fashionable, the head covering has come to symbolize the new ways for being a modern Muslim woman, and illustrate the ways in which Muslim women are accommodating tradition.

The use of the veiling garments as sites of consumption and style are not limited to Egypt but can be found among Muslim communities globally. Another study based on ethnographic research in Egypt, Sudan, and Jordan found that veiling references gendered segregation and notions of privacy in the public arena, the identity of the group and rank, respectability, and power.

Recent scholarship has also examined the discursive production of the hijab in popular culture and state ideologies of nationhood and belonging. Shirazi, for example, shows how the connection between hijab and jihad was constructed through the use of postage stamps, billboards, banners, and poster art and film that depicted women as supporters of the Islamists in Iran. According to Shirazi, the veiled woman has become a symbol in Iran of the country's defense against cultural Westernization.

Vendetta

Jonas Grutzpalk
Department of Social Sciences, FHöV NRW, Bielefeld, Germany

Vendetta is the Italian word for a social phenomenon that is also known as blood vengeance, blood feud, or simply as feud. Generally speaking, a vendetta is a conflict between families which cannot or is not solved by law. Hence, vendettas are common in societies with no or hardly any monopoly of force in the hand of the state. But vendettas also appear in policed societies, often being a phenomenon connected with migration. Here vendettas impress police, medical, or social workers by the amount of emotions and physical force that seem to play a central role in them.

On the other hand "vendetta" is quite a slippery term. Sometimes literature or movies on the subject give the impression that a vendetta is part of an unofficial set of strict rules. The Albanian word "kanun," which describes the traditional set of ideas that surround vendetta, emphasizes that point of view. But these unwritten "codes of honor" are themselves very much subject to linguistic and social change.

The Italian word has its roots in the verb *vendicare,* which means "to take revenge." It is uncertain whether *vendicare* can etymologically be traced back to *vim* (force) but this would make perfect sense as people who commit a vendetta often resort to violence. The word "feud" on the other hand obviously goes back to an Indo-Germanic root meaning "enmity" or "wrath."

The social roots of blood feud can be retraced at least to the Bronze Age. The universal basis of every blood feud is the idea that only blood may wash away blood. "Whoever sheds the blood of men by men shall his blood be shed" is the Biblical explanation of this concept, found at Genesis 9:6. From a sociological point of view, vendetta is (1) a mechanism that serves to keep violence from spreading into society as it limits its use to the conflicting parties alone, (2) a way to maintain a social equilibrium in tribal societies, and, most importantly, (3) a tool of security management in societies that do not have a police force that is concerned about public order.

Keywords to vendetta are family, honor, and manliness. One might feel tempted to follow William Shakespeare ("what is honor? A word") and regard them as a mere words. But these words stand for legal traditions that have been in effect from ancient times to our days. As these terms change meaning and importance in the course of the different social histories, also the words vendetta or blood feud as such actually describe various traditional forms of conflict management.

In Albanian, for example, the word *besa* stands as much for honor as it stands for hospitality and thus describes a network of people who are ready to defend each other against offenders. The Turkish language has two words for honor: *Namus* and *Şeref.* While *Şeref* is the kind of honor one can gain and lose individually, *Namus* describes the honor of a family. And the Sicilian ideal of the *uomo d'onore* (man of honor) is one of the many examples of a culture in which each man is obligated to prove his manliness, for example, by avenging himself when wronged.

Migration brings together different cultural interpretations of family, honor, and manliness. The results of such encounters can be astonishing. The killing of Hatun Sürücü by her brothers in Berlin in 2005, for example, was also openly applauded by non-Kurdish youths. They were mainly impressed by what they understood as a defense of honor and manliness. This shows that a cultural background might explain one part of blood feud in modern societies. But social integration or the absence thereof is another important key to understanding vendetta. In 1952, the French doctor Frantz Fanon described what he called the "North African Syndrome": When asked to localize their pain, Fanon's immigrant patients (mostly from Algeria and Morocco) answered that their entire body hurt. Fanon interpreted this as a neurosis caused by their disregard by the French majority. Such a painfully felt lack of integration might indeed reinforce family bonds in migrant milieus and reinvigorate even long forgotten ideas of blood vengeance.

Immigration often is a family business. Migrants in most cases tend to immigrate into social contexts they know from their home countries. At an early stage of migration a certain cultural segregation is thus to be regarded as normal. Family ties at this stage of migration are very tight. Immigrants coming from a cultural background that encourages blood feud might feel even more bound to its unwritten rules. In Germany, for example, this is the case with some Kurdish, Lebanese, and Turkish families.

The most famous form of vendetta has been depicted in many movies about Sicilian families in North America. Pino Arlacchi argued that vendetta has – in the hands of Mafiosi – been transformed into a market on which violence is traded. But still, the main ingredients of a vendetta constitute components of today's Mafia: kinship, security, honor, and readiness to use violence in order to defend it honor and family. Mafia families describe themselves as *coscas* (artichokes). Like the leafs of an artichoke, the members of a *cosca* cover and protect each other from the outside world. The picture of the artichoke might help to understand why it sometimes is extremely difficult to even talk to people with a cultural background that favors blood feud.

Honor killings are another social phenomenon that can be connected with vendetta. The notion of honor describes the capacity of a family to defend itself against any kind of intrusion or offense in those societies that rely on blood feud as legal tool. But this notion loses its sense in policed societies. The campaign "honor is protecting my sister's freedom" operated by the nongovernmental organization *Terre des femmes* in Germany quite successfully helps youths from different cultural backgrounds to give a new meaning to honor, one of the key components of vendetta.

Vietnam

Christopher A. Kenedi
Auckland District Health Board, Auckland,
New Zealand

Vietnam's history is one of struggle against outside control. It is essential to have a minimal understanding of recent Vietnamese history and culture to be able to address the health needs of Vietnamese immigrants. Records suggest that Vietnam was a subject state to China for almost 1,000 years until the tenth century. It remained free for much of the next 900 years but in a state of persistent conflict with neighbors and sometimes within its borders. It was during this period that Vietnam began to adopt Buddhism. In the nineteenth century, the French invaded, imposed colonial control, and propagated Christianity. During this time, calls for self-rule were ignored or suppressed by the French who established a plantation economy and ruled primarily from the south of the country.

World War II

The Japanese occupied Vietnam during World War II under the auspices of the Vichy French regime that was beholden to Nazi Germany. Ho Chi Minh, considered the founder of modern Vietnam, established a Communist movement for the long-term goal of overthrowing the French after the war. He initially allied himself with the Chinese Nationalists and USA against the Japanese occupiers. As the war neared its conclusion, the Japanese overthrew the French colonialists and declared Vietnam to be independent. Simultaneously, in 1945 a severe famine struck Vietnam killing one to two million people out of a population of ten million, and led to social instability and popular revolts against both the Japanese and the remnants of French colonial society.

First Indochina War

At the conclusion of the war in 1945, the Allied powers returned Vietnam to French control. The Viet Minh – a group led by Ho Chi Minh, attempted to declare independence after Japan's surrender, but chaos and conflict led to continued famine and their forces were pushed out of the cities. The Viet Minh fought a guerilla war against the French until the Chinese communists under Mao Zedong reached the Vietnamese border in the 1950s and began supplying heavier weapons and providing training. This led to a catastrophic defeat of elite French troops at the Battle of Dien Bien Phu in 1953 and, 1 year later, Vietnam was again divided – this time at the 17th parallel. In 1954, control of North Vietnam was given to the communist Viet Minh, and the South became the State of Vietnam, with a plan for unification elections to be held in 1956. At least 800,000 people – mostly Catholics – moved from North to South Vietnam, and 52,000 are believed to have moved from South to North. During this time, the People's Republic of China decreased its support for the Viet Minh, and North Vietnam became a close ally of the Soviet Union. The unification elections were not held because the American-supported South Vietnamese believed they would lose control of the country to the communist Viet Minh.

Second Indochina War

The 1954 division led to the Second Indochina War (referred to in the USA as the Vietnam War) from 1960 to 1975. It began with indirect American support in the 1960s and escalated to years of continuous bombing campaigns and massive commitments of troops and resources from the USA and its allies. In the face of massive public opposition and political lack of will, the USA signed the Paris peace accords and withdrew from Vietnam in 1973. Two years later, South Vietnam fell to the forces of the Communist north. By the end of the war, more than 3.1 million Vietnamese had been killed and 2.6 million injured. This marked the end of 116 years of foreign control of Vietnam and 30 years of continuous warfare since the end of World War II.

After the unification of Vietnam in 1975, more than one million Vietnamese who were considered to have collaborated with foreign enemies of the new Communist State were placed in "reeducation camps," and 165,000 of them are estimated to have died there. Reports state that one in three South Vietnamese families had a relative in a reeducation camp and that the average sentence was for 10 years under harsh physical and mental conditions. At least 34,641 survivors are known to have fled to the USA after their release with 128,068 of their family members.

Conflict returned 4 years later in 1979 when Vietnam (with Soviet support) invaded Cambodia to topple the Khmer Rouge, allies of the Peoples Republic of China. The Khmer Rouge were believed to have killed 21% of all Cambodians in a genocidal campaign. This led to an aborted Chinese invasion of northern Vietnam and the expulsion or fleeing of 450,000 ethnic Chinese refugees from Vietnam by boat or across the border to China. Between 1975 and 1995, more than three million people are thought to have fled Vietnam, Laos, and Cambodia, many as "boat people" who ended up across the world. Some estimates suggest that as many as 250,000 boat people died on their journey. The ones who survived did so in extremely harsh conditions, often languishing in refugee camps for years with the constant threat of return to the country they had fled.

Emigration, Refugees, and Exodus After the War

Almost 1.4 million refugees from Southeast Asia ended up in the USA after this period of war and conflict; 1.1 million of them are thought to have been Vietnamese, the majority living in California and Texas. More than 250,000 Vietnamese refugees are thought to have settled in Orange County, California alone. A significant percentage of Vietnamese refugees were fathered by some of the more than three million male American personnel stationed in Vietnam during the war. These children often experienced discrimination and abuse in Vietnam because of their illegitimate parenthood.

Even after 2000, one out of seven Vietnamese who went to the USA did so up to 25 years after the end of the war. Studies of the Vietnamese immigrant experience have suggested that assimilation in the USA has been difficult, although the majority have been naturalized as American citizens over the years. Two-thirds of all Vietnamese immigrants in the USA have limited English proficiency. Vietnamese men are less likely than other foreign-born residents to be employed. There are more than 150,000 Vietnamese in Canada, and their experience is reportedly similar to Vietnamese-Americans.

Australian-Vietnamese comprise 0.8% of the Australian population – 159,848 people in the 2006 Census. Ethnic Vietnamese also comprise the largest Asian population in Germany. The majority of them arrived in the 1960s or 1970s as refugees from the Second Indochina War, and many originally settled in the former German Democratic Republic (East Germany), where they were the largest immigrant group. Other Vietnamese immigrants, numbering in the tens of thousands for each country, settled in the eastern bloc nations of Europe and Russia. Norway accepted almost 20,000 Vietnamese as refugees after 1975.

In Cambodia, Vietnamese are thought to make up as much as 5% of the population, although no reliable data exist. Vietnamese immigrants in Cambodia have at times been subject to violence by the majority ethnic Khmer population; antagonism by the Khmer was one of the reasons given for the Vietnamese invasion of Cambodia in 1979. However, Vietnamese immigrants returned to Cambodia when that nation's market economy was opened after improved political stability in the 1990s.

French-Vietnamese have had communities in France since the late nineteenth century, concurrent with French colonization. Unlike the USA and other nations with large Vietnamese populations, the French-Vietnamese are characterized by high degrees of assimilation and strong identification with their adopted nation, especially in the second generation.

Following years of polarization between the Vietnamese government and many who fled during and after unification, relations with "Viet Kieu" or overseas Vietnamese have begun to improve as Vietnam tries to encourage the return of Vietnamese who can bring capital and expertise.

Labor Migrants

Prior to 1999, other than cross-border migration, only official state enterprises could send workers abroad. Since 1999, private enterprises have been allowed to do so. In 2002, there were approximately 46,000 Vietnamese workers overseas. The most common destinations are Malaysia, Taiwan, and Laos. The bulk of workers are domestic helpers, but others work in factories, low-skilled construction jobs, and the garment or the seafood and marine industries.

Human Trafficking

Human trafficking is a form of exploitation that involves controlling and transporting people through the use of force, deception, or coercion. It is reported to be the third most profitable criminal activity in the world after drug and gun smuggling and resulted in estimated worldwide profits of US$31 billion in 2008. Vietnam is a significant source for trafficking in persons. Women were trafficked primarily to Cambodia, Malaysia, China, Taiwan, and South Korea for sexual exploitation. Women were also trafficked to Hong Kong, Macau, Thailand, Indonesia, the UK, Eastern Europe, and the USA. At the same time, Vietnam imports trafficked Cambodian and Chinese women, who work in the local commercial sex industry.

The Cambodian sex industry appears to be heavily controlled and staffed by Vietnamese, with the workers being paid subsistence wages and subject to violence. The traffickers are reportedly organized crime syndicates, who obtain women referred by relatives, friends, intimate partners, and neighbors. In 2004, a report by Cambodian police estimated that more than 50,000 Vietnamese women were brought into Cambodian brothels. One-third are estimated by UNICEF to be under the age of 13 years. Young Vietnamese girls who are virgins are highly sought after by traffickers, as they are believed to be free from HIV or sexually transmitted diseases. Reports state that they are bought for as little as a "week of use" at a time and confined to a hotel or guesthouse room for the duration.

Trafficked women are at high risk of sexually transmitted diseases and often have their access to health care and diagnostic testing restricted by their employer. Healthcare workers who see victims of trafficking may not realize their patient's history or at best may mistakenly screen them only for domestic violence.

One female trafficking program of quasi-legal status seen in Vietnam consists of marriage agencies. Marriage services are illegal in Taiwan, but heavily patronized; in 2005, it was estimated that more than 118,000 Vietnamese women had been brought to Taiwan as brides. These women are particularly vulnerable to domestic violence, rape, and forced labor as they have little recourse or access to information or resources. Women sometimes arrive to find themselves in indentured servitude. According to reports from the United Nations High Commissioner on Refugees, at least 3,000 women had been left stateless by divorce or being disowned. This particularly impacts their health and their children's education as they may not be eligible for state services if they return to Vietnam. Marriage agencies are also used in South Korea, involving thousands of Vietnamese women and South Korean men from rural areas.

Vietnamese Culture and Communication

Like many Southeast Asian cultures, importance is given to the family over the individual. Elder family members are given significant weight in decision making, and families are expected to care for elders. The oldest male will often be given the role of speaking for the family, and this can be difficult for Western healthcare workers who may not understand why a female or younger patient is deferring or refusing to make a decision if the spokesperson is not present. Because there is a cultural tendency to avoid conflict with authority figures, Vietnamese families may appear to be passive when they do not respond to cognitive reasoning by doctors and nurses.

Vietnamese may expect immediate relief through the prescription of a medicine or a procedure. A failure to provide a medication or intervention may result in their seeking medical attention elsewhere. Accepted alternative forms of health care not only include traditionally Asian herbal medicines and interventions (e.g., acupuncture, cupping), but also access to Western medicines from nonphysician practitioners, including pharmacists and "injectionists." Providers should be aware of the risk of discontinuation of medicines after symptom relief and provide adequate counseling regarding potential risks should the full regimen not be completed or "leftover" medication shared with others. The treatment of asymptomatic chronic diseases – such as diabetes, hypertension, hypercholesterolemia, and HIV – can be challenging if not handled with due care to the patient's need for education about the nature of chronic disease and reinforcement of adherence. This should be offered in Vietnamese if the patient's English language ability is limited. In addition, some patients may believe that Western pharmaceutical dosing is too strong for them due to differences in physical size, and patients may choose to self-adjust doses.

Despite these independent belief patterns, Vietnamese society gives great respect for medical education and training. However, they may not be accustomed to seeing the importance of patients and doctors working together in a cooperative healthcare process. It may not be expected to have doctors probe extensively and perform a thorough review of symptoms, especially regarding sensitive health issues such as sexual and mental health. By the same token, extensive discussion and explanation of options or treatments in English can be difficult for primarily Vietnamese-speaking patients to follow.

