History and Politics

Little is known about the history of the Indian cultures living in the area before Columbus. Two main cultures were in the area: the Tayronas in the Caribbean Region and the Muiscas in the highlands near Bogota, who were considered to be as advanced as the Incas in Peru. Many of the Indian tribes were decimated by warfare and illness, reducing the indigenous population a great deal and causing the increase of the slave trade from Africa by the beginning of the sixteenth century.

The Colombian territory was explored by Rodrigo de Bastidas from the north, Vasco Nuñez de Balboa from the northeast, and Gonzalo Jimenez de Quesada in the center of the country, where he founded the city of Bogotá. Almost from the beginning several rebel movements were commenced against the Spanish domination but they were not successful until 1804 when St. Domingue (present-day Haiti) won its independence.

In Colombia, a movement initiated by Antonio Nariño led the opposition against the Spanish government. This was followed by the independence of Cartagena in 1811. Following the rebellion headed by Simón Bolivar, independence from Spain was declared in 1819 with the creation of the Republic of Colombia; this was organized as a union of Ecuador, Venezuela, and Colombia (which included Panamá). This union did not last long and Venezuela became independent in 1829, with Ecuador doing the same 1 year later. In 1903, the Department of Panamá, influenced by the United States, became independent.

After a period of political stability, Colombia was devastated by an incredible conflict known as "La Violencia" ("The Violence") caused by bloody fights between members of the two political parties following the April 9, 1948, assassination of the leader of the Liberal party, Jorge Eliecer Gaitán. During the next several years, thousands of Colombians were killed until the military coup of Gustavo Rojas Pinilla and the government of the Military Junta. There were additional violations of human rights, including forced recruitment, the disappearance of individuals, and sexual violence.

After the military regimes, the two traditional political parties agreed to the creation of a "National Front" whereby the Liberal and Conservative parties would govern jointly. This agreement eliminated "the Violence" but many believe that the contradictions and disagreements between the parties were the forces responsible for the development of the Marxist-oriented groups such as the M-19, the Revolutionary Armed Forces of Colombia (FARC), and the National Liberation Army (ELN).

To complicate this fragile and violent sociopolitical situation, powerful and violent drug cartels developed in the late 1970s, 1980s, and 1990s. These cartels influenced and financed the illegal armed groups, thereby creating incredible instability in the government and severe violence in the nation. This led to one of the largest displacements of people in the world, with more than two million Colombians leaving the country.

In August 2000, the United States government approved "Plan Colombia," pledging $1.3 billion to fight drug trafficking. President Pastrana used the plan to undercut drug production and prevent guerrilla groups from benefiting from drug sales and expanded the rights of the military in dealing with the rebels.

As a result of the internal violence, approximately 1.6 million individuals had been internally displaced by mid-2005. In 2003 alone, almost one-half of internal displacements were believed to be the direct result of actions of the paramilitary and guerilla groups, with the remaining displacements due to the actions of other illegal groups and the Colombian military.

In May 2002, Alvaro Uribe of the Liberal Party was elected president and promised to increase the attack on the guerrillas, increasing military spending and seeking US military help. Many believe that Colombia is back on track to recuperating from years of violence and unlawful acts.

Economy

Historically Colombia has had an agrarian economy, a situation that has changed rapidly during the twentieth century. Colombia is rich in natural resources and its main exports are petroleum, coal, coffee, and gold. Also, Colombia is the world's leading source of emeralds and the largest exporter of flowers to the United States (70% of the market). Tourism is also a popular industry in Colombia with close to three million visitors per year despite warnings about security.

Despite its political difficulties Colombia has enjoyed a strong economy with a healthy growing of the Gross Domestic Product (GDP). The country had a recession in 1999 but recovered well and has one of the highest rates of growth in Latin America. Nevertheless, Colombia continues to have serious social problems, with 20% of the population having a 63% share of the income/consumption and approximately 18% of the population living on less that $2 a day.

Immigration to Colombia

Historically there has been relatively little immigration to Colombia from other countries. Spain initially discouraged immigration to the area beginning in the early 1500s, in order to prevent other countries from claiming its colony. More recently, the violence associated with the civil war (La Violencia) has dissuaded individuals from resettling in the country.

Currently, skilled workers are welcomed in the country and work visas may be available. Venezuelans make up almost one-half of current immigrants to Colombia (41%), and Ecuador follows second (8.5%). Other foreign nationals living in Colombia include citizens of Spain, Germany, Italy, Lebanon, and several Latin American countries.

Emigration from Colombia

As a result of the armed conflict, there has been massive emigration from Colombia during the past decade. Approximately one out of every ten Colombians now lives outside of the country. Primary destinations of Colombian citizens who have chosen to emigrate elsewhere include the USA; Canada; several Central American countries (Costa Rica, Guatemala, Mexico, and Panama); the Caribbean countries of Aruba, Curacao, and the Dominican Republic; various South American countries (primarily Venezuela, Ecuador, and Argentina); several European countries (primarily Spain); Australia; Japan; and Israel.

According to the Census Bureau's 2008 American Community Survey (ACS), there are 47 million Hispanics in the United States and close to 1 million of them are identified as Colombians, accounting for 1.9% of the US Hispanic population in 2008. Approximately two-thirds of Colombians are foreign born, compared with 38.1% of Hispanics and 12.5% of the US population overall. A proportion of the Colombians in the United States have received asylum or refugee status based on their persecution in Colombia. Colombia is believed to be the fourth-leading source of undocumented immigrants to the United States.

Most of the immigrants from Colombia (58.7%) arrived in the USA in 1990 or later and less than one-half (48.8%) are US citizens. The median age for Colombians in USA is 36 years, which is the same as the median age of the USA. The majority of Colombians in the USA speak English proficiently and have a higher educational level than the Hispanic population overall. They are also more likely to be married and live mostly in Florida (31.9%) and in the New York–New Jersey area (29%).

Remittances from the emigrants to their families in Colombia have risen by more than 20% per year since 1999. These remittances are believed to total more than three times the country's revenue from coffee exports and two and one-half times the revenue from coal. It is believed that more than three-quarters of these remittances are spent on the essentials of daily living, such as food, rent, and education.

Colorectal Cancer Incidence Among Immigrants

Colorectal cancer incidence, defined as the number of new cancer cases occurring within a defined time period, varies widely. In more developed countries, the colorectal cancer incidence is substantially higher than in less developed countries. Risk factors for colorectal cancer are increasing age, inflammatory bowel disease, a personal or family history of colorectal cancer or colorectal polyps, rare genetic syndromes and lifestyle factors, such as lack of physical activity, low fruit and vegetable intake, a low-fiber and high-fat diet, overweight and obesity, alcohol consumption and tobacco use. As immigrants move from less developed countries to more developed countries, they adopt the lifestyle of their host country, such as low fiber intake and high meat consumption, which increases their risk for colorectal cancer. For example, Chinese and Filipino persons who are born in Asia and later immigrate to the United States have a higher risk of colorectal cancer than their counterparts who remain in Asia. They have a lower risk of colorectal cancer than the general population in the United States because they may be slow to adopt the lifestyle of the host country. Studies of recent immigrants in the United States have shown an increased colorectal cancer incidence within one generation. There is very little information on colorectal cancer screening among immigrants in other countries. Therefore, this entry is limited to immigrants in the United States. In the United States, colorectal cancer is the third most common cancer and the second most common cause of cancer death. Most of the immigrants who arrived in the United States after 1970 were from countries in Latin America and Asia. The most recent statistics (2007) show that 54% of the foreign-born US population is from Latin American, 27% from Asia, 13% from Europe, and 6% from other areas, including Africa and Oceania.

Colorectal Cancer Screening Among Immigrants

Through screening, health care providers can capitalize on the relatively long premalignant phase of colorectal cancer. The progression of polyps into cancerous lesions is often slow; therefore, if found early, precancerous polyps can be removed. Additionally, colorectal cancer prognosis is tied closely to the stage at which the cancer is diagnosed. Almost 90% of colorectal cancer patients survive for at least 5 years if their cancer is diagnosed in its early, localized stage, but only about 10% survive for at least 5 years when the cancer is diagnosed at a late stage, when it has spread to other parts of the body. Thus, colorectal cancer screening tests are indispensable tools for identifying individuals early in their disease, when they are often asymptomatic, and allow for treatment that prevents further progression and metastasis. The US Preventive Services Task Force (USPSTF), an independent panel that issues guidelines on cancer screening, recommends routine screening of all men and women 50 years and older. This recommendation is based on several randomized trials that showed that regular screening after 50 years of age greatly reduces deaths from colorectal cancer.

Colorectal cancer screening is unique in that a number of different types of screening tests are recommended. The Fecal Occult Blood Test (FOBT), also called stool blood test, analyzes fecal material for the presence of occult (hidden) blood. For a stool blood test, individuals must collect a small stool sample and send it to a provider for analysis. Two types of stool blood tests are currently available. Guaiac FOBT uses the chemical, guaiac, to detect heme, a component of red blood cells; immunochemical FOBT or Fecal Immunochemical Test (FIT) utilizes antibodies against human hemoglobin protein to detect the presence of blood in stool. Alternatively, screening by endoscopy is more invasive and more expensive. In an outpatient procedure, a long, flexible instrument equipped with a video camera is inserted through the rectum to inspect the lower colon (sigmoidoscopy) or the entire colon (colonoscopy). With endoscopy, lesions can be visualized and those appearing precancerous or cancerous can be removed during the screening procedure. The ability to detect and remove lesions in one session makes this the preferred choice for health care providers and, in the United States, screening by colonoscopy is increasing in the general population. However, because stool blood tests are lower cost, more convenient alternatives, interventions to increase screening in larger populations often advocate their use. The US Preventive Services Task Force recommends annual stool blood tests for individuals 50–75 years old *or* sigmoidoscopy every 5 years *or* colonoscopy every 10 years. Other screening options are also available, such as virtual colonoscopy, double contrast barium enema, and digital rectal exam. Additionally, research involving experimental screening methods such as wireless capsule endoscopy showcases the technological advances in possible cancer screening modalities.

Despite the recommendations and multiple choices of screening tests, colorectal cancer screening is underutilized. In the general US population, colorectal cancer screening prevalences are substantially lower than screening prevalences for breast or cervical cancer by mammography or Pap smear. Several campaigns promote colorectal cancer screening and the proportion of the population that has received a colorectal cancer screening test according to the guidelines has steadily increased (from 20–30% in 1997 to almost 55% in 2008). However, screening disparities among racial/ethnic groups continue to persist. Based on a large California population-based survey (California Health Interview Survey), the prevalence of colorectal cancer screening increased significantly among Whites and Latinos but not among African Americans and Asian Americans between 2001 and 2005. Screening prevalence varied substantially among Asian subgroups, with Koreans, Filipino, and Vietnamese Americans having the lowest prevalence. Many members of these Asian subgroups are immigrants. In contrast, Japanese Americans who have a long history of living in the United States had one of the highest screening prevalences.

Another study conducted using data from the 2000 National Health Interview Survey concluded that foreign-born individuals not only had lower colorectal cancer screening prevalences than US-born non-Latino Whites, but also had significantly lower screening prevalences than US-born members of their ethnic community. In addition, a recent analysis of colorectal cancer screening in Filipino American immigrants suggests that within ethnic subgroups, more educated and acculturated persons with higher income may tend to obtain endoscopies, whereas more recent immigrants with lower levels of education and income tend to obtain stool blood tests. Thus, even within an immigrant group from the same country, disparities may exist with respect to the type of colorectal cancer screening test received.

Factors Associated with Colorectal Cancer Screening

Studies in general population samples have found certain demographic variables, such as higher education, higher income, having health insurance, and being married, to be positively associated with colorectal cancer screening and other cancer screening tests. Factors such as lack of symptoms, lack of time, inconvenience, lack of interest, cost, discomfort associated with the procedure, and embarrassment have been found to be common barriers to colorectal cancer screening. To date, only a few studies have explored factors associated with colorectal cancer screening in immigrant populations. Studies in several immigrant populations (Latinos, Filipino Americans, Korean Americans, and Chinese Americans) found that older age and longer duration of residency in the United States, having health insurance, and higher levels of education and income were associated with increased colorectal cancer screening. In these populations, barriers to screening include being unaware of cancer screening tests or underestimating their importance, lack of health insurance to cover screening tests, and not having a regular health care provider. Cultural barriers also play a role. They may include modesty (an issue when undergoing endoscopy), fatalism (there is nothing I can do to prevent getting colorectal cancer), crisis orientation toward health and illness (consulting a physician only when seriously ill), and use of Eastern medicine instead of Western medicine. For example, in one study, Latina women who were given access to free screening were more likely to get screened if they had less fatalistic attitudes. Undocumented legal status and use of home remedies instead of seeing a physician have also been suggested as barriers to screening for Latino immigrants.

A physician recommendation to get screened remains one of the most important promoters of colorectal cancer screening in the general population and among immigrants. California Health Interview Survey data suggest that Korean and Vietnamese Americans are less likely than other Asian American groups to report a recent doctor recommendation for screening. This may be due to language barriers, not seeing a physician for routine checkups, and not asking physicians for routine screening tests. In a study that explored why Korean American physicians did not recommend colorectal cancer screening to their Korean American patients, physicians identified the following barriers for recommending colorectal cancer screening: barriers directly attributable to the physicians themselves (i.e., lack of knowledge, fear of medicolegal liability), barriers associated with their patient characteristics (i.e., patient's unfamiliarity with the concept of screening and preventive medicine), and barriers that result from the limitations of the health care system or local clinics (i.e., lack of referral network for endoscopy, poor reimbursement). One study that included Latino and Chinese immigrants who were patients in a primary care clinic in New York found that the vast majority obtained a colonoscopy after a physician referral. This finding underscores the importance of a physician recommendation for colorectal cancer screening among immigrants.

Interventions to Increase Colorectal Cancer Screening

Programs and interventions to increase colorectal cancer screening have been developed and tested, although they are usually not exclusively targeting immigrants. Several interventions have been developed for Latino and Asian American populations, both of which have large proportions of immigrants. Programs may include reminder letters, educational videos and brochures, one-on-one or small-group educational sessions, and help for patients to make appointments for colorectal cancer screening and to "navigate" the health care system. Studies of clinic-based interventions, where patients are recruited at clinics and interventions are delivered by health professionals or trained peer navigators, have been shown to increase colorectal cancer screening among immigrants. These programs have the advantage that all patients have access to health care and can receive colorectal cancer screening at the program site. However, clinic based programs can only reach those immigrants who have health insurance and a regular source of care.

Immigrants who lack health insurance can be reached through programs at community-based organizations and churches that promote colorectal cancer screening. Only a few studies have been conducted among immigrants in nonclinical settings, and not all have been successful in increasing colorectal cancer screening. These programs typically include education to increase knowledge and awareness of the screening tests and discussion of barriers to screening and how to overcome these barriers. Some programs provide free colorectal cancer screening, typically a low cost stool blood test. Linguistically and culturally appropriate telephone counseling has also been shown to be effective.

Other programs to increase screening are targeting physicians to increase recommending screening to patients, and system barriers, such as instituting reminder systems at clinics. For example, the medical charts or electronic health records of patients who are not up to date with colorectal cancer screening can be flagged to remind the physician to recommend screening to these patients, and reminder letters can be mailed to these patients. In addition, health insurance coverage for colorectal cancer screening is increasing. For example, Medicare has expanded coverage to include all recommended screening tests, including colonoscopy. These programs are expected to increase colorectal cancer screening in future years in the general population and among immigrants.

Colonialism

Jennifer Burrell
Department of Anthropology, University at Albany, The State University of New York (SUNY), Albany, NY, USA

Colonialism is the long-term political, social, economic, and cultural domination of a people and territory by a foreign power. Modern colonialism can be traced to the European "Age of Discovery," particularly to colonizing projects carried out by the England, Spain, France, and the Netherlands that extended to the Far East and to the Americas. Throughout the nineteenth and into the twentieth century, colonialist regimes were established throughout the world, frequently with "civilizing" ideologies at their core, such as "the White man's burden," adopted by the British, and the "mission civilisatrice" of the French. Underlying these ideologies was the intent to move beyond governing to the modernization and eventual assimilation of people, often accomplished through great violence and through the establishment of cultures of terror.

Colonies took a variety of forms meant to support economic exploitation of people and land. These included (1) settler colonies, in which people from colonizing nations moved in large numbers in new territories; (2) dependencies, in which governing regimes or administrations managed local populations; (3) plantation colonies, in which land and people were used to produce agricultural products; and (4) trading posts, including forts and other quasi-military installations that controlled trading and selling in a particular area. Whatever the form, the project of establishing a colony and of producing colonial subjects entailed the implementation of power structures and division of places and people in ways that were frequently arbitrary inventions. New countries were produced through these encounters, as well as new categories of people. These hierarchies, categorizations, and other mechanisms of power shaped how colonizers and the colonized interacted and were able to move and make choices within a society, producing races, ethnicities, classes, sexualities, and ways of being in the world large. The colonized often experienced untold horrors as they were forced into imperialist projects. But as Cooper and Stoler argue in their 1997 *Tensions of Empire*, these mechanisms also produced contemporary Europe as a bourgeois society and order was remade and expanded in relation to imperialism.

It has been argued that colonialist ideologies persist in the world, under new labels, but with similar mechanisms. Escobar, for example, suggests that development and development policies have become as pervasive, effective, and controlling as their colonial counterparts. Development ideologies and projects have adopted categories that have shaped world thinking on how people are to be "helped" or pushed toward modernity, even as many of these projects do not succeed. Indeed, Ferguson suggests that development projects often fail, but something else is accomplished, often the expansion of State or governing power in realms where it was formerly thin on the ground or nonexistent.

Processes of colonialism and development (or underdevelopment) have been central to shaping our world and the possibilities that exist for all people. Many contemporary inequalities and disparities result from these processes, among them the struggles of indigenous people's throughout the world and the horrors of genocide in places like Rwanda, where the divisions that led to the mass killing were the direct legacy of the German and Belgian colonial projects in that region of Africa from the 1890s onward.

Colorectal Cancer

Timothy E. O'Brien
MetroHealth Medical Center, Cleveland, OH, USA

Incidence

Colorectal cancer is uncommon in developing countries but is the second most frequent malignancy in affluent societies. More than 940,000 cases occur annually worldwide, and approximately 639,000 people die from it each year. In the United States there were around 150,000 new cases of colorectal cancer diagnosed in 2009 and it was the second leading cause of cancer death. The risk increases with increasing age, particularly starting at age 50, and colorectal cancer is quite rare in patients under age 40.

Cause

Some studies suggest that a "Western diet," rich in fat, refined carbohydrates, and animal protein, may lead to colon or rectal cancer, particularly if combined with low physical activity. It has been proposed that a sedentary lifestyle allows greater exposure of the inner lining (epithelial) cells of the colon or rectum to carcinogenic substances in the diet. Some studies suggest that this risk can be reduced by decreasing meat consumption (particularly processed meat), increasing the intake of vegetables and fruits, and increased exercise. Immigrant populations rapidly reach the higher level of risk of the adopted country, another sign that environmental factors play a major role. Although there are inherited forms of the disease, genetic susceptibility appears to be involved in a small number (less than 5%) of cases. Patients with longstanding inflammatory bowel disease, particularly ulcerative colitis involving the entire colon, are also at increased risk.

Before becoming invasive cancer, cancers of the colon and rectum generally start out as benign (i.e., nonmalignant) growths of cells lining the colon (endothelial cells) called polyps. After further damage to the endothelial cells' DNA, their growth becomes disorganized and uncontrolled. The cells become abnormal or dysplastic, a precursor to cancer. After more DNA damage (presumably from environmental toxins), the dysplastic cells become malignant and invade into tissue; at this point the cells are called colorectal cancer cells (adenocarcinoma). Because of the relative orderly progression from adenomatous polyp to dysplasia to overt carcinoma (cancer), screening tests which detect nonmalignant polyps are an effective way to prevent the development of colorectal cancer by removing the earlier precursor form of the disease before overt cancer has developed.

Screening

The best screening test for colorectal cancer is a colonoscopy. It is recommended that all people should get a screening colonoscopy starting at age 50; if it is normal then the screen should be repeated every 10 years. Patients with a first-degree relative (parent, sibling, or child) with colon or rectal cancer should have their first colonoscopy at an age 10 years younger than their relative was at their diagnosis. Screening colonoscopies are covered by most health insurance carriers in the United States and Medicaid patients starting at age 50. Virtual colonoscopy involves a noninvasive radiographic test of the colon and rectum. It may be as effective as the colonoscopy in detecting most precursor polyps but is not yet widely available.

Other screening tests which have been shown to be effective in reducing colorectal cancer-related mortality include stool hemoccult testing and flexible sigmoidoscopy. Stool hemoccult tests (tests for blood in the stool) involve sending in three stool smears on a card, which are then tested for microscopic blood. This has the advantage of being inexpensive and easy to complete but is not very sensitive at detecting colorectal cancers, which may bleed intermittently or not at all. Flexible sigmoidoscopy is very sensitive at detecting polyps and cancers in the rectum and sigmoid colon but misses the rest of the colon, so that around 1/3 of colon tumors in men and 2/3 in women will be missed with this test. Its sensitivity can be improved, though, if a barium enema (a radiographic imaging study) is combined with the flexible sigmoidoscopy to image the rest of the colon.

Clinical Manifestations

Many patients will not have any symptoms and are diagnosed through a screening test, such as a colonoscopy. Colon cancer patients may present with symptoms of iron deficiency anemia, such as fatigue, or notice a change in stool caliber, have vague abdominal pains, or less commonly notice blood in their stools. Rectal cancer may become noticeable as pain on defecation, blood in the stools, or obstructive symptoms such as lower abdominal pains, nausea, and vomiting.

Staging

Like most cancers, colorectal cancer goes through four stages. The stage determines prognosis and is based, in part, on depth of penetration into the bowel wall. Stage I cancers invade into the layer just underneath the colon or rectal lining (submucosa) or into the muscle layer; stage II tumors go all the way through to the bowel wall but without involvement of surrounding lymph nodes; stage III cancers involve surrounding lymph nodes; and stage IV means that the cancer cells have spread (metastasized) to other organs (usually the liver or lungs). All patients with stage I, II, and III are potentially curable; most stage IV patients are not curable but there are some exceptions (see below).

Treatment

Early Stage Colon Cancer

Stages I–III are treated with surgical resection, which is potentially curable. Following surgery, those with stage III (node involvement) should be offered chemotherapy. This has been shown to significantly improve survival and reduce recurrence of colon cancer.

Early Stage Rectal Cancer

Unlike the colon, the rectum is not enveloped by a protective sheath called the peritoneum. For this reason, rectal cancer recurs far more commonly in the area of resection (locally), as opposed to throughout the body (systemically). As a result, treatment for early stage (stages I–III) rectal cancer is different than that of colon cancer. Radiation, which interferes with DNA replication and treats one small area (local), plays an important role. Chemotherapy, which is given intravenously or orally, is delivered by the blood to all the tissues of the body (systemic therapy). Because patients with early stage rectal cancer may recur locally or systemically, both chemotherapy and radiation are indicated. Combined chemotherapy and radiation should be offered prior to surgery in patients with stages II and III rectal cancer. This has been shown to result in better local control of the rectal cancer than having surgery followed by chemotherapy and radiation. These patients are all treated with curative intent.

Advanced Colorectal Cancer

Most of these patients are incurable. The exception is the patient with localized spread to one part of the liver which can be resected, along with the primary colon or rectal cancer.

Without treatment, patients with metastatic colon or rectal cancer will live about 12 months. Over the past decade tremendous progress has been made, such that the median survival now with modern therapies is about 2 years. Treatment regimens include systemic chemotherapy along with bevacizumab, an antibody which is directed against vascular endothelial growth factor, a substance which allows blood vessels around tumor cells to grow. Studies have shown that the addition of this agent to chemotherapy improves survival time. In addition, a newer class of drugs called epidermal growth factor receptor (EGFR) inhibitors also improves the effects of chemotherapy. These drugs, which include cetuximab and panitumumab, are antibodies against EGFR on the colorectal cancer cell. They are effective only in patients whose colorectal cancer cells do not have a mutation called k-ras. If the cells are mutant in k-ras, which is seen in about 40% of cases, then the EGFR antibodies will not work.

All of these patients should be encouraged to enroll onto clinical trials, as this will be the only way to make improvements in the management of colorectal cancer. This is particularly important for immigrant minorities, who are often underrepresented in clinical trials.

Summary

Cancers of the colon and rectum are particularly common in immigrants coming from affluent countries. Screening tests can detect these at precancerous, highly curable stages and so should be done in anyone over age 50, or younger if in a high-risk group. Early stage colon and rectal cancer is very curable, with surgery playing the dominant role. Advanced colorectal cancer is generally not curable but recent advances have been made which have significantly improved the survival in these patients.

Communicable Disease of Public Health Significance

Mihaela-Catalina Vicol
Department of Bioethics, University of Medicine and Pharmacy "Gr. T. Popa", Iasi, Romania

The risks of communicable diseases of public health significance reveal the need for early detection, prophylaxis, and treatment. From this point of view, dealing with an immigrant population usually means dealing with diseases with high incidence and prevalence in their origin country. For example, hepatitis B virus is endemic in Asian countries; consequently, 15% of Southeast Asian immigrants are chronic carriers of this infection and the percentage of carriers among Indo-Chinese immigrants is between 14% and 20%. This is why, currently, almost every country has a set of screening procedures for different communicable diseases of public health significance, in order to avoid the possibility of disease transmission within the population, to detect diseases early, and to treat them promptly. For example, according to American Public Health Association (2002), and to the US Centers for Disease Control and Prevention (CDC), immigrants are screened prior to their entry into the USA and prior to adjustment of status for several communicable diseases with potential impact on public health. These include tuberculosis, syphilis, HIV infection, chancroid, gonorrhea, granuloma inguinale, lymphogranuloma venereum, and Hansen's disease. Prior to entry in the USA or during the period of adjustment, intending immigrants are also required to complete or to demonstrate completion (as age-appropriate) of a set of immunizations for several vaccine-preventable diseases such as hepatitis B, influenza B, mumps and measles, pertussis, polio, rubella, tetanus, and diphtheria toxoids. Depending on the native country, other diseases might be considered, such as malaria, varicella, etc. Immigrants who are found to test positive for such diseases usually are treated. In addition, besides screening for diseases listed above, and the documentation of vaccine history and vaccination required, immigrants are also screened for drug addiction and for physical and mental health disorders that could determine harm to the person or to the others.

Besides this situation of legal immigrants who must pass through a screening filter for communicable diseases that can potentially impact public health, there is the situation of illegal immigrants. In their cases, they cannot be screened. In addition, they may not seek healthcare except for emergencies, out of fear of deportation because of their illegal status. This may have a great impact on the public health. It has been asserted that the health status of illegal immigrants is poorer than the rest of the population and that their access to healthcare is limited by different kind of barriers.

Although screening for communicable diseases that may impact on public health plays a very important role in the control of disease transmission, early detection and treatment are also critical. This suggests the need for the early detection and treatment of such diseases in the immigrant population that settles for some time in their second country. This issue relates directly to the extent to which health care is accessible to immigrants and particularly those with uninsured status, low income, illegal immigrant status, language and cultural barriers, social barriers, etc. For example, a significant decrease in the prevalence of tuberculosis (TB) has been noted among US native citizens. Unfortunately, this decrease has not been mirrored by a similar decrease in the prevalence of TB in the US immigrant population. In 2003, in New York, the rate of tuberculosis was four times higher among foreign-born citizens (especially among individuals born in China, Ecuador, Haiti, Mexico, India, and the Dominican Republic) than in US-born New York citizens.

These data argue for the need for efforts in addition to the screening currently conducted prior to or upon immigrants' arrival to their destination country. It indicates the need for health policy measures to improve and to stimulate immigrants' access to health care. Such measures may have positive consequences not only for the health of immigrants, but also on the general population.

Communication Barriers

Martha Womack Haun
Valenti School of Communication, University of Houston, Houston, TX, USA

Communication is the process by which senders and receivers of messages establish shared meaning in a specific context. Effective communication requires that a message, verbal and/or nonverbal, oral or written, be created by the source and be successfully understood/received at the destination by the receiver/target. This may involve people, animals, or computers. This is an ongoing, reciprocal, transactional process. Transactional means that we are sending and receiving messages simultaneously, even when we are asleep. Various barriers can result in the poor or distorted reception of the message.

Poor Message Creation

The speaker or sender has a responsibility to create a message that is clear, coherent, and understandable by the receiver. If the sender does not consider the interests and educational level of the receiver, the result may be confusion and/or rejection of the ideas in the message. Poor reasoning, disorganization, irrelevant or confusing examples can all result in messages that are not effective for the receiver. The receiver is an important part of this process and can contribute positively by paying attention to the messages. The environment must be conducive to message exchanges. It should be free of distractions and interruptions. Barriers in the communication cycle may occur at any point and may be attributed to the message, sender, receiver, or the environment.

Noise

The term noise is often used to refer to disruption or interference in the communication process. Noise may be external as poor technical reception, interference in the environment such as a door slamming, a phone ringing, loud music, people talking loudly near you, or other factors that make it impossible for the receiver to clearly hear the message being sent.

More often the “noise” is internal. This may be psychological noise such as daydreaming or wishful thinking. Instead of paying attention to the other person, minds wandering, thinking about things that need to be done or plans that need to be made may disrupt the receiver’s attention. Sometimes the language being spoken is not familiar or comprehensible. Lack of a common language quickly reduces the communication exchange to a series of hand signals and other nonverbal signs. The same language may be used but the meaning of the words being used is different. Vocabulary words like “expediency,” or “dissonance,” or “integrity,” may be strange to the receiver. This is called “semantic” noise. Inability to accurately assign meanings in a timely manner destroys the communication process.

Double Meanings

Messages between senders and receivers are usually both verbal and nonverbal. In any language, the use of the voice – through pitch, inflection, tone, and timing – adds nuances and meanings to the words so that what is understood as having one meaning on the verbal level actually takes on a different meaning on the nonverbal level. “Come see us again,” said in a flat tone of voice may suggest that the return visit should not be any time soon. Thus, greetings that have special cultural contexts and meanings may be offensive if not used correctly and trigger unexpected or negative responses.

Disconfirming Communication

In interpersonal communication intentionally or unintentionally barriers may be created by poor listening and by the type of responses given to the other person. When listening, do you give the other person your full attention or are you trying to do several things at the same time? Can you repeat back in your own words accurately what the other person has said? Are you leaving out part of the message? Adding bits and pieces? Or simply incorrectly stating the content?

When someone is talking to you, do you look bored by averting your eyes and yawning frequently? Do you ignore what they are saying? Do you make an unrelated response or simply change the topic, content, or direction of the conversation? Such responses are perceived very negatively and result in poor communication, creating barriers to future effective communication.

Aggressive Communication

Sometimes receiver responses are hostile and have a negative emotional element. Persons may intentionally use “trigger” words and say things (perhaps through name-calling) to emotionally arouse and annoy the other person and initiate a conflict. Picking an argument and blaming it on the other person by showing dissatisfaction with a selected restaurant, movie, or television show, for example, is an aggressive approach that is a strong communication barrier.