Complex or prolonged illness will often be viewed as a combination of factors rather than the traditional reductionist thinking taught in Western allopathic medicine (e.g., Occam's razor). When diagnosed with an infection, Vietnamese patients may see a role for spiritual factors and a loss of balance in internal "humors" (hot and cold in particular). Thus, some patients may choose to "mix and match" modalities. The management of a specific condition may include seeking advice from a spiritual practitioners and herbal remedies in addition to filling a prescription. Healthcare providers should be aware of the potential for this addition of external healthcare approaches and the potential risk for drug interactions and poor response to prescribed treatment.

Pregnancy

There are a number of cultural traditions surrounding pregnancy and childbirth. Although the importance of prenatal care is well known, recent immigrants may not know it is freely available under health insurance options available in many high-income countries. Miscarriage is associated with eating too many humorally "hot" foods as well as intercourse during pregnancy or raising one's hands above the head. Post-partum women are considered vulnerable to a loss of body heat.

Mental Illness

PTSD and depression can be serious issues among Vietnamese immigrants, especially former military and civilians who survived the wars in Indochina. Life experiences with bombing campaigns, or living as boat people and/or in refugee camps where people were at risk of rape, predation, and violence can all contribute to long-term mental health issues. Immigrants to western countries may describe isolation, harassment (verbal, sexual, or physical), stigma, and loss of status.

It is commonly difficult for the Vietnamese to discuss mental illness, and practitioners should be alert for psychosomatic presentations of PTSD and depression when vague symptoms are reported that do not respond to commonly prescribed treatments. Investigations of vegetative functions like sleep, appetite, and motor activity may be more useful than traditional markers of mood and guilt.

While most clinicians strive to establish a good rapport, with Vietnamese patients, a strong alliance and validation of the patient as a partner in the provider–patient relationship is crucial before introducing the idea of psychiatric care or referral. This may take several visits and even then should be introduced slowly and sometimes indirectly. Local Vietnamese community support organizations can be invaluable in providing advice in many cases. In smaller communities, confidentiality can limit clinicians' ability to access them without prior patient approval.

Tuberculosis (TB)

Vietnam has reportedly exceeded WHO targets for addressing TB and is the only country of the 22 nations with the highest prevalence of TB to do so. As of 2007, it was reported to have a low incidence of multidrug-resistant TB, and current figures suggest a relatively low HIV prevalence rate of 0.5%. However, rates of TB detection are not decreasing, suggesting that there may be a new epidemic emerging among Vietnamese in Vietnam, particularly among young adults. It is not clear if this represents increasing HIV disease, internal migration, better detection, or increased spread of drug-resistant TB from China.

Ethnographic studies of TB in Vietnamese in Vietnam suggest that providers need to address a number of specific misconceptions, including (1) "everyone has TB", (2) the BCG vaccination leads to immunity to TB, and (3) the issue of blood loss and X-rays mentioned above.

Infections remain the most common cause of death in Vietnam. However, as the Vietnamese economy improves and people are living longer, patients are increasingly developing chronic diseases like diabetes and cardiovascular disease.

Vigilante

Cathleen A. Cerny
University Hospitals Case Medical Center, Cleveland, OH, USA

"Vigilante" is derived from the Spanish word for "watchman" or "guard." Merriam-Webster defines a vigilante as a member of a volunteer committee organized to suppress and punish crime summarily, as when the processes of law are viewed as inadequate, and more broadly as a self-appointed doer of justice. More simply, a vigilante is someone who illegally punishes for perceived offenses. Vigilantes may seek to enforce existing laws or they may have their own concept of right and wrong.

There are abundant examples of vigilantes in popular culture. Most of the time, they are portrayed as "good guys" rather than as criminals. Robin Hood was embraced by the common people because he "stole from the rich and gave to the poor." Zorro protected the people of his land from corrupted officials. Many of our comic book superheroes could be classified as vigilantes. Batman, The Punisher, and Daredevil became crime fighters because of violent losses in their pasts that the law was helpless to do anything about. Dexter Morgan, a fictional character created by Jeff Lindsay, is the serial killer who kills other serial killers.

Real-life vigilante groups have existed throughout history, each with their own agenda. Like the fictional examples above, some have been perceived as righteous and beneficial to society; others have been viewed in less positive light.

- In colonial America, the Regulator Movement was composed of private citizen volunteers who wanted to punish banditry.
- The Sea Shepherd Conservation Society has been fighting illegal fishing and whaling practices since 1977.
- The Bakassi Boys of Nigeria formed in 1998 to fight crime when police were ineffective.
- The Irish National Liberation Army punishes criminals who harm the working-class people of Ireland.
- The Davao Death Squad in the Philippines carries out extrajudicial punishment of criminals.

Some of the most active vigilante groups across history have been those opposed to illegal immigration. These vigilante groups promote Nativism which is the policy of supporting native-born citizens or established inhabitants over immigrants.

More people immigrate to the United States than to anywhere else in the world. They come in pursuit of the American dream. There are those that feel that resources and opportunities for Americans are being unjustly given to non-Americans. Extremist Nativists literally believe American ideals and traditions are being destroyed by illegal immigration. Accordingly, vigilante groups have sprung up to remove illegal immigrants from the USA and to prevent people from illegally crossing our borders.

As far back as the 1800s, there were vigilante groups in the United States with an interest in removing unwanted immigrants from the country. The San Francisco Committee of Vigilance was formed in 1851. Although the primary focus was on crime and government corruption, they also deported illegal immigrants. Interestingly, immigrants to the United States sometimes formed their own vigilante groups to combat those they felt were trying to oppress them and restrict their chances for success in a new land. The fabled Molly Maguires (1870s) was a secret group of

Irish immigrants formed in Northern Pennsylvania who used terror tactics to combat coal mine owners. There is historical debate as to whether or not this group actually existed in the US. Some evidence suggests that the Mollies were just as much the victims of vigilantes as they were victimizers.

The original Ku Klux Klan was formed after the American Civil War by Tennessee veterans of the Confederate army. The Klan used terrorism and murder as tools of oppression against minorities. Their goal was to restore White supremacy. Although Black Americans were their number one target, the Klan was also anti-Catholic, anti-Semitic, and anti-Communist. All the various versions and manifestations of the Klan over the years have taken an anti-immigration stance.

In modern times, regulating immigration across the United States-Mexican border has been a hot-button political issue for over a decade. There are several vigilante groups that have dedicated themselves to stopping illegal Mexican immigration including the American Border Patrol, Civil Homeland Defense, and Ranch Rescue. Some of these groups organize armed patrols of the border. To discuss one example in more depth, the Minuteman Project was founded by Jim Gilchrist in October 2004. This organization describes itself as a "citizens' Neighborhood Watch on our border." Gilchrist, a Vietnam veteran and Purple Heart recipient, has been a very controversial figure in the immigration debate. He said he founded the Minuteman Project because he was tired of law enforcement's failure to enforce existing immigration laws and prevent the "invasion" of our country by Mexican immigrants. The Minuteman website boasts that the organization is "operating within the law to support enforcement of the law."

The internet has endless links to and about organizations dedicated to discussing illegal immigration across the US–Mexican border. Some of these websites view the vigilante groups favorably and other links are highly critical of the methods used by the vigilantes to achieve their goals. The Border Action Network and the Southern Poverty Law Center are two organizations that have been vocal about abuses done by some citizen border patrol groups. Sadly, anti-immigration extremists have resorted to violence and even murder to achieve their goals. Illegal border crossings take place in isolated areas where violence against the immigrants is less likely to be witnessed. Individuals who survive the crossing are unaware of their rights. They rarely report abuses because they know they will be detained while the case is looked into. The motivation to return to Mexico and reattempt the crossing is greater than the motivation to seek justice for violent offenses.

Anti-immigration vigilante groups are not restricted to the United States. After the United States, Russia was second greatest immigration destination in the world in 2008. According to a 2/14/09 Newsweek article on "The Kremlin Vigilantes" by Owen Matthews and Anna Nemtsova, there were 7 million migrants, 2.8 million legal and about 4 million illegal immigrants to Russia in 2008. During preceding years of economic expansion, immigrants were accepted and found semi-skilled labor jobs. Now that the economy is suffering and unemployment is high, there is backlash against foreigners. Per this article, violence against foreigners has greatly increased and some of the hate crimes have been horrific. The Movement Against Illegal Immigration (DPNI) and the Youth Guard have indicated willingness to train vigilante groups to assist police in locating illegal immigrants. In February 2009, Italian Prime Minister Silvio Berlusconi legalized private, night-time unarmed citizen groups to patrol the streets and report suspicious individuals to police. This is part of the plan to crack down on illegal immigration. People who oppose this decree consider the citizen groups to be vigilantes.

In summary, vigilantes are citizen volunteers who take the law into their own hands. Across time, vigilantes have been viewed both positively and negatively depending on the historical context and the actions taken by the groups. Anti-immigration vigilante organizations can be found around the globe. In the United States, there are several vigilante groups dedicated to monitoring the US–Mexican border. When emotions and socioeconomic pressures are high, vigilante groups can resort to violence to achieve their goals. We must be mindful of human rights violations perpetrated against immigrants, both legal and illegal.

Violence

Linh Phan[1], Doug Brugge[2]
[1]Department of Nursing, University of Massachusetts Lowell, Lowell, MA, USA
[2]Department of Public Health and Community Medicine, Tufts University School of Medicine, Boston, MA, USA

Introduction

Regardless of whether the crime is physical, property based, or drug-related, it negatively impacts communities, including immigrant communities, particularly with regard to mental health. Despite the overall decrease in crimes of large urban cities in the USA that also have large immigrant populations, crime continues to impact perceptions of safety and overall general well-being.

Crime and Health

Criminal acts provoke fear. Fear of crime can push people to relocate from an area if they are able to do so, increasing the social disparities within that area, especially in urban settings. Crime and the fear it engenders decrease quality of life. As quality of life decreases, community social relations can become strained and the residents can become increasingly stressed by the crime. Due to the strain on social relations over time, a community's economic status may also decline as the area is avoided or abandoned. Another reaction to crime or the fear of crime is feelings of helplessness. Positive associations with one's surroundings increase one's perceptions of safety. However, when people feel helpless, they often choose not to return to the neighborhood if they are able to leave. When the negative environmental aspects of a socially disempowered community dominate, it is difficult for individuals, both within and outside the community to feel welcomed and safe.

Immigrant Communities and Crime

Research findings are mixed regarding immigrants and crime, suggesting that the prevalence of victimization is similar between immigrants and US-born adults. For example, foreign-born populations in Chicago were disproportionately locating in the safest neighborhoods. On the other hand, a study that analyzed the impact of street crime on Boston's Chinatown, one of Boston, Massachusetts's immigrant communities, indicated high concentration of crime, including violent crime. The researchers concluded that the zoning of the Boston adult entertainment district next to Chinatown was the major source of crime.

Among school-aged Latino children, first-generation immigrant students were more likely to feel unsafe, while less likely to be a victim of school violence. Third- and second-generation students were more likely to be victimized. This is consistent with a broader literature showing worse health and educational outcomes with increased length of stay in the USA. In addition, native English-speaking Latino students were less likely to be victimized at school. It may be that socioeconomic income has more of an impact on victimization than generation. As the student's family income increased, their fear for safety decreased.

Other research suggests that the concentration of Latinos has no effect on the incidence of Latino homicide. The immigration of Latinos into the ethnic enclaves may decrease the incidence of robbery and may stabilize conditions for the population. Apparently, this finding does not hold in Black communities, where violence does not decline when Black populations become more concentrated. Adolescence and violence are often associated. However, immigrant concentration has been found to deter violence among adolescent youth.

Domestic violence is distinct from other forms of violent crime in that it is often underreported, and this may be particularly true for immigrant families. The immigration process and acclimation to a new host country is a stressful time in most families. US-based research involving Chinese immigrants suggests that the power relations among couples may change following immigration to the USA due to the male spouse's loss of income in relation to the wife's gain in income. As a result, the patriarchal societal structure to which some Chinese immigrants are accustomed may change, with a resulting loss of decision making power by the male. This shift in power relations has been found to be a leading predictor of domestic violence.

In some cultures where women may have financial dependence on their husband, they may be reluctant to report abuse due to lack of independent resources. Undocumented family members may be at higher risk of both abuse and inability or unwillingness to report the abuse due to fear of deportation. In addition, immigrant women may not have information about shelters that can assist them in leaving the abusive relationship. Language and economic barriers may also impede immigrant women's efforts to obtain information about the legal system within the host country and to avail themselves of legal procedures that may help to alleviate their abusive situations. US-based research has found that the prevalence of domestic violence is similar in immigrant and native communities, but the severity of violence and how each immigrant community addresses the violence varies. It is critical that resources be established within immigrant communities that addresses the need for housing, health, education, and employment, in addition to shelters for women of domestic violence.

Violence Against Women Act

NOËL BRIDGET BUSCH-ARMENDARIZ
School of Social Work, Center for Social Work Research, The University of Texas at Austin, Austin, TX, USA

The Violence Against Women Act (VAWA) was signed by US President William Jefferson Clinton in 1994 and was reauthorized in 2000 and 2006. When it was passed, VAWA was considered by many advocates as first and the most comprehensive recognition of and response to domestic violence and sexual assault in US history. In general, the VAWA allocated funding to the states for training, prevention, and intervention services and created new criminal penalties for these crimes.

The Battered Immigrant Women's Protection Act was included in the 2000 reauthorization and provided additional legal remedies for immigrant or noncitizen battered victims. Today, three legal remedies exist for noncitizen immigrant victims of domestic violence: self-petition, cancellation of removal, and battered spouse or child waiver. The self-petition remedy allows noncitizen domestic violence victims, who were married to or recently divorced from a US citizen or legal permanent resident, to apply for legal permanent residence without the assistance of the abusive partner. To make these claims respondents must show a history of substantial physical or mental abuse in the context of an intimate relationship. Cancellation of removal is a remedy for noncitizens that are in or in threat of being placed in deportation proceedings. The Battered Spouse or Child Waiver is for victims who have a conditional "green card." This remedy allows for the conditional permanent residency requirement to be waived before the typical 2-year period. These legal remedies explicitly recognize the power and control dynamics experienced by noncitizen immigrant victims.

Noncitizen victims and their legal representatives are utilizing these remedies in federal immigration courts. Many of these cases are being handled by faculty and law students working in immigration clinics in schools of law, by nongovernmental organizations, and individual attorneys often on a pro bono basis. For example, American Gateways (formerly known as Political Asylum Project of Austin) in Austin, Texas, has a program to provide free and low cost legal services to immigrant battered victims. Many other organizations and individual attorneys throughout the USA also provide these vital legal services to noncitizen battered victims.

Immigration law is very complex, and therefore experts are often needed to provide clarification on substantive issues related to the claim. Experts may also offer the court an opinion on the credibility of a respondent and the consequences of deportation in VAWA cases. Experts are also often needed to educate the court on the prevalence, dynamics, and complexity of domestic violence, the effects of trauma and abuse on victims, the impact of deportation on the victim and children, and may need to discuss a lack of resources or dynamics of how domestic violence is viewed in the respondent's country of origin.

Vision and Eye Care

Sylvia H. Paz
Division of General Internal Medicine & Health
Services Research, Department of Medicine, University
of California Los Angeles (UCLA), Los Angeles,
CA, USA

Blindness and visual impairment are one of the top five leading causes of disability in the USA. Representing a critical public health problem, these conditions have a major impact on society as well as on individual's quality of life. Having a history of eye disease – cataracts, diabetic retinopathy, macular degeneration, and glaucoma – has been associated with having a higher risk of visual impairment and blindness.

Because prevalence and progression of most of these eye diseases can be controlled with adequate and timely vision care, the importance of routine eye examinations cannot be overstated. National guidelines suggest a comprehensive dilated eye exam once a year for the general population over 40, and more often for those with a history of eye disease.