An effective communication exchange involves both cost and rewards. It takes time to stop and talk with a person. Are you satisfied with the return? Was the exchange positive or negative? Did you feel satisfied after the communication or did it cost you time you didn’t have? Did it cost other resources? Did you have to buy dinner or forego some other activity of interest? Repeated cost escalation will ultimately become a barrier to effective communication. Rewards of effective communication include the satisfaction of being clearly understood and of developing positive successful relationships.

Positive or Negative Arousal

People like to hear positive, confirming, complimentary messages. Criticism, disagreement, or hostile remarks are uncomfortable. Senders and messages that create this “negative arousal” may generate avoidance. Remembering names and remembering conversations, for example, indicates active listening and interest in the other person and is positive arousal. Negative arousal, however, poses a significant communication barrier.

The Environment

The communication environment affects the effectiveness of the communication process. Noisy, crowded public places make it difficult for persons to hear each other and concentrate on what is being said. If the room is too hot or too cold, or the furniture is uncomfortable, persons may find it impossible to concentrate. A culturally different environment may result in discomfort. A pleasant, quiet restaurant or a walk in the park on a nice day may provide the needed comfort and privacy to offset such barriers.

Blaming

Blaming the other person is a common barrier and occurs when we do not take responsibility for our reactions to messages. “You’re just stupid” (name-calling), as an example, could be restated more productively as “I’m sorry but I don’t understand what you are saying.” Saying “You make me so angry” (blaming the other person), for example, could be stated more effectively as “I feel disrespected when my car is returned with no gasoline in it,” or “I feel unimportant to you when you keep me waiting for an hour for dinner.”

Lying

While small untruths or omissions of information may be viewed as acceptable to protect the feelings of another person or to keep a confidentiality, telling blatant untruths (fabrication or falsification) or failing to report known information (omission) or intentionally dodging or avoiding an issue by making irrelevant responses or changing the topic creates negative and unproductive communication.

Inappropriate Disclosure

As people explore the process of getting acquainted, they typically reveal information layer by layer, a little at a time, and by taking turns. Safe, factual information about themselves is revealed initially and, after some time, more personal, intimate details about themselves not known to "the public" is disclosed. This process involves risk and trust with a danger that the other person may not like them when the information is revealed. There is also a risk that one or both of the parties will not keep certain information confidential. Conversely, if a person reveals too much information too quickly, discomfort will result because the receiver does not know how to handle so much new information at one time.

Information Load

Too much information received too quickly exceeds the individual's ability to handle or manage the information and it becomes overwhelming to the receiver. Too little information, however, creates a boring or uninteresting situation for the receiver. Individuals have their own rate and capacity for handling simple or complex information.

Disrespect

The individual point of view (ethnocentrism) is a common human characteristic. Attitudes are based on values, beliefs, and experiences that have evolved over time. With aging, the more likely such attitudes are to be "locked in" to our personality. Disrespect or disdain for persons who do not share these attitudes, may be a tremendous barrier to effective communication. It may result in contempt or anger for those holding opposing viewpoints. Such emotions and attitudes can be barriers to effective communication.

Conclusion

An understanding of interpersonal communication is important so that barriers such as aggressive communication, blaming, disrespect, and other causes of poorly constructed messages may be avoided. The following perspectives can be helpful in creating positive communication: (1) Fearful environments such as job interviewing or a threat of deportation may require extra care in message creation. (2) When cultural norms and nonverbal expressions are unfamiliar, communication may breakdown. (3) Language may be a significant barrier to overcome. (4) Positive arousal, negative arousal, and double meanings of words are all intensified by language. (5) Lying, blaming, and disrespect may occur when cultural differences exist or life experiences include a history in which immigrants have been lied to or disrespected. (6) Disclosure may be difficult when an individual has a history of punishment or is threatened with deportation. (7) Often immigrants have interpreters to reduce these problems, especially in health care circumstances, but sometimes these are children or other family members who may misinterpret. Immigrants may often experience an unfamiliar culture as well as a foreign language that exacerbates the communication challenges. Communication is an essential process and each person has an important responsibility to make it successful!

George Washington University, Washington, DC, USA

Immigrant and Refugee Populations: A Brief Demographic Portrait

To understand the evolving composition of immigrant communities, a brief portrait of current immigrant/refugee population patterns is useful. According to a recent United Nations (UN) report on migration, there were close to 200 million immigrants in 2006, about 3% of the world's population. The distribution and nature of immigrant communities is intricately connected to the overall pattern of *globalization* and its inherent flow of labor. The countries with the highest number of immigrants include the United States, the Russian Federation, Germany and other European nations, Canada, Saudi Arabia, India, and the Ukraine. However, countries with the highest percentage of immigrants are primarily in the Middle East, reflecting labor requirements. Regions that are the major sources of immigrants include Asia (e.g., China, Indonesia, India, Philippines), Latin America/Caribbean (e.g., Mexico, Central America), and Africa (e.g., West Africa, Congo, Somalia, Sudan, Ethiopia). Refugees are also migrants, but forced migrants, not moving for reasons of labor or family but to escape violence, disaster, or political persecution. The source countries for refugees vary considerably depending on political situation, but most recently include Afghanistan, Iraq, Somalia, Democratic Republic of the Congo, and others. Depending upon the nature of available labor as well as (for refugees) resettlement patterns, immigrant communities may be urban or rural, though predominantly the former.

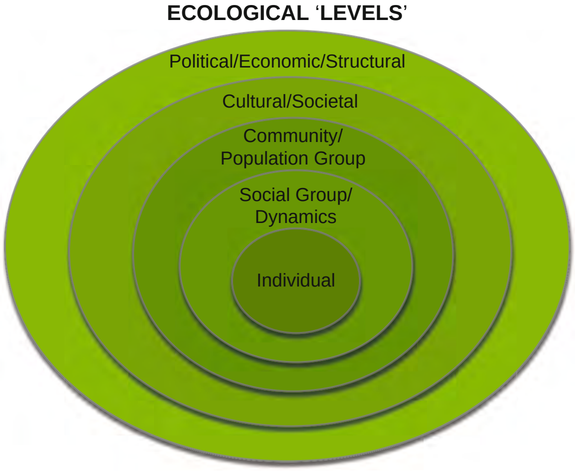
Defining Immigrant/Refugee Communities

The term "community" is used in so many contexts that before outlining its meaning in terms of immigrant/refugee health, it is worth reiterating some of that usage. "Community" can refer to:

- A geographic and social space that has boundaries of some kind where people live and interact.
- An emotional feeling – for example, one can feel a "sense of community" with other individuals due to a situation (e.g., a shared emergency) or shared commitment (e.g., with respect to faith). Anthropologist Victor Turner referred to this sense of social togetherness as *communitas*.
- A group of individuals who share an interest or lifestyle pattern, and who interact with each other regarding that interest, as in "the community of recreational fishing boat owners."
- A self-identified ethnic or national population, as in "the Italian community," which may or may not refer to people living in a specific geographic space, but could in fact be global. It could also be an "imagined community" whose existence can be seen as a construction in the popular imaginary.

There are also other kinds of definitions: *intentional communities* for example, are voluntarily formed by groups of people who want to put in practice a particular philosophy of living together, whether religious, environmental, or utopian; *virtual communities* are groups of people who interact regularly via the Internet around games, issues, or interests.

For this essay, since the focus is on public health, "community" may include any of these to some degree, but primarily we are referring to a geographically bounded space that can be understood as a *social ecology*. That is, within that bounded (yet porous) space, there is a particular combination of individuals who live and/or work there, social groups, cultures and practices, economic relationships, environmental conditions, and resources, all interacting to form a certain kind of interdependent sociocultural unit. Moreover, this "unit" is nested within larger political, economic, social, and cultural structures, so it cannot be considered in isolation. Community is defined in this way in part to interact, theoretically and in practice, with the *ecological model* of health determinants now prevalent in public health literature, which can be visually depicted as, for example, concentric circles illustrating multiple levels of influence on a particular health issue – moving from the individual, to social groups and networks, to community and society, culture and political economy (Fig. 1). It is also intended to encompass



Community. Fig. 1 "Levels" in the ecological model of health

the structural relationships between communities and the social orders of which they are a part.

Studying Communities: Anthropology, Sociology, and Media/ Communications Perspectives

Both anthropology and sociology have long traditions of studying urban and rural communities in ways that have had increasing impacts on public health approaches. In sociology, the focus has been on social networks, social capital, hierarchy and class, and patterns of social relations. Studying communities as unique sociocultural settings and as representative of particular cultures was indeed the domain of traditional ethnographic work in anthropology, in remote, rural, and urban communities. It is only more recently that anthropologist Robert Redfield's portrayal of relatively self-contained "little communities" has changed, with more recent work addressing the nature of specific urban or rural communities in relation to broader and transnational structures of power and globalization, and in keeping with the broadening of anthropological inquiry beyond place-based strictures. Much of the work on health issues within medical anthropology takes this latter perspective. In addition, contributions from media and communications studies show that those transnational structures must also include the broad reach of media and online activities, which can have multiple impacts on immigrant communities, from increasing assimilation, to fragmentation that occurs when different (e.g., generational) segments of the community use those media in very different ways. These impacts affect health and health-related behavior.

Challenges in Defining Immigrant/ Refugee Communities

Multiple population groups and subgroups. Defining a community in the context of immigrant/refugee health presents complex challenges, even as the nature and composition of a given community is tied to important factors affecting health, including language issues, access to care, beliefs/practices, social and cultural capital, and socioeconomic status. Most communities with immigrant/refugee populations do not consist of just one such population, although in some cases – such as Hmong communities in California in the USA – there is primarily one population. A community in which the author collaborates for public health interventions, for example, includes peoples from South Asia, the Caribbean, West Africa, and Southeast Asia, along with a predominant Central American/Latino segment. Moreover, even within specific immigrant groups in a community, there are subgroupings of significance. In the same community referred to above, the Central American population includes immigrants from El Salvador, Guatemala, Honduras, and Nicaragua, as well as immigrants from neighboring Mexico. Each of these groups present significant differences: the Guatemalan immigrants, for example, are largely indigenous peoples, some whose first language is not Spanish. In the metropolitan area overall, the Vietnamese immigrant population encompasses people who came to the USA in successive refugee "waves," each of which involved different circumstances, personal resources, and demographic characteristics. The Thai and Korean metro area populations, on the other hand, did not come as refugees. As another example, in the urban Caribbean immigrant communities of Amsterdam, The Netherlands, there have been separate populations from Suriname, Curacao, and Aruba – all from former Dutch colonies in the Caribbean/South America. Yet even the two Antillean immigrant communities (From Curacao and Aruba) have their differences.

Urban versus rural/small town. Most immigrant/refugee communities are found in "gateway" urban or suburban settings, but this is not always the case. There are important rural and small-town immigrant/refugee communities, for example, in the West, Southwest, and East Coast areas of the USA, in Canada, in South Africa, and other locations. Often these communities are linked to employment sources such as agricultural work, food processing, mining, or light assembly/manufacturing. In the case of refugees, they may also be located in certain areas because of organizations that were involved in their resettlement.

Generational issues. The successive immigration waves are connected to generational segments in the community, which are much more of a factor for immigrant/refugee populations than for others. Typically, for migration from less-developed to developed countries, first generation immigrants arrive in the host country with better than average health, but may then experience a decline over time. The decline is related to a number of factors that can be seen as an immigrant/refugee health *trajectory* First generation adults often bring with them diet and other health practices that may or may not be protective (e.g., high salt or carbohydrate intake), but which had different impacts in the home country where physical activity was connected to daily work and transportation patterns were different. In addition, the process of migration itself may have involved trauma and severe deprivation, which have health consequences after arrival. Depending upon the kinds of services available in the host country, access to care may be very limited. Finally, the first generation is more likely to be comfortable with indigenous, home-country health beliefs and practices, and may not utilize biomedical-based services.

Children of these first-generation immigrants, on the other hand, are more likely to adopt developed country dietary and lifestyle patterns, including fast food and sedentary free time. The parent generation may not know about the risks associated with such practices and may even value them as signs of attainment in the new country. In addition, family organization in a community may be affected by language, where the largely home language-speaking first generation becomes dependent on its more fluent and acculturated children for certain needs.

Legal issues. As another key dimension, some immigrant/refugee communities include significant numbers of undocumented members, while others do not. This often depends upon the political circumstances surrounding emigration, and whether those circumstances were recognized by the host government as enough to warrant support for asylum, resettlement, and other assistance. The degree to which legal status is an issue for one or more populations in an immigrant community affects a range of health-related factors and plays a key role in social marginalization.

Transnational relationships. Moreover, immigrant communities are typically *transnational* – including individuals and families who move back and forth from their home countries, and where host and home-country populations are linked by *remittances* – transfers of money and resources to the home community. These remittances in turn create a social and economic infrastructure linking the sending and receiving communities and countries across formal borders. According to the World Bank, total remittances flowing to the developing world amounted to $316 billion in 2009, with a 6.2% increase expected for 2010, despite recent economic conditions.

Health Interventions and Communities

The interplay of immigrant/refugee populations and sectors within communities forms one of the most delicate and political dimensions affecting health and health interventions, and may be one factor either impeding or supporting community efficacy with respect to addressing health issues. As explained further under the entry entitled "Community Programs," gaining some understanding about the complex composition of these communities is an important starting point for planning any health-related intervention. Based on the epidemiological data, it is then necessary to determine whether interventions need to be directed to:

- All subgroups within the geographically defined area (the entire community)
- One or more social or cultural subgroups in the geographic area
- A subset of individuals who are involved in specific risk behaviors (e.g., injection drug users, sex workers)

- In some cases, a subset connected to a particular organizational or employment category/type (e.g., day laborers or restaurant workers)
- Economic, political, and social structures (business, the health care industry, policymaking bodies, community-based organizations) that have an impact on the health problem in that community

Thus, whether it is for immigrants/refugees or any population, the necessity of understanding the nature of the community as an overall phenomenon, as well as in relation to specific health concerns, is a key part of health program planning and implementation.

Community Health Workers

Ximena Urrutia-Rojas[1], Mary Luna-Hollen[2]
[1]Management Policy and Community Health, University of Texas-Houston School of Public Health, San Antonio, TX, USA
[2]University of North Texas Health Science Center, Fort Worth, TX, USA

Background

For over 300 years many communities around the world have been utilizing lay health workers as a source of regular health care services in the absence of trained medical professionals. The 1978 the World Health Organization's (WHO) *Declaration of Alma-Ata* emphasized the use of community health workers (CHWs) as a key strategy for the delivery of basic health care services. CHWs are distinguished from other health professionals because they are hired primarily for their understanding of the populations and communities they serve, conduct outreach a significant portion of the time playing multiple roles, and have experience in providing services in community settings. In the USA, formal participation of trained workers in this role has been documented since the 1950s. By the late 1960s and early 1970s, CHWs were experimentally utilized in some of the low-income communities as a model of intervention for disease prevention and health education. Within this model, individuals with good personal and community skills and some health care training became valuable members of a health care team and help to improve patient communication and disease prevention in underserved communities facilitating early diagnosis of diseases and providing a more effective patient follow-up and improved health outcomes.

The federal Migrant Health Act of 1962 and the Economic Opportunity Act of 1964 mandated outreach activities that included employment of community-based service aides in many neighborhoods and migrant worker camps. The largest system to formally use the skills of CHWs in the USA was established in 1968, when the Indian Health Service adopted the fledging Community Health Representative Program from the Office of Economic Opportunity. The program was designed to bridge the gaps between people and resources and to integrate basic medical knowledge about disease prevention and care.

The Community Health Worker National Workforce Study published in March of 2007 by the US Department of Health and Human Services Administration (US HRSA) described the evolution of the CHW workforce in four periods:

1. The early documentation period (1966–1972) is characterized by engaging CHWs in low-income communities and was more related to developing antipoverty strategies than to specific programs for disease prevention and health care.
2. The period between 1973 and 1989 was characterized by special projects funded by short term public and private grants, often linked to research with universities.
3. The State and Federal Initiatives Period followed between 1990 and 1998 when standardized training for CHWs received greater recognition. Many bills were introduced for CHW but none passed.

The latest period (1999–to present) is significant for public policy actions. Legislation addressing CHWs' training and certification was passed in several states and the Patient Navigator Bill was signed into law as a major piece of legislation at the Federal level addressing the work of CHWs. Of note is that the 2003 Institute of Medicine (IOM) report on reducing health disparities made recommendations regarding CHW roles in impacting health disparities.

Coordinated efforts to professionalize the field in the USA began in the 1990s when CHWs from across the country agreed to use the title "Community Health Worker" as an umbrella term for the dozens of job titles that were in use among the workforce. At the same time, CHWs began to initiate local and national efforts to organize into professional networks and associations. Standardized training for CHWs also started to be developed in different areas of the country in the 1990s, including the Community Health Education Center (CHEC) of the Boston Public Health Commission. A second CHW training program, the Outreach Worker Training Institute (OWTI) of the Central Massachusetts Area Health Education Center (CMAHEC), was initiated in 1999 with its courses starting in 2001. Massachusetts and Texas are two examples of the participation of the CHWs/*Promotores de Salud* at the community and health system level. Texas has ~3,500–5,000 CHWs/*Promotores de Salud*, the majority of whom are of Hispanic ethnicity. The Texas Department of State Health Services (TDSHS) certification training includes 160 h of training and 20 h of CEUs every 2 years to maintain state certification. The curriculum meets 8 competency areas: communication skills, interpersonal skills, service coordination skills, capacity-building skills, advocacy skills, teaching skills, organizational skills, and knowledge base on specific health issues. Institutions continue to provide program-specific training additional to the certification training. Clients of CHWs/*Promotores de Salud* are generally immigrants, women, those uninsured, homeless, rural residents, migrant workers, and colonia residents.

In 2001, the American Public Health Association passed an official policy resolution, "Recognition and Support for Community Health Workers' Contributions to Meeting our Nation's Health Care Needs," which identified the need to "brand" the profession in order to promote policy, program development, program evaluation, and the growth of the field.

In light of the increasing need for delivering effective health care to the low-income minority populations, the Health Resources and Services Administration (HRSA) and Bureau of Health Professions of the US Department of Health and Human Services (USDHHS) conducted an extensive study between 2004 and 2007 on the CHW workforce as a component of cost-effective strategies addressing the health care needs of underserved communities. The Health Resources and Services Administration 2007 study identified five roles of CHWs in the health care process: (1) member of health care delivery team, (2) navigator, (3) screening and health education provider, (4) outreach/enrolling/informing agent, and (5) organizer. These roles were not always mutually exclusive. This model of care enhances productivity of the medical team in certain situations, such as patient-provider communication and tracking patients with unreliable addresses or transportation.

Promotores De Salud

All of the world's cultures have a lay health care system made up of people who are natural helpers-community members whom neighbors approach for social support and advice. CHWs work throughout the world in countries such as Africa, Brazil, Korea, India, Ethiopia, China, Vietnam, Bangladesh, Haiti, Kenya, and Mexico. They work in areas such as surveillance, respiratory treatment, immunizations, birth control injections, chronic disease management, eye care, TB, neonatal mortality reduction, vaccinations, child survival, Malaria, and anemia.

In Latin America and Latino communities in the USA, the term *Promotores de Salud* refers to CHW, community members who advocate for the well-being of their community and have the necessary training, experience, and dedication of their time to help improve the health and wellness of their community members. In the USA, *Promotores de Salud* are lay members of the community, who work either for pay or as volunteers in association with the local health care system in both urban and rural environments. They usually share ethnicity, language, socioeconomic status and life experiences with the community member subgroups they serve. They are usually of Hispanic/Latino descent, live in the Hispanic neighborhoods and immigrant communities, speak the Spanish language, and desire to help educate and empower the community on health issues. They come from all walks of life; they may have little education or be trained nurses, dentists or doctors from their countries of origin such as Mexico.

Nationwide, there were approximately 86,000 CHWs/*Promotores de Salud* in 2000. Approximately 17 states are currently in some stage of state certification (Alaska, Arizona, California, Connecticut, Florida, Indiana, Kentucky, Massachusetts, Mississippi, North Carolina, New Mexico, Nevada, Ohio, Oregon, Texas, Virginia, and West Virginia). There are currently 6,300 estimated employers of CHWs/*Promotores de Salud* for the nation as a whole. Nationally, paid positions range from $7–$15/h. In some areas they are paid via stipends, other incentives such as mileage reimbursement, or other types of compensation.

Implications for Immigrant Health

Because the health of immigrant populations has the potential to deteriorate when they move to the host country there is the need to assist them with culturally appropriate services. *Promotores de Salud* have been granted the roles of health educator, client advocate, outreach, and health system navigator because they share the same cultural identity and can relate to the needs of the new comers in the host country. Similar levels of acculturation in terms of shared language and years of residence by the *Promotor* and the immigrant persons can play a vital role in improving immigrant's trust and addressing their concerns. Unlike physicians, nurses, and other allied health professionals that work primarily in clinics or offices, *promotores* work mainly in community-based settings and in clients' homes. This community-based work allows them to reach deep into their communities and to connect people who are isolated and hard-to-reach with needed health and human services such as immigrants.

The potential of *Promotores de Salud* to assist immigrants and to improve their health have attracted the attention of several organizations that are funding innovative approaches to deliver health and social services to immigrants with the participation of *Promotores de Salud*. Examples of health services and health promotion activities include: (1) the Blue Cross and Blue Shield of Minnesota Foundation Healthy Together initiative that promotes the mental health and social adjustment of new Americans; (2) the Deaf Community Health Worker project, in St Paul Minnesota that provides community health worker services to deaf immigrants and their families to help them navigate the health care system; (3) The Vietnamese Social Services of Minnesota, in St. Paul, that provides mental health and social adjustment support for newly arrived refugees from Burma through the use of a community health workers; (4) the Faribault Diversity Coalition that engages immigrants and long-time residents in creating inclusive, welcoming communities in Faribault; and (5) the Mayo Clinic, Rochester, Minnesota project that documents how community health workers in primary care medical practices improve patient health outcomes.

The CHW/*Promotores de Salud* are definitively making a difference and improving the health and the lives of immigrants and newcomers in communities in the USA and throughout the world.

Community Organizing

Chad T. Morris
Roanoke College, Salem, VA, USA

Immigrant health efforts are frequently more successful when community members play a significant role in goal setting, planning, and implementation. Community organizing refers broadly to any effort to bring together members of a given community to assist in the creation of social change. In practice, community organizing efforts vary greatly. Some community organizing efforts are expert-driven, beginning in a social service agency or academia, while others trace their (grass)roots to community members themselves. Targeted participants may include individuals, established organizations, or both. The goals of the organized group may approach multiple issues or a single issue, with varying degrees of specificity. Further, community organizing efforts vary tactically from conflict-based, wherein one or more community entities are specifically opposed, to consensus-based, wherein agreement from all stakeholders is seen as key to achieving the group's goal(s). "Community" in this context often refers to a particular geographic location, but may also be based on shared interests or characteristics (e.g., ethnicity, immigrant status).

In all cases, the principal benefit of community organizing is the combination of multiple perspectives and resources to affect change. This benefit is an increasingly common focus in public health practice, including efforts at health promotion and policy change for immigrant populations. While broader efforts at community organizing have arguably existed for millennia, the term itself is emergent from immigration and poverty discussions in the late 1800s, having first come into use alongside social reform efforts such as the settlement house movement in England, the USA, and Russia. Labor, civil rights, and other social movements worldwide throughout the nineteenth and twentieth centuries served to add to evidence of the effectiveness of community-based social change strategies. Today, such strategies are deemed by health and development agencies to be crucial not only for creating change, but for building community capacity to ensure sustainability and future problem-solving ability.

Community organizing is defined broadly by some as an overarching term synonymous with "community development" and "community-building," but specifically by others as a methodological practice within community development, with community-building as an intended outcome. Evidence-based medicine, community-based participatory research, and the proliferation of the coalition model are all similar methodologies designed to bring multiple perspectives and/or resources to bear in support of public health efforts, including immigrant health programs, and have all been encouraged by the World Health Organization (e.g., the Healthy Cities Movement) and other health and development agencies. Community organizing includes these benefits and may make use of the methodologies mentioned above, but differs in that community members play a role in community organizing efforts beyond that of serving merely as consultants or focus group/survey/interview respondents. This is especially important in immigrant health efforts, as such efforts are in danger of further marginalizing those they purport to serve absent immigrant voices in planning and implementation.

Elements of Successful Organizing Efforts

Successful community organizing efforts frequently begin with the identification of key community stakeholders – individuals or organizations within a given community whose networks are strong and who have a clear desire to create change. There is ample evidence that organizing efforts focused on immigrant communities should involve members of the immigrant population as early in the planning process as possible. Ideally, the organized group grows as additional stakeholders are added through member networks and purposeful flow of information about the group's existence into the broader community. Effective leadership, diverse participation, and clear goal setting are seen as crucial elements of successful community organizing. Leadership skills such as conflict management, resource mobilization, and communication have all been found to correlate positively with effectiveness of community groups. Many successful immigrant-focused community organization efforts can be traced back to one or more dynamic leaders *within the immigrant community* with the time, energy, interpersonal skills, and community rapport necessary to coordinate change efforts and influence community participation. Agencies that have sought to create community organization efforts have often encountered success by turning over group leadership to a community member.

Diverse participation is critical in both conflict- and consensus-based organizing efforts. Diverse participation combats marginalization by ensuring that multiple perspectives are included in any discussion of social change, heightens the chance of collateral benefits of organizing efforts in terms of increased community connectedness, and serves as a source of group momentum and influence. Diverse participation, however, requires that communicative barriers arising from different socioeconomic status, culture, historical background, and ethnicity be openly acknowledged and addressed. Members of oft-marginalized community groups, immigrant groups included, may, for understandable reasons having to do with historical and ongoing inequity, be reluctant to fully discuss their perspectives, holding back "hidden transcripts" that would be of great value to the change effort. Open discussion leads to the rapport required to bring hidden transcripts into group consciousness. Effective community organizing efforts do not ignore inequities and power imbalances in the community for fear of creating offense, but instead address them freely and openly, acknowledging that such differences continue to exist in society. Similarly, and especially in the context of immigrant health efforts, leaders should avoid viewing individual group members as spokespersons for the entirety of a particular ethnic or cultural group, preferring instead to continually expand group membership to include a wide variety of perspectives that reveal the complex interaction of gender, age, ethnicity, socioeconomic status, and other factors in shaping perspectives. Effective community organization efforts begin with this inclusiveness in mind, but also remain vigilant in ongoing recruitment in order to keep the group from becoming insulated from the broader community.

As noted above, the goals of a given community organizing effort may vary in their specificity. Highly specific goals (e.g., hosting a health fair in a community with a high immigrant population) are effective in keeping a group moving in a unified direction, but may not achieve involvement from community members who have other priorities. Broad goals (e.g., improved fitness and nutrition for a city's entire immigrant population) may appeal to a larger cross section of community members, but differing expectations of how to achieve said goals may result in frustration and barriers to effectiveness. In all cases, it is recommended that goals come from the immigrant community itself, not from a specific sponsoring agency or group. As many public health efforts are grant-driven, this may necessitate work alongside members of the immigrant population in grant writing, as well. The freedom of immigrant and other community members to establish their own priorities results in more community involvement and greater program efficacy. Second, goals should be clearly communicated to each group member and reinforced frequently. This practice helps ensure that the group doesn't spend time and resources on efforts that some group members see as tangential, thus avoiding departures as member expectations aren't met. Finally, goals should be periodically addressed and, if needed, redefined in accordance with changing community perspectives and resources.

Conflict-Based Versus Consensus-Based Organization

Both initial and ongoing stakeholder identification may require community organizers to envision one of two theoretical pathways: conflict- or consensus-based organization. Conflict-based organization, such as that popularized in the 1970s by Saul Alinsky's Industrial Areas Foundation and similar efforts and used still today in some immigrant-focused organizing efforts, typically entails opposition to one or more established groups, such as policy makers or businesses that are seen as directly opposing or blocking the change community members desire. Protests and the media often play central roles in conflict-based organization, which tend to be designed to force change through pressures created by increased community awareness of a particular practice. Conflict-based organization is largely based on a perceived power disparity between the community and those the group is fighting, and may be best indicated in situations where there is ample evidence that those in power have no interest in creating change. Supporters of conflict-based organization posit that this strategy improves the group's focus by creating a common "enemy," thus giving community members added motivation for participation in the group while simultaneously building a commonly held sense of community connectedness or ownership ("communitas" and "social capital" are terms frequently used to describe this phenomenon). Scholars who advise against conflict-based organizing observe that such tactics do result in large numbers of community participants, but that said participation tends to be minimal and brief, such as attendance at a particular protest event. Further, there is the belief that negative targeting of key stakeholders in an effort at social change is ineffective in the long run as it has the potential to create ongoing animosity between targeted decision makers (who are often in positions of power) and already-marginalized community groups.

Consensus-based community organizing intentionally brings multiple stakeholders together with the expectation that effective outcomes will emerge as multiple perspectives and resources are combined. This type of community organizing is particularly useful in cases when governmental and social services agencies seek to improve outcomes by engaging the community knowledge base and creating change that is driven by the community itself, thus improving sustainability. Consensus-based community organizing may also have a non-agency, or grassroots, origin. While most consensus-based organizing efforts do not succeed in bringing *all* possible stakeholders to the metaphorical table, neither do they specifically target particular individuals or groups as enemies. Effective consensus-based organizing programs in immigrant health focus on identifying individuals and organizations that are willing to work for change, building a diverse member base inclusive of members of the immigrant community as well as those in positions of influence over, and those influenced by, the immigrant community. Through various discussion-based consensus-building interactions (meetings are most common, but newsletters, focus groups, surveys, and other information-sharing techniques have also been successful – the key is that group members both share and receive information), a clearer picture of priorities for change (community needs), resources available (community assets), and mechanisms for achieving said change is achieved. Because the organized community is defining the focus of its efforts, the potential for development of an expert-driven, "top-down," program that leaves out or harms certain community members is minimized.

There are, however, limits to the number of community voices that can be effectively heard at a given time, or in a given meeting. As such, consensus-based approaches have a tendency to involve fewer people overall than conflict-based approaches. Reticence to seek diverse community involvement out of fear of multiple perspectives hampering group momentum is a common pitfall in consensus-based efforts, and perhaps particularly common in immigrant-focused efforts as "experts" discount the value of local understandings and networks, resulting in groups that falsely purport to be representative of a given community. A capacity for increased community connectedness exists in the consensus-based approach, but differs from that emergent from the conflict-based approach in that connections are made across levels of community influence but between fewer people overall. Finally, the consensus-based approach tends to address complexities surrounding a given issue more effectively than antagonistic approaches, which often rely on less nuanced oppositional viewpoints.

Many immigrant health-focused community organizing efforts have effectively combined conflict- and consensus-based approaches. A conflict-based grassroots effort that begins by protesting the closure of a health clinic, for instance, may transition to a consensus-driven approach after said clinic is preserved and group goals broaden to include local health promotion efforts. Similarly, a consensus-based group may decide that a march on the local mayor's office is an effective one-time strategy in raising awareness of the group's existence and concerns. As in all aspects of community organizing, care should be taken to ensure that all group members are involved in decisions regarding group activities and approach.