Latinos comprise the largest minority group in the USA and the fastest growing segment of the population. From a socioeconomic and biologic perspective, Latinos seem to be at a higher risk for visual impairment and blindness. Additionally, Latinos are overrepresented amongst immigrants with lower health care quality and thus too often do not receive the eye care they need. For example, Latinos comprise over 90% of hired farm workers in the USA. Of this subgroup, more than two thirds have never had an eye health care visit. Lower socioeconomic status and poor health literacy are examples of some of the factors that are present at a higher rate in immigrant subpopulations, and that are often associated with worse care. Most studies done on immigrant populations have focused on maternal and child health, depression, infectious diseases, tobacco and substance use, chronic diseases, and cancer. Vision and eye care have not been commonly studied. This is important because of the existing disparities that exist in relation to actual eye care. Especially concerning is the fact that there is a growing older population and that many eye diseases are treatable and preventable when diagnosed in their early stages. For example, those who are over 65 are at a higher risk of having other medical problems such as hypertension and diabetes mellitus that cause direct changes to the retina when poorly controlled. These conditions may result in subsequent vision impairment and other eye problems which elevate the risk of vision loss. The Los Angeles Latino Eye Study is the first and largest epidemiologic study of eye disease in the Latino population in the USA. Furthermore, it is the first investigation of its kind to evaluate the prevalence of blindness and visual impairment, as well as major eye diseases in the Latino population.

Eye Care Use in Latinos

Visual impairment and blindness may cause significant morbidity and mortality when not appropriately and timely treated. These conditions especially affect health and quality of life in older adults. Activities of daily living, psychological health, physical health and work-related activities are some examples of how visual impairment may affect subjects. Significant disparities among different segments of the population have been extensively reported. Latinos are one of these groups which are not receiving adequate eye care per recommendations of the American Academy of Ophthalmology. Data from the Los Angeles Latino Eye Study revealed that approximately 63% of the study participants had eye diseases which had not been previously detected. For example, more than 75% of the people with glaucoma in this study, a potentially blinding condition, had no history of the disease or treatment. In the case of age-related macular degeneration, the leading cause of visual impairment and blindness in the USA, only 21% of study participants with the disease had visited an eye care provider in the last 12 months, as recommended per guidelines. Lastly, Latinos have a high prevalence of diabetes mellitus. Diabetic retinopathy is an ocular disorder which is a frequent complication of diabetes. Sixty-five percent of those study participants with diabetes had not complied with vision care guidelines for people with this disease. Language differences, health education, having diabetes, and insurance coverage are primary risk factors for not getting appropriate and needed eye care in this population. Facilitating vision care access and thus providing timely detection and treatment of eye diseases would greatly decrease the burden of visual impairment and blindness in this population.

Visual Impairment and Blindness in Latinos

A person is visually impaired when daily activities are challenging even when wearing regular glasses, contact lenses, taking medicine, or having had surgery. There is no universally accepted definition of visual impairment. Even though many evaluations solely include a measurement of visual acuity, the definition of visual impairment includes a measurement of peripheral visual field as well. The three most commonly used definitions of visual impairment are:

1. Best-corrected visual acuity (VA) of 20/40 or worse in the better seeing eye (including 20/40). Visual impairment was categorized as mild (20/40–20/63),

moderate (20/80–20/160), or severe (20/200 or worse).

2. Best-corrected VA worse than 20/40 but better than 20/200 (not including 20/40 or 20/200).
3. Best-corrected VA worse than 20/63 but better than or equal to 20/400 (not including 20/63 but including 20/400). This definition has been used by the World Health Organization.

Data from the Los Angeles Latino Eye Study suggest that Latinos have a higher age-specific rate of visual impairment than other ethnic groups in the USA. The overall prevalence for visual impairment was 3.0% with a range that went from 0.9% for the younger subjects (40–49 years) to 27.8% for the older subjects (≥80 years). The overall prevalence of blindness was 0.4% with a range from 0.2% for those 40–49 years old, to 4.2% for those 80 or older. Higher rates were seen in older Latinos as well as in female Latinos. Commonly found risk indicators were lower socioeconomic status, unemployment, having lower levels of education, having a history of eye disease, and having diabetes. Those with higher levels of education (12 or more years) were less likely to be visually impaired. In comparison to other ethnic groups in the USA, this study confirmed Latinos having the highest age-specific rates of visual impairment of any racial/ethnic group in the USA. Specifically, Latinos seem to have higher prevalence of visual impairment and blindness than non-Hispanic Whites in the USA, and lower prevalence than African Americans only in the younger ages but higher rates in older individuals. Screening and early treatment would thus be helpful to decrease the burden of eye disease caused by visual impairment.

Lens Opacities

Lens opacities or cataracts, which are mostly related to aging, are a clouding of the lens in the eye which affects vision. Cataracts are the leading cause of visual impairment in the USA. As with most eye diseases, prevalence is more common after 40. However, even though people may have cataracts in their 40s and 50s, cataracts start affecting vision on those subjects who are 60 or older. There are three major types of age-related lens opacities categorized based on their location. Nuclear opacities occur in the central region of the lens; cortical occur in the region surrounding the central core; and posterior subcapsular opacities occur at the back of the lens. The Lens Opacities Classification System II (LOCS II) is a system based on photographic standards to classify the severity of cataracts. There are three definitions of lens opacities: "*All lens changes*" are defined with the presence of at least one gradable lens opacity according to the LOCS II; "*Any lens change*" is defined as any of the three types that is gradable in either eye; and "*Single and Mixed lens changes*" of opacities refers to the presence of one or more different types of opacities in one subject.

Data of the Los Angeles Latino Eye Study reveal that all types of lens opacities increase with age. Twenty percent of study participants had "*all lens changes*," 7.6% had cortical-only opacities, 3.5% had nuclear-only opacities, 0.4% had PSC-only opacities, and 5.9% had "*mixed-type opacities*." Latina women have a significantly higher rate of lens opacities than Latino men. As in the general population, the risk of cataracts increases with age, diseases like diabetes, exposure to sunlight, and personal behaviors such as smoking and alcohol intake. The study data also revealed significant visual impairment associated with lens opacities. This is important because cataracts are a treatable cause of vision loss; therefore the importance of timely vision care cannot be overestimated in the reduction of visual loss in Latinos.

Diabetic Retinopathy

Diabetic retinopathy is a leading cause of vision loss in the USA, the most common eye disease in people with diabetes. It is one of the complications of diabetes and the most common of those which affect the eye. It is caused by changes in the blood vessels of the retina. People with diabetes are at a significantly higher risk of losing their vision than those without the disease. When left untreated, diabetic retinopathy may cause severe vision loss or blindness. There are four stages of diabetic retinopathy: mild nonproliferative retinopathy, the earliest stage with small areas of swelling in the retina's blood vessels; moderate nonproliferative retinopathy some progression with some blocked blood vessels; severe nonproliferative retinopathy with more blocked blood vessels starting to leave some areas of the retina with no available blood; and proliferative retinopathy in which new blood vessels start appearing as the retina sends signals of undernourishment. These new blood vessels are abnormal and while they do not directly cause vision loss, they are fragile and can leak which consequently may cause severe vision loss or blindness.

There is an increased risk of diabetic retinopathy with longer duration of diabetes. Furthermore, Latinos have a high prevalence of type 2 diabetes mellitus and therefore are at a greater risk of developing diabetic retinopathy. Data from the Los Angeles Latino Eye Study revealed a threefold increase in risk of visual impairment in persons with diabetic retinopathy versus those without diabetes. Of those participants with diabetes mellitus, 46.9% had diabetic retinopathy. Data from this study also revealed that lower education, being uninsured, not having had a routine physical examination in the previous year, and having higher levels of glycosylated hemoglobin were risk indicators for increased noncompliance with recommended vision care. Even though comparisons of the prevalence of diabetic retinopathy among different groups are difficult because of different definitions and techniques used, data from this study suggest that Latinos may have higher rates of more severe diabetic retinopathy which affects vision, when compared to non-Hispanic Whites in the USA. Given that vision loss from diabetic retinopathy can be prevented with timely vision care, guidelines recommend that subjects with diabetes have a dilated eye examination at diagnosis and yearly thereafter.

Glaucoma

Glaucoma is the second leading cause of blindness worldwide. Glaucoma refers to the disease in which the pressure inside the eye increases damaging the eye's optic nerve. When left untreated, glaucoma may result in vision loss and blindness. However, vision loss can be avoided with early treatment. Any increase in ocular hypertension does not mean that the subject has glaucoma, but rather the subject is at an increased risk of developing glaucoma. Glaucoma is defined only after the optic nerve has been damaged. This damage can happen at different levels of high pressure for different individuals. Data from the Los Angeles Latino Eye Study revealed an overall prevalence of glaucoma of 4.74% and of ocular hypertension of 3.56%. Three risk factors were associated with glaucoma in the Latino population: age, family history, and diabetes mellitus. In fact, the oldest group of Latinos ($\geq$80) had a 20-fold higher risk than the youngest age group in the study (40–49 years) while siblings showed a higher risk for glaucoma than the parent–child relation. With regard to diabetes, study participants with the disease had a prevalence of glaucoma 40% higher than those without diabetes. With regard to demographic risk factors, study data showed a higher risk of glaucoma in males, unmarried status, and being unemployed. When comparing the result of this ethnic group with others in the USA, the rates of glaucoma were significantly higher than those of non-Hispanic Whites. Latinos also have a high prevalence of ocular hypertension when compared to other ethnic groups. Over 75% of study participants with glaucoma were previously undiagnosed. This rate is higher than most rates found in other population-based studies stressing the need for timely eye care services in this population.

Age-Related Macular Degeneration (AMD)

AMD, the leading cause of visual impairment and blindness in the USA, is a disease that affects the macula by blurring the central vision or the vision needed to see clearly straight ahead. It is associated with aging and gradually affects the sharpness impeding to see fine detail. There are two types of AMD: wet and dry. Wet AMD occurs when abnormal blood vessels start to grow under the macula and often leak blood or other fluids. Damage to the macula occurs producing fast loss of central vision. In the early stages of wet AMD straight lines start appearing as wavy. Dry AMD has three stages: Early AMD is when people start having drusen, yellow deposits under the retina which do not cause vision loss, but when they start to grow in number and size, the risk for AMD starts increasing; intermediate AMD has either many medium-sized or a few large drusen and some blurred spots may start appearing; advanced AMD occurs when people have a breakdown of light-sensitive cells in the central retina in addition to drusen. The blurred spot in the center starts growing. Data from the Los Angeles Latino Eye Study revealed an overall prevalence of early AMD of 9.7% (range from 6.2% to 29.7% in those younger subjects 40–49 years to those 80 or older), and overall prevalence of advanced AMD of 0.5% (ranging from 0% to 8.5% in those same age groups). Risk factors for

AMD found in this study are age, smoking, obesity, race, family history, and being female. Even though the risk of developing increases with age, Latinos appear to have comparable rates of AMD when compared with other ethnic groups. However, a considerably high percentage of AMD in Latinos is undiagnosed. Specifically 98% of AMD detected in the Los Angeles Latino Eye Study had not been previously diagnosed.

Eye Care in Latinos

When compared with other ethnic groups, Latinos in the USA have one of the highest rates of visual impairment. Visual impairment and blindness are associated with untreated eye disease. Latinos have a high prevalence of diabetes and therefore are at a greater risk of diabetic retinopathy. Latinos also have a high risk of cataracts and glaucoma. Many risk factors for undetected eye disease are present at a higher rate in this population. Some of these factors which are sociodemographic and modifiable are lower socioeconomic status, lower education status, lower acculturation, being uninsured, and never having had an eye examination. The American Academy of Ophthalmology recommends that Latinos who are a high-risk population group receive a comprehensive eye examination every 1–3 years between the ages of 40 and 54 years, every 1–2 years between the ages of 55 and 64 years, and every 6–12 months after the age of 64 years. Given the high rates of undiagnosed eye disease, blindness, and visual impairment, data suggests that this ethnic group is not receiving recommended vision care. Although visual impairment and blindness are largely preventable, they will continue to be an important health problem in aging Latinos, without increased use of eye care services.

Vitamins

Kristin A. Cassidy, Hiren C. Bhakta
Department of Psychiatry, Case Western Reserve
University School of Medicine, Cleveland, OH, USA

Vitamins are organic molecules that are crucial for normal function and growth. They are used by the body to create energy and build important biological compounds. Only a relatively small amount of vitamins are required to survive compared to carbohydrates, fats, and proteins. The word “vitamin” can also be used to refer to these nutritional compounds when found in food sources or to a pill or tablet supplement that contains one or more of the compounds.

When a person shows signs and symptoms of not consuming enough of a vitamin, it is considered a vitamin deficiency. The opposite situation, vitamin toxicity, occurs when a person shows signs and symptoms of having consumed too much of a particular vitamin.

The classic example of vitamin deficiency that occurs with immigration is Vitamin D deficiency where an individual migrates from a climate with more sun exposure to a climate with less. Factors such as skin color and lifestyle changes associated migration also compound the risk. Vitamin A is another vitamin that has been documented to be potentially deficient in immigrants. This is because there are different types of vitamin A and the foods that normally contain them may change in availability for the immigrants. Folate has been shown to benefit pregnant women and their newborns in developed countries such that taking extra folate in vitamin form is standard care during pregnancy. Despite the availability of vitamins, some women fail to take these vitamins because they are unaware of their benefits. In some cases the women choose to manage their prenatal care by the standards of the country from which they emigrated. Finally, it is important to recognize that the immigrants from some countries may have different beliefs regarding the practice of medicine than what is accepted by developed countries and the World Health Organization. For example, Ayurvedic medicine in India is a traditional model of medicine that offers a variety of treatments in the form of natural products and supplements, often called “vitamins” by those that use them. There have been cases reported of lead or mercury toxicity after taking these types of vitamins and furthermore some products are sold by frauds and do not contain what is advertised. The National Center for Complementary and Alternative Medicine is a US institute that studies the products of variant medical practices to assess scientifically whether they are effective or not and may be a useful resource for a practitioner that comes across an immigrant taking a foreign “vitamin.”

Health professionals often subdivide vitamins into two main categories, *fat-soluble* and *water-soluble*, based on the chemical properties of the vitamin (Table 1). This chemical difference is reflected in the way the human body digests, stores, utilizes, and excretes the vitamins. This important distinction has several clinical applications.

The fat-soluble vitamins are Vitamin A, D, E, and K. While each individual vitamin has its own specific properties, as a group there are several common traits. For fat-soluble vitamins, the body is only able to absorb these vitamins along with fat or oil. Therefore, when eating foods rich with fat-soluble vitamins, it is important to eat something that contains at least a small amount of fat in order to allow the body to transfer the vitamin from the digestive tract into the blood stream. For example, when eating a salad, it is important to use a dressing that contains some oil or fat in order for the body to make use of the fat-soluble vitamins that are in the vegetables. Furthermore, any problems in the digestion or absorption of fat, resulting from a number of medical conditions (e.g., celiac disease, Crohn’s disease, cystic fibrosis), can result in fat-soluble vitamin deficiency.

Once in the blood stream, fat-soluble vitamins are delivered to tissues by special molecules, called micelles, formed from chylomicrons and lipoproteins (a type of fatty protein). Fat-soluble vitamins are stored in fatty tissue and the liver. The body can maintain normal function for periods of time without the intake of these vitamins by using what is stored. However, if intake of the fat-soluble vitamins does not resume once the stores are depleted, it can lead to deficiency. Since fat-soluble vitamins are stored in this way and are not excreted as efficiently as water-soluble vitamins, high intake of these types of vitamins have a greater potential to lead to toxicity.

The water-soluble vitamins are each of the Vitamin B subtypes (Vitamin B1, B2, B3, B5, B6, B7, B9, and B12) and Vitamin C. Water-soluble vitamins are dissolved in water and are therefore sensitive to the way the foods containing them are processed and cooked. Steaming is the preferred method of preparing foods that contain water-soluble vitamins to ensure that these essential nutrients remain available for use by the body. Since food is not fully submerged in water during steaming, this process retains more water-soluble vitamins than boiling does.