Community Programs

Mark Edberg
Department of Prevention and Community Health, School of Public Health and Health Services, The George Washington University, Washington, DC, USA

The Scope of Community Programs

Community programs in this discussion will refer to health-related programs that are implemented at the community level and designed to address factors and characteristics of the community – in this case, immigrant/refugee communities. The term program in this sense does not generally refer to a clinical intervention or medical facility itself, but to a broad range of interventions that may or may not be linked to a clinic/medical facility, encompassing *health promotion and primary prevention* efforts, *support services* for individuals who are ill (e.g., transportation, meals), or interventions to *mitigate impacts or secondary transmission* for those already affected (e.g., tuberculosis, HIV/AIDS), or *human rights and protective* programs (e.g., protection against exploitation of women). Most community programs fall in the first category of health promotion or primary prevention. These programs include education, public information/awareness campaigns, screening, outreach, patient advocacy and language interpretation, policy and public advocacy, and targeted behavior change efforts, and are typically implemented by community-based (CBOs) or nongovernmental organizations (NGOs), with funding from a government agency, global NGO, or foundation; evaluation as well as technical assistance are often provided through the latter organizations, a private consulting organization, or a college/university.

What Is a Community?

While there are many definitions of *community* for public health purposes the definition provided in the separate entry entitled "Community" is useful here: Community refers to a geographically bounded space that can be understood as a *social ecology*. That is, within that bounded (yet porous) space there is a particular combination of individuals who live and/or work there, social groups, cultures and practices, economic relationships, environmental conditions, and resources, all interacting to form a certain kind of interdependent sociocultural unit. Moreover, this "unit" is nested within larger political, economic, social, and cultural structures, so it cannot be considered in isolation. This definition is intentionally aligned with the *ecological model* of health determinants now prevalent in public health literature, which refers to multiple levels of influence on a particular health issue – individual, social groups and networks, community and society, culture, and political economy. It also includes consideration of the structural relationships between communities and the social orders in which they are embedded.

Communities are complex, and composed of multiple subgroups and layers. In immigrant/refugee communities, the interplay of subgroups can be crucial to marshaling the necessary resources to address an issue programmatically. Moreover, immigrant/refugee populations have unique patterns of health and health risk that include health beliefs/practices from the home country; trauma and distress related to difficult migration experiences, including refugee camps; victimization during migration; loss of resources; and, when in the new country, loss of status and multiple barriers finding income and housing, much less health services, and generational or immigration "wave" differences.

One truism for community interventions is that the intervention itself is almost always just part of the picture. Because a community is involved, the interests, needs, politics, resources (or lack thereof), and social structures of the community will inevitably play a role, in several ways:

- *The politics of selecting target population(s) and health issue(s) to be addressed*. As noted, in any community there are a number of health issues that are important in some way. Specific health issues may have political dimensions, in the sense that an advocacy group or particular interests within the community are trying to increase attention and resources directed to that issue. At the same time, the health issue of focus may be determined by available funding sources – state, local and global.
- *Coalitions and community structures of power*. Even beyond the selection of target populations and health issues, implementing a community program is typically done through – or at least in collaboration with – community structures of some sort. These may include: government agencies or a specific decision maker; community leaders; task forces or committees; a *community advisory board*; faith community representatives; businesses; advocacy groups; grassroots community organizations; professional groups, including organizations or associations of health providers; and community coalitions.

Any of these kinds of groups and partnerships may have their own motives related to the politics of the community, of preserving or enhancing their position in the community, of gaining control over a particular (health) issue in order to be able to set the agenda, or other reasons. In addition, any of these groups may have internal conflicts and divisions that stem from individual rivalries or different goals/interests.

Community expertise. Despite all the complexities, there is no better expertise on the community than expertise from the community itself, and the diverse groups within it. These are the individuals who know community habits and customary practices, knowledge and attitudes, language, social groups, where things happen (locations), and much more. For this reason, it is important to establish a collaborative relationship so that the community and other program-related (outside) expertise are integrated.

Levels of Intervention

Given that communities are a mixing bowl in which multiple health-related factors interact, implementing a program typically requires some selection of contributing factors or groups. It is necessary to determine whether a program/intervention should be directed to:

- All subgroups within the geographically defined area (the entire community)
- One or more social or cultural subgroups in the geographic area
- A subset of individuals who are involved in specific risk behaviors (e.g., injection drug users, sex workers)
- In some cases, a subset connected to a particular organizational or employment category/type (e.g., day laborers, or restaurant workers)
- Economic, political, and social structures (business, the health care industry, policymaking bodies, community-based organizations, global organizations) that have an impact on the health problem in that community

Program decisions often have to do with scale. Is it more effective to address the community in general with a broad-based or multilevel intervention? Or should the program try to reach a smaller, targeted group or setting that is at high risk for a particular health problem? Broader interventions can be called *community* interventions; the more targeted kind can be called *interventions in a community.* These terms are related to the way in which the Institute of Medicine in the USA classifies different types of interventions: *universal* prevention interventions are those that target a general population; *selected* prevention interventions are those that target individuals or groups that are at high risk for a particular health problem; and *indicated* preventive interventions are those targeting families, groups, and individuals with multiple risk factors for a health problem (e.g., programs that combine multiple types of activities and treatment to address multiple factors that occur together as a *syndemic*, such as poverty, high diabetes risk, and poor diet).

In general, community interventions, if effective, tend to result in smaller changes, but over a larger (absolute) number of people. Mass media and community mobilization programs are of this type. Interventions in a community, if effective, tend to result in higher rates of change but with a smaller number of people. Outreach and specialized education or skill-building programs fall in this category. These kinds of programs can sometimes lead to broader community change if the targeted subgroup is influential or acts as a bridge to the community as a whole with respect to a health condition (e.g., sex workers and the spread of HIV/AIDS). Finally, a program might not focus on individuals at all, but on systems or policies in the community that affect access to care (e.g., requirements for gender representation, language interpretation, or culturally competent staff).

The Process: Assessment, Planning, Implementation, and Evaluation

For any kind of community program, there is basically a four-stage process involved. These same general stages are part of most planning models used for community programs in public health, including the PRECEDE-PROCEED and PATCH models, or COMBI (Communication for Behavioral Impact) in global health communications efforts (other planning resources available from the Global Health Council, www.globalhealth.org). The four stages are:

- *Assessment:* Conducting an assessment is the basis for identifying the nature of the problem, what the key contributing factors are, and who (which populations/subpopulations) is affected. Data useful for assessment may include local public health epidemiological data as well as interviews, surveys, focus groups, or other data you collect from key stakeholders and population representatives.
- *Planning:* Once you have completed (or are provided with) an assessment, the next task is to design/select an intervention that is appropriate for the problem, contributing factors and population group, and to identify and link up with the

resources, community collaborating partners, and staff needed to implement the program. It is also at this stage when an evaluation should be designed that matches what the planned program seeks to achieve. For immigrant/refugee programs, the planning stage is especially important because it is at this point when collaborations with community groups are key.

- *Implementation:* Carrying out the intervention also means collecting ongoing *process* data about how the program is being implemented, and in some cases adapting the program based on what is learned during implementation.
- *Evaluation:* There are three basic types of evaluation. The terms used occasionally vary, but the three types are: (1) *process evaluation* – ongoing program data that help determine if the program is implemented as planned; (2) *outcome* evaluation that assesses short-term changes resulting from the program (e.g., knowledge/skills change, new regulations, behavior changes); and (3) *impact evaluation* assessing longer term changes resulting from the program, such as increased utilization of health services, change in a specific environmental risk that was causing a problem (e.g., pollution sources), or actual change in the incidence/prevalence of a particular health condition. In the current program environment, evaluation is very important because that is where the *evidence base* for a particular program is derived, which in turn impacts potential funding.

Other Issues: Tailoring, Adapting Programs, and Sustainability

Built into this four stage process is the idea of *tailoring* – ensuring that the community program (1) is based on an assessment and understanding of the health problem *as it takes shape in a particular population, subgroup, or community;* (2) includes the community in designing, implementing, and evaluating the program; (3) refers, as much as possible, to situations, people, and issues relevant to the target community/population; (4) uses language and materials appropriate for the audience; and (5) schedules and locates activities so that members of the target population can participate.

Develop vs. adapt? Though every community and population is unique, a decision must be made about whether to develop a program or to adapt an existing one. There are often at least some commonalities across situations and communities with respect to a particular health problem, and programs may have been developed before that can be adapted – though this should be done carefully in order not to implement a "canned solution" to a unique situation. Potential program models for adaptation can be found through US or global agency clearinghouses, nonprofit associations focused on a particular health problem or population, professional associations, or government "model programs" databases. In the USA, such databases or compilations are available at the US Centers for Disease Control and Prevention (CDC) and through other agencies in the Department of Health and Human Services. In the global context, model program/best practice information tends to be disease-specific. UNAIDS, for example, has published such information, but exclusively with respect to HIV/AIDS programs.

Sustainability. This is a sometimes vexing issue that routinely arises with respect to community programs. Funding for such programs is often relatively short term – three or 4 years. In complex community contexts, putting a program in place, and then achieving change, may take longer than that. Thus issues of sustainability and community capacity building must become part of program planning and implementation, for example, training/hiring members of the community to operate the program; engaging community stakeholders (business, civic organizations, etc.) that will have a stake in maintenance of the program; seeking additional sources of funds; applying for continuing funds, and training community members in these skills; and linking the program to others like it as well as to practitioners in the field.

Community-Based Participatory Research

Linda S. Martinez[1], Flavia C. Peréa[2]
[1]School of Arts and Sciences, Community Health Program, Tufts University, Medford, MA, USA
[2]Department of Public Health and Community Medicine, Tufts University School of Medicine, Boston, MA, USA

Community-based participatory research (CBPR) is an applied research approach designed to link theory, research, policy, and practice to inform decision making and foster positive change. CBPR provides academic institutions with a model to bring students, researchers, and community members together with a shared purpose to work toward mutually beneficial goals. In addition, CBPR incorporates knowledge sharing between community and academic partners, and collective social action to address societal inequities. Unlike traditional research approaches, CBPR recognizes the value of diverse community perspectives, and the knowledge they bring to the research process. As such CBPR emphasizes community participation and power-sharing throughout the research process, as well as ownership, capacity building, and empowerment. CBPR approaches are aimed at addressing the underlying social, political, and economic inequities that impact community health and well-being.

CBPR has been described in the literature as emerging from the earlier area of action research cultivated by Kurt Lewin in the 1940s and the work of Paulo Freire in the 1970s. These approaches to research, like present day CBPR, accentuate the need to engage community voices that are not often represented in the research process, particularly those impacted by social inequities. Furthermore, early CBPR approaches such as participatory action research (PAR) sought to reduce the oppressive nature of research by promoting power-sharing, and the notion of "research with," as opposed to "research on" the community. CBPR today comes in many different forms which include but are not limited to the earlier models of action research.

The Process

Integral to CBPR is the research process – a focus on how partners come together in a joint effort to assess and identify community priorities, develop intervention strategies, and decide what strategies are used to facilitate participation, the enhancement of relationships, capacity building, and empowerment. The process in CBPR is vital, as it is centered on the development of trusting relationships between institutional and community stakeholders based on mutual respect, shared decision making, and equity among partners. Because CBPR is asset based and underscores the importance of building on existing community knowledge, all partners are encouraged to contribute throughout the entirety of the research process, learn from one another, and share resources for the creation of sustainable interventions that reflect community concerns. With CBPR, the partnership itself can act as a catalyst for change, as residents, community leaders, and researchers take collective action toward a shared vision and mutually established goals.

CBPR goals include empowering residents so they may act to advance positive social change at the community level and empowering researchers to engage in research that is meaningful. Empowerment means that communities and researchers alike feel they have the ability and skills to act on the contextual factors that shape local living environments. As such, empowered communities require opportunities for both participation and capacity building, as do empowered researchers. In CBPR, participation refers to the extent to which members of the partnership engage in project activities, fulfill their identified roles, and take on new roles. To overcome potential participation barriers, it is important to provide capacity building to assure that partners feel as though they can fully contribute. CBPR builds community capacity for self determination and leadership, through the development of new relationships and the provision of skills necessary to achieve community health goals. Capacity building provides the partnership with a shared language and strengthens technical expertise among the group by building on individual strengths and valuing the creativity diverse partners bring to the table. Developing partner capacity is necessary if the benefits of participation that facilitate empowerment are to be achieved.

Because it is focused on empowerment and participation, CBPR has been identified as a promising approach to developing interventions to tackle health inequities. Its focus on community participation in science allows for the design of health interventions that are community relevant and culturally appropriate, tailored to the values, experiences, practices, and worldview of community members. This is critical as inequities in health have been well documented, yet poorly addressed. A complex set of interrelated social, political, economic, and environmental factors are responsible for the proliferation of health inequities, and the factors that create and sustain them vary across communities among racial/ethnic, cultural, and linguistic minority groups. It is therefore necessary to engage in research that may, by design and intention, lead to evidence-based interventions to address inequities, especially in underserved immigrant and minority communities. Using CBPR, researcher content area expertise is contextualized by community knowledge, leading to the development of effective health interventions that address community health concerns. Simultaneously, community mobilization and empowerment has the power to spark local policy change to address distal factors that sustain inequities, such as inadequate education and a lack of economic opportunity.

Underlying Assumptions

There are four key assumptions upon which the principles of CBPR rest. First, partnership is authentic and as such results in “co-learning.” Working side by side in collaboration with community partners facilitates the development of new knowledge on the part of both the university researcher and the community member. While the community partner may be learning about the nature of the research process the researcher simultaneously may be learning about the distinct characteristics of the community and the ways in which historical policies or sociopolitical context shapes the health and well being of community residents. This knowledge is significant from a public health perspective, particularly given the complexity of communities and the multiple factors that determine health in a given community. A second important assumption is that the direct capacity-building efforts are built into the CBPR process. Building community research capacity is essential, as capacity is associated with participation. By building community research knowledge in conjunction with mutual respect and shared decision making, research partnerships can empower community members to participate in the decision-making process. For example, research often involves language that is not common, as well as discipline-specific acronyms. Such language can create barriers to participation and exclude those not trained as researchers. Capacity-building efforts such as trainings can be used to increase community knowledge of research terminology, thereby reducing language and disciplinary barriers that curve participation, creating a shared language. Thirdly, knowledge garnered should be of interest to and benefit all partners. That is to say that all partners should be aware of the research findings and interested in the outcomes, implying that all are involved in the design and have a stake in or ownership of the research outcomes. Finally, it is assumed that the partnership has committed for the long term. Given the complexity of health disparities and the multiple factors that contribute to both creating and sustaining them, efforts at addressing them require a commitment over time. For example, a research partnership that designs and implements an intervention may be years later using their findings to advocate for local policy change.

The Challenges

Despite its benefits, the challenges to engaging in effective CBPR are many. Researchers have described key ethical challenges for the CBPR partnerships, for example, the notion of research that is. With CBPR the study focus or research question is described as emerging from the community. However, this is not generally the case as community priorities involve improving or creating services and programs, assuring access and grassroots action, not research. More often it is the case that the community is approached by a researcher with similar interests, the challenge being how to ensure that the focus area of the researcher is that of the community. Additionally challenging is discerning who or what constitutes community. Do agency leaders and service providers make up community or actual residents living in the community and if so, who? In essence, how can we be sure that the research agreed upon is reflective of community priorities, and that the partners at the table are representative of community? This is especially true given the disconnect that often exists between community service providers and consumers of services. As researchers begin to partner with communities, particularly immigrant communities, to engage in research partnerships it is essential that they explore the notion of who/what constitutes community first.

Insider–outsider tensions are also described as a challenge in CBPR. Communities are complex, adaptive systems with unique sociopolitical histories; as such tensions can arise as the result of historical distrust of outsiders, such as researchers. Even when there is a cultural or racial concordance between researchers and the communities with which they are partnering, research holds a level of power and privilege that can lead community members to perceive them as outsiders. As such, partners must reflect on their position and what they bring to the table, recognizing their roles. Similarly, because CBPR is often practiced to address racial and ethnic disparities in health, issues of racism must be addressed – particularly as Whites are overrepresented among researchers.

Dissemination is an additional challenge faced by CBPR partnerships. Consider the different ways in which researchers and community partners disseminate their work. While researchers are interested in scholarly publications, community partners are more likely to produce reports, use findings to improve service delivery, or to advocate for additional services. These activities are associated with different time frames – where community dissemination is immediate and scholarly dissemination is time consuming. In addition, researchers may want to hold back on sharing findings until peer-reviewed articles have been published, which is an ethical dilemma if the goal of CBPR is to move from research to action. This is particularly true because a basic principle of CBPR is to share research findings using them as a tool to facilitate grassroots action.

Conclusions

Although CBPR poses a number of challenges to researchers and the community, its benefits cannot be denied, partnering with community contextualizes research and interventions giving them meaning and relevance. This is crucial if the deleterious effects of the social hierarchy that produce and sustain health inequity are to be addressed. In addition, CBPR has the potential to generate new knowledge that is community specific and the power to move findings from theory into practice. Incorporating community perspectives and expertise throughout the research process increases the capacity of researchers to engage in the community and the capacity to incorporate research findings in advocacy efforts. This is particularly relevant as community demographics shift, given that new immigrant populations may experience the determinants of health differently, calling for community-specific and culturally appropriate interventions.

Community-Oriented Primary Care

Community-Oriented Primary Care: Past and Present

Background

Community oriented primary care (COPC) is a defined systematic approach to health that brings the community into the primary care planning and health care delivery process. COPC aims to improve the health of the community, not just those receiving direct patient care services. Unlike traditional medicine, COPC is based on principles in the fields of epidemiology and public health in addition to primary medicine and preventive care. The team of health practitioners, health professionals, and community leaders comes together to address the specific health needs within diverse communities on a local and global level.

COPC originated during the 1940s in South Africa through the efforts of Sidney and Emily Kark, two physicians that implemented a health delivery system in an impoverished, rural area of South Africa (Pholela, Natal). Appointed by the South African Government, Dr. Sidney Kark was given the task of developing a primary care system that focused on curing diseases as well as disease prevention. The framework he introduced centered around five basic questions to be investigated: (1) What is the community's current state of health? (2) What are the factors that have contributed to this health state? (3) What is being done about it? (4) What more can be done and what is the expected outcome? and (5) What measures are needed to continue health surveillance of the community and to evaluate the effects of the existing programs?

A population-based system, COPC requires: (1) a community-based, primary care practice; (2) an identifiable population or community for which the practice assumes responsibility for effecting change in health status; and (3) a planning, monitoring, and evaluation process for identifying and resolving health problems. The central tenet is to treat the patient in the community context. As an example, the first proposal for the United States Office of Economic Opportunity-funded health centers in the United States notes that: “the need is not for the distribution of services to passive recipients, but for the active involvement of local populations in ways which will change their knowledge, attitudes and motivation.”

The World Health Organization (WHO) and United Nations Educational, Scientific and Cultural Organization (UNESCO) endorsed the COPC model at the Alma-Ata Conference on Primary Care in 1978. In 1982, the Institute of Medicine in the United States convened a conference on expanding research into COPC. Following the conference, progress toward fuller implementation of COPC concepts in the United States and elsewhere were noted. COPC has continued to expand in the developed and developing world. COPC as an approach to specific clinical issues such as chronic heart disease management, application of COCP for pediatric populations and for migrant Muslim women in Germany, and evidence of COPC in Spain and Brazil underscore the expansion of COPC to vulnerable populations and communities globally.

The COPC model combines applied epidemiology, collaboration with the community to prioritize health issues, and define the community interventions, evaluation, and monitoring. This model promotes collaboration and coordination among the community and health care professionals; creating an environment whereby trust is created among the community, the health system, and health care practitioners. These linkages tie together the needs assessments, interventions, and outcomes.

Components of COPC

COPC transforms the traditional, doctor–patient health model into a health care provider–community health model. Since the 1970s, the WHO has recognized the importance of community participation and its benefits. These benefits include increased health benefits, efficiency, equity, and self-managed care. Unlike the traditional clinical practice model, the COPC program model relies heavily on input from the surrounding community and then develops a health plan that will address the community’s specific needs. The COPC model contains three basic components: (1) a primary care practice providing accessible, comprehensive, coordinated, continuous, and accountable health care services; (2) a defined community for whose health the practice has assumed responsibility; (“Community” refers to either geographic or social communities, or a combination of both; groups that form within the workplace, church, or schools; or persons enrolled in a common health plan, but not made up of the active patients in a practice); and (3) a cyclical process that includes six important steps:

Defining the Community

Defining the community is an integral part of the COPC process, since the term “community” can be defined many different ways, and relies on presumptions about geography and patient populations. Inaccurate definition of the community can impede the COPC process by misdiagnosing the population and suggesting the wrong intervention. A clear understanding of the population that will be served and making community involvement easier throughout the process is essential for success. While the Karks’ initial work focused on a geographically defined community, communities can also be defined by sex or gender, race, or other demographic descriptors; by language, religion, or other cultural groupings; by employment status, immigration status, or other legal categories; or other characteristics. While quantitative data are essential to achieving an understanding of a community, qualitative data such as focus group findings, oral histories, or key informant interviews can also play a critical role in understanding what defines a community.

Characterizing the Community

Following the definition of the community, the next task is to describe the community. The characterization of a community, using parameters such as geographic or political boundaries, languages, ages, social norms, economics, and the environment can be compared to the general population and other peer communities to help sharpen an understanding of the specific characteristics of the community. Boundaries such as census tracts, health services areas, ZIP Codes, and even political jurisdictions are considered in characterizing the community profile. Birth and death data, health care utilization data, topographical characteristics, socioeconomic data, health attitudes survey data, and any other variables which influence an individual's health can be incorporated. By gathering data on the community, a snapshot of health status will be formulated and health problems will be identified for intervention. Understanding and describing the community its groups and issues are essential before any planning occurs.

Prioritizing Community Health Problems

Identification of health problems for intervention includes weighing and prioritizing issues suggested from community leaders, health advisory boards, and needs assessments. Selecting the first among many issues to be addressed is a crucial step in the process. Community involvement plays a critical role in this part of the COPC process. Determining priority areas rely heavily on what the community views as their greatest concerns. Planners must weigh the views and perspectives and avoid prioritization schemes that favor one subgroup of the community over another. Community priorities are often directed at issues with a bearing on health status but seem to have little relationship to the medical care system. These issues can include such variables as: education, access to meaningful employment, teenage pregnancy, transportation, and safety. Clinicians who dismiss these issues as irrelevant to clinical care, or unchangeable, risk losing the support of the community stakeholders involved in the COPC process. These priorities reflect the determinants of health as defined by genetic endowment, social circumstances, environmental exposure, health care and behavioral patterns.

Detailed Assessment of the Health Problem

Health problems selected as priorities must be completely assessed by the planning team. Assessment of the problem requires the analyzing of available data whenever possible (disease incidence and prevalence data, survey results, mortality rates, etc.). However, data may not adequately describe the problems, especially in communities with lack of access to health care or where surveying the community is difficult. Estimates and anecdotal data generated by those most familiar with the community may help make up for missing data. Community members and stakeholders included in the assessment process can bring their own perspectives to the issues. For example, the community members may be able to help the planning team understand how past health interventions have fallen short, or why community members have responded to a survey in a particular way. As the team examines each health problem, relationships between seemingly unrelated health problems may emerge, noting relationships specific to this community. Unexpected opportunities for synergy, coalition-building, or efficiencies may be uncovered while assessing prioritized health problems.

Intervention

After a complete assessment of the problem has been conducted, the intervention is developed. Several approaches may be identified; however, the COPC team will analyze and choose the most successful, practical, and feasible intervention for the population. The intervention will also be problem specific. Factors such as insurance status, available resources (equipment, staff, facilities, etc.), access to transportation, potential language barriers, as well as social and cultural norms are factors influencing the implementation of the most appropriate intervention. Interventions must be scientifically justifiable, evidence-based, and shown to be effective in practice. They must also be reviewed, accepted, and approved by community members to ensure feasibility.

The provision of primary care clinical services such as adult health, pediatrics, or behavioral health are often the focus of a COPC intervention. However, especially for low-income communities or those with problems with access to health care, interventions may need to go beyond physician care to include access to prescription drugs, transportation to the site of healthcare services, help with language or cultural barriers, safety for patients, referrals for specialty or hospital care, nutritional assistance, chronic disease management education, or other health-related services. A COPC planning team that has done the work of involving the community throughout the process will be less likely to be surprised by barriers to achieving optimal health.

Evaluation

Evaluation of the intervention is a necessary component of the COPC process. By measuring specific outcomes, the COPC team can identify what components of the intervention worked, what components did not work, and why. Evaluation of the outcomes leads to a reassessment of the priorities and determines if the process merits continuation in the community Evaluation should be an aspect of the initial plan that accounts for the impacts of services and permits adjustment of services as needs change. The completion of the evaluation step includes outcomes that support the next cycle of the planning process, keeping community contacts engaged and other stakeholders available for the subsequent redefinition, and refocusing of assets and reevaluation of outcomes.

COPC Today

For over 25 years, the COPC model has been used in many types of health care environments in assessing disease risk factors, addressing previously unrecognized health problems, assessing the cost-effectiveness of strategies, and identifying and targeting the skewed distribution of various diseases. Today, the COPC model has been applied in a wide variety of clinical settings, from the rural villages in South Africa, to urban clinics in the United States and Israel, to general practices in the United Kingdom. Below are two current examples:

Hadassah Community Health Center: Kiryat HaYovel, Jerusalem

Hadassah Community Health Center has used the COPC model since the 1960s and continues to demonstrate and teach the model. As a result, there has been a measurable reduction in a nemia due to pregnancy, hypertension, cardiovascular risk, an improvement in disparities in infant development between the privileged and unprivileged, and an increase in the use of family planning.

Parkland Health and Hospital System: Dallas, TX

Parkland is one of the largest public hospitals and health systems in the United States and falls under the jurisdiction of the Dallas County Hospital District, whose primary purpose is to provide medical aid and hospital care to the indigent and needy that live in Dallas County. Parkland's outpatient clinic system utilized the COPC model from its inception in the 1980s and continues to do so. The system consists of 11 centers providing multiple primary care services (pediatrics, adult health, dental services, and adolescent health) as well as a robust homeless outreach division and a network of school-based clinics. The Parkland System has instituted clinics for refugee health, optometry, podiatry, and behavioral health care after analyzing demand for services. An annual review of outcomes and epidemiologic data is integral to the system. Demographic change in this fast-growing county has driven shifts in resources and new center construction as patient populations follow jobs and affordable housing around the county. All Parkland COPC centers have standing community advisory boards that review service offerings and serve as liaisons to the community. These boards also include representatives from other stakeholders in the community, including health care providers, nonprofit organizations, schools, and civic groups. The Parkland COPC clinic system sees over 300,000 clinic visits per year, the majority of which are uninsured or on Medicaid.

Conclusion

COPC as a model of primary health care can provide primary care based on the needs of the community, whether that community consists of immigrants, specific ethnic groups, vulnerable populations, or a homogeneous group. The model focuses on including the community decision makers, providing prevention and health promotion as core competencies, and community and individual problem solving. Immigrants can benefit from a process that includes their contributions in designing services to suit their particular needs. COPC is designed to create a system of care that opens access and is designed to use the existing assets of a community. It should improve efficiency and effectiveness and as a worldwide model should be advantageous as a primary care model in any type of location, be it urban or rural, developing, or developed.

Compadrazgo

Maura I. Toro-Morn
Department of Sociology and Anthropology, Illinois State University, Normal, IL, USA

The practice of *compadrazgo* (godparenting, ritual kinship) goes back to the colonization of the Americas by Spain and Portugal. Historically, *compadrazgo* (godparenting) has been (and still is) a cultural practice connected to religious rituals through a person's life: baptism, confirmation, first communion, and marriage. Through each of these rituals, *padrinos* (godparents) enter into social relations of obligation and close friendship with members of another family. Historians suggest that the practice of *compadrazgo* shaped social and cultural life during and after the colonization and settlement processes in Latin, Central America, and the Caribbean. Visiting *comadres* (godmothers) was an important social activity for women because it cemented gendered and family bonds between women of the same social class. The practice of *compadrazgo* extended family bonds beyond those of blood-related family members. Although the practice has been attributed to the Spanish and Portuguese colonizing elites, there is evidence to suggest that complex sponsorship ceremonies also existed among Aztec and Mayan Indians prior to colonization. After colonization, descendants of indigenous people have also adopted this cultural practice. Historians also maintain that the tradition of *compadrazgo* was embraced by Africans and their descendants in the Americas as a way to create bonds of obligation between people.

The most popularly known form of *compadrazgo* is connected to a child's baptism. At the time of the baptism, surrogate parents (padrinos) are named and introduced to the community through the baptism ceremony. The selected madrina (godmother) and padrino (godfather) become compadres (godparents) of the child's parents. By accepting the role of padrinos, the couple promise to care for the child in the event that something happens to the biological parents. The most significant religious commitment is the promise to help raise the child according to Christian/religious values.

Today, *compadrazgo* is both a religious and cultural practice that characterizes Latino families across the hemisphere. Researchers have conducted numerous studies about the practice of compadrazgo in Mexico. They have documented how the cultural significance of this practice extends beyond the relationship of responsibility to a godchild, but more importantly in the relationship between *compadres,* which become social ties between two families. Therefore, Hispanic/Latino families tend to be large and each child is entitled to padrino and madrina, thereby increasing the number of people an individual considers kin. A clear advantage of compadrazgo is that it increases the social capital and resources of individuals and families.

Anthropologists argue that underlying *compadrazgo* relations lie a complex structure of relations, hierarchy, and behavior that needs to be studied more systematically. Research conducted in Oaxaca, Mexico, for example, confirms that *compadrazgo* rituals continue to be connected to the religious rituals of baptism, confirmation, and first communion, but that the most prestigious and onerous is the ritual connected to the baptism ceremony. In Oaxaca, godparents pay for the child's baptismal clothing and other needs. When the child marries, they pay for the wedding clothing, offer a large gift, and in some cases may sponsor a party for the newlyweds at their house. Confirmation godparents also incur some expenses in that they are also responsible for the child's clothing and provide a chest or cabinet for when the child marries. First communion godparents are expected to give a godchild a large wedding present. In Oaxaca, the responsibilities and expectations of godparenting bind community members in deep and complex ways, including most principally the organization of production and labor relations. Godparents with social class status (merchants) recruit godchildren and compadres as workers.

In US Hispanic/Latino communities, compadrazgo represents an important cultural institution. For some groups, migration entails the loss of supportive social relations as exemplified by compadrazgo ties. Among Puerto Ricans in the Northeast, for example, researchers have found that the loss of compadrazgo ties has led to poor evaluations of the quality of life and as a consequence poor health outcomes. In contrast, for Dominicans and Colombians, compadrazgo ties are used to facilitate migration. In many rural communities of the Dominican Republic and Colombia, everyone has a "compadre" in the USA. There is also evidence that among some Hispanic/Latino groups, small recreational clubs also offer immigrants an opportunity to facilitate compadrazgo bonds. There is evidence to suggest that compadrazgo ties play a major role in the settlement process as well. Compadres lend each other money, offer help in finding employment, may offer a place to stay in the process of migration, and/or secure business contacts. It is unclear, however, whether these compadrazgo ties function the same way for immigrant men and women.

There is some anecdotal evidence to suggest that second-generation Latinos in the USA continue to practice godparenting rituals. Maria Hinojosa's memoir of the birth of her son, Raul, includes an account of the baptism ritual they developed to maintain this family tradition. Although they felt strongly about the Catholic tradition of padrinos, they made a few adjustments. Raul had four sets of godparents, one for each element, fire, water, air, and earth. During the ceremony, the godparents formed a circle and each set of godparents stood on the four cardinal points. Each set of godparent gave the child a symbolic present for each element. There was drumming and singing and their friends were invited to say or give something to Raul. In the end, Maria Hinojosa writes that they "were creating a new kind of family for him. These people would be his familia now, his mentors and teachers and caretakers, the people who made up his days and nights, the people who may not have been tied by blood but instead by love, and to be frank, by the convenience of proximity."

Compliance

Michele G. Shedlin
College of Nursing, New York University,
New York, NY, USA

The term compliance is generally used to refer to consumer/patient acceptance of recommended health behaviors, and is often assessed by the extent to which a person's behavior coincides with medical or health advice. It is frequently used in relation to the acceptance of specific required behaviors such as consistent and correct use of medicines or the following of dietary restrictions to correct or prevent a particular outcome or condition. Other terms for these phenomena are adherence, concordance, cooperation, and conformity. Since the term compliance can infer an asymmetric and hierarchical relationship between provider and patient, and the expectation implied is that a consumer/patient will accept provider instructions and will cooperate, there is a clear current preference for the term adherence. Adherence, in fact, implies a more informed and participatory decision by a consumer/patient to follow provider recommendations and/or protocols for medical treatment.

Problems with compliance are seen as manifested in missed appointments, failure to take medications, lost prescriptions or medications, and medication misuse. Also, discontinuation of protocols and medications are equated with noncompliance, even when discussed in the light of such obstacles as responses to unwanted collateral effects of the recommended behavior/procedure/medication.

Most research has focused on the factors influencing poor compliance and has examined patient characteristics, particular illnesses, or medications most associated with noncompliance. However predictive ability would seem to come from an understanding of psychosocial factors affecting compliance, especially health beliefs including perceptions of vulnerability, the meanings/implications of illness and disease, the perceived costs and benefits of complying, and the quality of the provider–patient relationship. Other factors which may influence compliance are *trialability* (ability to test out what is recommended), *comprehension* (how well the behavior/procedure or medication required is understood), and *cultural acceptability* (how consonant it is with cultural values and a sense of well-being).

The capacity of the consumer/patient to comply is another important consideration. Understanding the cultural acceptability of the required behaviors or health effects of a protocol or medication, while crucial to correct use and continuation, is not sufficient. Lifestyle issues, family influence and behavior, cost, convenience, risk of stigma, and accessibility are factors which may influence a patient's ability to comply. Addiction, or even the occasional use of illicit drugs or abuse of alcohol, is another factor which may interfere with an individual's ability to comply.

Noncompliance by immigrants is usually attributed to a lack of understanding of the instructions because of language or educational levels, or the willful refusal or misunderstanding on the part of the individual or family. If these assumptions determine the provider/patient interaction in a medical consult, they may limit communication and thus the resolution of erroneous assumptions, fears, and inadequate information which undermine recommended behaviors. This is especially true where self-administration and daily motivation are required. The effects of this type of consumer/patient–provider relationship exist despite the fact that in many cultures this dynamic is an expected one, especially between male physicians and female patients. But culturally appropriate or not, the role/status of the provider and the expectations inherent in the term "compliance" can serve as barriers to the correct use and continuation of a medicine or medical protocol. Compliance is affected not only by the provider/patient communication, but such salient issues as the perceived roles and expected behaviors of provider and patient, the characteristics of patients and providers, the type of protocol or program involved, the criteria for compliance, and many other aspects of the context and quality of the health care encounter.

Understanding compliance (and the behaviors, attitudes, knowledge, and motivation supporting it) must include identification of the social and cultural factors affecting behavioral decision making which vary with a complex array of factors in immigrant lives. An individual's or family's decision not to accept or to follow medical advice may be quite reasonable based upon their knowledge, experiences, or beliefs. Furthermore, continual exposure to controversies and contradictions, even in rural areas and traditional communities of sending countries, can foster fears and a lack of confidence in the alternatives being offered in a new country or community or type of provider. One of the problems in understanding "compliance" is that it is largely understood through outcomes. Except by the analysis of body fluids to determine the presence or absence or actual levels of a medication, for example, providers are usually unable to identify noncompliance until such outcomes as pregnancy, increased viral loads, or frank illness. Methods of assessment such as pill counts and self-report can only provide clues about compliance.

There are various steps which can be taken by programs and providers to enhance compliance: Some of those which involve a consideration of specific immigrant needs are:

1. Encouragement of questions in the initial consultation and in follow-up visits when new issues and concerns may have emerged; obviously, a lack of questions does not necessarily indicate satisfaction or compliance, especially in traditional cultures.
2. Understanding of the patient's level of comprehension of what is recommended.
3. Emphasis on the advantages and the attributes of what is recommended which are culturally acceptable; address the aspects of a medication or procedure which may have negative cultural interpretations.
4. Provision of information about health benefits and their meanings to the individual patient.
5. Direction of attention to media issues or local myths which may undermine required behaviors.
6. Assessment of patient characteristics which would act as barriers to their ability and desire to comply.
7. Assessment of the situational factors which might influence desire and ability to comply.
8. Satisfaction with patient–provider relationships and other aspects of the medical/family planning encounter can facilitate cooperation, understanding, and communication.
9. Referral to, or creation of, a culturally appropriate and accessible mechanism for patient support, especially for counseling and information regarding obstacles to compliance.

Clearly, these recommendations place greater responsibilities on the provider. Especially difficult in some cases may be the responsibility to recognize and have some understanding of immigrant needs and the cultural factors which may affect a patients' motivation and ability to comply. In multicultural settings, the challenge obviously includes a commitment to developing culturally informed and knowledgeable health care teams.

Confianza

Patricia Documet
Department of Behavioral & Community Health Sciences, Graduate School of Public Health, University of Pittsburgh, Pittsburgh, PA, USA

In Spanish, *confianza* means "hope or firm belief in something or someone," and also "familiarity." Indeed, in the English language literature on Latinos, *confianza* is used for both "trust" and "familiarity," not one or the other but together.

Confianza is a necessity for any personal relationship that includes meaningful interactional behavior within the Latino culture. *Confianza* provides a comfortable, safe space, where the person can be himself or herself, with no need for false pretenses. A relationship with *confianza* is by definition personal, involves an informal way of relating that enables the formation of a special bond, and opens the possibility for sharing feelings and concerns at a deep level. Such a relationship also carries the understanding that the information being shared must be kept confidential and not disclosed to others who are not *en confianza.*

Like other cultural characteristics, *confianza* has to be learned through socialization. The importance of relationships within the extended family in Latino culture could be at the root for the perceived need for *confianza.* Such intra-family relationships are expected to involve *confianza* and, in turn, are held as the ideal for all other meaningful relationships. The presence of *confianza* within a relationship enhances the quality and value of the interaction. This quality, in turn, gives credibility to the relationship.

Confianza is closely related to two other integral characteristics of Latino culture: *personalismo* and *respeto. Personalismo* is the importance of personal relationships. *Respeto* is the use of appropriate deferential behavior toward others based on age, sex, social position, economic status, and authority. The exercise of *personalismo* and *respeto* in Latino culture engenders *confianza.* Interestingly, a Spanish version of the Therapeutic Collaboration Scale (TCS) is composed of 14 items that measure *personalismo*, *respeto*, and *confianza* because they are crucial constructs for Latinos' daily lives and for the development of a useful therapeutic relationship.

Confianza develops under certain conditions that relate to *personalismo* and *respeto*: a caring attitude, mutuality, informal communication styles, and repeated contact. A caring attitude shows that the person matters to the other and is demonstrated by asking questions, listening attentively to what the person has to say, or showing interest in the person's family. Mutuality refers to the sharing of information or experiences. It can also take other forms, from as simple as exchanging a few phrases in Spanish as a way of connecting, to talking about commonalities of food or family background. For example, many educators use their own youth experiences to communicate with students and foster *confianza.* The crucial aspect of these exchanges is the understanding that is established between the different parties, even if they have unequal power. The informal communication style, characteristic of *confianza*, helps in creating a connection. However, this informality should not be seen as a lack of *respeto*; a person could still maintain his or her position within the family/social hierarchy, while communicating informally with others who are older or younger or who hold more or less authority. Repeated contacts are also necessary, because a single contact can only demonstrate the potential for *confianza. Confianza* can only develop with time, and the investment of a valued resource, such as time, is a way of showing that one cares.

Latinos use *confianza* to evaluate all relationships, including professional ones (e.g., service providers). In fact, some researchers have argued that *confianza* is the cornerstone for any supportive relationship, especially those that involve giving and receiving information and suggestions. Latinos tend to rate highly physicians who inquire about the patient personally, take time to explain a diagnosis or procedure, and relate some personal information, however small, during the encounter. These same physicians could also expect higher compliance from their Latino patients. The benefits of *confianza* have been demonstrated in breast-feeding promotion, cancer screening, domestic violence and social work services, education, and psychotherapy. For example, *confianza* in the doctor coupled with a comfortable communication style has been shown to decrease the embarrassment associated with Pap tests, while the lack of *confianza* resulted in higher embarrassment levels and doubts about the service or the tests. In general, Latinos feel that doctor–patient relationships in health care settings in the United States are often rushed and impersonal, and make it difficult to foster *confianza*. The bureaucratic infrastructure and the lack of continuity of health care have also been shown to hinder the development of *confianza*.

Confianza can be purposively constructed and needs to be maintained. Cultivating *confianza* makes sense because it can help bring a great deal of cultural understanding into therapeutic or service relationships. Taking the time to develop *confianza* shows that the provider has the best interest of the patient, client, or student at heart.

The same principle that we apply to personal relationships can be applied to organizational settings. Developing relationships with Latino organizations could foster "indirect *confianza*" for the provider and enhance its credibility. As with personal relationships, organizational relationships require sincerity and trust to establish a bond that can exist over an extended period of time, and are based on proof of positive and contributing actions. This approach could also be used for recruiting research participants. Community members who trust a Latino agency are more likely to trust the research institution that has taken the time to develop a relationship of *confianza* with the agency.

Convention Against Torture

Kathrin Mautino
Mautino & Mautino, San Diego, CA, USA

The Convention Against Torture (CAT) is the common name for Article 3 of the United Nations Convention Against Torture and Other Forms of Cruel, Inhuman or Degrading Treatment or Punishment. The CAT as enacted in the United States provides that an individual will not be returned to a country where there are substantial grounds to believe that the individual will be tortured.

Torture is defined as any act by which severe pain or suffering, whether physical or mental is intentionally inflicted on a person. It does not include pain or suffering incidental to lawful sanctions, including the death penalty. However, the regulations state that lawful sanctions that "defeat the object and purpose" of the CAT can be considered torture. In other words, an individual can argue that some punishments for crime rise to the level of torture even if they are lawful punishments for crimes.

An individual can receive CAT relief based upon past torture and the possibility of future torture. Health care professionals trained in recognizing the mental and physical signs of torture are priceless when it comes to developing a successful CAT application. Although some individuals may have obvious physical scars, some individuals inflicting torture have become more sophisticated in developing techniques such as water-boarding, that do not leave a physical sign. Mental health professionals who can write an authoritative statement as to whether, in their opinion, a victim has suffered past torture, are extremely important to the preparation of a good case.

CAT relief differs considerably from asylum. In asylum, an individual must establish a well-founded fear of persecution based upon race, religion, nationality, political opinion, or social group. Well-founded fear is often described as a "reasonable person" standard – a reasonable person in that situation would be afraid. CAT relief requires establishing that it is "more likely than not" that an individual will be tortured – a higher standard than for asylum. In addition, CAT does not require showing that the torture is because of one of the five grounds for asylum.

Individuals granted refugee or asylee status are eligible to apply for permanent resident status after being in the United States for 1 year. Individuals granted CAT relief are not eligible for permanent resident status. CAT relief maintains the person under the jurisdiction of the Executive Office for Immigration Review (Immigration Court), in a status known as withholding of removal. Individuals in such status cannot leave the United States except in rare circumstances, although they are eligible for work authorization. These individuals are deemed still to be in removal proceedings. Normally, individuals granted withholding of removal are not imprisoned or otherwise detained by the government.

Individuals are ineligible for asylum if they are guilty of certain serious crimes, have themselves persecuted others, or are a security threat. However, such individuals remain eligible for deferral of removal pursuant to the CAT. Deferral of removal is more limited than withholding of removal discussed above. Under deferral of removal, the individual can be imprisoned in the United States. Most individuals who are ineligible for withholding of removal are subject to mandatory detention by the government. Such detained individuals are entitled only to have their detention reviewed at regular intervals to determine if the reason for detention remains. In effect, some applicants for CAT relief are accepting life imprisonment in the United States, rather than return to the country of citizenship.

At any time, the government can move the Immigration Court to reopen a deferral of removal case based upon new evidence that the individual will not be tortured, including diplomatic assurances from the individual's country of citizenship. The Immigration Judge is required to hold a de novo hearing, meaning a review of all of the underlying facts and the relevant law, on whether or not the individual still qualifies for relief. The individual in question also can move to have the deferral of removal order terminated – he or she would then be deported to the country of citizenship.

CAT relief is defensive in nature. The regulations provide that the Immigration Judge is the only person who can consider a claim for relief under CAT; unlike asylum, there is no administrative method to apply for CAT relief. Asylum applications generally must be filed within 1 year of an individual's entry into the United States; however, there is no time limit for applying for CAT relief.

Convention on the Prevention and Punishment of the Crime of Genocide

Cristina Cazacu Chinole
Center for Ethics and Public Policies, Bucharest and Iasi, Romania

The Convention on the Prevention and Punishment of the Crime of Genocide was the first human rights treaty that was adopted by the General Assembly of the United Nations on December 9, 1948. The key provision of this Convention is that genocide is declared to be a crime under international law and is punishable regardless of whether it is committed in a time of peace or in a time of war. This distinction is important as genocide is seen as different from "crimes against humanity," whose legal definition specifies wartime.

Genocide (from Greek: *genos*, people or race; and Latin: *caedere*, to kill) is the systematic attempt to destroy and/or eradicate an ethnic, national, racial, or religious group. The term was used for the first time by the Polish writer Raphael Lemkin in 1944, in his work about the Nazi occupation of Eastern Europe. Lemkin, who fled from Germany during World War II to the USA, drafted the International Convention on the Prevention and Punishment of the Crime of Genocide.

Yet, although the term “genocide” as such is new, the practice of extermination of entire groups or population is common throughout the entire history of mankind. It was the Holocaust, the systematic killing of Jews, Gypsies, Slavs, political opponents, and the so-called social deviants like homosexuals and the mentally disabled in the Nazi extermination camps that prompted the call for international legislation to prohibit and punish such deeds. The development of legal thinking and procedures after World War II, especially about war crimes and crimes against humanity, paved the way for the development and the adoption of the Genocide Convention. Even if the world was still in shock after the horrors of the Nazi regime, it took a while until the Convention was ratified by the necessary 20 States, and entered into force in January 1951.

As of today, 140 States have ratified the Genocide Convention, a treaty that is in line with the priorities set by the United Nations and the modern human rights movement, aiming to eradicate racism and xenophobia. More importantly, it stresses the role of criminal justice and accountability in the protection and promotion of human rights. The Convention is one of the important pillars of the framework of protection of national, racial, ethnic, and religious minorities from various threats to their very existence.

Unlike other human rights treaties, there is no specific monitoring body or expert committee but it contains the provision that any Contracting Party may call upon the competent organs of the United Nations to act under the United Nations Charter in any way that may be suitable to prevent and suppress acts of genocide.

The Convention is relatively brief, with just 19 short articles. The Preamble of the Convention affirms that genocide is contrary to the spirit and aims of the United Nations and is condemned by the civilized world, since genocide has inflicted great losses on humanity at all periods of history. It also stresses that international cooperation is necessary “to liberate mankind from such an odious scourge.”

The first Article provides the important clarification that genocide can be committed “in time of peace or in time of war” and that it is a distinct crime from crimes against humanity. The crime of genocide is defined in the second Article, as any of a number of acts which are committed with the intent to destroy, either as a whole or in part, a national, ethnic, racial, or religious group, killing members of the group; causing serious bodily or mental harm to members of the group; deliberately inflicting on the group conditions of life calculated to bring about its physical destruction in whole or in part; imposing measures intended to prevent births within the group; and forcibly transferring children of the group to another group.

According to the third Article, not only is genocide to be punished but also the conspiracy, the direct or indirect incitement, attempt or complicity to commit genocide. The fourth Article states that there should be no immunity since persons that commit genocide or any of the acts enumerated previously should be punished regardless, even if they are constitutionally responsible rulers, public officials, or private individuals.

The fifth Article contains provisions about the legislation that Contracting Parties have to adopt in order to provide effective penalties for persons guilty of genocide, or any of the other acts enumerated in the third Article.

The sixth Article of the Convention stipulates that any person charged with genocide shall be tried by a competent tribunal of the State in the territory in which the act was committed, or by an international penal tribunal that may have jurisdiction over the Contracting Parties. The next Article stipulates that genocide shall not be considered to be a political crime for the purpose of extradition and, in such cases, Contracting Parties pledge themselves to grant extradition.

Pursuant to the eighth Article, any Contracting Party may call upon the competent organs of the United Nations to take such action under the Charter of the United Nations as they consider appropriate for the prevention and suppression of acts of genocide or any of the other acts enumerated in the third Article.

The following Article stipulates that any disputes between the Contracting Parties relating to the interpretation, application, or fulfillment of the Convention, including those relating to the responsibility of a State for genocide or for any of the other acts described previously, shall be submitted to the International Court of Justice at the request of any of the parties to the dispute.

Although it is considered a pillar of the framework of international humanitarian rules, the Genocide Convention has been criticized for its limitations. Due to the vague and unclear definition of genocide, prevention and punishment of genocide is difficult. Moreover, Article XI requires that the members of the UN have to ratify the document, but there are many States which did not ratify it, for nearly 50 years. On the ground that the Convention violates sovereignty, the USA did not ratify the convention until 1988. At the time of its ratification, the US stipulated that the USA would not be subject to the jurisdiction of the International Court of Justice and that US laws would take precedence over the Convention. Nevertheless, in 1990, the US Congress passed the Immigration and Nationality Act (INA) (8 U.S.C.A. § 1182), that stipulates that aliens guilty of genocide are excluded from entry into the USA, or deported when discovered.

Another flaw is that there is no committee or monitoring body for this Convention to ensure implementation and compliance, like the Convention on the Elimination of All Forms of Discrimination Against Women, International Covenant on Civil and Political Rights, and United Nations Convention Against Torture and Other Cruel, Inhuman or Degrading Treatment or Punishment. After several requests for setting up a treaty body, by adopting an additional protocol to the Convention, or passing a resolution of the General Assembly, in 2004, the Secretary General of the United Nations established the high-level position of Special Adviser on the Prevention of Genocide.

The limitations of the Genocide Convention are obvious since, in spite of its provisions that State Parties should "prevent and punish genocide," millions of people still have died without intervention in Cambodia, the former Yugoslavia, the Democratic Republic of Congo, Sierra Leone, Rwanda, and Darfur.

Cortisol

Luis F. Ramirez
Quality Outcomes Training, Brecksville, OH, USA

Cortisol is a hormone produced by the zona fasciculata of the adrenal cortex. There are two adrenal glands, each of which weighs about 4 g, located on top of the kidneys. Each gland is composed of two distinct parts: the adrenal medulla and the adrenal cortex.

The adrenal medulla secretes the hormones epinephrine and norepinephrine and the adrenal cortex secretes a group of hormones called the corticosteroids produced by three different layers of the medulla.

The zona glomerulosa secretes aldosterone, the zona reticularis secretes adrenal androgens, and the zona fasciculata secretes the glucocorticoids cortisol and corticosterone. These hormones are synthesized from cholesterol and have similar formulas but different functions.

Cortisol is referred as the “stress” hormone because it plays an important role in the stress response. Together with norepinephrine, cortisol is released during times of threat and is critical to survival. Cortisol aids in survival by redistributing energy when an individual is under attack. To do so it suppresses functions not needed for immediate survival, including reproduction, immune response, digestion, and pain. Cortisol promotes vital functions, including heart rate and blood pressure, while shunting energy to the brain and muscles to speed up thought processes and fight or flee.

However, chronic high levels of cortisol cause gastric ulcers, thinning of the bones, and possibly brain damage. In animals, stress has produced a reduction of neurotrophins which in turn decreases the growth of new neurons in the hippocampus. These actions may affect memory and mood leading to depression and feelings of fatigue. Stress also impairs the immune system which can lead to an increase in infections and possibly increase rates of cancer.

Stress also affects the cardiovascular system and patient suffering depression and heart disease have five times higher risk of sudden death than the patients without depression.

Persons suffering posttraumatic stress disorders are also predisposed to cardiac problems.

The disorder of hypercortisolism is called Cushing’s syndrome and the one causing hypocortisolism is known as Addisson’s disease. These are serious conditions that need immediate treatment. The main problems with Addisson’s disease are electrolyte imbalance, inability to regulate blood pressure, muscle weakness, inability to tolerate stress leading to cardiac problems, neurological problems, shock, and death.

The Cushing’s syndrome is characterized by mobilization of fat from the lower part of the body with extra deposition of fat in the thoracic and upper abdominal regions. Also there is an edematous appearance of the face with acne and hirsutism. Persons suffering Cushing’s syndrome are feeling weak and are susceptible to infections.

Increases in cortisol levels have been associated with the development of mental disorders, especially depression. The immigration process, legal or otherwise, is a stressful situation which will produce an increase in cortisol levels.

The development of mental disorders is the final outcome of a complex series of events in which cortisol is part of the process and methods of reducing the levels of cortisol may be beneficial in the management of these disorders.

Besides these disorders, there are different factors affecting cortisol levels. Among the ones increasing levels besides stress are ingestion of caffeine, sleep deprivation, anorexia nervosa, some oral contraceptives, and prolonged physical exercise. Factors reducing cortisol levels are music therapy, massage therapy, laughing and the experience of humor, and in general relaxation exercises. The ingestion of omega-3 fatty acids can also lower levels of cortisol.

Council for International Organizations of Medical Sciences

Sana Loue
Department of Epidemiology and Biostatistics, Case Western Reserve University School of Medicine, Cleveland, OH, USA

The Council for International Organizations of Medical Sciences (CIOMS) was formed in 1949 by the World Health Organization (WHO) and the United Nations Scientific and Cultural Organization (UNESCO). CIOMS strives to facilitate and promote international activities in the biomedical sciences. In furtherance of this goal, CIOMS has issued *International Guidelines for Biomedical Research Involving Human Subjects* and *International Guidelines for Ethical Review of Epidemiological Studies*. Each of these documents addresses issues relating to informed consent, risks and benefits, vulnerable populations, and ethical review.

Several of the guidelines in each of these CIOMS' documents are relevant to the conduct of research with immigrant populations. For example, Guideline 13 of the *International Guidelines for Biomedical Research Involving Human Subjects* advises that special justification is required for inviting vulnerable individuals to participate in research and that their rights and welfare must be protected. Refugees and displaced persons are explicitly recognized as vulnerable in the context of conducting research in the commentary to this guideline. Individuals who are politically powerless are also identified as vulnerable; this could encompass individuals who are illegally present in a country and individuals who have recently immigrated to a country and are unfamiliar with its culture or systems. Similar provisions exist in the *International Guidelines for Ethical Review of Epidemiological Studies*.

Although other Guidelines in each of these documents do not refer specifically to immigrants, they are clearly relevant to the conduct of research with immigrants. These relevant provisions include the proscription against undue inducement to participate in research, the provision of information to prospective participants in language that is understandable, and the need to balance the risks and benefits of participation. Depending upon the focus of the study and the immigration status of an individual, the balance of risks and benefits for immigrants may be significantly different from that for native-born individuals. For example, a breach of confidentiality in the context of a US-based questionnaire study relating to drug use could potentially lead to jail or imprisonment for some participants, but to deportation for only noncitizen immigrant participants.

Cross-Cultural Health

Rika Suzuki[1], Iqbal Ahmed[1,2]
[1]Department of Psychiatry, John A. Burns School of Medicine, University of Hawaii, Honolulu, HI, USA
[2]Department of Psychiatry, Tripler Army Medical Center, Honolulu, HI, USA

Culture is defined by a group's distinct values, norms, and beliefs, including understanding of life and death.

It is shared among individuals who identify themselves similarly. Culture is passed down from generation to generation, and is a core part of every individual. Communication style, spirituality, familial roles, sense of autonomy versus collectivism, and behavioral and social norms are among the many factors that comprise one's identified culture. These factors help to shape one's understanding of health, what causes illness, what appropriate responses to illness are, and how illness should be treated. Thus, culture can profoundly impact how one approaches health care, from individual interactions with providers and staff to the larger exchange with health care systems and organizations.

What Is Cross-Cultural Health?

Cross-cultural health can be defined as an approach to health care that attempts to reconcile differing cultural values, behaviors, and practices about health. In this way, it strives to accomplish effective health care across different cultures. For its providers, cross-cultural health care involves both an awareness of one's own attitudes and beliefs, and an awareness of others' attitudes and beliefs, about health and illness. Cross-cultural health at an individual level entails everything from how a provider and patient interact; how they negotiate screening, diagnostic, and treatment interventions; how education is communicated; and how long-term relations are maintained between them.

At the systems level, cross-cultural health encompasses issues at the community, public health, and organizational level. Pertinent tasks include management of illness but also health promotion, and screening and education for illness prevention, including administering preventive medications to varied population groups. Examples include cultural attitudes toward blood pressure screenings and administration of the H1N1 (influenza) vaccine to those at risk. Also included in cross-cultural health at the systems level are the various strategies health organizations undertake to promote better relations with their culturally diverse patient populations. This includes education of providers and other care team members as well as outreach to patient groups. A necessary task in effective cross-cultural health care is the examination of those factors that pose barriers to care across cultures. Much of the literature to date focuses on the negative health impacts of cultural differences. Relatively less literature exists about how different cultural beliefs (which may deviate from biomedical models) may be protective in terms of health.

What Is the Relevance of Cross-Cultural Health?

In the USA, as well as in almost every country in the globe, the population is becoming increasingly diverse. For example, by the year 2030, the ethnic minority population in the USA (African Americans, Hispanics, Asian/Pacific Islanders, Native Americans, and Alaskan Natives) will grow from 28% to over 40% of the population. In the decade of 1990–2000, the number of people in the USA speaking a language other than English at home increased from 31.8 million to 47.0 million. Currently, 21 million Americans are limited in English proficiency. Linguistic differences, however, are just one facet of cross-cultural health care. Beliefs and attitudes, including religious, have been shown to have a large impact on an individual's health behaviors, according to studies on cross-cultural health care. In his formative anthropologic work on culture, illness, and care, Kleinman states that "70 to 90 percent of all self-recognized episodes of sickness are managed exclusively outside the perimeter of the formal health care system." This suggests that, with the steady increase in the minority populations in the USA in the past 30 years, many more individuals than ever before may seek out culturally based resources (family/friends, religious authorities, traditional healers, self-help groups, etc.) prior to seeking help from formal health care providers. In part, this may be due to a desire to avoid encounters that could potentially be costly, difficult, uncomfortable, or frustrating, and in the worst cases, offensive.

Where Do We See Cross-Cultural Health Care Today?

Cross-cultural health is carried out in a wide variety of settings today – outpatient community clinics, private health clinics, local hospitals (emergency room, inpatient units), offices of social work and other health care staff, disease prevention clinics (tuberculosis, sexually transmitted disease clinics), community health screenings, and specialized settings (substance abuse clinics, domestic violence shelters, homeless shelters, nursing homes, hospices, and rehabilitation clinics).

Cross-cultural health care also takes place in pharmacies, where patients are often educated by pharmacists just prior to receiving their medications.

Challenges of Cross-Cultural Health Care

Cross-cultural health care at its best will work towards decreasing the prejudices, misunderstandings, and assumptions between providers and their patients to enable care that is both meaningful and effective. Imagine the scenario of a newly immigrated young Chinese woman with reproductive difficulties presenting to a Los Angeles community clinic. One can imagine the possible frustration she and her family may be experiencing in the couple's futile attempts to conceive a child. Childbearing, across all cultures, is indeed a valued life task. However, this woman's distress may be more profound than we might imagine given her cultural context. Traditionally, in some Chinese subcultures, the ability to bear a male child is highly valued. It becomes clear that the initial interface between a provider and this patient and family will be critical in addressing their distress and concerns, and in clarifying their understanding of a possible physical problem. They may not accept, if in fact she is infertile, that she cannot have a child, much less a male child. Frustration, grief, understanding, and support will need to be skillfully managed in the context of what infertility means to the patient and family in their Chinese subculture.

How Do We Know We Are Achieving Cross-Cultural Health Care?

Cross-cultural health care, at its best, is a candid exploration and negotiation of culturally based beliefs about health and illness, which leads to a reconciliation of attitudes about how best to achieve good health outcome. It can thus be viewed as happening on a continuum. Reaching the goal would be defined by achieving optimal screening, detection, and management of a patient's illness and preventing future illness. It would also be defined by an enduring relationship built on trust, increased understanding of differences, and mutual respect. Differing views about health and illness will not be compromised but rather enhanced in an ongoing dialogue between health care provider and patient, or between a health care system and patient population. A critical component of cross-cultural health is cultural competence – defined as the ability of a provider or health care system to deliver care that is culturally appropriate, well informed, and tailored for the recipient of the care.

There are a variety of ways to conceptualize cross-cultural health. Structurally, it can be considered at both an individual level and at a systems level. As the individual level is discussed in detail in a separate chapter on cross-cultural medicine in this encyclopedia, it will be discussed only briefly here.

Cross-Cultural Health at an Individual Level

At the individual level, cross-cultural health is the approach to care in which a provider or other health care member engages with a patient in an exploratory, nonjudgmental way so as to elicit the patient's understanding of his/her health concern. This involves learning about the factors that affect the patient's presentation, including cultural and social factors. This is best accomplished by structured questions targeted at eliciting the patient's views about his/her illness, treatment options, and prognoses (the patient's explanatory model for illness) as well as the patient's fears and concerns. Economics, ethnicity and acculturation, spiritual beliefs/practices, family and personal dynamics (gender role, parental roles, individualism, collectivism), and academic or occupational demands all may impact health-seeking behaviors and attitudes toward health care. Culturally based gender roles in a family, for example, may be instrumental in defining how health discussions take place and how rapport is built with the provider. Cultural health beliefs ("folk beliefs") may also help or hinder one's health-related behaviors, including treatment adherence. Thus, providers of cross-cultural health care must listen and demonstrate self-awareness to open the door to a genuine discussion between himself/herself and a patient.