Vitamins. Table 1 Key facts about specific vitamins

Vitamin	Also known as	Primary Functions	Potential Sources	Special Considerations
Fat-soluble vitamins				
A	Carotenoids Alpha-carotene Beta-carotene Beta-cryptoxanthin Retinol	Bone development Cell growth Healthy skin Immune system Reproduction Vision	Carotenoids: Broccoli; cantaloupe; carrots; mangoes; peaches; romaine lettuce; spinach; sweet potatoes. Retinol: eggs; fish; fish oil; fortified cereal, juice, and milk; liver.	*Carotenoids* are converted by the body into **Vitamin A**. **Retinol** is preformed **Vitamin A**. Most American diets consist of foods with high amounts of **retinol**, but diets from other parts of the world, especially from impoverished areas, rely primarily on **carotenoids** in fresh fruits and vegetables. It is possible to develop toxicity from consuming too much **retinol**, but not from **carotenoid**.
D		Regulates calcium absorption Bone formation Bone break down Maintains normal levels of calcium in the blood	Egg yolks; fatty fish; enriched milk and cereal; liver; sunlight. Sunlight exposure initiates a reaction in the body that produces Vitamin D.	The rates of **Vitamin D** deficiency are high in developing countries. Sunlight is the main way humans get enough **D**. Factors such as the use of sunscreen and length of time spent outside impact the ability of the body to utilize sunlight to create **D**. In climates that do not get much sunlight and during seasons when there is not much sun, it is important to get **D** from other sources. Aside from fortified products, dietary sources often do not supply adequate amounts of **D**. Lighter skinned people require less sunlight than darker skinned people to create the required amounts of **D**. Problems in bone structure and formation become apparent when an individual is **D** deficient. Rickets, osteoporosis, and osteomalacia are types of bone disease associated with **D** deficiency.
E	Tocopherol	Antioxidant Red blood cell production Helps the body to use Vitamin K	Almonds; asparagus; avocados; corn; nuts; olives; peanut butter; spinach; sunflower seeds; vegetable oils such as sunflower, corn, and soybean.	Smokers require higher levels of **Vitamin E**. Low fat diets are vulnerable to **E** deficiency because generally fats are a rich source. **Vitamin E** is susceptible to damage in processing, preparation and storage. Individuals taking blood thinners or other medications should check with their medical provider before taking **E** supplements.

Vitamins. Table 1 (continued)

Vitamin	Also known as	Primary Functions	Potential Sources	Special Considerations
K	Phylloquinone/ phytol Menaquinone Naphthoquinone	Blood clotting May help build and maintain strong bones	Bacteria that naturally live in the colon; broccoli; cauliflower; green beans; green leafy vegetables; some vegetable oils; soybeans.	Long-term use of antibiotics may kill the **Vitamin K** produced by the gastrointestinal tract. Blood thinners and other medications are affected by **K** intake.
Water-soluble vitamins				
B1	Thiamin Thiamin pyrophosphate (TPP)	Breakdown of food into energy Heart functioning Muscles Nervous System	Asparagus; brown rice; cereals; eggs; flour tortillas; kale; liver; oranges; pork; potatoes; whole grain bread; yeast. Absent from white rice and processed carbohydrates.	Beri beri and Wernicke-Korsakoff Syndrome are two important deficiencies that can occur when not enough **thiamin** is consumed. Alcoholism is associated with these deficiencies because it disrupts the body's ability to absorb **thiamin**. Some foods in developed countries are fortified with **thiamin**.
B2	Riboflavin	Breakdown of food into energy Healthy skin Red blood cell production Tissue repair	Asparagus; bananas; dairy products; eggs; fortified cereals; green beans; green leafy vegetables; kidney; liver; meat; nuts; okra; yeast.	**Vitamin B2** degrades when exposed to sunlight. Foods containing this vitamin should be stored in opaque containers. Milk is an important source of **B2**. In cultures that do not emphasize dairy in the diet, other sources must be identified to provide adequate levels.
B3	Niacin Nicotinic acid Nicotinamide	Breakdown of food into energy Digestive system Healthy nerves Healthy skin	Bread and enriched bread products; eggs; fish; meat; mushrooms; nuts; poultry. Can be created in the body from protein rich foods containing tryptophan (such as turkey).	Diets based heavily on corn or maize, are at risk for niacin deficiency. Pellagra, caused by a **Vitamin B3** deficiency, can be avoided if the corn is prepared in a way that releases the vitamin from the plant. Large doses can cause serious side effects such as liver damage, ulcers, and rashes. **Niacin** has been found to lower levels of LDL cholesterol and triglycerides and to raise levels of HDL cholesterol.
B5	Pantothenic acid Part of Coenzyme A	Breakdown of food into energy Growth	Broccoli; dairy; eggs; fish; legumes; meat; sweet potatoes; whole grain cereals; yeast. Made by intestinal bacteria.	It is rare to find a **Vitamin B5** deficiency. Occasionally it is seen in alcoholics and many times it is associated with other B vitamin deficiencies.

Vitamins. Table 1 (continued)

Vitamin	Also known as	Primary Functions	Potential Sources	Special Considerations
B6	Pyridoxal Pyridoxal phosphate (PLP) Pyridoxamine Pyridoxine	Breakdown of protein Healthy brain function Nerve function Production of antibodies Red blood cell production	Bananas; beans; cantaloupe; legumes; meat; nuts; oranges; papaya; whole grains.	Large doses can cause numbness and neurological disorders. Deficiencies can cause confusion, depression, irritability, and sores in the mouth and are often associated with alcoholism. Certain medications including isoniazid (given for tuberculosis) and theophylline (for asthma) reduce the amount of **Vitamin B6** available in the body.
B7	Biotin	Breakdown of food into energy Growth	Grains; egg yolk; kidney; liver. Made by intestinal bacteria.	Critical for the healthy development of a newborn. Deficiency can cause hair loss and scaly rashes. Consumption of raw egg whites can cause problems with the absorption of **Vitamin B7**.
B9	Folacin Folate Folic Acid Pteroylglutamic acid	Breakdown, use, and creation of protein Cell growth and division DNA production Red blood cell production	Beans; citrus fruits and juices; dark green leafy vegetables; fortified cereals and grains; legumes; liver; nuts; pork; poultry; shellfish; whole grains. Processing, preparation, and exposure to light readily destroy this vitamin.	Many food products are enriched with **folate** in developed countries. **Folate** is crucial for the health of a developing baby, especially during the first few weeks of pregnancy (when a woman may not even realize she is pregnant). Women who may become pregnant are advised to take supplemental **folic acid** to prevent birth defects.
B12	Cobalamin	Breakdown of fat Maintenance of the Central Nervous System Red blood cell production Replenishes various enzymes in the body	Dairy; eggs; fish; fortified grain products; meat; poultry; shellfish.	Can be stored in the body for future use. It can be stored in the liver for years. Requires special secretions in the stomach to be properly digested. Individuals who have had certain types of stomach or small intestine surgery must take **Vitamin B12** supplements. **B12** deficiency can cause anemia.
C	Ascorbate Ascorbic acid	Antioxidant Assists in the absorption of iron Collagen production Essential in healing of wounds Growth and repair of tissue Repair and maintenance of bones, cartilage, and teeth	Broccoli; cantaloupe; citrus fruits and juices; green peppers; leafy green vegetables; strawberries; sweet and white potatoes; tomatoes. Vitamin C is very sensitive to heat and light, and can be damaged during processing, cooking, or storage.	Severe **Vitamin C** deficiency is referred to as scurvy. Some signs of scurvy include anemia, bruises around hair follicles, fatigue, depression, and bleeding gums. Scurvy is usually seen in malnourished older adults. Areas of the world that do not have access to fruits and vegetables have higher levels of scurvy. Cigarette smokers require higher amounts of **C** than nonsmokers.

Once water-soluble vitamins enter the body, they are available for use by all cell types via the blood stream. With the exception of Vitamin B12, water-soluble vitamins are not stored for long periods of time by the body and are readily excreted in the urine. Therefore it is important to ensure that these types of vitamins are consumed daily. Many foods are fortified with these types of vitamins in the United States.

The World Health Organization and the Food and Agriculture Organization of the United Nations established the Codex Alimentarius Commission, which has created international standards and guidelines for food since 1963. Many developed nations have their own standards and guidelines that are utilized in lieu of the Codex Alimentarius. When considering the amount of vitamin an individual must consume per day to maintain good health, there are two different organizations that offer recommendations in the United States, The Food and Nutrition Board and The Food and Drug Administration.

The Food and Nutrition Board has conducted large population studies since 1943 to determine the amount of nutrients required for subgroups of individuals. These recommendations are called *Dietary Reference Intakes* (DRIs), and more specifically this umbrella term describes a set of values that includes Estimated Average Requirements (EARs), Recommended Dietary Allowances (RDAs), Adequate Intakes (AIs), Estimated Energy Requirements (EERs), and Tolerable Upper Levels (ULs). These values are specific for each nutrient and account for factors such as age, gender, and pregnancy status. Health professionals (e.g., nutritionists and dieticians) utilize these recommendations to make appropriate individualized plans for their patients.

The Food and Drug Administration (FDA) has its own set of recommendations that are called *Daily Values*. These values are an aggregate of Reference Dietary Intakes, which are used for vitamins and minerals, and Daily Reference Values, which are used for nutrients that do not have an established RDA. These values are used to convey the amount of nutrient in a food relative to the total amount of that nutrient that is recommended to be consumed daily. For vitamins this is reported on nutrition labels as a percentage.

Immigrants need to be aware of different labeling standards in their new country. Changes in the consumption of different vitamins due to the culinary culture of a new home country may cause health issues for some individuals. In addition to vitamin deficiencies caused by diet changes, individuals migrating from locations close to the equator to climates closer to the poles should be aware of a potential for Vitamin D deficiency due to the relatively lower levels of exposure to the sun. Most vitamin-related health issues in immigrants can be corrected by adjusting diet or adding vitamin supplements.

Vulnerable Populations

Oana C. Stinga
University of Medicine and Pharmacy "Gr. T. Popa",
Iasi, Romania

Despite the widespread use of the term, there is no single definition of vulnerability and its conceptualization varies across discipline. The word itself derives from the Latin word *vulnerare*, meaning "to wound." The concept of vulnerability is applied to various populations in the context of health care in order to establish how health care resources are to be allocated and who is to be considered eligible for special benefits, and in the context of health research to identify those who must be afforded special protections in order to protect them from potential exploitation and abuse. Vulnerability in the context of health care may result from the delivery of health care services on the basis of color, class, caste, religion, age, ability to pay, or other characteristics of the population, rather than on the basis of need. As a result, these persons are at increased risk for morbidity and premature mortality.

In the context of health research, vulnerability may also result from illness, an inability to access needed care, cognitive challenges or limitations, societal marginalization and disempowerment, and/or reduced control over one's own environment and decision making. As a result, these persons may be at increased risk of exploitation and abuse in research. Kipnis developed a taxonomy that distinguishes between six types of vulnerability within the research context: cognitive, juridic, deferential, medical, allocational, and infrastructural.

In general, vulnerability results when a group lacks adequate power, prowess, intelligence, resources, strength, or other needed attributes to protect its own interests. Although vulnerability is generally conceived of as a characteristic that is fixed and immutable, this definition suggests that vulnerability of populations may change over time as groups gain or lose power or other resources necessary for their informed and voluntary decision making. The definition further suggests that membership in a population identified as vulnerable may shift over time. As an example, immigrants as a group might be considered to be vulnerable due to an inability to navigate the health care system of their new country, an inability to speak the language of the host country, difficulties in adjusting to their new environments, and the stress of migration. However, there is a significant difference between an individual who immigrated recently and one who immigrated as a young child 40 years previously. Accordingly, although groups may continue to be identified as vulnerable, the individuals within those groups may no longer be individually vulnerable. In the context of research, the researchers must achieve a balance between protecting the vulnerable group and recognizing and respecting the autonomy of each individual participant.

In contrast to the previous conceptualization of vulnerability, some scholars have suggested that vulnerability attaches to groups which, within a specific society, have been devalued on the basis of one or more characteristics, e.g., race, ethnicity, religion. In this case, the characteristic of the group is not immutable and the vulnerability of the group cannot change in the absence of a redistribution of power within that society.

In the context of research, the classification of populations as vulnerable varies depending upon the laws and regulations adopted with the particular country. International documents related to ethics in research and scholarly literature in the field of bioethics have characterized these populations as vulnerable: homeless persons, immigrants and refugees, mentally ill and disabled persons, chronically ill and disabled individuals, individuals who are suicidal or homicidal, families characterized by abuse, persons living with HIV/AIDS, mentally ill and disabled individuals, high-risk mothers and children, residents of rural areas, non-English speakers, individuals lacking access to health care, racial and ethnic minorities, economically disadvantaged persons, those who are educationally disadvantaged, soldiers, and students.

The concept of vulnerability is not without controversy. It is often noted in the literature that vulnerability is an inherent aspect or characteristic of human existence. DeBruin has argued that, in the context of research, groups should not be identified as vulnerable and that the focus should be placed on the concepts of special risk and empowerment. Kottow suggests that a distinction must be made between the concepts of vulnerability and susceptibility. He argues that vulnerability is encompassed within the principle of justice and requires the equal protection of all members of a society, whereas susceptibility refers to a state of destitution which must be specifically designated in order to trigger the application of palliative measures. Some scholars' writings have suggested that the categorization of populations as vulnerable subjects those persons to pity and that the use of the term is paternalistic and demeaning.

War-Affected Children

Suzanne Mallery
Department of Psychology, La Sierra University,
Riverside, CA, USA

Exposure to war has particularly pernicious and wide-ranging effects on children beyond the risks associated with actual physical injury or death. Armed conflict disrupts education; forces families to flee their homes; separates children from their parents and relatives; destroys health care systems; produces shortages of food and clean water; and puts children at risk of being coerced into child labor, prostitution, or soldiering. In short, war disrupts all of the familial and societal safety systems that allow this vulnerable group to mature into healthy, productive adults. In the Democratic Republic of the Congo in the first decade of the twenty-first century, for example, a series of mortality studies by the International Rescue Committee demonstrated that in war zones, indirect consequences of war such as starvation and disease may account for as much as 86% of fatalities due to war, with children being disproportionately affected.

Child protection in the climate of modern warfare is particularly difficult. Unlike wars of the past, which were largely between states, the wars of today are increasingly internal conflicts involving non-State actors such as drug cartels, Al Qaida, and national resistance movements, often with varying levels of support from States. Many of the traditional protections afforded by the Geneva Conventions, treaties and other instruments of international law, and peacekeeping forces are explicitly intended to apply conflicts between States rather than to conflicts involving non-State actors. While States are signatories to treaties and conventions on human rights, many non-State actors feel free to disregard such conventions, putting children at increased risk with fewer international resources to protect them. An even more concerning trend is that children and other civilians are increasingly targeted as victims in modern warfare.

In times of armed conflict, the loss of family and social protection for children occurs for a variety of reasons. Education may be disrupted for obvious reasons such as destruction of school buildings or unsafe roads between homes and schools, but also because of lack of availability of teachers, use of school buildings to house displaced persons, or a need for children to carry out the duties of adults who are fighting or have been killed. Additionally, schools have increasingly become targets of attacks, an offense designated as a grave human rights violation under humanitarian law.

Children and families may be displaced because conflict has limited access to some other necessity. For example, even if there is no active fighting in an area, destroyed irrigation systems or the recruitment of child soldiers may mean that abandoning the home becomes the only option for survival. Children and families may end up in refugee camps or temporary housing or they may become homeless. Children who become separated from relatives or who are orphaned are at especially high risk because they need to fend for themselves. Such children are particularly vulnerable to rape and ongoing victimization such as recruitment into child soldiering, slavery, unwanted marriage, or prostitution. Registration, child protection, and family tracing are key components of intervention programs designed to aid unaccompanied children.

Increasingly, children are also threatened by abduction in times of war as a way of terrorizing civilian

Sana Loue & Martha Sajatovic (eds.), *Encyclopedia of Immigrant Health*, DOI 10.1007/978-1-4419-5659-0,

populations. Such children may be abducted from homes, refugee camps, or schools and may be forced into slavery, nongovernmental armed forces, or trafficking for sexual purposes. Children who become soldiers generally witness and are forced to participate in murder, sexual assault, and torture, and girls often are forced to sexually service the males of the group. Drug problems are rampant. Once the children have participated in such activities, they fear they will not be accepted back into the community and fear for their lives at the hands of their fellow soldiers. Such children become deeply traumatized, and the process of rehabilitation is difficult. Rehabilitation programs are sponsored by a variety of international groups and consist of disarmament, demobilization/demilitarization, and rehabilitation and reintegration into the community (DDR). The goal of such programs is to assist former child soldiers to become accepted, productive members of their communities and to address problems that arise as a result of their participation in armed combat. Unfortunately, such programs are not always well-suited to the needs of girls, who often are not combatants, but are used as cooks or sexual slaves. Such girls and any children born to them need to be a focus of renewed effort in the implementation of these programs.