Cross-Cultural Health at a Systems Level

At a systems level, cross-cultural health care works at a larger scale and targets populations and communities. Whether in private or public health organizations, aims are to identify and negotiate potential barriers to care by examining trends among various groups in their health-related behaviors. Linguistic and cultural differences are bridged via written or oral communication aids, such as brochures, community screenings/education, and liaison persons such as translators or interpreters. Disparities in health care for US ethnic minority populations persist not only as increasing disease burden by minority populations but also in the level of satisfaction expressed by minority patients. The systems-based approach is particularly important because it is often the case that minority patients from immigrant populations are first seen in larger community or private hospitals rather than in smaller scale clinics. Because cultural factors impacting health care are multidimensional, cross-cultural health strategies at a systems level must aim to negotiate potential barriers in multiple ways.

Strategies for Systems-Based Approach to Cross-Cultural Health Care

Some of the ways that health care institutions and organizations can exercise cross-cultural health care involve application of tasks applied at the individual level. However, at a systems level, strategies can optimize ways to reach the masses by understanding group identity and shared thinking processes. By appealing to common characteristics among larger groups of people, important health information can be disseminated and health behaviors impacted. The strategies can target primary, secondary, and tertiary prevention and thus are a potential means to impact health care globally.

Examples of several strategies that can be employed at a systems level are:

- Mandated training of health care providers, employees, and trainees in cultural competence
- Specific outreach strategies for the prevention and treatment of illness, which include:
  - Peripheral strategies to educate and appeal to specific cultural groups
  - Evidential strategies to enhance a cultural group’s perception of the relevance of specific health issues
  - Constituent-involving strategies drawing on the experience of particular group members
- Linguistic strategies to make health care more accessible and effective
- Sociocultural strategies that address health issues in the context of larger social and cultural considerations

Strategies for a Systems-Based Approach: Mandated Training in Cultural Competence

Within larger health organizations, a tendency can develop for providers, staff, and management to generalize about behaviors of minorities. These tendencies are often reinforced through repeated experiences with similar presentations. For example, health employees might assume Hispanic or Asian patients manifest psychiatric complaints as physical ones, or that Asian male patients underreport pain symptoms. They may not fully appreciate expressed complaints if they perceive that some patients overreport symptoms. Understanding the meaning of an illness to the patient in his/her cultural context requires that providers and staff not make assumptions based on stereotypes. To achieve effective cross-cultural care, it is imperative to understand common cultural trends but also to approach each patient as a unique individual. Part of this task entails differentiating subculture from culture. An older African American man from a rural town in Georgia may hold different beliefs about health care than a young African American man living in Los Angeles, California. Also, an African American and a Vietnamese American may hold similar views about health issues by virtue of being longtime residents in the same community. Because it is not possible to know about every culture and subculture, the best strategy is to keep an open mind and explore belief systems by nonjudgmental inquiry.

The methods of such an inquiry and the appreciation for this kind of exploration can be taught early in professional training. Hiring minority faculty/teachers with firsthand knowledge and experience, implementing core requirements in cultural competency (didactics, clinical experiences), and evaluating standards for meeting requirements are some of the ways cross-cultural health practices can be taught. For large health care organizations, similarly structured employment training in cultural competence can be implemented. Hiring of multiethnic staff and experiential workshops with routine evaluation of effectiveness are additional ways to standardize competency in cross-cultural health care. Such training can be overseen by formal committees with clear competency guidelines and reassessments as necessary.

The focus of the training should be multidirectional and not unidirectional. There is an interaction of different cultural beliefs of the providers and the recipients of health care. The providers' culture includes the medical culture with its own belief system about the doctor–patient relationship, attitudes about other systems of care, and adherence to treatment.

In addition, providers bring to the table their own family cultural background. Cross-cultural health care at a systems level should strive toward a meeting of minds. It is a negotiation of the belief systems and explanatory models of patient/family and provider, but also of the health care system at large.

Specific Outreach Strategies: Peripheral, Evidential, and Constituent-Involving Strategies

Kreuter, Lukwago, Bucholtz, Clark, and Sanders-Thompson discuss specific strategies to promote health care in cross-cultural settings using culturally informed tactics. These strategies can be applied to many different cultures. As such, they are a compelling means to enable outreach to immigrant and other minority populations.

1. *Peripheral strategies* use design in a deliberate way to create and distribute materials and promote health programs that will appeal to specific groups. As an example, to communicate the importance of early detection of breast cancer to a Mexican immigrant population, the use of bright primary colors with bold messages and images may be more effective than utilizing the light pink signature ribbon symbol. Information delivered this way would likely appeal to the Mexican cultural aesthetic of colorful schemes and patterns. Bold, clear messages may be more consistent with cultures expressing higher emotive affect. For cultures whose family hierarchy is matriarchal, patients may respond best to brochures with images depicting older women educating younger family members. Peripheral strategies thus utilize specific images, themes, designs, lettering, and color schemes to appeal to cultural aesthetics as well as belief systems. In essence, it is the use of marketing to achieve a cross-cultural health goal.
2. *Evidential strategies* enhance a cultural group's understanding of the relevance of a particular health issue. These strategies work at a systems level by highlighting health epidemiology, that is, diseases specific to a given cultural group. By presenting information about the prevalence of high blood pressure in African Americans or the prevalence of strokes in Japanese Americans, the intent is that the statements will raise the level of concern and perception of individual vulnerability to the health problem. Kreuter references Weinstein's precaution adoption model – the notion that perceiving others like you have this problem can stimulate one's own decision to act to prevent the problem for oneself.
3. *Constituent-involving strategies* draw on the experiences or insights of specific members of a group being targeted for health education. These individuals serve as a liaison between other group members and the health care organization or system. They may be cultural leaders, folk healers, or trained paraprofessionals. As a member of the target group, they help to contextualize health care in culturally specific ways for both other group members and for the health care organization. By enhancing communication bidirectionally, these individuals can promote trust and understanding in health care discussions. They can offer insights into preferred strategies, communication styles, family dynamics, and other factors that may influence the patient's or target group's approach to health care. Finally, they may bridge overt language gaps.

Linguistic Strategies to Make Health Education More Accessible and Effective

Rogler et al. in 1987 appropriately called linguistic accessibility "the lowest common denominator of cultural sensitivity." Language-related strategies in cross-cultural health may seem obvious and fundamental but can be complex because they must be carefully integrated with sociocultural context. Also, current strategies are still contending with problems regarding consistency and standardization of quality.

In an overview of strategies to overcome barriers, Sherry Riddick discusses several important ways that health care organizations and systems can address language and cultural barriers. She describes the use of bilingual/bicultural providers, bilingual/bicultural health workers, employee language banks, professional interpreters, and written translation materials as key strategies. However, there are many subtle challenges entailed in the use of these resources.

Bilingual/bicultural providers: Riddick points out that even when providers and health care workers speak the patient's language, issues of credibility and trust arise.

Linguistic skills of the provider or health care worker do not equate to competency of communicating health information in a culturally appropriate manner. There is a need for standardized evaluation of linguistic skills, competency in health knowledge, and cultural appropriateness.

Bilingual/bicultural health workers: With bilingual workers, their utility is multifold – they have the potential to provide outreach, to promote community participation in the health care system, and to educate providers about cultural awareness. Their role in the system is limited however if they are not situated with primary providers or larger organizations. Often, they work in parallel with the system but in a different setting, that is, at an external case managing agency. This can lead to a breakdown in communication, which may negatively impact patient care and perception of care.

Employee language banks: Language banks are in-house employees used for interpreting or translating, in addition to their regular work duties. This strategy has potential economic and health benefits. However, such an arrangement is prone to abuse of employees, who may be pulled from their usual duties to provide interpreting services. These individuals may lack formal language training, which can lead to dangerous miscommunication about a health problem, diagnosis, or treatment. Successful use of language banks would require that systems formalize the use of such employees by providing the appropriate training, job descriptions, and compensation.

Professional interpreters: In his systematic review of the impact of medical interpreting on quality of health care, Flores concluded that the most rigorous studies on patient satisfaction have shown highest satisfaction with bilingual providers and trained telephone interpreters. Ad hoc interpreters (family, friends, nonmedical or untrained staff) resulted in significantly lower patient satisfaction. Patients who need but do not get interpreters have the lowest satisfaction. Thus, a key determinant in the success of cross-cultural health care will be improvements in linguistic accessibility.

Sociocultural Strategies, Considering Health Issues in a Social and Cultural Context

These strategies may best be described as culturally specific approaches to health care. Horky and Becker define cultural competence as possessing the set of values, beliefs, and practices that enables effective work across cultures. In this, they stress the importance of having the ability to honor the beliefs, language, interaction styles, and behaviors of patients but also the staff providing the care. Cross-cultural health care is therefore a process. It is a dynamic, ongoing relationship between patients, providers/staff, and the health care system at large.

Sociocultural strategies are categorically very broad. Social factors can include but are not limited to a patient's family and social supports, insurance status, occupational status, economic status (including access to resources such as transportation), health and nutritional status, and recreational life. Cultural factors include acculturation, spiritual beliefs, interpersonal dynamics, and beliefs about health, illness, and mortality. Sociocultural strategies would incorporate all of these factors into health care discussions to help bridge communication and understanding between the patients and the health care teams.

Example: Applying Sociocultural Strategies to a Minority Group

In order to conceptualize how these strategies can be effective, it may be useful to focus on a specific cultural group. The African American population is a diverse group. Every geographic region has unique subcultures with variability in practices and beliefs, particularly if religious affiliations influence beliefs. In applying sociocultural strategies at the systems level, however, the focus should be on identifying key similarities that may be generalizable across a majority of the African American population. Literature on the African American population has shown consistent findings about the larger culture among patient populations – strong emotional impacts of a history of slavery and the Tuskagee study, a history of racial disparity in health services and economic opportunities, poor health literacy, a tendency to advocate home remedies, and the strong role of religion and faith in beliefs about health and illness.

An understanding of the key influences in a cultural group's history and evolution in their country of residence allows providers and organizations to tailor approaches to care. For example, for the African American patient population, providers can be trained to inquire sensitively about nonbiological beliefs about illness (folk treatments) and attitudes rooted in spirituality and church affiliation. They can also explore for any negative health encounters in the past, which may impact the patient's approach to health care today. This would include but is not limited to past exposure to prejudicial treatment. At a systems level, health care organizations can formalize alliances with community churches to promote health screening and educational seminars. Clergy, for example, may be key members of the health care team for an African American patient admitted with end stage kidney disease. Clergy may be instrumental in the patient's and family's coping with decisions about dialysis and need for long-term care.

There are numerous ways in which organizations can practice and improve cross-cultural health care by taking the time to learn the history and belief systems of different cultural groups in their community. Ongoing epidemiologic research will continue to be a vital way for health care organizations, particularly managed care, to allocate resources so that quality health care is ensured to minority populations in ways that respect their culture and beliefs.

Conclusion

Cross-cultural health presents a rich arena for improvements in overall health care. Furthering the community's understanding of what it is and how much it can impact the well-being of all our populations is a key task for the future.

In many US health professional training programs, cross-cultural curriculums are already implemented and being evaluated for their efficacy. Providers and health care systems will face the challenge of keeping up with the diverse populations whom they serve, as minority populations increase exponentially in the next half century. No longer will it be enough to acquire biomedically based understandings about health and illness (medical competence). Cultural and nonbiomedical understanding about health and illness (cross-cultural competence) will play an increasing role in health care competency.

Cross-Cultural Medicine

Julienne Ong Aulwes[1], Iqbal Ahmed[2]
[1]Department of Psychiatry, John A. Burns School of Medicine, University of Hawaii, Honolulu, HI, USA
[2]Department of Psychiatry, Tripler Army Medical Center, Honolulu, HI, USA

Culture is commonly defined as shared beliefs and attitudes of a group. In the diverse world we live in, currently, culture undoubtedly shapes ideas of disease causation and what is considered to be acceptable treatment in accordance with a person's worldviews and religious beliefs. Many patients find comfort in their worldviews which are internally consistent. The clinical encounter will vary depending upon cultural understanding of health and illness. The expectations of the roles physicians play in one's life also differ depending on what culture you are from. Lastly, culture and ethnicity affect the prescribing practices of physicians' and patients' acceptance of medications.

Culture and Concepts of Health and Illness

Each culture has beliefs about how bodies function normally and abnormally. Gaining insight into a patient's understanding of what constitutes disease and the illness process is the first step in appreciating the patient and developing a therapeutic alliance. For example, the traditional Han Chinese system conceives of human beings as being part of the universe that is regulated by the opposing forces of *yin* and *yang* (male/female, hot/cold, wet/dry, dark/light, earth/heaven) which are always changing. Good health and well-being are maintained by finding a balance between *yin* and *yang* and diseases are treated by restoring this balance. Asian cultures believe that foods have "hot" and "cold" properties and associate these with the nutritional qualities, medicinal value, and healing power of most foods. This concept of health exists in other Asian and Latino health belief systems as well.

Traditional Mexican beliefs of health include the importance of balancing hot/cold and wet/dry concepts that were probably influenced by traditional concepts of native peoples, such as the Mayans and Aztecs, and by the colonialist Spaniards whose New World concepts originated with Hippocrates' theory of disease and the four humors. The traditional holistic system of healing in India, *ayurveda* ("science of life"),was built on the ancient knowledge in the Atharaveda text about the three humors: *Vita, Pitta* and *Kapha* more than 3,000 years ago. Each person's prescribed lifestyle of diet, exercise, and meditation is designed to maintain his or her specific balance between the three humors. The focus is on establishing and maintaining balance of the life energies within the individual, rather than focusing on particular symptoms. Ayurvedic medicine recognizes that each individual has a unique constitution and thus, treatment and prevention is based on the individual, not on illness, disease, or symptomatology. This system of healing has influenced other Asian systems, such as the Thais.

Every healing system has beliefs about how the natural realm is connected to the social and supernatural aspects of life and how these beliefs relate to health, illness, and healing. The *natural realm* reflects the connections between people and the earth, such as soil, plants, water, air, and animals. The *social realm* refers to the connections between people of different ages, genders, lineages, and ethnic groups. The *supernatural realm* is characterized by the connections between the human world and the spiritual world and includes religious beliefs about birth, death, and the afterlife. Religion and spiritual beliefs are some of the strongest influences on health systems. For example, Chinese medicine is interwoven with and influenced by Taoism, Ayurvedic medicine by Hinduism, and Tibetan medicine by Buddhism. People's religious beliefs are intertwined with their interpretations and experiences of health and disease. Many African American women, for example, across all socioeconomic levels, believe in the power of prayer and God's healing power to treat and cope with breast cancer. This belief can often lead to a delay in seeking professional health care despite being an important source of emotional support for many African Americans.

In trying to understand how the patient views a particular illness, the physician should ask the patient what the illness means to him/her and what treatments the patient is currently undergoing. It is important to elicit pertinent history by inquiring about what alternative therapies the patient has already tried and what providers he/she has already seen. There is often a "hierarchy of care" in many cultures, where patients would first try home remedies, prior to seeking care from the folk sector (traditional healers or religious leaders), and lastly approaching the professional sector (such as a physician) only when all other therapies have failed.

In the popular or lay sector of healers, treatments are usually provided by family members or by the patient and may include practices such as massage, coining, cupping, burning, incantations, medicines, or wound dressings. The folk sector of healers usually consists of priests, shamans, herbalists, or bonesetters. Treatments are usually culturally integrated and congruent and require some sort of payment usually in the form of gifts which may be monetary, material items, or involve exchange.

The professional sector of healers includes conventionally trained allopathic medical personnel (physicians, nurses, dentists, pharmacists) and those trained in complementary and alternative medicine (acupuncturists, homeopaths, Ayurvedic and Chinese medicine specialists, etc.). Formal education and licensing are required and an apprenticeship may be involved. Monetary payment is standard, usually paid by third-party insurance or in the form of cash payments. Healers from each sector may refer, ignore, or compete with each other. In many countries, various folk healers exist in parallel providing specialized or generalized services.

Arthur Kleinman, a prominent American psychiatrist and one of the world's leading medical anthropologists, calls people's ideas about an illness their explanatory model. Explanatory models consist of five components: (1) timing and onset of symptoms, (2) pathophysiological processes, (3) the etiology of the condition, (4) natural history and severity of illness, and (5) appropriate treatments. The ill person, family members, medical providers, and social networks have their own explanatory models about the illness, which may be complementary or contradictory. The more the agreement that exists between explanatory models of all parties involved, the less likely there is conflict. Kleinman et al. designed eight questions to elicit patients' explanatory models: (1) What do you call the illness? (2) What do you think has caused the illness? (3) Why do you think the illness started when it did? (4) What problems do you think the illness causes? How does it work? (5) How severe is the illness? Will it have a long or short course? (6) What kind of treatment do you think is necessary? What are the most important results you hope to receive from this treatment? (7) What are the main problems the illness has caused you? (8) What do you fear most about the illness?

Cross-Cultural Care

Patient role is influenced by culture, especially in relating to the clinician and adhering to treatment recommendations. There might be unique feelings toward the clinician related to the perceived cultural orientation of the clinician based on racial and power differentials. Patient role and feelings, in turn, affect the beliefs and expectations about the therapeutic alliance and the treatments prescribed by the clinician. Clinicians may also be affected by their perceptions of a patient's illness based on racial or ethnic characteristics, which can influence their diagnosis of the illness and beliefs about likely treatment response. They might perceive patients from certain ethnic backgrounds as having more psychopathology, as being more likely to need medications, as needing more "potent" medications, and as having a worse prognosis for their illness. Clinicians have been found to overpathologize symptoms found in African Americans and Hispanics, and possibly to minimize symptoms in Caucasians.

Culhane-Pera and Borkan recommend six fundamentals to assist healthcare professionals in providing quality cross-cultural care. Health care providers must know themselves as cultural beings, know their patients as cultural beings, have attitudes that express respect and engender trust, develop communication skills that facilitate mutual understanding, apply a culturally appropriate interview model during the clinical encounter, and develop cross-cultural negotiation skills that build therapeutic relationships. The goal is to provide medically, linguistically, and culturally appropriate health care interactions irrespective of the cultural background of the patient and provider, in order to deliver excellent health care service with optimal outcomes.

Culture is something that all humans possess and being aware of one's own cultural beliefs, values, and assumptions is extremely important in providing quality health care that is culturally sensitive. Adverse effects on health care delivery can occur when interacting with people of different cultural beliefs, values, and ethics because of one's own biases and unchallenged assumptions. Thus, self-awareness and identification of sensitivities, reactions, biases, and centrisms are key to providing culturally competent care.

Health care professionals should strive to familiarize themselves with their predominant patient population's traditional lifestyles, religions, social structure, histories, and prior experiences with health care, ranging from lay and traditional healing systems to Western biomedicine. Identifying similarities and differences between the patient's traditional health care system and Western biomedicine can be helpful in delivering excellent health care. Expectations of the patient–provider relationship should also be explored in order to identify areas of congruence and incongruence.

Patients in general respond best to health care providers who can express respect and engender trust across cultural gaps in their behaviors with their patients, families, and communities. Respect is a cross-cultural concept that is demonstrated and experienced in different ways. As a health care provider, being culturally humble can facilitate the clinical encounter when dealing with patients of different cultural backgrounds. One needs to commit to self-evaluation and self-critique, to rectify the power imbalances in the patient–physician relationship and to develop nonpaternalistic clinical and advocacy partnerships with communities on behalf of individuals and defined populations.

Different cultural milieus dictate what a phrase, a word, or gesture may mean. When working with different groups, it is recommended that one be familiar with differences in nonverbal and verbal communication for these groups, including eye contact, personal space, gestures, greetings, touching, and body parts. Verbal communication differences must also be addressed. It is important to learn basic greetings and medical words and become proficient in working with interpreters. Generally, it is preferable to work with trained interpreters rather than children, adult family members, or untrained individuals who happen to know the language. It is important to choose interpreters that are acceptable to patients and their families in terms of their sex and ethnic group, and who can translate in the first-person singular style "word for word" rather than phrasing or summarizing. In addition to providing linguistic interpretation, it is helpful if the interpreter can also serve as a cultural broker.

There are several different cross-cultural communication models that can be applied to clinical encounters when interacting with a diverse patient population. The patient-centered model encourages health care providers to explore both the patient's disease perspective and illness experience. One should also strive to understand the whole person in the context of individual development, the family life cycle, and the larger socioeconomic and cultural context of people's lives. It is important to find common ground in the clinical encounter with good patient communication skills that lead to mutual decisions. One can incorporate prevention and health promotion, and enhance the patient–clinician relationships, while being realistic about the realities of clinical medicine.

Lastly, it is important for health care providers to develop cross-cultural negotiation skills. Difficulties may arise from different patient and provider health beliefs, expectations of life-cycle events, desires for treatment, moral values, or ethical principles. If providers have objections to requests from patients or their families for care or refusals of care, they have to decide if they are objecting based on challenges to their personal moral beliefs, personal preferences, or professional integrity. Health care professionals must negotiate treatment alternatives with the patient, family, and possibly community members as well. If negotiation is unsuccessful, the provider must either accommodate the patient or transfer the care to another provider. Challenges to personal integrity may be resolved by utilizing an ethics committee that has community input. To avoid harmful consequences of unintentional biases, physicians must (1) be aware that disparities exist in health care, (2) be aware of their own assumptions and preferences, and (3) take actions so that their biases do not negatively impact care.

The cross-cultural interview is one that requires time and patience. Cultural dynamics such as cultural norms, communication styles, and family dynamics all influence the clinical encounter. A person's concept of time and punctuality, facial expressions, body language, and personal space and touch issues are all relevant factors when interviewing a patient. For example, persons from Latino or African American culture may have a more relaxed sense of time, and schedules are considered less important than personal relationships. Non-Western cultures tend to view time as flexible as compared to Western cultures where time is equivalent to efficiency and considered an important entity. One can explain the importance of punctuality in the Western medical setting if a patient is late.

In the Latino culture, "small talk" can contribute to establishing trust (*confianza* in Spanish) between the patient and the clinician. Patients may frequently nod in agreement or say they understand something even if they do not comprehend. They may avoid asking questions due to embarrassment or respect. In such cases, it is helpful to have patients repeat the instructions in order to verify their understanding. Nodding vigorously may signify respectful attention but not necessarily agreement or understanding.

In Western cultures, eye contact signifies respect and attentiveness; however, in many non-Western cultures, direct eye contact may indicate disrespect of authority and/or sexual interest, and thus, patients may sometimes avoid eye contact with physicians out of respect, especially if they are of a different sex or social status. Clinicians should speak slowly and simply to the patient using concise sentences and a normal tone of voice. They should also address patients by their formal name if they are uncertain of how to address them. In many non-Western cultures, using one's first name as a greeting denotes disrespect, as compared to Western culture, where greeting on a first name basis helps to build rapport and denotes informality. If an interpreter is present, the clinician should speak directly to the patient.

Personal space and the degree of physical touch also differ among various cultures. Western cultures view personal distance as denoting professionalism and objectivity. Latinos may interpret Westerners as being distant while conversing because they prefer more personal space. Some cultures such as Orthodox Jews and people from Islamic sects do not allow opposite sex touching, not even hand shaking. It is helpful for clinicians to explain what they will be doing when working with low-touch societies (e.g., Asians). The physical examination should be conducted in a culturally sensitive manner, noting specific male–female dynamics particular to the patient's background. For example, in some cultures, a chaperone of the same sex must be in the room for a physical exam if the provider and patient are of opposite sex, while in some cultures only a clinician of the same sex as the patient is permitted to conduct a physical exam.

Physical gestures also differ among cultures. The "thumbs up" sign may be interpreted as a profane gesture in Iran. The "okay" sign in North America may be considered obscene in Latin America. Many Asian cultures consider patting a child on its head, exposing the sole of the foot, or pointing with the foot an insult. In many countries of Asia and South America, using the index finger to point or beckon someone is considered rude and disrespectful. Rather, beckoning is done with the palm faced down and all fingers are waved inward. Many cultures consider the left hand "unclean" because it is often used for personal hygiene. Thus, prescriptions and samples should not be given with this hand.

Culture and Medication Response

Ethnicity has been reported to affect medication response due to genetic differences among the different groups affecting drug metabolism and cellular differences in organs such as the brain. The focus discussed here will be on the effect of culture on medication response in nonbiological aspects of medication response such as in the degree of patient adherence, placebo effects of medications, and other behaviors affecting drug interactions including dietary habits and other alternative treatments such as herbal remedies. Variables involved with these nonbiological effects are related to the patient, the clinician, and their relationship; cultural beliefs about illness and medication; and the actual process of giving and receiving medications.

Culture influences personality and behavior patterns; perception of stress and coping style, including manner of utilization of social support; and interaction, including transference, with the clinicians. These variables influence the process and outcome of medical treatment, including medication response. It has been suggested that individuals from cultures that emphasize independence, struggle, and action (typically Western cultures) are likely to require more medication than patients whose personalities are shaped by cultures that emphasize interdependence and social adaptation (typically Asian cultures).

How one reacts to stress and utilizes social support are both thought to be important factors affecting medication response (needing different dosages and levels of medications) and prognosis of psychiatric illness. For example, in families of patients with schizophrenia with higher levels of "expressed emotion" (frequent criticism, hostility, and emotional overinvolvement), there is a poorer response to medications. There appears to be differing levels of expressed emotions in different cultural groups: Anglo-American families have been reported to have higher levels of expressed emotions than British families, who, in turn, have higher levels of expressed emotions than Hispanic families.

Culture also influences the role of the clinician in terms of one's prescribing habits and decision-making process in regards to the clinician's role and "healing power," the desire to please the patient, feelings about the patient including biases about race and ethnicity, and professional norms and values. Even when there is no indication for medications to be prescribed, the clinician may do so in order to comply with patient demands and thus placate the patient.

Certain cultures may objectify healing through medicines which serve to facilitate particular social and symbolic processes. This may be considered the "symbolic" effect of medication as compared with the pharmacological or "instrumental" effect. The symbolic effect includes characteristics such as "life" or "healing power" of a drug, and the attribution of value. Patients may experience and associate certain emotions with the use of certain medications. Some characteristics of medicines may have cultural meaning, including their form or consistency, the sensation experienced after taking the medicine, the source of the medicine, the packaging of the medicine, and the mode of administration of the medicine.

Form or consistency of medicine refers to the physical characteristics of the medicine: tablet, capsule, liquid, color, size, amount, and even the name of the medicine. The color of the capsule has been reported to affect placebo response differentially in different ethnic groups. For example, white capsules are often viewed by non-Hispanic Whites as analgesics whereas African Americans may view them as stimulants. On the other hand, black capsules are often viewed by non-Hispanic Whites as stimulants and by African Americans as analgesics. Yellow pills are often viewed as appropriate treatment for depression in Europe, and red capsules are perceived as suitable for strengthening the blood in Sierra Leone. Culture may also affect the amount of medicines purchased by patients. In El Salvador, patients buy medicines in multiples of four, since the number has ritual significance.

The sensation experienced after taking medicine refers to the reaction that occurs including the taste, such as bitter or sweet. Some cultures believe bitter medications to be more potent and effective. Certain types of aftertastes are considered to be indicative of the effect of the medication, either therapeutic or adverse, in some folk systems of medicine.

The source of the medicine (whether from plants, derived from animals, or is synthetic) can have a psychological impact on medication response. For example, many Muslims do not use alcohol-containing medications because of religious reasons, and they along with orthodox Jews may not use medications containing porcine products. Other concerns related to sources of medication include whether the manufacture is foreign or domestic, and the degree of difficulty in obtaining the medication. Western medicines may be viewed as more potent, faster, and superior for acute illnesses, whereas herbal medicines are seen as milder, slower, and better for chronic illnesses.

The presentation and packaging of the medication and location of distribution can influence the patient's perception of its value and perceived efficacy. The traditional belief in Eastern herbal medicines, which consist of several herbs, has accustomed Asians to polypharmacy. Many physicians in Japan, Korea, China, and Taiwan often use polypharmacy as standard practice and frequently do not disclose the contents of medicines to the patients. This contributes to the mystery of the contents which gives more therapeutic power to the treatment. Asian patients widely accept polypharmacy and view a good doctor as being skillful in combining different kinds of drugs.

The mode of administration of a medication has significant meaning to patients' perception of treatment efficacy. Injectable agents are frequently believed to be more potent than oral medications. The experience of pain from the injection may contribute to this perception.

After a clinical encounter, one should be aware that in many cultures, it is required to demonstrate one's gratitude with a gift and its refusal may cause offense. Gifts are frequently offered to ensure the best possible care for the patient (a "soft" bribe for the caregiver). Gifts may come in the form of food, animals, small trinkets, or money. If the gift is culturally inappropriate (e.g., money), one can suggest an alternative such as food that could be shared with the rest of the staff.

The conveyance of bad news or a negative prognosis also varies among cultures. In the United States, it is customary to only inform the patient in accordance to Health Insurance Portability and Accountability Act (HIPAA) regulations. However, in many other cultures, the family is informed first and then they decide if and when the patient should be informed. This violates HIPAA regulations if one is practicing in the United States. The patient or family may become angry at the health care provider if this custom is not followed because it is felt that giving someone a bad prognosis removes hope and becomes a self-fulfilling prophecy. Physicians should ask patients how they would like their family to be involved and then explain to the family that informing the patient first is the standard US medical practice.

Some benefits of possessing cross-cultural skills include better patient outcomes with greater patient adherence, improved access to care, reduction in health care disparities, and an awareness of the hazards and benefits facing the patient from traditional caregivers. One should be aware what aspects of traditional care can be adapted to a Western biomedical setting and know what aspects need to be rejected due to danger to either the patient's spiritual or physical health. It is imperative that health care providers learn about the ethnic populations they serve in order to provide efficient, effective, patient-centered, quality care. Providers should also know themselves and their patients as cultural beings, have attitudes that express respect and engender trust, develop communication skills that facilitate mutual understanding, be able to apply these knowledge, attitudes, and skills in clinical encounters, and develop cross-cultural negotiation skills.

Cultural Adaptation Resources

Ken Crane[1], Suzanne Mallery[2]
[1]Department of History, Politics, Society, La Sierra University, Riverside, CA, USA
[2]Department of Psychology, La Sierra University, Riverside, CA, USA

Many factors affect the well-being of immigrants as they enter a new society. Particularly significant is the mode of incorporation, that is, how they are received by the host community and the strategies they develop in response. This is often shaped by background factors such as language proficiency, socioeconomic status, race/ethnicity, and legal status. The mode of incorporation is key to an immigrant's access to crucial resources, including health care, education, and employment.

Host Community Integration/Incorporation

First of all, the way in which a government recognizes or refuses to recognize the status of immigrants is significant to adaptation. Immigrants' legal status can determine whether they have access to resources necessary for successful integration. For example, Iraqis fleeing war and sectarian violence by going to Jordan are granted only temporary protection by the Jordanian government, with the condition that they will be resettled in another country in 6 months. They are not allowed to work and receive only minimal aid through the United Nations High Commissioner for Refugees (UNHCR), forcing them to find support among other Iraqis and in the informal economy. Fortunately the official position does not restrict the movements of those given the status of "asylum seekers," and they are allowed to attend school and receive medical care at government hospitals. However, their marginal, transitory status provides little motivation to become part of Jordanian society.

It should be noted that cultural adaptation to a new society might begin before individuals arrive in their country of destination. A study of Sudanese refugees by Chrostowsky showed that those who had lived in Cairo before being resettled in the USA had an easier transition than those who had lived in Eritrea or Kenya. The reason is that many of the women worked as domestics during their transitional stay in Cairo where they had fewer language barriers (some Sudanese speak Arabic, albeit a different dialect), and gained familiarity with electricity and household appliances. Because they had an easier time finding work than Sudanese men, the women assumed more of the breadwinner role in family, anticipating the radically different constructions of gender roles to be encountered in the USA.

There are a number of assumptions about immigrant adaptation. The first is that immigrants naturally, for the better, assimilate or acculturate, that is, blend in with the host community, and the faster they do so the better for their own good. The second assumption is more recent and takes the opposite view, that immigrants are following a pattern of resistance to assimilation, refusing to learn the host country language and fit in with the dominant culture. Both assumptions are faulty and not supported by research.

In the USA, scholars of immigration such as Alejandro Portes and Ruben Rumbaut found that acculturation occurs along a continuum. Near one end is a more “selective” mode of acculturation, often involving conscious strategies by parents to socialize children into the culture of the ethnic community. Within this mode of adjustment parents and children in immigrant families tend to acculturate in similar directions and retain more traditional values and language. Parents and children tend to be highly involved in ethnic institutions (e.g., religious congregations), further keeping both generations acculturating in roughly similar directions. This pattern does not, as is often assumed, preclude the acquisition of English language ability and cultural competency in the wider American community. Studies of immigrant children reveal an ability to acquire bicultural/bilingual skills within constantly evolving frames of ethnic identity.

On the other side of the continuum is where children indeed acculturate rapidly, but parents lag behind, their lack of language skills making them dependent on their children to deal with the outside world. Thus, “generational dissonance” occurs as parents have difficulty guiding a highly acculturated second generation. This pattern is associated with such negative dynamics as the loss of parental authority and children’s rejection of the parents’ culture.

The mode of incorporation is shaped by many factors, including the type of community where immigrants live. Immigrants who settle in an urban enclave of co-ethnics, full of shops, churches, and people who speak the same language and share similar cultural norms, will experience a mode of incorporation different than those living in a more isolated suburban neighborhood.

It should be stressed that immigrants are proactive in the process of adaptation; it is not something that is done for them or to them. The rapidity by which immigrants establish networks, clubs, and organizations such as churches, is an example. Crane and Millard observed that the rapid creation of viable social institutions, such as religious congregations, demonstrated that new immigrant Latinos in the Midwest could create organizations that significantly benefit their constituencies and represent them in their new hometowns. Therefore, it should be acknowledged that cultural adaptation among immigrants is typically a process negotiated by immigrants themselves via the mechanism of entrepreneurial activity, education, mutual assistance organizations, and religious institutions as well as via other expressions of human agency.

This does not rule out the important role of individuals, organizations, and governmental institutions external to immigrant groups. Ultimately, success in American society requires resources beyond what private organizations can supply, particularly for language acquisition, education, health care, and financial capital.

Another factor that has led to new types of organizations involved in cultural adaptation is mutual group suspicion among new immigrants, various immigrant groups, and the host community. This leads to newcomer immigrants maintaining separate social networks. Their reasons are understandable – particularly if they have experienced suspicion and hostility from the host community. As Godziak and Melia observe, ethnic communities serve to “cushion the impact of cultural change and protect immigrants from outside prejudice...” The anthropologists Grey and Woodrick identified a “20-60-20” pattern in Iowa, where roughly 20% of the Anglo community sees the influx of Latino newcomers as basically positive, 20% react negatively, and 60% adopt a “wait and see” attitude. Because of mutual suspicion and the marginal status occupied by many new immigrants, public interaction between groups is more difficult, even if most individuals on both sides desire to get along. The fear that this engenders among immigrant populations produces additional barriers to finding an established place in a new community and to getting the necessary resources.

Fortunately, many concerned nonimmigrant citizens have proactively formed organizations to mitigate negative sentiment and constructively address the acceptance of new immigrants and bridge the gap between cultures. These organizations, an example being Heart and Hands, Inc., of Plymouth, Indiana, or TODEC in Perris, California, provide services to the new immigrant community, such as English language classes, job training, citizenship preparation, and translation and referral to other essential services, such as health care. In communities where immigrant communities are not well established, it is common that service organizations emerge that serve “all” immigrant newcomers.

As immigrant communities grow and become better established, they commonly create their own organizational structures to provide services to a specific language, nationality, or ethnic group. The advantage in this practice is that immigrant communities can mobilize mutual assistance resources faster in a more appropriate fashion to particular culturally defined needs, bypassing the more cumbersome mechanisms of public services. The risk associated with strong ethnic organizations is that they may further serve to isolate immigrants culturally and socially. This can present a further barrier to gaining English language proficiency.

Language Acquisition

In most cases, acquisition of the host country language is essential for overall success, to avoid exploitation, for upward mobility, and to retain control over and connection with children who are rapidly losing the mother tongue. Most immigrants to the USA enter an environment in which English is dominant, although some regions and communities may have significant bilingual populations. It is not unusual that immigrants will encounter expectations that “they need to learn English,” and “they need to adapt to our ways.” Local fears of immigrants “not integrating” into “our way of doing things” are common reactions. Fennely found that lack of English ability is interpreted by the host community as choosing not to “assimilate” and as rejecting American culture and “creating their own isolation.”

The 2000 census revealed that four out of five immigrant families spoke a language other than English at home. For people who see their place in American society as only temporary, there may not be an incentive to learn English. Even for those who intend to become citizens, the English language requirement is minimal. Furthermore, the demands of family and work schedules make it difficult to take advantage of classes. Nevertheless, as Gozdziak and Melia point out, most immigrants recognize the value of learning English and seek out ESL (English as a Second Language) programs. Their research also describes the many types of ESL or ENL (English as a New Language) programs created to accommodate the needs of immigrants. These include public and alternative schools with day and evening schedules, public library programs, and nonprofit organizations that offer low cost classes, often allowing the whole family to attend and providing childcare.

Often immigrants must draw on resources within their own community organizations for help in language barriers. The UNHCR reports that Albanian refugees from Kosovo resettled in Spain had to create their own Albanian-Spanish dictionary with key words and phrases that could be used by new arrivals and Spanish settlement workers.

Economic Self-Sufficiency

A crucial area of cultural adaption concerns economic self-sufficiency through employment or entrepreneurial initiative. With the exception of immigrants who are highly skilled professionals, new arrivals often find work in niche-markets and informal economies of ethnic communities. While this may work in the short term, it may not be a long-term, permanent option, and immigrants moving into the mainstream job market may face many barriers in the job market related to culture and language. Many countries have created specific programs to increase the changes of economic success for immigrants. For example, in Germany, refugees seeking help in finding employment work with a separate agency, the AWO, which works specifically with refugees to provide job assessment and placement support. In the Australian state of Victoria, refugees are provided with similar services within the same mainstream employment service, but through government workers who are provided special training to deal the immigrant populations.

Mentoring programs have also emerged, whereby immigrants who have achieved successful careers provide mentoring services to new arrivals. In the UK, a program developed by doctors who had been refugees now provides coaching, placements, and qualifying exams to qualified immigrants.

Many immigrants contribute greatly to host country economies through creation of new business. Family and ethnic networks may be sources of otherwise difficult to find start-up capital. The challenge of finding adequate start-up capital for entrepreneurial immigrants has led to an increasing number of microenterprise programs worldwide targeting immigrants and refugees. The UNHCR reports that refugees from Ireland to Burkina Faso have taken advantage of grants and easy term loans programs to assist small business.

Personnel and organizations working with immigrants also play a role in educating employers about the culture and religious needs of immigrant workers, for example, taking into consideration time for religious observance, prohibitions against handling certain food items, and gender role restrictions. The UNHCR advises that agency staff need to be careful not to inflate the skills or exaggerate the needs of refugees. Rather they should be seen as "normal people in extraordinary circumstances."

Accessing Culturally Appropriate Health Care

Immigrants worldwide often face significant obstacles to accessing health care that is culturally and linguistically appropriate and affordable. Even in places like New York City, which has a long history of dealing with diverse immigrant populations, barriers persist. The following description of these difficulties in New York and elsewhere in the USA has parallels in many other countries.

A recent report from the New York City Department of Health and Mental Hygiene noted that foreign-born adults are less likely than native-born adults to have a primary care provider; have Medicaid or health insurance; or receive regular preventive health measures such as colon cancer screenings, pap smears, or cholesterol screening. This difficulty accessing medical care is especially pronounced for recent arrivals and those who lack adequate proficiency in English (Low English Proficiency or LEP). Many undocumented immigrants actively avoid encounters with health care systems for fear of being turned over to immigration officials and deported. As a result, they may not have access to preventive care, routine screenings, or early treatment, seeking medical assistance only once potentially treatable conditions have progressed to the point of being severe.

Health care costs can be a significant barrier to accessing care for immigrants. Department of Homeland Security statistics indicate that one third of foreign-born individuals in the USA were uninsured in 2007, compared to less than 15% of those who were born in the USA. A Pew Hispanic Center report found that almost 60% of undocumented adults lacked health insurance coverage.

The Personal Responsibility and Work Reconciliation Act of 1996 (PWORA) barred states from using federal funds for Medicaid or the Children's Health Insurance Program (CHIP) for most undocumented immigrants and recent immigrants (within 5 years of arrival, regardless of immigration status), but allowed funds for some emergency Medicaid services. The result is a lack of preventive care. The 2009 CHIP reauthorization law, CHIPRA, changed regulations to allow states to use federal funds to provide Medicaid or CHIP to legal immigrant pregnant women and children, but not to other groups. Immigrants are also less likely than native-born citizens to have health care benefits provided by their employer.

Even immigrants who have insurance have less access to and lower use of medical care than do native-born individuals. Both linguistic and cultural barriers contribute significantly to making health care systems relatively inaccessible to many immigrants.

The U.S. Department of Health and Human Services Office of Minority Health issued National Standards for Culturally and Linguistically Appropriate Services in Health Care. Four of these standards mandate language access in health care in any medical facility that is a recipient of federal funds. These standards require facilities to offer competent language assistance services such as interpreters and bilingual staff to any patient who needs those services.

Despite these standards, often no qualified interpreter is available to the patient, leaving LEP patients to rely on family members, friends, other patients, or strangers to translate for them, resulting in a loss of privacy and accuracy. Reliance on children poses particular problems, as it causes role reversals in the family structure, and children often lack the vocabulary and understanding of complex issues to translate accurately. Additionally, children may wish to avoid sensitive topics, which can slant the information given.

Bureaucratic, large, and impersonal health care systems are often extremely difficult for immigrants to navigate, and cultural insensitivity can be enough to drive them away from seeking care or make receiving care a negative experience. Birth and death are particularly difficult times, with health regulations, safety rules, and hospital practices often interfering with the practice of cultural and religious rituals such as burying a newborn's placenta, touching the lips of a baby with honey or preparing the dying for passage into the next life. Physicians and patients may also have differing ideas about the causes and treatment of illness, which can cause misunderstandings and conflict. Patients may be using traditional, complementary, or alternative medicine in addition to the medical treatment offered by an MD, but unless both parties are able to communicate and know what to ask, this information may not be available to the physician. Patients may not volunteer information for fear ridicule or rejection if they reveal alternative treatments.

In general, immigrants' access to key resources can be facilitated or hindered by their mode of acculturation and by the availability of others in the community who can assist in making this transition. Community-based private organizations can provide an important bridge between immigrant families and participation in the wider society, connecting them to programs that provide resources for education and advocacy. Ultimately, nonimmigrants and a variety of immigrant groups need to cooperate together for a truly successful and diverse society to emerge.

Cultural Appropriateness

- ► Cultural competence
- ► Cultural humility

Cultural Background

Cătălin Jan Iov
University of Medicine and Pharmacy "Gr. T. Popa", Iasi, Romania

The number of immigrants worldwide has almost doubled during the past 50 years. It is now estimated that there are 191 million immigrants worldwide, 115 million of whom live in developed countries. In fact, 75% of immigrants live in just 28 countries. One-third of all immigrants have made their new home in Europe, and another fifth have settled in the United States.

All of these immigrants carry with them their habits, beliefs, and lifestyle from the countries of their births to their new host countries. In short, they carry with them their cultures, which are the sum of all beliefs, attitudes, models, templates, living style, and any other characteristics that promote relationships among the group members. The concept of culture also includes codes of manners, dressing style, language, religion, rituals, and systems of beliefs. These elements often identify immigrants as a distinct group in the host country. The culture frames individuals' social lives and actions and differentiates the groups.

The differences between cultures may not be obvious unless individuals from different groups occupy the same space or contiguous spaces. It is critical that the host cultures adapt to the new incoming cultures, particularly in view of increasing globalization and increased diversity.

Host Culture Attitude

The entry of any culture into a different one will always generate reactions. Scholars have suggested that the level of hostility directed to the newcomers by individuals in the host country depends on the degree of similarity between the new host culture and the immigrants' original culture; it is hypothesized that the more similar the cultures, the less the level of hostility or antagonism.

A common way of understanding a culture and the extent to which cultures are similar or different is by reference to four elements: values, norms, institutions, and artifacts. Values refer to what is important for the society, what is important for the family, what is important in general in life. Norms consist of all behaviors that are judged by the culture to be appropriate in dealing with different situations. The institutions are those structures that are governed by the values and norms. The values and norms within a society derive from unwritten law (common sense) and written law (such as punishing all those that are breaching the norms and values). The artifacts are the products of a cultural history.

Attitudes toward cultural diversity as a result of immigration have been found by researchers to be associated with individuals' age, sex, and race. For example, some groups, such as Algerians and some other North African French persons, may continue to be stigmatized, marginalized, and discriminated based on racial reasons despite their legal status as citizens. Young educated females have been found to be more open to exposure to new cultures than older men.

Cultural Background and Health Care

In the health care context, five issues relating to individuals' cultural background are of primary importance: the style of communication, the existence and extent of mistrust and prejudice, decision making and family dynamics, traditions and spirituality, and sexual and gender-based issues.

Cultural background may affect doctor–patient communication and, accordingly, the doctor–patient relationship. For example, a medical team trying to provide medical treatment may find that the treatment conflicts with the patient's beliefs. Such dilemmas may be amplified when the patient's language differs from the provider's language. Differences in the cultural background between the provider and the patient may also bring different expectations. For example, the Western concept of health delivery stresses a collaborative model of communication between the health care provider and the patient. However, in many cultures, medical decision making requires the involvement of the family and not only the individual patient. In yet other cultures, individuals are accustomed to a more paternalistic model of relationship between the doctor and the patient. In many Eastern Europe cultures, for example, the doctor–patient relationship is one of trusting the doctor without asking too many questions about the treatment. The cross-cultural care model proposed by Betancourt and Cervantes requires consideration of the patients' cultural background. Successful cross-cultural medical education would assist health care providers to develop the skills necessary to provide care to individuals of diverse backgrounds.

Religious beliefs may also affect provider–patient communication and the patient's willingness to agree to particular treatments. For example, some immigrant groups may favor the use of prayer, meditation, or traditional preparations to treat an illness, rather than Western medicine. Provider sensitivity to and accommodation of these varying beliefs to the extent possible are critical to the development of a successful provider–patient relationship and open lines of communication.

Culture-based norms relating to sex and gender are also important in the health care context. Kopp, Réthy, and Chapuis reported on the case of a woman who presented to an emergency room for a gynecological problem. The patient and her husband initially rejected care from the male physician on duty based on their religious beliefs. However, they later agreed that the male physician could care for the woman after a religious authority explained that the religion did not prohibit the examination by a male physician because it was a medical emergency.

Accordingly, it is critical that health care providers consider in each particular case all of the factors that define an individual, including the person's attitudes, understandings of health and illness, language, and religious beliefs. A primary goal should be the development of a good relationship with the patient and smooth communication.

Cultural Competence

Linda S. Martinez[1], Flavia C. Peréa[2]
[1]School of Arts and Sciences, Community Health Program, Tufts University, Medford, MA, USA
[2]Department of Public Health and Community Medicine, Tufts University School of Medicine, Boston, MA, USA

Driven largely by immigration, the USA, like Europe and Canada, is becoming ever more diverse. For example, it is anticipated that the country will have a minority-majority population by the year 2042, largely the result of immigration from Latin America and the Caribbean, as well as both Africa and Asia. This underscores the importance of understanding different cultural experiences in the health care realm. These demographic shifts have exaggerated an already present cultural distance between the medical community, which is predominantly upper middle class and White, and the general population. As such, health care organizations are grappling with ways in which to both understand and meet the needs of diverse communities that are not always reflective of their employees and/or providers. Cultural competence has been proposed as a mechanism by which to bridge the cultural distance between patients and health care providers.

Cultural competence is a component of patient-centered care. In 2001, 7 years after being charged by Congress with improving the ability of health care providers to deliver culturally competent care, the United States Office of Minority Health published National Standards for Culturally and Linguistically Appropriate Services (CLAS) in Health Care. The overall aim of the CLAS standards is to address health care disparities through the delivery of culturally and linguistically competent care in health care services. As such, culturally competent health care organizations provide treatment services that effectively meet the needs of their patients, while considering the cultural, linguistic, and/or socio-environmental context of patients. Similarly, culturally competent providers bridge sociocultural divides, allowing them to recognize and understand the needs of diverse patient populations with varying cultural beliefs and behaviors.

Cultural Competence and Inequity in the Delivery of Care

The modern day health care system is founded on traditional beliefs of Western biomedicine, thereby forming its own unique culture built on a distinct cultural orientation and perspective, inclusive of distinct assumptions and beliefs about patients, providers, and the nature of health care. Cultural competence involves understanding the ways in which individual and community level practices and beliefs influence health, and the delivery of health care. Both patients and providers bring with them into the health care exchange a set of beliefs, experiences, and practices that shape their behavior and interactions. *Unequal Treatment*, a report commissioned by the Institute of Medicine, brought a new dimension to our understanding of cultural distance and the contributions of providers to health care inequality. The report found that systemic, provider, and patient level factors take away from the overall quality of care. More specifically, patient race and ethnicity are primary predictors of health care quality.

Culture also contributes to the divide between patients, providers, and the health care system. Culture, although often confounded with race and ethnicity, is more than race and/or it influences behavior, including health practices and interactions. Culture can be influenced by social constructs such as race and ethnicity, but additional factors such as religious beliefs, family structure, class, place, and time coupled with socio-environmental and sociopolitical context also contribute to cultural variation. Such variation can result in cultural distance as well as disconnects both between and within groups. For example, how patients describe their relationship to the biomedical system may vary dependent on the cultural context of the patient. The same can be said for providers describing their cultural distance from patients, and patients describing their cultural distance from providers.

Cultural distance contributes to poor quality care for racial and ethnic minorities including new immigrants. Cultural distance is a by-product of social, economic, political, and historical factors, which result in divergent health beliefs, communication barriers, mistrust, and bias. Socioeconomic and racial segregation – both associated with the social hierarchy in the USA – isolate individuals geographically, socially, and culturally. Isolation and unfamiliarity leave individuals vulnerable to the effects of bias and stereotypes. That which is unknown is more easily understood when grouped or categorized.

Social cognition is the unconscious process by which we categorize or group individuals – how our minds make the unfamiliar familiar. For example, providers, when interacting with patients of a background that is foreign to them, draw upon past experiences, perceptions, and stereotypes to make sense of that which is unknown, which can lead to health care disparities. Thus initiatives that promote cultural competence are important as they encourage providers to (1) meet patients where they are at, (2) avoid using mental shortcuts and stereotypes, and (3) broaden their worldview to assure understanding of patient cultural context, thereby engaging patients in treatment as opposed to maintaining cultural distance.

Cultural Competence as a Market Strategy

Beyond addressing health care inequity, cultural competence by some has been described as a market strategy in addition to a means by which to reduce racial and ethnic disparities in health care. Researchers have found that experts from managed care, academia, and government describe cultural competence as a mechanism by which to improve access to quality care for diverse, new immigrant communities. In addition, it has been described as a way for health care provider and payer organizations to increase their market share in a rapidly changing world demographic. This is significant; it represents a paradigm shift solely viewing cultural competence as the right thing to do in addressing disparities to a focus on good business practices in a shifting market. By providing culturally competent care, care that seeks to meet patients where they are at both culturally and linguistically, health care organizations can differentiate themselves from their competitors, increasing their market share.

Four interconnected financial reasons for organizations to provide culturally competent care have been outlined in the literature. The first being clear, *appeal to minority consumers. With the growing proportion of minority consumers in the market* many businesses, including the health care sector, seek to reach the minorities. Cultural competence in this sense would provide organizations the tools needed to differentiate their services in the market. The next two reasons are based on the same premise, to compete for purchaser business. Brach and Fraser report that providing culturally competent care allows health care organizations to compete for *private purchaser business* and to respond to *public purchaser demands*. They explain this in that cultural competence will increase performance quality scores, increasing their appeal to private purchasers, while at the same time facilitating compliance with public purchaser rules and regulations. Finally, it has been identified as a means to improve cost-effectiveness. As providers who confront barriers in communications are likely to order additional diagnostic tests and thus incurring greater costs, cultural competent organizations would have the linguistic capability to better capture medical history and reducing the need for unnecessary testing.

Conclusions

Cultural competence has the potential to reduce care health disparities, by increasing patient access to quality health care though a respectful patient provider relationship. In addition, culturally competent health care makes good business sense. The hope is that diverse populations plus cultural competence leads to better communication, increased trust, better assessment, more appropriate diagnostic services, improved outcomes, and over time the reduction of racial and ethnic disparities in health.

Cultural Humility

Andrew J. S. Howie
Mental Health and Drug and Alcohol Services,
Far West Local Health Network, Broken Hill,
NSW, Australia

In the context of health care, the term "cultural humility" denotes an attitude of appropriate respect by a health professional toward the culture of her clients or patients, where this differs from her own.

As an attitude, rather than knowledge of a body of facts about other cultures, or a set of acquired relevant cultural skills, cultural humility is a necessary condition of the combined task of gaining relevant knowledge of other cultures, developing a set of skills necessary to apply this knowledge in theoretical clinical situations, actually applying the knowledge in complex real life situations, and accurately monitoring the outcomes in terms of patient and client satisfaction, and other beneficial or detrimental effects.

The term therefore is used in contrast to other similar terms such as "cultural competence," "cultural safety," "cultural sensitivity," and "cultural proficiency," all of which emphasize appropriate cultural knowledge and skills brought to the clinical encounter.

In the modern health care discussion the term "cultural humility" was coined by Tervalon and Murray-Garcia, who describe it as incorporating "a life-long commitment to self evaluation and self critique, to redressing the power imbalances in the patient physician dynamic, and to developing mutually beneficial and non-paternalistic clinical and advocacy partnerships with communities on behalf of individuals and defined populations."

Hunt characterizes it as "not… an examination of the patient's belief system, but [a] careful consideration by healthcare providers of the assumptions and beliefs that are embedded in their own understandings and goals in the clinical encounter."

Described in this way, the concept of cultural humility is brought very close to the generic philosophical virtue of humility, and embraces the multidisciplinary nature of clinical work, emphasizing ethical commitment to continual professional improvement, and professional egalitarianism applied in the context of the multidisciplinary study of individuals in communities.

Tervalon and Garcia use the term in the context of medical education, emphasizing (1) patient-focused interviewing and care where, for example, patient-initiated questions and agendas are tolerated, as the physician relinquishes the role of expert in recognition of the fact that the patient is uniquely qualified to help the physician understand the complex intersection of the elements of a patient's cultural identity; (2) community based care and advocacy, where maintaining the client's cultural context as much as practicable is intended to be empowering; and (3) institutional consistency, where care is taken to ensure that polices are formulated and consistently applied so as to minimize the disadvantage, wherever practicable, to clients from minority cultures.

Subsequent literature has addressed areas as diverse as the assessment and diagnosis of illness and dysfunction, management of disability, and psycho-education in physical and mental health, including programs for families of children with special needs, psychiatry and psychotherapy, substance abuse, midwifery, gynecology and neonatal care, cancer care, public health, the measurement of quality for managed care organizations, the indigenous practitioner, and cultural practices with health consequences. Clearly there is scope for more research.

A strength of the concept of cultural humility is that as it emphasizes attitudes and habits of mind rather than specific domains of knowledge and skill, a clinician is readily able to bring cultural humility to unfamiliar situations, where knowledge and skill may be lacking, and seek to develop these as the relationship with her patients deepens.

A possible weakness of the concept is that it can be unclear what the scope and limits of cultural humility are, as unseemly haste to avoid "the hegemony of one culture over another" may lead to a de facto cultural relativism. However the practice of health care assumes that suffering and failure of function are what characterize an illness or disability, and in the extreme case a society or culture cannot tolerate or approve of these among its members and remain consistent with other values it embraces.

Practically speaking, a person dealing with a health professional of another culture, who was showing appropriate cultural humility, would expect to have her values respected, to experience receptiveness to her questions, and to receive questions asking for further information regarding her cultural values, roles, and expectations, all of which may enhance the value of the clinical encounter. Acknowledging that cultural humility (where present) may not always be fully expressed, a failure to experience this may indicate a lack of cultural humility on the part of a clinician. A remedy for this could then be found by a complaint or appeal to the authorities of the institution, the ethical base of which will express principles based on respect for autonomy, beneficence, non-maleficence, justice, and professional integrity, all of which also find expression in the notion of cultural humility.

The notion of cultural humility is fundamental to other cultural competencies, and is well supported from the perspectives of many related disciplines in health care. Increasing work on the concept of cultural humility in future academic and clinical discussion would be welcomed.

Culture

► Cultural background

Culture Shock

Sana Loue
Department of Epidemiology and Biostatistics, Case
Western Reserve University School of Medicine,
Cleveland, OH, USA

The term “culture shock” was introduced by Kalvero Oberg in 1954 to refer to an “abrupt loss of the familiar” or the “shock of the new.” Culture shock is caused by the anxiety that is associated with the loss of familiar signs and symbols that permeated one’s life before reaching the new environment.

Culture shock occurs in various stages or phases, which have been variously termed incubation, crisis, recovery, and full recovery; elation, depression, recovery, and acculturation; and contact, disintegration, reintegration, autonomy, and independence. The first phase of culture shock is often referred to as the “honeymoon phase” because the individual feels excitement about the many new things that he or she is experiencing. This phase may last for hours, days, weeks, or months.

The feeling of excitement that is experienced during the first phase of culture shock gradually diminishes as the individual begins to be aware of the differences that exist between his or her previous and current environments. This second phase is often characterized by the experience of many practical problems, an increase in misunderstandings, feelings of frustration, a sense of loneliness and uneasiness, and a decrease in self-confidence. This second stage often lasts about 6 months, but its exact length depends on the individual and his or her specific circumstances. Many people also experience physical symptoms of culture shock during these stages. These can include lethargy, headache, difficulties sleeping, a loss of appetite, and digestive irregularities.

During the third stage of culture shock, the individual will begin to adjust to the new environment or reject his or her new situation, blaming others and adopting negative coping mechanisms, such as substance use and self-isolation. During the final stage, the individual gradually adjusts and adapts to the new environment and experiences an increased sense of control and belonging.

Immigrant children may have a particularly difficult time adjusting to their new country and may experience severe culture shock. They may feel embarrassed because they do not speak the same language as their classmates or because they or their families look “different.” They may be unable to verbalize their feelings and may act out in frustration; accordingly, it is important that teachers have patience. They may also experience difficulties with their parents. The parents may want to continue the use of their primary language and the observation of their usual traditions, but the children may want to discard both their native language and their traditions in favor of those of their new country.

Immigrants may experience a greater degree of culture shock if specific practices classified as common social behaviors in their countries of origin are considered to be abusive and criminal acts in their new host countries. As an example, some countries might consider beating one’s wife to be an acceptable response to her challenge of her husband’s authority, but in the United States, this could be considered partner violence and could result in criminal prosecution.

The extent to which an immigrant experiences culture shock, and the rapidity with which he or she adjusts to the new environment is highly dependent on his or her personal experiences. Individuals who immigrate to a new country with their families are less likely to experience intense feelings of culture shock and/or may move through the various stages more quickly, because they have the support of their family members. Immigrants whose language is the same as that of their host country, and whose culture in their country of origin is similar to that of their new host country, may also be less likely to experience culture shock.

The extent to which an immigrant experiences culture shock also depends on individual factors. Individuals who are very resilient to change are less likely to experience difficulties in their new environments.

A variety of interventions have been suggested to help immigrants adjust to their new country and minimize their experience of culture shock. This includes the development of leisure activities that include physical exercise; enrolling for language classes to learn the language of the host country; and volunteering in the new community, which provides a mechanism for meeting new people and becoming integrated into the community. It is important that the immigrant try to keep an open mind about his or her experiences and not interpret everything through the cultural lens of his or her country of origin, since a behavior or saying may have a very different meaning in the new culture. A sense of humor may also help to alleviate the feelings of frustration, anxiety, and confusion that are part of culture shock.

Immigrants who return to their country of origin, for example, to visit family or friends, may find that they experience culture shock when they arrive in their country of origin. The immigrant may find that their family members and friends have changed during this time, and that their previous place of residence has also changed.

Culture-Bound Syndromes

► Culture-specific diagnoses

Cupping

Kristin Bright
Department of Sociology & Anthropology, Carleton University, Ottawa, ON, Canada

Origins of Cupping

Cupping therapy (*huoquan qi* in Chinese; and *al-hijamah* in Arabic) is a practice whereby glass or bamboo cups are applied to the surface of the skin and through suction and negative pressure, the skin and superficial muscle are gently drawn into and held in the cups. Based on the holistic principle that the body relies on a balance of energies to function properly, cupping is used to remove accumulated stress, tension, and cold channels from the body; promote blood flow and healing; and restore balance. Widely practiced in China, Taiwan, India, Pakistan, Iran, Saudi Arabia, the Gulf States and parts of Africa and the Middle East, cupping is commonly used in immigrant communities (e.g., Asian, Arab, Mediterranean) in the USA, Canada, Europe, Australia, and New Zealand.

The earliest recorded use of cupping is in the *Ebers Papyrus* of ancient Egypt (1550 BCE) where cupping was indicated for the removal of foreign matter from the body. Hippocrates (*ca.* 460–370 BCE) and Galen (*ca.* 129–200 CE) also described cupping as an effective remedy for numerous disorders and a means to evacuate toxins, reduce inflammation, arrest fevers, and restore humoral balance. One of the first records of cupping in China is by Taoist alchemist and herbalist Ge Hong (281–341 CE) who prescribed the use of cups in the form of cattle horns for the draining of pustules, boils, and carbuncles. During the Qing Dynasty, Zhao Xuemin (1719–1805) included an extensive chapter in his materia medica on *huoquan qi* or "fire cupping": the use of bamboo or pottery cups to treat headache, dizziness, abdominal pain, and snakebite.

In the 1950s, cupping was established as an official therapy throughout China; and today there are numerous Traditional Chinese Medicine (TCM) research institutes with ongoing clinical trials in cupping therapy (see below). In South Asia, cupping is a common therapeutic practice in Unani-tibb or Greco-Islamic medicine. Based on the principles of Hippocrates, Avicenna, al-Majusi and others, Unani-tibb advises the use of cupping (*al-hijamah*) to draw inflammation toward the surface of the body; divert inflammation from an important organ to a less important one; dispel humors from an affected organ; and alleviate pain. Unani physicians or *hakims*, like their TCM counterparts, use cupping to treat a number of muscular, circulatory, and neurological disorders.