As terrorism has increased and children have been used in terrorist plots or as combatants, the arrest and detention of children in times of war is an increasing problem. Such children may be held in ways that violate international juvenile justice standards, and their detention may continue after hostilities have ceased. Additionally, children may be used to place or smuggle small arms or landmines, and children are disproportionately victims of landmines and unexploded ordnance for years after the cessation of hostilities.

Children subjected to the adversities of conflict are often affected for many years. Their physical and mental scars may impact them for life, and disrupted education decreases their future earning power and the potential to improve their standard of living. Although many children are never able to surmount such obstacles, a surprising number of children are resilient in the face of adversity. Protective factors that contribute to resilience include individual factors, such as strong social skills and the ability to find meaning in the situation through religion or a personal value system; family factors, such as the presence of a caring parent who protects and supports the child; social support from the community or peers; a caregiver who manages stress well; adequate child care and education systems to maintain a sense of normalcy; and cultural and political values emphasizing and funding the support of children and other vulnerable parties. When intervention programs support such factors, children have a greater chance of being resilient in the face of conflict.

Finally, there are a variety of international legal mechanisms to support children's rights and secure justice for children who have been caught in wars and other conflicts. The United Nations Convention on the Rights of the Child focuses on children's rights to safety, education, care from a parent or parent-substitute, health services, protection from abuse, and freedom from exploitation or unreasonable detention. There are also two Optional Protocols to the Convention that protect children from participation in armed conflict and trafficking/sexual slavery. The United Nations, regional organizations, individual States, and NGOs are all charged with ensuring these rights, and war crimes affecting children are under the jurisdiction of the International Criminal Court (ICC).

The nature of modern conflicts, documentation of the effects of war on children, and our understanding of factors that contribute to resilience all need to be considered in developing truly effective child protection programs for the children of the twenty-first century. Over the past few years, international humanitarian law has begun to be applied to non-State actors perpetrating war crimes against children. This is a promising trend and highlights the need for creative thinking and the development of new policies and programs better suited to modern types of conflict. New ways of addressing the protection of children in times of conflict are essential for the rebuilding of shattered societies.

Water

Harry D. Hatters
Volunteer on Water Projects, Cleveland Catholic Charities-Diocese of Cleveland, Cleveland, OH, USA

Water is necessary for sustaining all life and, while abundant, is neither uniformly distributed nor universally pure. The importance of water to all life is demonstrated by the general concentration of living species in and around water sources. Indeed, physical health (and economic health) of a community is intrinsically connected to the availability of water resources. The prosperity of agricultural enterprise, animal husbandry and many industrial ventures depend directly on water availability, while water quality and associated hygiene practices to a large extent determine the physical health of community inhabitants.

The lack of water distribution is one of several factors resulting in the widespread existence of "subsistence farming" in sub-Saharan Africa and many other parts of the world. The lack of adequate water for farming frequently results in inadequate nutrition or imbalances in the nutrients, vitamins, and minerals in the diets of immigrants adversely impacting their health.

Water Distribution and Quality

The hydrological cycle represents the pattern by which water recycles through the environment. Heat from the sun evaporates water from ocean, lakes, and plant life; evaporation is effective in separation of virtually all contaminants and is a primary mechanism for water purification. Additionally, UV light from sunshine destroys the DNA of many bacteria and viruses. Condensation of airborne moisture in the form of rain or snow is the primary source of both surface water and groundwater available to all biological entities. Surface water primarily occurs in the form of streams, rivers, and lakes, while groundwater (literally water penetrating the earth) travels through the soil to aquifers (i.e., underground beds or layers of permeable rock, sediment, or soil that contains or conducts water). Typically, groundwater enters lakes and rivers through underground springs. Surface water and groundwater generally commingle as water returns to the oceans.

The purity of raw water is largely impacted by the conditions encountered during the path it takes on journeys from the clouds to the user. Condensate from the air will contact particulates, aerosols, and other airborne contaminants, scrub them from the air, and incorporate them into the rain or snow and thus into surface water. During transit, surface water also typically contacts and incorporates numerous surface-dwelling bacteria and viruses from fecal matter of humans and animals, as well as contaminants from farming and industry. By contrast, groundwater traveling within the aquifers, which typically have fine sand and gravel layers, is highly filtered during the low velocity flow (commonly ~15 m/day) of the water through the media. As such, groundwater rarely contains evidence of biological pathogens; however, it frequently contains dissolved salts of the subsurface inorganic materials it contacts. In most instances, the levels of these salts encountered is harmless or even helpful for ingestion; certain other dissolved salts can be hazardous to adults for longer term ingestion (e.g., As, Cd, and Pb) or even short term to infants (e.g., NO3 and Pb). Untreated groundwater (from wells) is typically safer for consumption than untreated surface water because the latter can be contaminated with biological pathogens which can generate severe short-term illnesses.

Waterborne Pathogens Affecting Severe Illness

The impact of water quality on public health has been and continues to be a primary focus of the World Health Organization, WHO, which publishes guidelines for potable water uses. Unfortunately, not all sovereign States provide or enforce regulations based on these guidelines. The WHO water quality guidelines available online provide the most comprehensive current information on water quality.

Microbes such as pathogenic bacteria, viruses, and parasites are the most common and widespread health risk to drinking water. These microbes enter the water either through contact with airborne biological contaminants or more commonly through contact with biological wastes within the soil. The later typically comes from uncontrolled or unsanitary disposal of human or animal wastes. The ability of these pathogens to replicate within the human body makes them a major source of severe infectious diseases. The variety of pathogenic microbes is extensive and the WHO has recommended stringent test procedures and zero tolerance for an indicator microbe (*E. coli* bacteria – ubiquitous in infectious waste products). Rather than identifying a specific bacteria or virus, these tests provide an indication that harmful pathogens are present.

The WHO also publishes guidelines on the maximum desirable chemical contaminant levels (for both inorganic and organic chemicals) in potable water. Most inorganic contaminants in water are harmless or even needed for good health, while others are deemed toxic to the body for long-term exposure (i.e., As, Cd, and Pb). Nitrates (NO_3) in drinking water can be harmful or fatal to infants. More recently, the WHO has undertaken study and development of guidelines for >50 organic chemicals including contaminants in water from human/animal discharge of endocrine disrupters (from pharmaceuticals) as well as byproducts of water disinfection operations (i.e., Trihalomethane (THMs) from reaction of chlorine or other halogen compounds used in water treatment with organic substances in the water). Guidelines also exist for radionuclide content in drinking water.

Since immigrants from rural Third World villages can have a long history of consuming water contaminated with waterborne pathogens, they are frequently observed to have stomach problems (including stomachaches and severe bloating), chronic diarrhea, intestinal worms, or other health problems including river blindness as well as residual issues from these contaminants.

Even in medium-sized to large cities where water treatment infrastructure exists many of the facilities are incapable of providing pathogen-free potable water to the citizenry and the existence of many illnesses or death from waterborne pathogens have been observed. Two colleagues from different major cities privately shared their experiences with the personal loss of loved ones who succumbed to waterborne illnesses. In each case, a breakdown in the water system maintenance was cited as the probable cause of the incursion of the pathogens. In spite of attempts to minimize waterborne diseases, immigrants always have the possibility of presenting such illnesses regardless of the areas from which they hale.

Waterborne Diseases

The majority of waterborne illnesses are caused by contamination of the drinking water supply by bacteria, parasites, protozoa, and viruses. The leading symptom of illness is diarrhea amounting to four billion cases annually and resulting in over 2.2 million deaths with bacterial infection (e.g., Campylobacteria). Dehydration and other illness complications are the major causes of death. Typhoid (17 million cases annually) and cholera (140,000 cases annually) are also major waterborne bacterial infections. Waterborne parasites annually infect >1.5 billion individuals and account for 300,000 deaths, primarily from schistosomiasis. Discussions of specific waterborne infections as well as statistics are available at the World Health Organization (WHO) web site.

Water Quality Impact by Age

Studies have shown that the highest incidence of death from waterborne diseases occurs in children between the ages of 1 and 5. Prior to age of 1 year, most children in rural villages are breast-fed and the infant is generally not exposed to waterborne pathogens. By age 1, the infant's immune system has begun development but is ill-equipped to deal with the bacterial or viral contaminants in the water available to many poor villagers. When adequate precautions are taken, such as boiling, filtering, or chlorinating of the water, the infant will be able to attain 5 years with a minimum of disease complications from ingesting the impure water. By age 5, the child's immune system is usually more robust and able to deal with many waterborne pathogens.

Urbanization of Population

Immigration (or the movement of people to a nonnative region) has generally consisted of the uprooting of individuals or families from poor, rural villages or farms where the workers and families exist through subsistence farming or work as day laborers for small local farms. The lure of greater prosperity draws the rural poor to the larger towns and cities where they believe they have opportunities to improve their lifestyle. Cities have become centers where vast numbers of people compete for the most basic elements of life: for a room within reach of employment with an affordable rent, or vacant land on which a shelter can be erected without fear of eviction; for places in schools; for medical treatment; for access to clean drinking water; for a place on a bus or train; and for a corner on a pavement or square to sell some goods – quite apart from the enormous competition for jobs. Usually, governments have the power and resources to increase the supply and reduce the cost of these. Often, a family member leaving a rural village will find that the costs of urban living outstrip the wages provided by the position. In the best cases, they will be able to save a small sum of money to send back to their family and slowly bring other family members into the urban community.

Impact of Water Sources on Health Considerations

Numerous rural villages (and even cities) will be settled along the same stream or other water source. The impact of fecal waste entering the stream from a source upstream of the population center is obvious and can be disastrous unless the village inhabitants take precautions either in common (e.g., to hand-dig a river well or provide for filtration) or individually by treating their water (e.g., boiling or chlorinating).

In small villages, when water is suspected of being "bad" (i.e., contaminated with pathogens), local people will either boil the water (if firewood is available) or treat the water with household bleach. Alternatively, they may switch to drinking fresh fruit juices or carbonated soft drinks such as colas because they know the bottlers utilize purified water for beverage preparation. Unfortunately, purified bottled water is sometimes more costly than soft drinks. The acids and high sugar content of many soft drinks may be a major cause of tooth decay and associated poor dental health of immigrants. Recently one dentist had to extract 271 teeth over a period of 10 days from residents in one rural village because of inadequate dental health.

Ingestion of low doses of arsenic over long periods (~years) has been determined to be one source of lung and bladder cancers. Similarly, the ingestion of lead by infants and young children is well known to negatively impact the development of mental capacity. These and other heavy metal contaminants are occasionally present in drinking water (especially from groundwater sources) both in the USA and worldwide. In many areas, rural villages rely entirely on hand-dug or shallow-drilled wells for their potable water. Subsurface incursion of heavy metal salts into an aquifer from heavy metals ore mining or volcanic activity can result in excessive concentrations in the drinking water thereby yielding increased occurrences of associated illnesses within immigrant populations.

While many chemical elements in drinking water are harmless or beneficial, others such as fluoride can be beneficial at low concentrations (0.5–1 ppm desirable for preventing tooth decay) and detrimental at high concentration (leading to fluoridosis and bone decay). Unfortunately, most rural villages have no ability to monitor fluoride content in their drinking water. Water from some shallow drilled wells in east Africa have shown excessive levels of fluoride and instances of fluoridosis have been observed in older residents.

Impact of Loss of Disease Immunity

A common concern of health professionals working in rural village settings is that once individuals have access to potable water, it is possible over time to lose their immunity to waterborne contaminants resulting in increased potential for illness when they travel to areas outside their normal grounds. It is unclear to governmental officials how to best address this situation, since in many regions it is not practical from a cost perspective to provide purified water for all rural inhabitants.

Urban Versus Rural Water Quality Issues

Because of the public awareness of the importance of waterborne illnesses on the public health and economic growth, urban centers typically have provided (through tax revenues) for water purification and waste treatment on a larger scale. This means that residents generally have better access to water of improved quality; however, even in the most modern cities it is not unusual to have outbreaks of disease due to inadequate water treatment. Worldwide, significant epidemics occur in major cities when treatment facilities are inadequately designed to remove or destroy waterborne pathogens. The WHO has assisted governmental agencies worldwide to institute regulations pertaining to water quality and numerous water districts labor to improve water quality to achieve regulatory compliance. In many instances, implementation of ultrafiltration, UV light disinfection, and/or reverse osmosis technologies are being coupled with sedimentation, filtration, and chlorination to achieve improved protection of citizenry against waterborne illnesses. Currently, even with such controls water quality is a major issue because to date it has not been practical to provide clean potable water to all because of financial constraints. In cities, where access to information about current water quality is more available, residents can take action to purify their water by boiling; in rural areas, the information is not available and appropriate actions are often lacking. Use of the above technologies in rural settings is being jointly attempted by both governmental and nongovernmental (NGO) agencies. Frequently the availability of electrical power to implement some of these technologies is the limiting factor in achieving potable water of adequate purity.

Need for Development

While there is continuing need to develop cheaper, more effective water treatment technologies, it must be emphasized that – even if the water available to residents is free of pathogens and contaminants – if the individual does not properly handle that water, pathogens can easily be reintroduced into the purified water. Reintroduction occurs through the use of improperly sanitized transport vessels, through inadequate washing of hands and improper cleansing/rinsing of drinking vessels. Studies conducted by aid workers and epidemiologists have confirmed a need to train all citizens about the importance of hand washing and proper cleansing of transport and drinking vessels as a part of general hygiene practices.

Weight Control

Cătălin Jan Iov
University of Medicine and Pharmacy "Gr. T. Popa",
Iasi, Romania

Obesity is a medical issue most pressing in contemporary time. The problem has evolved from a public health issue to a global epidemic. The obesity problem is not new. Hippocrates recognized it as a factor jeopardizing individuals' health status. He commented that it is injurious to anyone to get more food than can be supported when no exercise is scheduled to compensate the excess. Today, there are increased risk factors associated with obesity, including: high cholesterol, an inactive lifestyle, osteoarthritis, sleep apnea and respiratory problems, cancers, heart disease, stroke, and diabetes. Hippocrates felt the medical condition a Western disease.

The World Health Organization estimates that currently there are approximately 300 million obese adults worldwide, with 115 million of these living in developing countries. Increasing obesity in the overall population has been linked to urbanization and its effect on reducing physical activity and increasing consumption of energy dense diets. It is predicted that in developing countries, there will be a dramatic shift in causes of mortality from nutrition-related chronic diseases. The last decades reported important population migration from underdeveloped to developed countries. The liberty and access to food, combined with the low price of food, put under medical attention new challenges related to weight. The issues are complex relative to weight and immigrants. Frequently, they emigrate from a situation in which there is a history of food scarcity, and their migration takes them to a locale in which usually there is more than adequate access to food. Subsequently, new medical cases are charging the host medical system. As they collaborate with the patient to establish a weight-loss intervention, health providers are admonished to consider cultural factors distinctive to the population being served and the barriers that patients articulate.

Cultural Factors

A variety of cultural factors come to bear on the weight loss process. One obstacle is that obesity is desirable in some developing societies. The perception of ideal body size varies with culture, ethnicity, educational level, and socioeconomic group and can influence the development of obesity. In Western societies, thinness is associated with self-control, elegance, youthfulness, and attractiveness. In those societies, women of higher socioeconomic groups are less likely to be obese. In some developing countries, however, the situation appears to be the opposite. Some researchers have posited that in certain developing countries – where resources are scarce – obesity is admired, seen as sexually desirable, and a symbol of social success and wealth.

Others' Body Size

Recent research suggests that the body size of those around individuals may serve to shape their social perception of what is healthy and appropriate in terms of weight and body size. The U.S. Department of Health and Human Services reports that data suggest that despite an increase in the prevalence of overweight and obesity in recent decades, overweight people have become less likely to perceive themselves as overweight. In turn, this may exacerbate the obesity epidemic by inhibiting individuals' motivation to maintain a healthy body weight or to initiative the process of losing excess weight.

In a recent study of a predominantly European American (EA) population, it was found that individuals were more likely to gain weight over three decades if their same-sex friends were obese. Other studies among children and adults support the tenet that peers can affect physical activity levels and caloric intake of individuals. It holds, therefore, that peers can potentially influence weight status.

Cultural Perceptions of Children's Body Weight

The prevalence of obesity has increased markedly in US children and adolescents in the past 30 years.

Obesity-related diseases formerly seen exclusively in the adult population are being recognized increasingly in obese adolescents and even younger children. Childhood obesity is increasing in all ethnic and racial groups; however, its prevalence is higher in non-White populations.

The reasons for the differences in prevalence of childhood obesity among groups are complex; they likely involve interplay between variables, including: genetics, physiology, culture, socioeconomic status (SES), environment, and others not fully recognized. Researchers contend that understanding the influence of these variables on the patterns of eating and physical activity will be critical to developing public policies and effective clinical interventions to prevent and treat childhood obesity.

Cultural Barriers to Weight Loss

Recent research has shed light on the various cultural barriers to weight loss that immigrants may likely experience in the new host country, especially those immigrants who are coming from significantly less-developed countries. Immigrants report receiving mixed messages when determining their appropriate weight. They indicate that their desire to lose weight to be healthy – influenced by professional advice and personal experience – often is in conflict with the idea that being overweight is healthy – influenced by the culture of family and/or country of birth. Immigrants describe discordance when adapting to the mainstream, leading to the loss of healthy traditional habits. Participants in recent studies have expressed their desire for culturally appropriate nutrition education and reassurance regarding healthy dieting from health care providers. Other emerging themes include the importance of interactions with peers during education and a positive response to group education.

White Supremacy

Brandy L. Johnson
Rynearson, Suess, Schnurbusch & Champion, L.L.C, St. Louis, MO, USA

White supremacy, in general terms, describes the belief that Caucasians are superior to other races and/or ethnicities. The term can also be used to describe a political ideology wherein it is believed the Caucasian race should dominate political and social matters. White supremacists believe those who are White are superior intellectually, morally, and ethically. The belief system typically prohibits interracial relationships, believing the White race should be kept "pure." Adolf Hitler's Third Reich and Apartheid are commonly cited as examples of white supremacy. White supremacists' beliefs are not limited by geography, but can be found in most countries that have a large White population. For example, white supremacy groups exist in North America, Europe, Australia, South Africa, the Russian Federation, and parts of Latin America.

White supremacy believers target individuals and groups of other races, for example, peoples of African and Asian descent. Native groups, such as Native Americans and Aborigines, have also historically been targets of white supremacists. However, white supremacy groups do not all agree on the definition of "white." Many white supremacists do not consider people of Jewish or Muslim descent, to be Caucasian. Thus, many white supremacists are anti-Semitic and groups such as the Klu Klux Klan, Aryan Nations, The Order, and the White Patriot Party adhere to an anti-Semitic ideology. Muslims are another group of peoples who are seen as inferior by many white supremacists.

White supremacy groups can be religiously and/or politically motivated. Religious white supremacist groups include Christian Identity, Aryan Nations, The White Order of Thule, and the Creativity Movement (formally known as World Church of the Creator). Groups such as National Alliance, the American Nazi Party, and the National Socialist White People's Party are more politically motivated. Some white supremacy groups are neither religiously nor politically motivated. The Klu Klux Klan, for example, follows the general supremacist ideology, but is not usually motivated by religion or politics. Racist skinheads and neo-Nazi groups are also well known types of white supremacists.

White supremacy has been on the rise in recent years. For example, in England and Wales, there were 54,286 racist incidents between 2003 and 2004. This number increased 7% to 57,902 between 2004 and 2005. According to the Southern Poverty Law Center, there were 926 hate groups active in the United States in 2008. This was up more than 4% from the 888 groups in 2007, and a 50% increase from 2000. Additionally, of the 7,780 hate crimes reported in the United States in 2008, 51.3% were racially motivated. This was an increase from 2007, where, of the 7,621 hate crimes, 50.8% were racially motivated. The majority of the racially motivated crimes were caused by an anti-Black bias. The Organization for Security and Co-operation in Europe (OSCE) reported 195 persons were charged with crimes motivated by racial or similar hatred in the Czech Republic. Included in the report were the following statistics: 463 racist crimes and 3,048 crimes with xenophobic motives were reported by Germany; 2,902 prosecuted racist crimes were reported by France; and 4,224 racist and xenophobic crimes were reported by Sweden. The increase in white supremacy beliefs and white supremacy groups can be attributed to multiple factors. Downturns in various economies and terrorist attacks have turned some toward such groups. In the United States, the election of Barack Obama as President and immigration debates served as recruiting tools for white supremacy groups. The popularity of the internet and social networking sites, however, may have been the largest contributor to the growth of white supremacy.

The internet has allowed white supremacy groups to flourish as they no longer have to rely on word of mouth or printed propaganda to spread their message. Instead, they are able to establish websites and chat forums that can be visited freely by anyone with access to the internet. The groups now have access to a potential audience that numbers in the millions and exceeds borders. White supremacists can now communicate with others in different states, territories, and countries. Propaganda has been posted by these groups, often under misleading tags or titles to increase viewership, on YouTube and MySpace Video. Finally, blogs and social networking sites, such as Facebook, Twitter, and MySpace, provide white supremacists with the ability to find and communicate with other like-minded individuals. Thus, the internet and social networking sites have provided white supremacists with tools that allow them to easily spread their message, recruit, and reinforce their beliefs. Moreover, the anonymity of the internet permits people to search for information or like-minded individuals without any social stigma. Similarly, the internet encourages such individuals to express and share white supremacy-based thoughts, ideas, and propaganda without this stigma. For example, many websites, including Yahoo and online newspapers, permit readers to post comments about the posted article. White supremacists have taken advantage of this to post racial and anti-Semitic comments. Additionally, the anonymity of the internet and the ability to reach across borders makes prosecuting hate crimes, such as credible racial/ethnic threats, difficult.

Many countries have laws that prohibit discrimination, hate crimes, and hate speech. However, countries that protect free speech tend to have varying approaches toward hate speech. In the United States, hate speech is protected by the First Amendment unless it incites imminent lawless action or qualifies as fighting words, obscenity, defamation, or true threats. Internationally, there are also measures in place to prevent such behavior. The International Covenant on Civil and Political Rights and the International Convention on the Elimination of All Forms of Racial Discrimination require its members to refrain from discrimination based on race, ethnicity, or national origin.

White supremacy crosses geographic and cultural barriers. Some white supremacists merely believe in keeping the Caucasian race, however they define it, pure. Other white supremacists encourage, or participate, in violence against non-Caucasians. While white supremacists seem to differ on the details of their doctrines, they share one common belief: the Caucasian race, as they define it, is superior to all others.

Women

Andrea M. Przybysz
Case Western Reserve University School of Law,
Cleveland, OH, USA

Being a woman in the immigrant context signals many of the same concerns that being a woman does generally. Immigrant women, depending on location, are simultaneously granted benefits unavailable to men and ignored or denied care provided to citizens and their male counterparts in institutional settings. Geographically speaking, there is a stark contrast between the benefits and disadvantages of being a woman while searching for opportunity or struggling to survive. The following discusses the ways in which female immigrants use gender to capitalize on rights in receiving countries that they are not afforded elsewhere while also considering the many burdens women face in obtaining care.

Recently, some of Central Europe's more generous welfare states, particularly France and Denmark, have faced economic problems which they attribute to a large influx of immigrants from Russia, Hungary, Bosnia, Iran, Lebanon, and North Africa. Each state essentially claims that its welfare system, which categorically provides equivalent health care to all individuals living within its borders (subject to certain limitations), is overly burdened by immigrants who have not yet invested sufficiently in the system. For instance, France provides vast protections to all mothers and children. The program, aptly named Protection Maternelle et Infantile ("PMI"), provides all pregnant women with a team of private-practice pediatricians, nurses, midwives, psychologists, social workers, and with financial incentives to make and keep appointments. The program's success is alleged to have led to, at least indirectly, a large influx of North African and Southeast Asian immigrants in Montmarte. This influx has significantly burdened the system to the extent that an entire building in the district has been given over to care for immigrant pre- and postnatal care.

Denmark, with its guest worker program, has experienced problems similar to those of France. The country estimates that 10–15 billion Kroner annually go to serve the welfare needs of immigrants. While Denmark's annual budget nears 500 billion Kroner, the cost associated with immigrant care has recently led Denmark to offer each immigrant 11,000 Kroner to resettle in their country of origin. While potentially a cost-saving mechanism for Denmark, this offer overlooks female immigrants who relocate to Denmark for the specific purpose of accessing quality medical care.

With a significant portion of female populations emigrating in search of work, one cannot forget the elderly populations that immigrants are leaving behind. Given that women still tend to be primary caregivers to elderly family members in much of the world, seniors are adversely affected when women leave their native countries to find work. As a result, many older women are left alone with little or no family or support. While there are positive instances when female immigrants achieve success at a high enough rate to send financial support home, it is increasingly the case that many elderly women face spending their last years alone in institutional settings.

Much like the unanticipated effects that increased support for women's healthcare has seen in the universal health setting, governments with large exoduses of women may experience an economic drain on the welfare system as a result of increased spending on elder care. In the event governments are not able to sustain adequate elder care for soon-to-be orphaned seniors, the quality of elder care may decrease and/or citizens remaining behind may be asked to contribute more into the welfare system. Unfortunately, while the first scenario is undesirable from a human rights standpoint, the latter scenario implicates a political tax which is a significant point of contention in general and even more so for individuals residing in countries and regions struggling financially – likely the same areas experiencing migration in the first place.

At the other end of the spectrum, the United States plays host to certain feminist ideals that are particularly hard on immigrant women in both the physical and mental health arena. Consequently, in an attempt to meet these standards that require women to excel both in the workplace and in the home, an overwhelming number of immigrant women in the US fail to take proactive health care measures. Though perhaps initially less devastating economically, women here forego preventive screenings, potentially resulting in increased health care costs when they seek emergency care. Examples of neglected screenings include: gynecological exams, pap smears, breast exams, birth control, menopause consultations, and nutritional health. The reasons for forgoing services vary widely, but can be attributed with some particularity to language barriers, power differentials between men and women, and prescribed gender roles for women to care for their families. Women's health is, however, important and in immigrant communities where women's needs are often subordinate to men's sexual desires and children's healthcare needs. But unfortunately, a failure to obtain appropriate care can seriously impair a women's well-being.

Not only do female immigrants deal with undue burdens regarding their own health, but also because women also tend to take care of the health needs of their families, female immigrants must often face large health systems that are foreign to their knowledge base and that often require an in-depth understanding of corporate entities. Because most access to health care at this point involves hospital-based care by a majority of male physicians and administrators, female immigrants seeking care for themselves or on behalf of their families must understand where to seek care, what appropriate care is, how to linguistically and culturally translate their concerns to professionals, and how to deal with opposite sex doctors who hold more power than they and with whom they may not be able to speak directly due to religious or cultural concerns that prohibit opposite sex interactions with unrelated individuals. Other social, economic, and political factors may also affect how female immigrants view and deal with health systems.

As young immigrant women attempt to identify with their new culture and begin to realize their own sexual identity, many may face struggles. Instead of developing an integrated self, young female immigrants are at risk of developing "split identities," requiring them to balance religion and family culture with the values and attitudes of the host culture. While this balance is not easy for any young woman living in today's modern society, young immigrant women may be at a particular disadvantage in cultures that condone attempts to police their bodies.

Policing women's bodies is one way that some immigrant men rationalize their superiority over the dominant host culture that in every other respect seems to degrade their existence and exert power over them. Men who adhere to this belief set reason that because they are able to control their women and their women's actions, they are morally superior to the host culture. Accordingly, they may believe that the host culture's ability to control the immigrant's life means nothing, the reason being that immigrant men would not choose to be part of that system, even if afforded the opportunity, with kept women. Policing women's bodies in immigrant communities runs a second important risk, namely, that immigrant community leaders deny the prevalence of domestic abuse in their communities. Leaders, most often men, implicitly condone violence by their silence or excuse the act as an acceptable coping mechanism for men who are dealing with hardships of the immigrant experience.

Lesbian immigrants often identify both with lesbian groups in their new culture and women from immigrant culture. Because many immigrant cultures are unfamiliar with lesbianism, the immigrant culture (immigrant women included) may tend to condemn lesbianism as an evil imposed upon immigrants by the host culture, rather than as a legitimate identity and a universal concept. Condemnation by one's immigrant community and female counterparts can impose difficult psychological burdens on lesbian immigrants seeking acceptance. Unfortunately, acceptance of lesbian immigrants within the new host cultures is still lacking, thus making acculturation in these circles particularly difficult.

As an example, although US immigration laws now allow LGBT individuals to seek refuge from persecution due to sexual orientation, some nonprofit organizations that provide assistance to refugees may deny their services to lesbians or provide them with suboptimal services. Lesbian refugees may be housed in the most dangerous neighborhoods without jobs, in conditions that are essentially similar to those they fled. While public discussion on this focuses mainly on gay males, it is not to say that females do not encounter similar problems.

Like lesbian immigrants, women from cultures where female genital cutting (FGC, also known in Western countries as female genital mutilation) is culturally acceptable, trafficked women and women in medical need of or desiring an abortion raise special concerns within the context of policing the female body. While these topics typically gain more exposure in the public discourse, they too are plagued with the same problems inherent in a male-dominated ordering of society. Both topics involve women subjugated to law where they must conform to someone else's idea of what should be done to their body – either cut or forced to become a mother.

FGC, a practice that ranges from minimally invasive cutting to full clitoridectomies, is sometimes likened to male circumcision. The cutting process, which occurs primarily in parts of Eastern and Western Africa, the Arabian Peninsula, and several Western countries, is much riskier than circumcision in the amount of blood expelled and the stress the procedure places on the vulva. Indirect risks resulting from inadequate conditions include: sepsis from unclean or improperly cleaned tools, septicemia from bacteria that reaches the bloodstream, urinary tract and pelvic infections, infertility, and fetal distress. FGC warrants consideration in a discussion of policing female immigrant bodies because the practice appears to be spreading by way of immigration to countries not typically associated with the practice and because the practice is thought to minimize female sexuality.

There are several arguments in support of FGC as a cultural virtue. These arguments include the notion that FGC is one of few acts that can ensure a woman economic stability and religious duty mandates such sacrifice. The first argument in support of FGC promotes the idea that cutting off particular vaginal folds evidences virginity and thus, the woman's purity. The second argument is weaker given that some Muslim communities tend to promote this idea despite its confirmed pre-Islamic origins.

The most reasonable explanation coincides with the quest for control in the battle of the sexes. FGC as a cultural phenomenon thus appears to be explained by the notion that women are sexually dangerous and must be transformed, or excised, in order for men to maintain social order, virtue, and morality. This explanation is consistent with the desire to control women and limit their sexual and social empowerment.

Abortion laws and the trafficking of women immigrants into various wealthy countries, much like FGC and reduced roles for lesbian immigrants, reinforce a patriarchal version of society in which men are permitted to dominate based on the ability to control both access to sex and in many instances, the product of sex. Abortion, like FGC, if done improperly can result in devastating health repercussions. Much of the world still does not condone abortion on request. The few countries permitting requests for abortion include: Tunisia; South Africa; Cape Verde; the Democratic People's Republic of Korea; Japan; Mongolia; Kazakhstan; Kyrgyzstan; Tajikistan; Turkmenistan; Uzbekistan; Cambodia; Armenia; Azerbaijan; Bahrain; Georgia; Syrian Arab Republic; the majority of Eastern Europe less Poland; the majority of Northern Europe less Finland, Iceland, and Ireland; the majority of Southern Europe less Greece, Malta, Portugal, and San Marino; the majority of Western Europe less Liechtenstein, Luxembourg, and Monaco; Guyana; Canada; the United States; and Australia. All in all, about 67% of more developed countries permit abortion on request versus a mere 15% of less developed countries. While more countries permit a woman to obtain an abortion for births resulting from rape or incest, statistics indicate that much of the world is still uncomfortable terminating a pregnancy. Here too, more developed countries permit termination at a greater rate than less developed countries for pregnancies following the perpetration of a criminal act, rape, or incest, 84% versus 37%. These statistics indicate that greater education and economic resources help accommodate a woman's choice and more importantly, her well-being. Unfortunately, the circumstances under which women most reasonably could not be expected to care for the health and well-being of another individual's life are the exact circumstances which legally often require a woman to do so. The impact of abortion laws often causes women to travel from their native country to countries where abortion is not criminalized. Alternatively, many women harm themselves as a way to circumvent the need for an abortion with the same results. Both these situations may adversely impact a mother's health and well-being; this issue must be addressed by legislatures to prevent future harm to women forced to immigrate in order to obtain an abortion and those forced to do so in countries where health care is inaccessible to those of little or no means.