Current Use of Cupping

In most parts of Asia and the Middle East, cupping is administered by medical practitioners, usually TCM doctors or Unani hakims. In the USA and other Western countries, cupping was historically introduced and practiced by immigrants from the Mediterranean and Asia in the 1800s and then spread to many parts of the USA flourishing as late as the 1930s in immigrant sections of large cities. On the Lower East Side of New York, cupping shifted from the domain of family doctors to barber shops, and one could see sign boards reading "cups for colds" on barber shop windows. Today, in rural parts of the Mediterranean, cupping is still practiced at home by families who put a set of cups in their first aid boxes or simply use a set of jam jars.

In the USA, Canada, Europe, Australia, and New Zealand, where there are sizable Asian communities (and hence an availability of trained practitioners) cupping is used alone or in tandem with other traditional therapies such as acupuncture, herbal medicine, massage, medicated steam, hydrotherapy, nutritional therapy, and in combination with biomedical treatments, such as pharmaceutical analgesics, nonsteroidal anti-inflammatory medications, orthopedic surgery, and physical and rehabilitative therapies.

For patients with arthritis, fibromyalgia, carpal tunnel syndrome, chronic back pain, chronic headache, and joint injuries, the appeal of cupping therapy is its use of low-tech equipment, its low cost, and its lack of side effects that might otherwise be experienced with analgesics. In the past decade, cupping has seen renewed popularity in the USA in the domain of complementary and alternative medicine (CAM) and health spas, with growing numbers of the general public using cupping, and more TCM and CAM practitioners training in the use of this therapy. New versions of "cellulite trimming" and "stress relief" cupping have cropped up on the menu of health spas in cities like New York and Los Angeles, creating an interesting contrast with the no-frills offerings found in Asian neighborhoods in Chicago, Los Angeles, New York, San Francisco, Toronto, Vancouver, and other cities, where cupping is still practiced in much the same way it has been for decades. Differences in technique and cultural milieu are reflected in cost: while a 30–40 min session with a holistic practitioner or spa technician can cost anywhere from $30 to $100, a session with a TCM practitioner in New York's Chinatown is closer to $10–$20. By contrast, in China the average cost of a session is 12 Yuan ($1.60) compared with an average 56 Yuan ($7.30) for herbal therapy.

The Procedure and Outcome

There are two primary types of cupping: dry and wet. In *dry cupping*, glasses are applied to the skin and either a gentle vacuum pump or flame heat is used to purge air from the cup. As the glass cup cools on the skin and a seal is formed, pressure within the cup declines, sucking the skin into the cup. Cupping glasses are typically applied for 10–15 min to the back, neck, hips, legs, knees, or arms. *Wet cupping* involves minor scarification of the skin so that a small amount of blood is drawn. Today, wet cupping serves as a modern substitute for venesection, in which larger quantities of blood were let out. Two other classifications exist in cupping as well: *stationary cupping*, where each glass cup is left in position on the skin and the cup is not moved; and *massage cupping*, where the glass cups are moved around the skin in a massage-like technique.

In regard to clinical evidence for the efficacy of cupping, a 2010 meta-review of the clinical literature conducted by Huisstede and colleagues found no evidence of long-term results of cupping in the treatment of carpal tunnel syndrome, but did find evidence for short-term benefit and relief of symptoms. The combination of acupuncture and cupping has been found to be of greater benefit in the reduction of pain and inflammation associated with acute arthritis and the reduction of pain associated with fibromyalgia, compared to the use of either cupping or pharmacotherapy alone. Cupping has also been found to be effective in the treatment of acute arthritis when combined with herbal medicine; in the treatment of fibrositis; and in the treatment of intractable migraine, when combined with acupuncture.

From a sociocultural standpoint, qualitative studies of cupping therapy and its rich historical and contemporary uses in immigrant communities are seriously needed. Such studies will enable public health and medical providers to understand the range of therapeutic applications of cupping in TCM, Unani, CAM, and biomedical contexts and the cultural meanings of cupping in widely diverse immigrant communities (e.g., African, Asian, Arab, Mediterranean). Importantly, as the number of individuals seeking cupping therapy increases in Western countries, providers should also be familiar with this practice so as to prevent any social and legal conflicts that may emerge from mistaken diagnosis, such as when cupping welts are misinterpreted as signs of violence or abuse as has been the case in Europe and in the USA.

Curandero

Konane M. Martinez
Department of Anthropology, California State
University San Marcos, San Marcos, CA, USA

Curandero is a Spanish term meaning “healer.” *Curanderos* (male healers) and *Curanderas* (female healers) are important community-based “folk” healers held in high regard within Latin American and Latino immigrant and transnational communities. Contemporary curanderos’ medical knowledge, beliefs, and practices are generally a mixture of pre-Hispanic medical cultures with Spanish and Catholic symbols and beliefs. The term *curandero* is a broad term that refers to a whole set of healers who utilize diverse methods in their practice. Each specialty has specific methods and a title that accompany it, and some *curanderos* specialize in more than one method. A *yerbero/a* is a herbalist who utilizes herbs to address health issues. A *Sobador/a* is a *healer* who utilizes massage to help alleviate pain or help a client recover from an illness or trauma. A *Huesero/a* is a bonesetter who manipulates injured bones, tendons, and muscles to alleviate pain and facilitate recovery from an injury. A *espiritisto/a* is a psychic medium who channels spirit beings and/or utilizes prayer to rid clients of physical, psychological, spiritual, and even social problems. A *partera* is a midwife who cares for pregnant women providing prenatal care as well as assistance with the birth of the child. Utilization of *parteras* in Latin America is widespread. For example, in some Mexican communities, *parteras* oversee a significant percentage, if not the majority, of births.

Curanderos often hear a “calling” to their profession and view this calling as a gift from God or other supernatural beings. Curanderos undergo an intense period of training during which their practical and spiritual knowledge is tested and affirmed. Generally, *curanderos* have a vast and specialized knowledge of the physical and supernatural worlds and employ this knowledge in their practice. Some *curanderos/as* are shamans who communicate directly with the supernatural through trance to heal. *Curanderos* attend to an individual’s physical, psychological, spiritual, and social well-being. This holistic approach to health is why many Latino immigrant communities seek out *curanderos/as* instead of, or in addition to, conventional medical care. Individuals and families seek out care from *curanderos* for diverse health issues that could range from cold relief to cancer. Certain *curanderos* can also address stresses associated with psychological or social states. For example, it is not out of the ordinary for an individual to approach a *curandero* for a *limpia* – cleansing with the goal of ridding themselves of a rash of bad luck that they are experiencing. A *curandero* is able to not only cleanse the person of the bad luck but provide for them an explanation of why they had the bad luck in the first place. *Curanderos* are the only source of care for common ethnospecific illnesses among Latino immigrant communities such as *susto* – fright, *mal de ojo* – the evil eye, or *coraje* – anger. *Curanderos* have the knowledge necessary to diagnose and treat these illnesses which historically have been dismissed by conventional medicine. There is, however, a growing set of research studies examining these types of ethnospecific illnesses and how they parallel the symptoms of conditions readily diagnosed in conventional medicine.

Utilization of *curanderos* among Mexican American and Latino immigrants has been a topic of research and inquiry among social scientists. Anthropologists in the 1960s argued that underutilization of conventional medical care by Mexican Americans and Latino Immigrants was a result of their continued use of *curanderos*. Most recent research, however, has revealed that socioeconomic issues and structural issues such as lack of health insurance, high cost of health care, undocumented status of many immigrants, and lack of culturally and linguistically appropriate health care services tend to play a larger role in limited utilization of conventional medical care for this community. Research has revealed that continued utilization and reliance on *curanderos* may actually be as a result to these larger socioeconomic and structural barriers. *Curanderos* provide easily accessible, affordable, and culturally and linguistically appropriate health care to Latino immigrant individuals and families. *Curanderos* share the same medical culture (world view, religion, views on the body, and beliefs about the causes of illness) as their clients, thereby facilitating communication, confidence in the provider, and adherence to treatment. Latino immigrant and transnational communities often have *curanderos* as members of their social networks who can be accessed either in the United States or in their community of origin. In the United States, *curanderos* are active members of Latino immigrant communities and are an important source of medical care. Curanderos are only a part of a complex system of community-based healing strategies and resources that also include home remedies and therapies, as well as "botanicas," which are small community stores that sell medicinal herbs, religious amulets, and products used in healing. Research shows that a large percentage of those patients who report complementing their medical care with these complementary and alternative medical practices often do not discuss them with their medical doctor. This withholding of information has the potential to impact patient-provider communication, as well as conflict with the treatment regimen prescribed by the medical doctor. Medical doctors should approach this issue in a culturally sensitive and competent manner as a way to gain the confidence of the patient to allow disclosure of information related to this topic.

Historically, there has been negative stigma attached to utilization of Latino complementary and alternative medicine (CAM) such as home remedies and *curanderos* among medical professionals. There has been, however, an increase of professionals who recognize the positive contribution of these community-based healers and resources. Health care professionals in some regions of Latin America and the United States have begun to collaborate and partner with *curanderos* in local communities as a way to meet the health care needs of residents in a more comprehensive and culturally sensitive way. Working in partnership with *curanderos* has also been successfully integrated into several health promotion interventions and awareness campaigns. Working in collaboration with CAM resources in the community as well as modifying the delivery of conventional medical care to mirror the way care is delivered in these community-based systems has been proposed by researchers as an effective way to reduce barriers to care, and improve the quality of health care delivered to Latino immigrants in the United States.

Customary Marriage

Laila Prager
Institute of Ethnology, University of Münster,
Münster, Germany

The term is usually applied to refer to various types of marriage or patterns of spouse selection, which in the widest sense can be classified as conforming to specific localized sociocultural traditions. “Tradition” in this respect can involve certain culturally or religiously established forms of performing the marriage ceremony or it can refer to the different types of normative marriage rules prevalent among various ethnic or religious groups. Generally, the term “customary marriage” is applied to denote marital relations which are considered to differ culturally from the US, Canadian, or West-European types of marriage, partly involving marriage patterns practiced among immigrant communities that many of the host societies declare as illegal, such as polygamy or first-cousin marriage. Customary marriages may be based on rules by which the circle of marriageable persons is limited to a large extent, as in the case of caste-like social systems, or other social communities whose marriage laws prescribe various forms of social, ethnic, or religious endogamy (the latter can apply likewise to Muslims, Christians, and other religious affiliations).

Among immigrant communities such types of customary marriage can differ from each other to a large extent, depending on the regional origin of the immigrants, and the respective marriage patterns may also combine several of the above mentioned features (i.e., Pakistani immigrants in the UK often upheld ethnic and religious endogamy and marry first cousins). Moreover, in immigrant communities customary marriages may take the form of arranged or forced marriages, often implemented by the elder generations who are concerned about the potential loss of their children’s “cultural identity” due to the influences exerted by the host society.

Customary marriages may entail several health problems, depending on the marital pattern. Polygamous marriages among immigrant communities, for instance, call forward the problem that in the Western host societies only the first wife is secured by her husband’s health insurance whereas his other wives are excluded since they have no legal status as spouses. Customary marriages may also be accompanied by mental health problems, particularly in case of forced marriages when pressure has been put on the couple by the parents and/or the wider social framework. Forced marriages may lead to the mental depression of one or both marriage partners, or to physical injuries in case of domestic violence. Mental depressions resulting from trans-generational conflicts may also occur among the generation of the parents if their children refuse to obey to the established patterns of traditional marriage rules, thereby challenging their parents’ authority and sometimes giving rise to irresolvable conflicts which may lead to the complete disruption of parent/child relations. Among various immigrant communities, particularly from the Middle East, nonconformance to customary marriage rules can entail several forms of honor-based violence or honor killing attempts, usually exerted upon women and frequently resulting in severe physical and mental health problems suffered by the victims.

Some societies or immigrant communities foster the idea that nonconformance to customary marriage rules is likely to entail physical or mental illness among the persons involved, particularly among the children who are supposed to suffer from disabilities or mental disorders inflicted by spiritual beings, the ancestors, or other cosmic forces.

Customary marriages based on marital relations between cousins have received the highest degree of attention in the Western host societies. Though cousin marriages are practiced by around 20% of the world’s population, they were largely tabooed in the USA where already in the nineteenth century many of the states decided to establish public laws in order to prohibit such types of marriage (Kansas 1858; 1860s: Nevada, North Dakota, South Dakota, Washington, New Hampshire, Ohio, and Wyoming). Cousin marriages during this period were often practiced among European immigrants and the respective laws were also intended to work against the migrants’ potential seclusion from their host society.

Recently, in some European countries (UK, Germany), there have been public debates as well whether to prohibit such types of marriages given the influx of migrants from the Middle East. Meanwhile, in France and Turkey, cousins have to present a medical health certificate before they are declared eligible to marry. Such laws are predicated on twentieth century Western biomedical assumptions according to which cousin marriages are supposed to entail a higher risk of hereditary diseases. Recent bio-genetic research, however, suggests that the risk of hereditary diseases resulting from such marital unions has been largely overestimated. According to a comprehensive survey undertaken by the National Society of Genetic Counsellors (NSGC), the risk of congenital defects resulting from first-cousin unions ranges from 1.7 to 2% above the background risk of 4.4% for pre-reproductive mortality, thus making any special preconception testing unnecessary. Other researchers, roughly averaging the statistics for birth defects and pre-reproductive mortality, noted that first-cousin marriage "only" increases the risk of adverse events by about 3%, which means that instead of 3–4% there can be a risk of genetic damage of up to 7%. Whereas some authors consider this increase of genetic risk as marginal, other commentators point to the fact that it nevertheless amounts to a doubling of potential genetic damage, thereby rendering the risk of first-cousin marriage highly significant. Furthermore, one has to differentiate whether a cousin marriage is conducted only once or repeatedly in every generation as practiced among various societies in the Middle East, Asia, Africa, Oceania, and South America. Whereas in the first case, the grandparents of the marriage partners are genetically unrelated, in the second case they are related due to preceding cousin marriages, thus increasing the risk of genetic disorders among the offspring. However, there exist hundreds of different recessive genetic disorders, many associated with severe disabilities and sometimes early death, and each caused by a different variant gene. One should thus bear in mind that not every society displays the same recessive genetic features, so that immigrant communities deriving from differing populations are subject to varying genetic risks.

Dementia

Renee Sorrentino
Massachusetts General Hospital, Quincy, MA, USA

Dementia is a disease process characterized by a progressive decline in cognition. The general criteria for diagnosing dementia include the development of multiple cognitive deficits manifested by memory impairment, aphasia (language disturbance), apraxia (impaired ability to carry out activities), agnosia (failure to recognize or identify objects), or a disturbance in executive function (problem solving or planning). These cognitive deficits cause major impairment in social or occupational functioning and represent a substantial decline from a previous level of functioning. Dementia is further defined according to the etiology including Alzheimer's disease, dementia with Lewy bodies, vascular dementia, frontotemporal dementia, mixed dementia, and dementias related to neurological disease, nutrition, endocrinology, infection, metabolism, and trauma.

The prevalence of dementia increases with age. The number of individuals with dementia, worldwide, is estimated to be over 35 million. Alzheimer's dementia is the most common type of dementia comprising 50–75% of dementia. Dementia with Lewy bodies (a type of abnormality seen in the brain cells of affected individuals) compromises 15–35% of dementia cases followed by vascular (blood vessel disease) dementia and mixed dementia (dementia of multiple causes) accounting for 5–20% of the dementia case respectively. The incidence of all dementias is expected to rise as the portion of the aging population increases. There are an estimated 5 million Alzheimer's disease patients in the United States and this is estimated to rise to 16 million in 40 years. Few studies have focused on the prevalence of dementia in the immigrant population. It has been hypothesized that immigrants have a higher rate of dementia but this has not been borne out in large, controlled studies.

Factors associated with the development of dementia include age, gender, genetic factors, comorbid illnesses, environment, and lifestyle. Age is the strongest risk factor for the development of all dementias. Gender is a risk factor for the development of Alzheimer's disease. The incidence of Alzheimer's disease in women is higher than that in men. Genetic studies in the field of dementia have demonstrated a significant relationship between the APOE genotype and the risk of Alzheimer's disease. Genetic variations in the APOE genotype are a major risk factor for the development in Alzheimer's disease. Genetic studies have also yielded a positive correlation between polymorphisms (gene variants) in one of the inflammatory genes and the pathogenesis (causes) of Alzheimer's disease. Dementia is associated with the following conditions: diabetes, infections such as HIV, traumatic brain injury, and cardiovascular disease. Diabetes, hypertension, and peripheral vascular disease are more commonly associated with vascular dementia but are also risk factors for the development of Alzheimer's disease. Environmental factors refer to nutritional status and exposure to toxic agents. The relationship between environmental factors and the development of dementia is unclear. It has been hypothesized that some metals such as aluminum, iron, copper, and zinc are related to dementia. In addition, several nutrients have been associated with the risk of dementia such as thiamine, vitamin B12, and niacin deficiencies. Sedentary lifestyles or the absence of significant recreational activity is a risk factor for dementia. Studies demonstrate that physical activity is associated with the preservation of cognition. The relationship between immigrant status and risk factors for dementia is not well studied. Immigrant groups with low socioeconomic status, often

Sana Loue & Martha Sajatovic (eds.), *Encyclopedia of Immigrant Health*, DOI 10.1007/978-1-4419-5659-0,

associated with less education, may be more vulnerable to dementia due to absence of the protective education factor. The young age of immigrants compared to natives may decrease the overall prevalence of dementia.

Protective factors against development of dementia include advanced education, moderate alcohol use, and diet. In studies which examined the relationship between educational level and dementia, individuals with less education had a higher risk of dementia. The association between education and dementia is not definitive as there is some speculation that individuals with lower educational level may have lower premorbid (pre-disease) cognitive function. Some studies have identified alcohol consumption as protective from dementia. However, other studies have shown that excessive alcohol consumption may be associated with an increased risk of dementia. Medications used to manage cardiovascular risk such as Statin medications, through an anti-inflammatory mechanism, have been shown to reduce the risk of dementia in some studies. However, additional studies are needed to confirm this relationship.

Causes of Dementia

The neurodegenerative causes of dementia are the most common. These include Alzheimer's disease, dementia with Lewy bodies, frontotemporal dementia, Parkinson's disease, and Huntington's disease. Alzheimer's disease, the most common of all the dementias, is a degenerative disease of the cholinergic system (neurotransmitter acetylcholine). Cellular and tissue abnormalities of Alzheimer's disease involve the development of amyloid plaques (deposits of protein) and neurofibrillary tangles (bundles of fibers) which interfere with the connection between neurons. Dementia with Lewy bodies is the second most common of the neurogenerative dementias. Its neurogenerative pathology is characterized by abnormal deposits of a protein, alpha-synuclein, referred to as Lewy bodies. Vascular dementia results from progressive changes in the blood vessels which result in ischemia or reduction in blood flow to the brain. Frontotemporal dementia results from the degeneration of the frontal and temporal anterior lobes of the brain. These affected areas cause disturbances in behavior and language. Parkinson's disease and Huntington's disease are neurodegenerative disorders of the basal ganglia, the nuclei which control movement.

Medical conditions such as endocrine abnormalities, infections, and metabolic disease can also cause dementia. Common endocrine disorders that can cause dementia are hypothyroidism, hypercalcemia (high calcium), hypoglycemia (low blood sugar), and vitamin deficiencies. Infectious causes of dementia include HIV, prion, or viral disease such as Creutzfeldt–Jakob disease and neurosyphilis. Liver or kidney insufficiencies result in metabolic derangements that can lead to dementia. Environmental causes of dementia include traumatic brain injury and external agents such as alcohol, heavy metals, or carbon monoxide.

Diagnosis and Symptoms

The diagnostic criteria for the diagnosis for dementia as outlined in the *Diagnostic and Statistical Manual of Mental Disorders, 4th edition, text revision (DSM-IV-TR)* includes the development of multiple cognitive deficits manifested by both (1) memory impairment and (2) one of more of the following cognitive disturbances (a) aphasia (language disturbance), (b) apraxia (impaired ability to carry out motor activities despite intact motor function), (c) agnosia (failure to recognize or identify objects despite intact sensory function), (d) disturbance in executive functioning (i.e., planning, organizing, sequencing, abstracting). These cognitive deficits each cause significant impairment in social or occupational functioning and represent a significant decline from a previous level of functioning. The diagnosis of dementia is based on a clinical evaluation, laboratory testing including structural tests, and neuropsychological testing. The clinical evaluation involves taking the patient's history, interviewing a caregiver or family member, physical examination, and brief cognitive tests (such as the mini-mental status examination). The history taking should include a thorough investigation of the onset of the patient's cognitive symptoms and duration. The level of functional impairment resulting from the cognitive symptoms should also be determined. A caregiver or family member may assist in the corroboration of history as well as providing additional information. Risk factors for dementia should be assessed. Dementia in immigrant populations is a poorly studied area. The majority of research of dementia in immigrant populations is from the United States which may not be generalizable to other immigrant populations.

A psychiatric examination including a psychiatric history and current psychiatric and behavioral symptoms should be elicited when assessing dementia. Certain psychiatric disorders may mimic dementia by causing cognitive problems. In addition, some dementing illnesses present with psychiatric or behavioral manifestations. The mental status examination and mini-mental status examination (MMSE) are brief examinations used to assess an individual's psychiatric presentation as well as cognitive abilities. The MMSE is the most widely used bedside evaluation for dementia. The MMSE is based on a score of 30. Patients with mild dementia score 18–26, those with moderate dementia score 10–18, and those with severe dementia score less than 10. The clock-drawing test (ask the patient to draw a clock at a certain time) is another frequently used examination to screen for dementia. The clock-drawing test evaluates executive functions and visuospatial abilities. Cross-cultural assessment of dementia is problematic related to language and literacy skills. The use of the mini-mental status examination and clock drawing, culturally biased screening instruments, may be invalid in immigrant populations. Immigrants may be unfamiliar with the information required to complete both tests. In order to reliably use these cognitive tests in immigrant populations, the tests need to be validated for examining cognition in different ethnic groups.

The physical examination should focus on medical conditions that cause dementia as well as signs of focal neurologic deficits. Laboratory and structural tests are used to rule out treatable and general medical causes of dementia. Neuroimaging with computed tomography (CT) or magnetic resonance imaging (MRI) provide an assessment of structural patterns of atrophy (cellular degeneration), ischemia (cell injury or death due to lack of oxygen), neurosurgical lesions such as tumors, subdural hematoma (bleeding under the skull), and hydrocephalous (excessive fluid accumulation in the brain). Functional neuroimaging (specialized forms of visualizing the brain) provides analysis of brain activity. These tests can help discriminate between types of dementia. Neuropsychological testing provides detailed information in various cognitive areas.

The hallmark of dementia is memory loss. Patients with dementia typically present with impairment in short-term memory followed by long-term memory. Additional symptoms of dementia include language impairment, such as word-finding difficulty, impaired ability to complete simple tasks such as using appliances or tools. Agnosia or difficulty recognizing objects may present with unfamiliarity to family members or friends. Disturbances in executive functioning include inability to solve problems, plan events, manage finances, or exercise good judgment. The neuropsychiatric manifestations of dementia include mood, psychotic, or behavioral symptoms.

Prognosis and Treatment

The prognosis and treatment of treatment varies according to the etiology. Most subtypes of dementia have a progressive and irreversible clinical course. The exceptions to this are the rare forms of reversible dementia such as dementia due to a nutritional deficiency, hypothyroidism, or a neurological condition called normal pressure hydrocephalus. The progressive decline in cognitive skills results in an eventual loss of an individual's ability to function, or care for themselves. Treatment modalities vary depending on the type of dementia. Some types of dementia can be treated by treating the medical illness that led to dementia. For most types of dementia, treatment is palliative and aimed at improving symptoms or delaying the progression of symptoms. There have been few immigration studies of dementia. As a result of the limitation of scientific data, little is known about the prognosis and treatment of immigrants with dementia. Future studies of ethnicity and migrant status in dementia are needed.

Dental Caries

Richard Niederman
Center for Evidence-Based Dentistry, The Forsyth Institute, Cambridge, MA, USA

Caries

Globally, caries is the most prevalent and least addressed preventable infection. The World Health Organization (WHO) data indicates that tooth decay affects 60–90% of school children and the vast majority of adults. In all populations studied, it disproportionately affects poor and minority populations; its prevalence is increasing internationally; and untreated caries has long-lasting detrimental educational, medical, and social effects.

Untreated, this infection leads to tooth decay or cavities. Decay in children is particularly insidious. Tooth decay can lead to severe pain impairing both learning and achievement – children in pain are inattentive in school, have increased absenteeism, and do not keep up academically. Additionally, 10% of children with untreated decay have sepsis, leading to increased morbidity and/or mortality.

This oral health problem extends beyond children to adults. In developed countries, visibly decayed or missing teeth are the outward markers of a "caste" system, connoting low educational achievement, faulty intellectual development, and/or poor parenting. Conversely, good dentition is important for nutrition, systemic health, educational success, and normal social interactions.

Fortunately, caries is a preventable bacterial infection. Over the last 40 years, pioneered by Ronald J. Gibbons at the Forsyth Institute in Boston MA, USA, it became clear that specific bacterial pathogens cause caries. From these findings evolved a twenty-first century preventive care model to reduce or eliminate this infection. However, this new care model has yet to replace the nineteenth century model of "drilling and filling," that is currently in vogue globally. Fillings neither reduce the infection nor affect the disease process causing cavities. Further, WHO data indicates that dentists are largely unavailable to provide fillings in both developing and developed countries (e.g., dentist to population ratios are: 1:1.2 million in Ethiopia; 1:300,000 in India; 1:2,100 in the United Kingdom).

Childhood Caries in Immigrants

To identify the current best evidence for childhood caries in immigrants, we searched MEDLINE (Search strategy: (Dental Caries OR Dental Caries Susceptibility OR Root Caries OR Dental Caries Activity Tests OR Caries Detector OR Dental Decay OR Tooth Decay OR Dental Cavity OR Dental Cavities) AND (Immigrant OR Immigrants OR Emigrant OR Emigrants) AND Limits: All Child: 0–18 years). The search identified 28 primarily cross-sectional studies addressing immigrant caries. Thus, what we know about the oral health of immigrants is largely demographic association, not a cause-effect demonstration. Further, the outcome measures of the studies vary considerably, making comparative estimates uncertain. Given these significant caveats, the consensus finding is that, where studied, immigrants have a significantly greater (usually > 2X) prevalence of caries compared to natives of new country of residence.

To identify the hypothetical causes of these health disparities, we again searched MEDLINE (Search strategy: (Dental Caries OR Dental Caries Susceptibility OR Root Caries OR Dental Caries Activity Tests OR Caries Detector OR Dental Decay OR Tooth Decay OR Dental Cavity OR Dental Cavities) AND (((Developing Countries) AND (Developed Countries)) OR (Economic Development)) AND ((Health OR Health Status) AND Disparities)). This search identified a single comprehensive study by Eduardo Bernabé and Martin Hobdell at the University College, London, UK. The most common unifying hypothesis was social determinants of oral health – a concept most clearly articulated by Michael Marmot also at University College, London, UK.

Social Determinants of Oral Health

The World Health Organization defines social determinants of health as: "the conditions in which people are born, grow, live, work and age." These social determinants (including their health system) are ultimately influenced by policy choices at the local, national, and global levels.

Focusing on children's dental caries, Hobdell pioneered a detailed examination of social determinants of oral health. Together with Bernabé, they found that, globally, both absolute and relative poverty affect oral health. On a global basis, there is a direct relationship between oral health and gross national income: oral health *increases* as gross national income *increases*. However, in rich countries, there is in inverse relationship between oral health and income inequality: oral health *decreases* as income inequality *increases*. The same is true for general health.

From these perspectives, we hypothesize that immigrant oral health depends on three primary social determinants (with nine sub-determinants) and three biological determinants:

1. The country of origin: (a) Gross national income per capita, (b) Income disparity, and (c) Cultural norms
2. The immigrant: (a) Social and economic status in the country of origin and (b) Social and economic status in the new country of residence
3. New country of residence: (a) Gross national income per capita, (b) Income disparity, (c) Cultural norms, and (d) Acculturation

The three biological determinants are:

1. The genetic heritage of the family
2. The bacterial colonization of the oral environment
3. Epigenetic effects on the genetic heritage

Prospective cohort studies to identify which of the foregoing determinants of immigrant health are the "critical few" and which are the "important many" are now needed.

Immigrant Populations

At the extremes, one would predict that when individuals move from poor countries with large income disparities to wealthy countries with less income disparity, the immigrant's oral health would be significantly less than those of the new country of residence.

Examples of this phenomenon can be commonly found. Globally, Latin America and the Caribbean exhibit the greatest wealth disparity, based on the Gini index, when compared to five other global geographic regions. Looking more closely at Latin America, 11 of the world's 20 countries with the greatest wealth disparity are Latin American. Further, roughly half of the region's poor live in the two largest countries Brazil and Mexico.

Mexico and the United States are examples of adjacent countries with substantial differences in absolute and relative wealth and disparity. The United States accepts more legal immigrants as permanent residents than all other countries in the world combined (~850,000 people/year), and immigration from Mexico accounts for 23% of this immigration.

For Mexicans migrating to the United States, current data supports the association hypothesis that inequality and poverty negatively encumbers oral health. In the United States, on average, 20% of elementary school age children have untreated caries (~ten million children). For Mexican-Americans, on average, 41% of elementary school age children have untreated caries – twice the United States average.

Studies of acculturation and literacy suggest that both factors inversely correlate with caries prevalence – an increase in acculturation and literacy correlates with a decrease in caries prevalence. Thus, as income status and education of the immigrant increases, caries decreases. Significantly, however, when preventive oral health care is provided to immigrant populations, oral health disparities are quickly ameliorated.

Solving the Caries Problem: A New Model for Comprehensive Caries Prevention

For the last half century, we have known that caries is a preventable bacterial infection. Globally, with this knowledge, numerous prevention programs have been proposed, and employed, in impoverished, developing, and developed countries. The most notable – the basic package of oral health care – was developed and implemented by Jo Frencken and his colleagues at the WHO Collaborating Center, Radboud University of Nijmegen, Netherlands. The concept is simple.

Comprehensive prevention both prevents new caries and inhibits the progression of current cares. There are three central themes to these prevention programs: (1) harden the teeth with fluoride to make the less susceptible to decay; (2) reduce or eliminate the causative bacteria; and (3) increase access and decrease costs by using dental hygienists or paraprofessionals, not dentists, to deliver care. This model is being successfully implemented in Europe (Nigel Pitts and colleagues, University of Dundee, Dundee, Scotland) Africa and Asia (Jo Frencken and colleagues), North America and South America (Richard Niederman and colleagues, Forsyth Institute, Boston, USA). Comprehensive prevention significantly reduces prevalence and incidence of decay, costs a fraction of dental office care, can be delivered where people learn, work, play, and pray, and brings care to people. This is in marked contrast to the current model of care that requires people to travel to obtain care.