In recent years, human trafficking has increased exponentially. The increase can be attributed to several factors. Government attempts to control trafficking are often ineffective due to the numerous channels of trafficking, the numbers of women who are trafficked, and the diverse destinations to which the women are transported. Additionally, the trafficked women often have inadequate language skills to enforce their rights.

The pattern behind trafficking indicates that men often poach women from many countries in the southern hemisphere and send them to wealthier countries in the northern, and primarily western, hemispheres. Women from Albania, Belarus, Bulgaria, China, Lithuania, Nigeria, the Republic of Moldova, Romania, the Russian Federation, Thailand, and the Ukraine are particularly susceptible to becoming victims of trafficking. Countries receiving a significant number of trafficked women include Australia, Belgium, Canada, Germany, Greece, Israel, Italy, Japan, the Netherlands, Thailand, Turkey, and the United States. Traffickers recruit women in origin countries by and through both direct and indirect means before transporting women to their final destination countries.

Indirect recruitment may occur when women are nearly forced into the sex worker industry because of desertion by their families or partners or because they are enticed into work under entirely false pretenses. Not infrequently, women marry military men on tour in their respective countries and follow their partners only to find their marriage dissolving when they arrive in the new country. After dissolution, some women may turn to the sex industry because they do not have the requisite language or technical skills to find work. Some women answer want ads for manual labor, sweatshop jobs, or are enticed away from their country of origin by the allure of a proper education, only to find themselves in situations in which they are sexually enslaved. In some instances, women are oppressed, economically depressed, born into poverty, and in some instances, born into brothels and raised in the sex industry; for some women in such circumstances, it may seem that moving to another country to continue the same way of life they have ever known is reasonable.

Regardless of how women arrive in new countries and become part of the sex industry, enforcement and criminalizing trafficking is problematic. In the United States, Los Angeles, California, and Southern Texas have both recently developed task forces to help quell the demand for sex workers. Unfortunately, the industry earns some 9.5 billion dollars a year; given the number of women who are present without resident or citizen papers and the number of workers who are unaware of their rights and without proper language skills it is difficult to regulate. Aside from enforcement, there is another challenge inherent to trafficking; many women believe that as bad as being part of the sex industry is or seems, it may be better than the conditions they faced previously in their countries of origin.

Though the state of women's care, specifically immigrant women's care, appears bleak, several coalitions have made enormous efforts to safeguard women. Organizations of note include: the United Nations Development Fund for Women ("UNIFEM"), UNICEF, and the United Nations High Commission for Refugees ("UNHCR"). UNIFEM works and raises funds primarily for internally displaced women through the world food program which helps strengthen women's economic security and empower women living in post-conflict regions or in trauma post-conflict.

World Health Organization

Gary Edmunds
Center for Minority Public Health, Case Western Reserve University, Cleveland, OH, USA

In 1919, which marked the end of World War I, the League of Nations was created in order to promote peace and security in the world in the aftermath of war. The League of Nations established the Health Organization in Geneva to prevent and control disease around the world.

In 1945, the League of Nations became the United Nations and in 1948, the Health Organization became the World Health Organization (WHO). The WHO is regarded as the world's leading health organization. Its objective is "the attainment by all peoples of the highest possible standard of health." It is an international health cooperative that monitors the state of the world's health and systematically attempts to improve the health status of individual countries and of the world collectively. Disease prevention and control, promotion of good health, interventions in disease outbreaks, initiatives to eliminate diseases through immunizations and development of treatment and prevention standards are contributions made by the WHO to international public health.

The WHO views the world as a series of open national societies, rather than as a collection of relatively closed communities. This latter view would impede the ability to address the problem of global inequities. Poor countries or poor people within countries suffer from multiple deprivations that lead to high levels of ill health; ill health maintains poverty. Consequently, the poor are often caught in the cycle of poverty and ill health.

Absolute poverty is still spreading in many parts of the world and disparities of health and wealth are growing between and within countries. Over one billion people are without the benefits of modern medical science. One out of every five persons in the world has no access to safe drinking water. Infectious diseases alone account for 13 million deaths a year, most of them in developing countries. Seventy percent of the poor are women; in the world's poorest country, an expectant mother's chances of dying in childbirth is 500 times greater than women in the richest country.

Many health leaders from Third World countries have pleaded for a world federation, a "new international economic order," as the only possible basis for creating conditions conducive to more equitable world health. In 1994, the budget of the United Nations Development Program was slightly greater than that of the United Nations High Commissioner for Refugees. This means that the general response tends to be as reactive as it is proactive. Moreover, the 10 developing countries with well over two-thirds of the world's "poorest of the poor" receive only one-third of foreign aid; it is these countries that are home to the greatest numbers of internally displaced persons. Increasing numbers of impoverished people are pressing ever harder on overloaded environments. If foreign aid budgets were closely directed proactively to impoverished people in the countries and regions concerned, they could help to relieve the problem while it is still becoming a problem and before it becomes entrenched.

The WHO has 193 Member States that appoint delegations to the World Health Assembly, the decision-making body. Member States and donors finance the WHO. The WHO also has collaborations with NGOs, the pharmaceutical industry and foundations such as the Bill and Melinda Gates and Rockefeller Foundations. These voluntary contributions from national and local governments, foundations and NGOs, UN organizations and the private sector have now exceeded estimated contributions from the 193 member nations.

In 1979, a global commission confirmed the worldwide eradication of smallpox in which the cost of worldwide vaccination had been close to $1 billion dollars annually. The last identified and treated cases were in East Africa, and the decade-long campaign came to $300 million. This accomplishment reinforced the idea that investment in health yields economic benefit and humanitarian relief. This represents the first conquest of a deadly disease and the WHO's greatest achievement of disease eradication through human effort. Today, the WHO addresses communicable diseases, noncommunicable diseases, mental health, family and community health, sustainable development and health environments, health technology and pharmaceuticals, and policy development.

Xenophobia

Kate Goldade
Program in Health Disparities Research, Family Medicine and Community Health, University of Minnesota, Minneapolis, MN, USA

Xenophobia encompasses negative attitudes and behaviors to exclude and vilify others pertaining to a particular ethnic or national group. Xenophobia is expressed as a defensive act by persons in groups that perceive a threat to their dominance. There is evidence that perceived disease threat predicts xenophobic attitudes. Negative consequences stemming from xenophobia include related acts of violence and bullying, a formation of negative ethnic identity in children, inhibited acculturation processes, and a general discord between ethnic and national groups. Xenophobia reflects structural violence or how history and political economy perpetuate social inequalities.

As a concept xenophobia is closely linked to stigma and discrimination. Stigma, a negative set of beliefs based on group belonging, is socially constructed through interactions but most often measured through perceived discrimination at the individual level. Growing more prominent in European countries, xenophobia is disproportionately directed at unauthorized migrants than legal or refugee migrants. Xenophobia contributes to the health burdens shouldered by immigrant populations around the globe, shaping experiences inside and external to the health system.

Health Consequences of Xenophobia

Violence motivated by xenophobia results in deaths, injuries, disabilities, trauma, and displaced persons. Violence against foreigners can cause movement of persons to displaced persons camps lacking infrastructure. Displaced persons are exposed to increased health risks due to unhygienic living conditions, poor clinical services, food insecurity, unsafe water sources, and greater exposure to infectious diseases. Further, bullying related to xenophobia places immigrants at greater risk for injury and harm.

Xenophobia determines the types of employment available to migrants. Often jobs open to migrants include hazardous working conditions and low pay. Workplace experiences may be shaped by xenophobia-related discrimination. Labor intensive jobs conducted without basic employment rights or entitlements to sick leave, health care, or convalescence time generate work-related accidents. Job insecurity and the discrimination perceived within the work sphere may cause stress and anxiety. By relation, loss of concentration places immigrant laborers at further risk of injury and peril to their health.

The prolonged stress of xenophobia leads to a physiological state of fear or hyper arousal. This state leads to increased allostatic load, a bodily stress response, which places migrants at greater risk for chronic illness. Perceived discrimination has been associated with increased incidence of chronic illness. Reports of discrimination have been linked to high blood pressure, respiratory problems, somatic complaints, negative self-rated health, and chronic health conditions.

Xenophobia-related discrimination has been associated with poor mental health. Anxieties related to experiencing xenophobia caused an increased need for mental health services. Among migrant groups such services have often been unavailable due to eligibility constraints based in legal status.

Health Care Seeking

Xenophobia provides an overarching context to the health care seeking activities of migrants. Contexts of xenophobia may compound rights-based limits on immigrant health care access such as lack of health care insurance or work-related limits on sick leave. Fear-based experiences of xenophobia may lead to

Sana Loue & Martha Sajatovic (eds.), *Encyclopedia of Immigrant Health*, DOI 10.1007/978-1-4419-5659-0,

avoidance of or delayed health care seeking. Migrants have avoided seeking health care services for a range of issues from prenatal care during pregnancy, broken bones, and abscesses. Aside from avoidance, delayed health care seeking results from xenophobia. Migrants delay prenatal and perinatal service seeking which likely leads to higher rates of perinatal mortality observed in many migrant groups. Migrants delay seeking health care for job-related injuries. The delay in seeking health care ensures that such injuries develop into longer term chronic problems.

Xenophobia shapes national legislation and thus influences health care access. Further, concern over limited health care resources can exacerbate xenophobia. In the United States, the federal welfare reform act of 1996, titled Personal Responsibility and Work Opportunity Reconciliation Act (PRWORA), foreclosed eligibility for Medicaid to most legally authorized immigrants for the first 5 years of residence. The law required that state governments providing benefits to undocumented affirm migrants' eligibility. Intended to save costs, the legislation inadvertently created categories of eligibility within migrant groups, thereby increasing xenophobia toward illegal immigrants.

In certain contexts, health care staff are obligated by law to denounce undocumented migrants seeking health care services. Providing adequate care is further compromised by an inability to adequately supply medications to clinics serving migrants. Immigrants experience frustratingly longer wait times. Immigrants are more likely to report discrimination of health care compared with US-born counterpart populations.

Xenophobia shapes immigrant health risks, outcomes, behaviors, and health care seeking. By generating violence, xenophobia places persons of particular national or ethnic identity at greater risk of injury, disability, and death. Discriminatory experiences in the workplace may generate poor health outcomes. Xenophobia results in avoidance and delayed health care seeking, thus intensifying and worsening conditions. Fears of deportation and legal obligations for health care providers to report unauthorized immigrants result from contexts of xenophobia. Stress and anxiety related to xenophobia generate mental health needs which may be stigmatized in certain immigrant groups. Availability of mental health services is often limited to authorized immigrants. Health care services within contexts of xenophobia may be characterized by discrimination, long wait times, and poor supplies of medication. As protective factors against harms of xenophobia, immigrant groups may organize to claim their rights, receive social and economic support from nongovernmental organizations, labor unions, or other institutions.

Y

Yoga

LaGenia Bailey
East West Healing Arts and Yoga, Chicago, IL, USA

Yoga is an ancient system for healing. The meaning of the word yoga may be defined as “yoking” or “bringing together.” Yoga, in its essence, is a union of the mind, body, and spirit. There is no aspect of life for which yoga does not have some benefit. The recent expansion in yoga speaks to the benefits in reduction of stress. The physical aspects help to bring movement to the body, oxygenating the musculature, and bringing balance to the habitual movements we do during our day. Spending time examining the internal landscape of the thoughts and emotions through meditation allows resiliency in the ability to adjust to everyday stressors. Pranayama or controlled breath exercises are a way to access control of the nervous system. All come together to give us the ability to adjust and course correct our life path for health, well-being, and resiliency.

The classic text and instructions regarding yoga come from the ancient writings of an Indian sage or wise man named Pantanjali. These writings are 200 short verses or sutras and date from an estimated time between 5000 B.C. and 300 A.D. They were passed down to students by song and are still taught this way in classic yoga schools. They have no religious binding and are nondenominational in nature. The sutras are a collection of guidelines and practices on which the structure of yoga is based.

The practice of yoga brings to each person certain benefits. As each person is different, variations on results occur in the practice of yoga. The commonly reported benefits of yoga may be summarized in three experiences: (1) an increase in a sense of well being and calmness; (2) less reactivity to stress and change; and (3) an increase in overall health, flexibility, and strength.

Any person of any age, ability, and level of health or fitness can do yoga. It is important to have an awareness of what your body can and cannot do safely when doing yoga. A good teacher should be able to help adapt the various practices of yoga to fit individual abilities, limitations, and past injuries. Always remember that yoga is a practice and a process, not a goal. Be gentle with yourself and allow time for observation and learning as you progress through your practice. One instructor used to say that movement of one telephone page at a time is enough. Just like a number of telephone pages added together result in a book of significant weight and volume, small advances achieved in yoga practice over time result in real progress from where one begins. As a last precaution, consult with your health care provider before starting any new physical activity.

Yoga is a physical, mental, and spiritual practice. The three most commonly discussed practices of yoga are postures (asana) to exercise and move the body, breath work (pranayama), which focuses on the energy of the body through the use of the breath, and meditation, which allows connection with one’s spiritual nature. The focus and relative balance of yoga practice rests in the needs of the yoga practitioner. Gary Kraftsow, director of the American Viniyoga Institute, recommends adapting the focus of practice depending on one’s age, physical and genetic characteristics. For people under 30 years of age, postures or more physical activity-based yoga would be most beneficial and should formulate the bulk of the practice. Between the ages of 30 and 70, a more balanced approach is the goal; therefore, the time is more evenly divided between asana, pranayama, and meditation. Meditation should predominate for people over 70 years of age with some gentle stretching and breath work.

In medical terms, no one has discovered exactly why yoga works. Yoga has long been known to help induce a sense of relaxation and peacefulness. By

Sana Loue & Martha Sajatovic (eds.), *Encyclopedia of Immigrant Health*, DOI 10.1007/978-1-4419-5659-0,

stretching and strengthening the body in a structured manner with the support of specific patterns of breath, we infuse the muscles, organs, and tissues with oxygen carrying blood. This gentle contraction and relaxation assists the body in cleansing the tissues of toxins and reducing the stress on the body. By focusing inwardly during movement, breath work, and meditation, there is a sense of peace. We know medically that the hormone cortisol is increased in the body during periods of stress. More and more research is pointing to cortisol as an important factor in acceleration of aging, worsening of depression and anxiety, disturbances in sleep, effects on the cardiovascular system, as well as feelings of well-being. If yoga helps induce relaxation, perhaps one of the mechanisms of its benefit may be an effect on cortisol and other stress-related changes in neurotransmitters, hormones, and neuropeptides. More research needs to be done to help delineate the effects of the practice of yoga in a physiologically measurable way.

More and more, people are turning to yoga as a complimentary treatment in combination with standard treatments to improve overall quality of life. There are many types of yoga practiced in the United States. The different types are generally named for the teacher who developed the type of yoga or the area of India from which the particular practice originated. Types of yoga that are known for their ability to adapt to the needs of special populations include Viniyoga, Phoenix Rising Yoga Therapy, Hatha Yoga, and Iyenger Yoga. Find an instructor with whom you can discuss your concerns, special issues, and goals for your yoga practice. The best teacher is one who teaches in a way that you understand and who works with the individual to achieve optimum health through a comprehensive, safe, and consistent practice. It is critical that the instructor and the student cocreate an environment which is safe and conducive to learning.

There are many places in which to learn more about yoga. Always remember yoga is a practice, and not a practice which should be perfect. May your practice bring you joy and health as it unfolds for you in the quest for improving your quality of life.

Youth

Sara Hirschfeld Lee[1], Rina Lazebnik[2]

[1]Department of Pediatrics and Adolescent Medicine, Rainbow Babies and Children's Hospital, Cleveland, OH, USA

[2]Division of General Pediatrics and Adolescent Medicine, Rainbow Babies and Children's Hospital, Cleveland, OH, USA

Immigrant youth, defined as children having at least one foreign-born parent, make up over 20% of the youth in the USA today. The majority of immigrant youth live in California, Florida, Illinois, New Jersey, and New York. However, immigrant populations are growing rapidly in other southern and western states, including Georgia, Tennessee, Oregon, and Colorado. Approximately 80% of immigrant youth have been born in the USA and are US citizens. Almost two-thirds of these youth have one or more parents who are not citizens. This lack of legal status can limit access to health care and school services, which in turn can affect physical and mental growth and development.

Immigrant youth, like any youth, are diverse, and it is difficult to generalize their overall development.

However, certain developmental and psychosocial issues are common across the population. For all teenagers, adolescence is a time of physical and intellectual maturation as children progress toward adulthood. The expected physical progression includes linear growth, weight gain, and the development of secondary sexual characteristics associated with puberty, such as breasts and menstrual periods in girls and facial hair and genital growth in boys. Physical development occurs earlier or later depending on nutritional status, overall health, and ethnic background. Children whose nutritional status has been compromised (by starvation or inadequate food supplies) or who have poor general health (because of chronic illness or undiagnosed medical issues) will enter puberty later, and girls will get their first periods later. Teenagers are usually self-conscious about pubertal development initially, but they do become more comfortable with the changes in the bodies of themselves and others. Adolescent sexuality also emerges during puberty; teenagers have sexual thoughts and feelings and may begin experimentation with the eventual developmental goal of forming stable relationships.

Depending on cultural beliefs or country of origin, normal developmental milestones – a first crush or a first date – may be met with anger or with limited communication between teenagers and parents even when topics presented at school are encouraged to be discussed at home. Some parents are not aware of the sexual culture in the USA to which youth are exposed in the media, society, or even at school and may, therefore be unable to anticipate or address questions about emerging adult sexuality.

As youth become adults, they must develop independence. Their initial attempts at autonomy can be characterized by loneliness and perceived moodiness. Teenagers try to dissociate themselves from their families, and parents may be concerned as teenagers spend more time away from home. Peer groups appear to take precedence over family as adolescents look to friends to help with self-image and behavioral codes. However, individual friendships eventually become more important than the large group, and family values can contribute to the adolescent identity and to the adults they will become. Along with developing independence, adolescents are also trying to define their identity – to explain, "Who am I?" Additional experimentation in this area is common as adolescents try out different roles and use their growing creativity and intellectual ability in defining a sense of self. Cognitively, adolescents are initially capable of primarily concrete thought and are unable to perceive the long-range consequences of their decisions. As their brains develop, they establish abstract thought processes and become more focused on the future. In some instances, the adolescent's declaration of independence may not be welcomed by parents unfamiliar with this type of psychosocial growth.

While this is the expected progression of youth development in the USA, the process varies within the USA and other countries as well as among the immigrant population. Perhaps most importantly, in the USA and other similar countries, adolescence is a long process, with much time given for youth to make their way through all the stages and tasks of development. Adolescence has been extended in part due to educational opportunities; many teenagers remain financially dependent on their parents into their early 20s as they complete their education. In other countries, youth may be faced with the responsibilities of adulthood more quickly. Parents of immigrant youth may not themselves have progressed through many of the stages described above and, during the acculturation process, can be confused by their teenager's actions. Immigrant parents may also have different views of adolescent experimentation; adolescent free time may be limited by higher parental expectations regarding school and work. High importance is not placed on adolescent social networking.

Adjustment issues among immigrant youth are common, and many of the stressors associated with immigration can contribute to these issues. Immigration itself is a disruptive and stressful event; immigrant youth must manage the loss of not only family and friends but of a common language and customs. While studies of migrant youth have found both higher and lower levels of mental health problems, many studies have found that immigrant youth are at high risk for mood disorders. Immigrant youth often have anxiety or depression, and they may demonstrate difficulty concentrating and sleeping. Immigrant youth at highest risk appear to be those without parents, those with learning or physical disabilities, those who have limited education or limited functioning, and those who have been separated from other family members for a long time. These adolescents may come from areas that do not have adequate mental health services, and their families may not use the mental health services available in the USA. Parents may not recognize sadness and withdrawal as warning signs, or there may be stigma or cultural barriers associated with seeking help. Even those who seek mental health services often have difficulty with access to care due to insurance, legal status, transportation problems, language issues, and long waiting times to see a provider.

Trauma also contributes to mental health problems and to adjustment issues. Posttraumatic stress disorder (PTSD) is common in the refugee population. Immigrant youth may have left their countries of origin as a result of war or natural disaster. Exposure to trauma at any age can place an adolescent at risk, particularly when adding the stress of resettlement. Refugees arrive in the USA with little cultural orientation – sometimes as little as 12 h of preparation; ongoing mental health issues can be exacerbated by both the trauma and quick resettlement. Poverty is an additional stressor. Immigrant youth have high rates of poverty – over a third of immigrant families have difficulty affording food. Poverty is associated with lack of access to medical care and with medical and mental health problems.

Despite these problems, immigrant families do have many strengths. They are more likely than their US counterparts to have two parents in the home along with an extended family. There is often a strong community of immigrants from the same country of origin. The community tends to place a high value on education, respect for family and elders, and tradition. Immigrant families are also generally healthy. The "immigrant paradox" demonstrates that, for example, Hispanic immigrants are healthier than US-born Hispanics despite higher poverty rates, less access to healthcare, and lower education levels.

While immigrant families do have strengths, they continue to face challenges. As adolescents begin to adjust to life in a new country, the expected parent–adolescent conflict is often amplified. School provides a means of acculturation for immigrant youth that their parents do not have. Adolescents, in their desire to "fit in," are more motivated to adapt to and to adopt new customs, enhancing their separation from parents. Immigrant youth learn English more quickly and may take on a more adult role as they become family translator and advocate. This role-reversal places adolescents in the parent role and causes tensions within families. Teenagers feel that their parents are unable to help them; they may be embarrassed by non-English speaking parents who have not adapted to American culture. Immigrant youth struggle to balance living in their old and new worlds. That struggle results in further withdrawal from the family and a perception by parents that their children are too "Americanized."

Some adolescent immigrants have been physically separated from their parents for a period of time. Either the parents arrived first or the children were sent ahead to stay with family. The disruption of family combined with loss of social and cultural norms can result in a sense of loss of control for both the adolescent and the parent. Adolescents and parents may have difficulty adjusting to the new role of parent as head of the household and to new family constructions. Immigrant parents may also have different expectations than US-born parents, and this may also contribute to family conflict. Adolescent immigrants may be expected to earn money or to act as babysitters. Immigrant youth whose parents are relying on them for support may feel uncomfortable in their adult roles and may "act out."

Part of "acting out" is the adolescent's attempt to form or participate in a peer group. Immigrant adolescents must develop friendships and rebuild the social networks they left behind in their countries of origin. Depending on the community in which they live, they may find other immigrant adolescents of similar background, or they may struggle with feelings of alienation and "otherness." Immigrant youth may be segregated in school racially, ethnically, and linguistically. There may be discrimination – real or perceived – that complicates the development of a cohesive sense of self. Some studies have demonstrated that immigrant youth are more likely to experience peer pressure to engage in risky behaviors such as substance use and sexual activities. Other studies show that immigrant youth are less inclined to use substances than their US-born counterparts.

Despite the many challenges, immigrant youth in the USA do well. The USA is, in many ways, a nation of immigrants. As immigrant youth adapt to American culture, they and their parents may also bring change to that culture. Immigrant youth who are able to maintain a sense of their own heritage identity while they take on new cultural values and customs have more positive psychosocial outcomes. Immigrant youth who can balance multiple cultures and identities can successfully integrate into and participate in the larger society.

Youth Antisocial Behavior

Thomas Evans
The Center for Clinical Psychology,
North Ridgeville, OH, USA

It is quite common for the typical adolescent to on occasion engage in delinquent behavior. The vast majority of teens who commit delinquent behaviors or engage in acts of violence will stop such activities as they approach adulthood. However, there is a small minority of teens whose illegal conduct persists into adulthood. The task of identifying the teens who are at a higher risk for continued illegal behavior into adulthood is a daunting one, and is one that is frequently asked of mental-health professionals who work with children and adolescents. This is a very difficult and challenging endeavor, and working with youths and their families who have immigrated to the United States can significantly add to that challenge.

There are many factors that lead to juvenile delinquency; this entry focuses on environmental influences. While these factors make youths from low-income families vulnerable to developing antisocial behaviors, children of immigrant parents are at even greater risk. The following provides an overview of this process.

Low interest in school or chronic academic failure is a significant risk factor for the development of antisocial behavior. For the immigrant youth, poor command of the host country's language can lead to significant academic problems if the school is not able to accommodate him or her. The youth may have a learning disorder that is not identified as such and may be dismissed as merely a "cultural learning barrier." The same can be said if the youth possesses an intelligence quotient (IQ) that is well below average. This may result in the youth becoming frustrated and eventually becoming disenfranchised. This may lead to the youth engaging in truancy or discontinuing his/her education.

Economic factors also play an important role in the development of delinquent behavior. Parents of immigrant children who have a limited education or poor command of the English language are likely to find employment in low-paying jobs. This may require the parents to work multiple jobs in order to meet all financial obligations, which in turn requires them to be away from their home the majority of the time. This situation can lead to an inability to provide adequate supervision. Youths who have become disenchanted with school will have little difficulty when it comes to being truant from school. With no parent available to make sure he/she goes to school, skipping school becomes an attractive alternative to going to class and not understanding the lessons being taught or being anxious about having to read aloud when he/she is not capable of doing so.

Adolescence is a period of time in which a youth is very susceptible to peer influence and desperately wants to fit in with a peer group. If the youth feels that he/she is subject to chronic ridicule, for example, not having funds to participate in activities with peers, this may lead to his/her engaging in stealing these items or finding ways to obtain money to pay for them. One of the easiest ways for youths from low-income households to make a lot of money quickly is selling drugs.

Limited economic opportunities for the parents of these youths makes affordable housing difficult and thus the family is likely to live in an urban area that tends to have higher criminal activity. This provides the youth an easy pathway to obtain drugs and learning how to sell them. Access to weapons is much easier and street gangs are much more prevalent.

It is easy to see how a youth who perceives himself/herself as an academic failure with no hopes of going to college and who looks at his/her parents' struggle to make ends meet can be seduced by a lifestyle of quick money with little effort and no discernable skills. It is also easy to see that associating with other delinquents affords him/her not only a peer group who accepts him/her, but also a peer group that offers even more opportunity to engage more diverse delinquent acts.

A frequently overlooked factor in the development of delinquent behavior is the difficulty accessing mental-health services. Funding for mental-health services is severely lacking, and gaining access to a child psychiatrist is often difficult, much less a child psychiatrist with experience or language capacity to work with diverse immigrant populations. It is not uncommon for there to be a 3-month wait for medication services. If a youth has, for example, attention deficit/hyperactivity disorder that requires appropriate medication, obtaining treatment may prove difficult. Also, individual therapy for issues such as depression or anxiety, or group counseling for problems such as anger management or social skills training may be difficult to obtain.

Family counseling is often the treatment of choice for youths involved in violent acts or chronic delinquency. However, transportation can be a challenge for low-income families. Further, it is often not possible for the parents of these youths to take time from their jobs to attend appointments that will require them to miss work on a consistent basis, yet another barrier to treatment. Families may also not recognize or accept their child has mental-health needs because of cultural differences in classifying such behaviors or due to the stigma associated with mental illness. Thus, immigrant youths' mental-health needs can often go unmet.

The factors in this article illustrate how societal challenges a youth of immigrant status faces can place the youth on a path toward chronic delinquency and violent behavior. For youths who face these challenges, they face multiple hurdles that can be hard to overcome without help. Immigrant families may find the most success in accessing the services and assistance they may require by contacting local social service agencies that specialize in their particular culture. These agencies are typically run by persons who have emigrated from the same nation as the families requesting help, and can provide valuable information as to how best to access these services and can even provide case management services to the neediest families.

Zionism

Kristin L. Hicks
Department of Psychiatry, Mount Carmel Health Providers, Columbus, OH, USA

Zionism, a term derived from Zion, a biblical word for Jerusalem, is based on the ancient nationalist attachment of the Jewish people to *Eretz Yisrael* (Land of Israel). As an ideology, Zionism holds that the Jewish people are a nation and should gather together in a single homeland. The first use of the term is attributed to Nathan Birnbaum, Austrian journalist and founder of the first Zionist student association in Vienna. Birnbaum coined the term in response to growing anti-Semitism directed at Jews in the late nineteenth century. Zionism was formally introduced as a nationalist movement by Theodor Herzl in 1897 at the first meeting of the Zionist Congress. Within the framework of a political organization, Zionists developed a plan to extend nationalist sentiment throughout the world's Jewish population and promote Jewish development in Palestine.

The emergence of Zionism in the late nineteenth century can be understood only in the broader context of European and Jewish history. Since ancient times, Jews were exiled from Israel. The majority of the Jewish population came to reside in the Diaspora of Europe, North Africa, and the Middle East and faced discrimination and persecution for centuries. For example, in 1516 the state of Venice decreed that Jews would only be allowed to reside in a walled area adjacent to the city called the Ghetto, a trend quickly adopted by other European countries. Ghettos were overcrowded, highly taxed, and provided a convenient target for *pogroms* (mobs).

With the French Revolution and advent of the Enlightenment in the eighteenth century, the Jewish people began to gain hope that humanity was moving toward a new tolerance and liberalism. At the French National Assembly in 1789, Clermont Tonnerre demanded that Jews as individuals be denied no rights, and emancipation spread rapidly throughout Europe. Despite emancipation, anti-Semitism grew and European Jews began to see that mere cultural assimilation was insufficient for achieving equal status as nationals in host countries.

Proto-Zionist groups began to form in the 1860s and the political movement was formally established by Theodor Herzl, a Viennese journalist and author of *Der Judenstaat* (The State of the Jews), in which he argued that the best way to avoid anti-Semitism in Europe was to create an independent Jewish state. Herzl united 200 delegates from around the world, representing every aspect of Jewish religion, cultural philosophy and thought, at the first meeting of the Zionist Congress in 1897 in Basel, Switzerland. At the Congress, Herzl was elected president, the Zionist Organization was established, and a declaration of Zionism's goals were outlined in the Basel Program.

The Balfour Declaration of 1917, stating Britain would facilitate the establishment of a national home for Jews, marks the second major turning point in the political Zionist movement. However, the Declaration also confronted Palestinian Arabs with the danger of losing their country. Zionists paid little attention to the first stirrings of the Arab National movement and few envisioned the possibility of a clash of national interests, which would sow the seeds of the Israeli-Arab conflict that continues today.

Between the first and second world wars, conflict arose within the Zionist Organization. Ahad Ha-Am, one of the foremost pre-state Zionist thinkers and founder of Cultural Zionism, began to speak out and disengage from the political movement. Ha-Am and followers of Cultural Zionism believed only the Messiah could reestablish Jewish rule in Israel and

emphasized a need for revolution in Jewish thought, rather than winning political support to achieve a Jewish state. With the advent of World War II and the Holocaust, a new faction of Revisionist Zionists, led by Vladimir Jabotinski, called for the creation of a Jewish army to defend the establishment of a Jewish majority in Palestine. The Political Zionist majority, in particular Labor Zionists, who believed that a Jewish state could only be created through the efforts of the Jewish working class settling in Palestine, rejected the ideology and tactics of the Revisionists as fascist. However, by 1946 Revisionist Zionists had rejoined the Zionist Organization, which would later be called the World Zionist Organization in 1960.

In 1947, the United Nations voted in favor of the partition of Palestine, proposing the creation of a Jewish state, an Arab state, and a United Nations-administered Jerusalem. Partition was accepted by Zionist leaders but rejected by Arab leaders, leading to civil war. The State of Israel declared independence in 1948, which marked the fulfillment of one of Zionism's main goals. After 1948, Zionism evolved into a movement dedicated to immigration for as many Jews as possible, land purchase for continued settlement, and political and economic support for Israel.

In summary, Zionism is based on historical ties and religious traditions linking the Jewish People to the Land of Israel. It encompasses several aspects and competing factions, but is most commonly thought of as the nationalist political movement that supported the reestablishment of a homeland for the Jewish people. Today about one-third of the world's Jewish population resides in Israel.