Systematic reviews of randomized controlled trials indicate that the following individual interventions can be cost-effectively delivered by paraprofessionals and significantly reduce caries. When used in combination, there appears to be an additive effect: (1) Silver diamine fluoride (>30% solution), to kill the pathogenic bacteria and harden the teeth (>90% decay reduction/year); (2) Fluoridated toothpaste (>1000 ppm), to facilitate tooth cleaning and harden teeth (>20% decay reduction/year); (3) Fluoride varnish to harden teeth (33% and 46%/year decay reduction in primary and permanent teeth, respectively); and (4) Glass ionomer sealants and atraumatic restorative treatment (e.g., no anesthesia, drilling, or rubber dam), to prevent decay occurrence (>80% decay reduction) and halt decay progression and (40–75% decay reduction/year), respectively. Initial work suggests that the natural sweetener xylitol, by inhibiting bacteria from attaching to teeth, and milk fluoridation to harden teeth, may each reduce caries. However the quantitative effect is not clear. Interestingly, both approaches also appear to reduce otitis media and school absence. Finally, salt fluoridation may be effective where water fluoridation is not feasible.

In sum, the benefits of caries prevention are fourfold. First, it can provide safe, effective, efficient, accessible, equitable care to a large patient population where people are located at a reduced cost. Second, if care is provided by local caregivers care will be culturally competent and relevant, and create new jobs. Third, the finding that oral infections have a multitude of negative medical and social consequences highlights the benefit of cost-effectively controlling this infection early in life. Fourth, twenty-first century caries prevention by non-dentists, offers the possibility of virtually eliminating the sequelae of this infection.

The Challenge

The challenge will be to overcome a century-old tradition of stakeholder infrastructure. The momentum of this tradition supports training, licensing, boarding, and compensation, all of which are secured by governments, professional schools, and regulatory agencies, who have a stake in the past. To overcome this barrier, at the extremes, care systems will need to implement either a “top-down” policy change, or a “bottom-up” disruptive innovation approach.

Given the momentum of tradition, the inertia infrastructure, and the difficulty of policy change, a top-down policy change seems unlikely. Alternatively, and much more likely, is a bottom-up, disruptive innovation approach articulated by Clayton Christensen and colleagues at the Harvard Business School in Cambridge, MA. This approach starts at the bottom of the social pyramid, and provides preventive care, with multiple demonstration programs in multiple countries. Independently, similar programs like this are being implemented by Frencken, Pitts, and Niederman and their colleagues. The challenge for innovators will be to quantitatively document increased care access, health improvement, and cost-effectiveness to support and secure long-term political, social, and financial sustainability.

Hopefully, were comprehensive caries prevention delivered by paraprofessionals, systematically disseminated and implemented, it could have an immediate cost-effective, beneficial impact in reducing caries and improving oral health among native, poor, and immigrant populations globally.

Department of Homeland Security

Kathrin Mautino
Mautino & Mautino, San Diego, CA, USA

The Department of Homeland Security (DHS) came into existence in 2003. It was created in response to the terrorist attacks of September 11, 2001 in an attempt to bring under one roof the various agencies and departments concerned with protecting the USA and responding to disasters – natural or man-made. It combined 22 different agencies from the Departments of Justice, Energy, Agriculture and Treasury, including the Secret Service, the US Customs Service, the Immigration and Naturalization Service, the Federal Emergency Management Service, the National Domestic Preparedness Office, and the US Coast Guard.

Some agencies were split into components and realigned with other agencies. The Immigration and Naturalization Service was split into three new agencies and intermixed with various agencies including the Federal Protective Service, US Customs Service, and Animal and Plant Health Inspection Service. The Immigration and Naturalization Service became the Immigration and Customs Enforcement (ICE), Customs and Border Protection (CBP), and the United States Citizenship and Immigration Services (CIS).

The idea behind bringing these agencies into a new federal department was to improve the security of the USA by improving efficiency and communication. In addition, proponents felt that the new department would allow for faster response times and improve the effectiveness of a response by better coordination between agencies.

Critics felt that the combination of so many varied agencies with different agendas into one department would increase confusion and lead to more inefficiencies. Since 2003, three directorates originally created have been eliminated and one agency has been returned to the original department. Also, talks continue about the advisability of certain combinations. For example, there is talk about recombining ICE, CBP, and CIS into one organization again.

Some critics point to the slow response to Hurricane Katrina in 2005 as evidence that the DHS model does not work. Occasional calls continue to remove certain agencies, such as the Coast Guard from under the DHS umbrella. Others argue that certain agencies or departments such as the Federal Bureau of Investigation should be brought into DHS in order to truly have one organization that has access to all the law enforcement and emergency management tools available in the USA.

The Department of Homeland Security has limited involvement with health-related issues. The Federal Emergency Management Agency (FEMA) is responsible for responding to natural or man-made disasters, including organizing the provision of emergency health services, shelter, and food, all of which are of course important for the maintenance and management of the public health. Similarly, the immigration-related agencies are expected to enforce laws designed to keep out non-US citizen individuals with health issues deemed to pose a danger to the public health. The Transportation Security Agency (TSA) similarly has responsibilities to quarantine any individual (US citizen or otherwise) suspected of being a danger to the public health.

Depression

Weronika Micula-Gondek
Department of Psychiatry, University Hospitals Case Medical Center, Cleveland, OH, USA

Depression: Overview

Depression is a medical condition that affects individuals of all racial, ethnic, and socioeconomic backgrounds. It is estimated that more than 15 million adults in the USA or about 6.7% of the population of age 18 and older suffer from depression in any given year. It is more prevalent in women than men and is the leading cause of disability.

Depression in Western Societies

The current understanding of phenomenology of depression is almost entirely based on studies of Western populations and has resulted in specific diagnostic criteria established in the *Diagnostic and Statistical Manual of Mental Disorders* (DSM) and International Classification of Diseases (ICD), commonly recognized by contemporary Euro-American psychiatry.

Based on those criteria, depression affects most aspects of life, interferes with daily functioning, participation in social activities, satisfaction with school and work, sleeping and eating habits and general health.

People suffering from depression exhibit a very low or irritable mood and inability to enjoy previously enjoyable activities. They are preoccupied with feelings of worthlessness, inappropriate guilt or anger, helplessness and hopelessness. They can exhibit difficulty with memory and concentration, and in severe cases they can have suicidal thoughts. Multiple physical symptoms, like disrupted sleep pattern, changes in appetite, reduced sex drive, fatigue, aches and pains, and digestive problems are common. The severity, frequency, and constellation of symptoms vary depending on the individual.

There are several forms of depressive disorders. The most common are major depressive disorder and dysthymic disorder. In major depressive disorder, also known as a major depression, a combination of symptoms disables and prevents a person from functioning. Dysthymic disorder is less severe and less disabling, but symptoms usually last for at least two years.

Other forms of depression have slightly different characteristics and may develop under unique circumstances. Postpartum depression is diagnosed within 1 month after a delivery. Depression as a part of seasonal affective disorder occurs during the winter months. Depression can also occur in the course of Bipolar illness.

There is no single known cause of depression. It results from a combination of biochemical, environmental, and psychological factors.

In addition to neurochemical changes in brain or genetic factors, any stressor, like trauma, loss of a loved one, or environmental factors can trigger a depressive episode.

Depression in Non-Western Cultures

Non-Western sufferers of depression make up approximately 90% of all depressed patients globally.

Based on research studies done across different cultural groups, depressive symptoms described in Western diagnostic systems are generally applicable and uniformly reported. However, a constellation of different indigenous experiences has been identified among various cultural groups. It accounts for a specific picture of depression among different ethnic groups.

The term “dysphoria” which is used to describe sadness, hopelessness, unhappiness, has dramatically different meanings and forms of expression in different societies. For Buddhists, for example, taking pleasure from things is the basis of suffering; therefore, a willful dysphoria is the first step for salvation. For some Muslims grief is a religious experience and the ability to fully experience dysphoria is the marker of person's depth.

There are differences described not only in the experience of depressive mood but also in symptomatology. In some of the African communities the first signs of illness are the dreams about witches attacking their vital essence. For some American Indians hearing voices of dead relatives is normal, not a sign of illness.

Dramatic differences were also found in the expression of bodily complaints associated with depressive illness not available for most of the members of Western society. Nigerians report "ants creeping in parts of the brain," and Chinese complain of exhaustion of their nerves and of their hearts being squeezed.

Depression in Immigrant Population: Risk Factors

Immigration is a process that includes the initial decision to migrate, the process of migration, and acclimatization to the new country.

Its path is filled with risks and stressors that are unique to immigrants both prior to and after their arrival. In general, immigrants are at higher risk for mental health problems, with depression and anxiety disorders being predominant.

Premigration and Migration Factors

Premigration and migration stressors include previous traumatic events in immigrants' homelands (war exposure, torture, terrorism), many of which prompt decision to migrate in the first place. These are often compounded by the loss of extended family, parental separation, and traumatic journeys to the USA (witnessing deaths, suffering physical or sexual assault, hunger, as well as continued rejection and suffering while seeking asylum) and survival as an immigrant.

Refugee populations arrive with memories of torture that intensify the shock of living in a new place. Those who survived the camps and other forms of brutality, must now navigate in the new culture which increases the sense of being traumatized and isolated.

Different immigrant groups have different degree of exposure to such trauma, with Central American, Cambodian, Tamil, Bosnian, and Cuban refugees being significantly affected.

Post-Migration Factors

For many immigrants it is not an extraordinary trauma, but the ordinary stress of everyday life, compounded by language and economic problems that causes their depression.

Changes in the living environment, difficulties navigating and negotiating social systems, financial concerns, discrimination, isolation, changing family structure and language barrier seem to be major factors in the emergence of depression in the immigrant population.

The majority of immigrants come to escape poverty in their countries and often have low education levels and little job skills. They inhabit inner city neighborhoods which have high prevalence of crime and live in overcrowded buildings in the atmosphere of impending danger. They suffer from feelings of loneliness, isolation, powerlessness, and dependency.

Change in living environment requires adaptation to new culture, people, and language. It often bears the burden of mismatched perceptions of living in the USA and the reality upon arrival. Immigrants' struggles are intensified by common lack of extended family and changing role status, like becoming primary bread winner or caretaker for the household.

Discrimination and prejudice are often the major stressors. They can originate not only from mainstream culture Americans but often from earlier-arriving immigrants who may feel threat to their job security and resources.

The process of cultural transition is as much of a psychological stress as a sociological one with significant implications for the immigrants. They may cope in different ways, like anxiously trying to meet the demands of both cultures, abandoning the culture of origin or trying to integrate the best of both. This is particularly challenging for older immigrants from China, Korea, Russia, and Eastern Europe. It makes them more vulnerable for depression because of an interaction of their traditionalism and cultural inflexibility, lack of family, language barriers, and physical limitations. The prevalence rates for depression among elderly immigrants have been described as high as 30%.

Another important factor is losing the social standing that people had prior to immigration. People who had a relatively high social status in their native countries because of their jobs, incomes, and education, may experience more frustration, uncertainty, and chronic stress which increase their risk of depression.

Treatment Options

Depression, even the most severe cases, is a highly treatable disorder. As with many illnesses, the earlier that treatment can begin, the more effective it is and the greater the likelihood that recurrence can be prevented. The most common treatments are medications and psychotherapy.

Antidepressant Medications

Depression is commonly treated with antidepressant medications that work to balance some of the natural chemicals in the brain called neurotransmitters. They include serotonin, norepinephrine, and dopamine and affect our mood and emotional responses.

The most popular antidepressant medications are selective serotonin reuptake inhibitors (SSRIs). These include fluoxetine (Prozac), Citalopram (Celexa), Sertraline (Zoloft), Paroxetine (Paxil), and Escitalopram (Lexapro).

Other types of antidepressants are serotonin and norepinephrine reuptake inhibitors (SNRIs). SNRIs are similar to SSRIs and include venlafaxine (Effexor) and duloxetine (Cymbalta). Another medication that is commonly used is bupropion (Wellbutrin) which works on the neurotransmitter dopamine.

SSRIs and SNRIs are popular because they do not cause as many side effects as older medications. Most common side effects associated with their use include headache, nausea, drowsiness, and increase in anxiety and sexual problems.

Older antidepressant medications include tricyclics, tetracyclics, and monoamine oxidase inhibitors (MAOIs). They can cause side effects like dry mouth, constipation, bladder problems, blurred vision, and drowsiness. People taking MAOIs need to be careful about the food and the other medications they take because of possibility of dangerous increase in blood pressure.

It can take 3 or 4 weeks until the medication takes effect. Some people take the medications for a short time but the ones with long-term or severe depression may need a long term treatment.

Psychotherapy

Psychotherapy has been shown to be effective in the treatment of depression and may be the best option for mild to moderate symptoms.

It is also known as talk therapy or counselling. During the sessions patients learn about causes of depression to better understand their illness. They learn how to identify and change unhealthy behaviors or thoughts, explore their relationships and find the better ways of coping with stress and setting realistic goals for life. Psychotherapy helps regain sense of happiness and control. It can ease sense of hopelessness and anger.

There are several types of psychotherapy. Cognitive behavioral therapy (CBT) is one of most commonly used for depression and it helps patients to identify negative beliefs and behaviors and replace them with healthy, positive ones. Other types include interpersonal psychodynamic therapy and supportive therapy.

Sometimes depression is so severe that patients require inpatient hospitalization in the psychiatric unit especially if they are in immediate danger of harming self or somebody else or are unable to take care of themselves properly.

Partial hospitalization or day treatment programs are also helpful.

The majority of outpatient psychiatric care occurs through community mental health centers.

Special Considerations for Treatment in Immigrant Populations

The use of community-based mental health services is extremely valuable in addressing the needs of immigrants and their families. However, several disparities have been identified between mental health of US-born citizens and minorities and immigrant populations. Some of them include diminished availability of mental health resources, lack of health insurance or transportation, cultural perceptions and societal stigma toward mental illness, racism, discrimination and barriers in communication.

Reluctance in help seeking is deeply influenced by cultural perceptions of symptom manifestation and culture-specific coping strategies. In many countries people do not talk about mental illness and in some languages there is no word for depression. Depression is a stigmatized condition and immigrants have much higher odds of reporting stigma related concerns, especially Latino and African women. The individuals who experience depression-like symptoms may not openly verbalize their concerns because of fear of being labeled "mad," or being worried about their family disapproval.

Symptom manifestation may vary and can be focused predominantly on somatic symptoms, such as body aches, tiredness, or headaches. This is distinct from Western-oriented terminology. It is the reason why about 50% of people from minority and immigrant populations never receive diagnosis or treatment for depression. It can also explain why most of the immigrants from rural areas seek help for their symptoms in the primary care clinics.

Addressing the issues of access to treatment and reducing the barriers should be dominated by development and delivery of culturally appropriate services. Service providers must be educated about the unique challenges that immigrants face that may reflect their ability and willingness to seek mental health services.

Psychotherapy and process groups should be organized and provided by culturally competent clinicians.

Another critical function placed upon community mental health services is help with housing and vocational training, allowing the beginning of integration and acculturation with a new community.

Patient education about mental health treatment, efforts to assure privacy and effective stigma-reducing educational campaigns are also helpful for immigrant populations.

Detention

Mihaela-Catalina Vicol
Department of Bioethics, University of Medicine and Pharmacy "Gr. T. Popa", Iasi, Romania

Immigration detention refers to the policy of holding individuals suspected of visa violations, illegal entry, or other like circumstances. This policy is applied until the immigration authorities decide to grant a visa and release the individual into the community, or to repatriate him or her to the country from which he or she departed or in which they were born.

In the European law context, several provisions are relevant to immigration detention. The first one is a European Union directive adopted in 2003 that stipulates that asylum seekers within the European Union "may move freely" within the host member state territory. Another paragraph stipulates that "for legal reasons of public order, Member States may confine an applicant to a particular place in accordance with their national law." Also, another provision of the same directive relates to maintaining family unity: "Member States shall take appropriate measures to maintain as far as possible family unity as present within their territory, if applicants are provided with housing by the Member State concerned." Another important legislative act is the "Guidelines on All Stages of the Forced Return Process" adopted by the Council of Europe's Committee of Ministers in 2005, which stipulates that people in immigration detention in Europe pending their removal from territory "should not normally be held together with ordinary prisoners" and also that "that principle of the unity of the family should be respected and families should therefore be accommodated accordingly."

All of these provisions underscore the fact that the immigrant is a human being and also that the status of an individual seeking asylum is not to be equated with the status of a prisoner. Family values are to be recognized and protected. In order to have an overview of this issue and also to analyze the impact of detention on immigrants' health, the situation in different countries shall be compared.

In Germany, every person without legal authorization papers to be in the territory, including persons whose "asylum claim has been rejected and who are subject to . . . deportation" is subject to detention. The regulation in some of the detention centers provides that detainees are allowed to exercise for only "one hour in the yard" and that they have to ask for permission for every small gesture, like "to open a window. . .or fetch hot water for tea." It is obvious that such regulations may influence in a negative way the physical and mental status of the immigrants.

Until 2002, Australia had similar regulations in centers called "immigration reception and processing centers." The 2002 publication *Children out of Detention Report* showed that "detention itself is a damaging environment for children," that "detention itself is the cause of significant mental health problems in children, additional to the trauma and persecution already experienced by them in their home country and during their journey to 'freedom.'" Beginning in 2005, the development of alternatives to detention was proposed. Currently, all families with children under the age of 18 are integrated into a program based on "community detention."

Some Asian States like Indonesia and Malaysia are known to imprison immigrants for visa violations. In comparison, some immigrants in the UK are detained if they have been serving a prison sentence which has expired. (The 2002 UK Nationality, Immigration and Asylum Act in 2002 changed the name of "detention centers" to "removal centers.") In 2008, the UK Home Office published data that showed that 2305 people were detained in "removal centers" under Immigration Act powers. Of these individuals, 1980 immigration detainees were male and 35 were children under the age of 18 years. As of 2006, there have been approximately nine suicides in the UK detention centers.

In the United States, some reports indicate that between 2003 and 2008, approximately 104 mostly young individuals have died in detention of the United States Immigration and Customs Enforcement or shortly afterward; medical neglect may have contributed to 30 of those deaths. One of the most recent changes is the opening of centers specifically to house noncriminal families.

Summarizing, many reports have concluded that immigration detention may have negative consequences on the physical and mental health of detainees, especially those who are children. There have been reported deaths and suicides in detention centers. The environments created by internal regulations may adversely impact detainees' quality of life. The practice of detaining immigrants in ordinary prisons and detainees' lack of access to adequate health care raise critical human rights' issues.

Dhat

Gary Edmunds
Center for Minority Public Health, Case Western Reserve University, Cleveland, OH, USA

Dhat syndrome was first described by Norenda Wiq in 1960. However, Morris Carstairs, a British psychiatrist-anthropologist, had made note of the appearance of this syndrome in earlier clinical observations. Dhat is classified as both a neurotic disorder and a culture-bound syndrome by the *International Classification of Diseases, 10th edition* (ICD-10). Dhat syndrome is also classified as a culture-bound syndrome by the *Diagnostic and Statistical Manual of Mental Disorders, 4th edition, Text Revision (DSM-IV-TR).*

The word *dhat* is the English derivation of the Sanskrit word *dhatus*, indicating the seven essential elements of the human body: *rasa*, fluid from digested food; *rakta*, blood; *masma*, muscle; *meda*, fat; *ashti*, bone; *majja*, marrow; and *sukra*, semen. The imbalance of these elements is believed to injure one's health. Because semen is thought to be the source of physical and spiritual strength, its loss is perceived as both a loss of energy and the cause of physical and spiritual injury.

Both patients and some practitioners attribute the symptoms of dhat to a white discharge in the patient's urine; this is interpreted as the loss of semen in nocturnal emissions through urine and as the result of masturbation. Additional reported symptoms include fatigue, weakness, anxiety, loss of appetite, guilt, and sexual dysfunction. Other functional somatic syndromes present with similar symptoms.

It has been suggested by some researchers that individuals suffering from dhat may be predisposed to amplify somatic symptoms. They may be unable to discuss sexual issues openly because of cultural mores and, as a result, may have misconceptions about masturbation. When the individuals become stressed, they may focus their attention on symptoms of fatigue and changes in the turbidity of urine and misinterpret these symptoms as evidence of semen loss through their urine. This, in turn, may lead to increased anxiety and help seeking. Depression and anxiety have been noted in men presenting with dhat in both psychiatric clinics and in clinics for the diagnosis and treatment of sexually transmitted infections.

Dhat is now reported primarily from individuals between the ages of 20 and 38 who are from the Indian subcontinent. However, historical records suggest that the same syndrome once existed in Europe, the United States, and Australia. It is thought that the syndrome disappeared as the result of significant economic and social changes.

With increasing migration and globalization, more clinicians outside of the Indian subcontinent are likely to have patients who present with concerns about dhat. Accordingly, it is important that the clinician consider not only known biological and psychological factors, but also relevant sociocultural factors in diagnosing and treating a patient who presents with dhat.

Diabetes Mellitus

Josiemer Mattei
Bouvé College of Health Science, Northeastern University, Boston, MA, USA

Background

Diabetes mellitus is a metabolic condition characterized by elevated concentrations of blood glucose (sugar) derived from food sources, which may be due to lack of production or proper regulation of insulin. After a meal, blood glucose level raises and the pancreas releases insulin, a hormone, so that cells throughout the body take in the glucose and use it as an energy source. Unregulated blood sugar levels may lead to several physiological complications. There are three types of diabetes mellitus, defined by the cause of insulin deregulation:

1. Type 1 diabetes (T1D), formerly known as juvenile diabetes, is usually diagnosed in children or young adults, and is characterized by a lack of insulin production. Insulin is completely obstructed by autoimmune responses that destroy pancreatic β cells.
2. Type 2 diabetes (T2D) is the most common type of diabetes. People with the condition do not produce enough insulin, or body cells do not regulate it properly, a condition known as insulin resistance. In T2D, resistance to insulin occurs because muscle, fat, and liver cells do not respond well to insulin and cannot take up the glucose circulating in the blood. The result is elevated blood glucose and insulin, as the pancreas produces more insulin to help the accumulated glucose enter the cells.
3. Gestational diabetes occurs in some pregnant women – it affects about 4% of all pregnancies – without a previous diagnosis of diabetes, who develop elevated blood glucose during gestation due to insulin resistance caused by hormonal changes.

A person may also have prediabetes, a condition where blood glucose levels are higher than normal but not high enough to be classified as diabetes. This is known as impaired fasting glucose (IFG) or impaired glucose tolerance (IGT).

Prevalence

Over 285 million people worldwide have diabetes. As of 2007, 23.6 million children and adults in the USA had diabetes, accounting for 7.8% of the population. The number reflects both diagnosed (17.9 million) and undiagnosed cases (5.7 million). Additionally, 57 million people have prediabetes. Each year, 1.6 million new cases of diabetes are diagnosed in people aged 20 years and older. T2D represents the majority of diabetes cases; T1D accounts for only 5–10% of all cases. The prevalence and incidence of T2D increase with age. Almost one in four of people aged 60 years or older has diabetes. Diabetes rates are similar by sex; however there are striking differences by race. In adults, the prevalence of all types of diabetes is 6.6% for non-Hispanic Whites, 7.5% for Asian Americans, 11.8% for non-Hispanic Blacks, and 10.4% for Hispanics, with more variation among ethnic subgroups. Among the three major Hispanic subgroups, Cubans have the lowest prevalence (8.2%), followed by Mexican-Americans (11.9%), then Puerto Ricans (12.6%). There are geographical differences in prevalence of diabetes in the USA, with more diabetes cases reported in the southeast states.

High prevalence of diabetes has been reported among immigrants of several countries, compared to the native population, including the USA, Canada, Denmark, Belgium, Spain, India, and the UK. Region of birth among US immigrants is a factor for disparities in prevalence of diabetes; immigrants from the Indian subcontinent, from Mexico, Central America, or the Caribbean are more likely to have diabetes than European migrants. Moreover, diabetes increases with longer residence in the USA, stabilizing at 10 or more years of residence, with the largest effect among immigrants arriving to the USA at 25–44 years of age.

Similar disparities in mortality rates as those observed with prevalence are reported by race/ethnicity. Overall, diabetes was the seventh leading cause of death in the USA. As of 2006 close to 234,000 deaths were attributed to this disease and many more people die because of complications related to diabetes.

Risk Factors and Prevention of Diabetes

Genetic and environmental factors have been strongly tied to diabetes mellitus. Several genes have been pointed out as likely contributors to predisposition of T1D, most of them mapping to immune regulation pathways. Environmental factors that have been implicated with increased prevalence or risk of T1D include viral infections and other microbial stimuli, cold temperature, winter season, or lack of sun exposure. Some dietary behaviors, such as breastfeeding, may have a protective effect. Prevention of T1D has proven difficult so far. Prevention trials have been largely unsuccessful, and the focus is on lifetime management of the disease.

The genetics of T2D are more complex; several genetic variants have been implicated in predisposing to the disease at different combinations, with variations among racial/ethnic subgroups. Having a first-degree relative with T2D is one of the strongest risk factors for the disease; about 30–70% of the risk for T2D could be attributed to genetics. Some other non-modifiable risk factors for diabetes include older age and race/ethnicity (Black, Asian, Native American and Hispanic). Physiological risk factors include being overweight (Body Mass Index (BMI) $\geq$ 25 kg/m^2), hypertension, HDL-cholesterol level <35 mg/dL (0.90 mmol/L) and/or a triglyceride level >250 mg/dL (2.82 mmol/L), history of a cardiovascular condition, and being a women with polycystic ovary syndrome or who delivered a baby weighing >9 lb or was diagnosed with gestational diabetes.

There is strong evidence that the following lifestyle risk factors increase risk for diabetes, independently from obesity: physical inactivity (sedentary practices), smoking, and poor dietary habits including high intake of sugar-sweetened beverages and foods with high glycemic index or glycemic load (such as rice cakes/crackers, white bread or white rice). Additionally, moderate alcohol intake has been associated with decreased risk for diabetes. These lifestyle factors provide the main opportunities for prevention of T2D, particularly exercising at least 30 min a day, and maintaining a diet high in fiber and polyunsaturated fats, and low in saturated and trans fats and in refined sugars. Managing other biological risk factors, such as controlling blood pressure, losing and keeping off weight, and monitoring blood lipid levels, may also significantly prevent the disease. People with prediabetes may need drug therapy to further prevent development of diabetes.

Classification, Diagnosis, and Symptoms of Diabetes

The most common laboratory test used to diagnose diabetes is measuring fasting blood glucose. The American Diabetes Association (ADA) sets the diagnostic cut point at $\geq$126 mg/dL (7 mmol/L). An oral glucose tolerance test (OGTT) is another common diagnostic tool; 75 g of anhydrous glucose dissolved in water are given to the patient and blood sugar is measured at time intervals, over a period of 2 h (time span could vary from 1 to 3 h). Diabetes is diagnosed for those with values of $\geq$200 mg/dL (11.1 mmol/L) at 2 h. An OGTT is usually administered to pregnant woman during the 24–28th weeks of gestation to test for gestational diabetes. Measures of glycosylated hemoglobin, or HbA1c, are taken to confirm diagnosis of diabetes and/or monitor blood glucose control in diabetes patients. A value $\geq$6.5% is considered elevated. Any test resulting in values above the designated cut points should be repeated before a diagnosis of diabetes is confirmed, unless the patient shows classic symptoms of hyperglycemia (high blood glucose).

The classification for prediabetes, or individuals with high risk for future development of diabetes, is defined as having IFG (fasting plasma glucose between 100 mg/dL [5.6 mmol/L] and 125 mg/dL [6.9 mmol/L]) or IGT (OGTT values from 140 mg/dL [7.8 mmol/L] to 199 mg/dL [11 mmol/L]). Additionally, HbA1c values of 5.7–6.4% indicate high risk for diabetes.

Testing for T2D is recommended for adults 45 years or older, as well as those with risk factors or symptoms of diabetes. Testing for T1D in children is usually done after the child exhibits other signs and symptoms of diabetes. Although diabetes can manifest without symptoms, common ones include frequent urination, extreme thirst and hunger, and fatigue. People with T2D may also experience unexplained weight gain or loss, frequent infections, blurred vision, slow healing, and tingling/numbness in the extremities.

Complications of Diabetes

Health Complications

Diabetes mellitus is a serious metabolic disease that, if untreated, can lead to several complications. Because multiple organs are involved in the regulation of insulin and in glucose uptake, the range of complications is large and varied. The major concern is hyperglycemia, or extremely elevated blood glucose. Developing other risk factors, like gaining weight or having high blood pressure, is also commonly observed in diabetes patients. Having diabetes increases the risk of having a heart attack, stroke and other cardiovascular conditions, particularly at an earlier age. Skin infections and disorders, eye diseases (retinopathy, cataracts and glaucoma), and nerve damage (neuropathy) could arise, and tend to appear after several years of living with diabetes. Nerves from various systems may be affected, leading to further complications such as sweating, sexual dysfunction, gastric problems, loss of coordination, and loss of sensation in the feet. The latter is of great concern, as it increases the risk for foot sores and injuries that if untreated could culminate in amputation.

Ketoacidosis is another serious complication that can lead to diabetic coma or death. The condition is due to the production of ketones, a by-product of burning fat for energy (because glucose cannot be used). Ketones accumulate in the blood and are excreted in the urine; this is a warning sign of uncontrolled diabetes and possible diabetic ketoacidosis. Another complication of diabetes is that kidney function may be altered because blood albumin leaks into the urine. Kidney failure may occur with advanced stages of diabetes and kidney damage. This condition requires dialysis, a procedure where blood is filtered to remove metabolic wastes and extra water while adding new vital chemicals (artificially doing the function that the kidney can no longer perform), or a kidney transplant is needed. Imbalances in thyroid function are also observed, especially in those with T1D.

Psychosocial and Economic Effects

Managing diabetes may burden the mental health and well-being of the patient, as well as the caregiver. The stress and anxiety of monitoring and controlling a lifelong condition can bring mental distress and strong, negative feelings. Although having diabetes does not cause depression, people with the metabolic disease have higher risk for becoming depressed.

There is also a high economic burden for the individual as well as the healthcare system. For a patient, the cost of treatments for diabetes adds up through a lifetime of having the condition. This is particularly true for low-income racial and ethnic groups, and immigrant groups lacking proper health care or coverage, and who have diabetes disproportionately. For the US health care system, the total cost of diagnosed diabetes amounted to $174 billion in 2007, including $116 billion for direct medical costs and $58 billion for indirect costs (disability, work loss, premature mortality). The total cost increases to 218 billion when accounting for undiagnosed diabetes ($18 billion), prediabetes ($25 billion), and gestational diabetes ($623 million).

Treatment for Diabetes

Unfortunately, finding a definitive cure for diabetes has been elusive. Yet, significant strides have been made toward defining successful treatments for the disease. A person diagnosed with diabetes mellitus should be followed by a team of clinical experts, as multiple tests and treatments, across various medical disciplines, may be administered. Monitoring blood glucose is critical in managing the disease. Home blood glucose tests are available to ease the burden of constant testing. The ADA has established guidelines on self-monitoring of blood glucose as part of an effective therapy strategy to help prevent complications and adjust medications and physical activity appropriately.

For those with T1D, measuring sugar in the blood must be done several times a day; while for patients with T2D and with glucose control, tests can be done less frequently. HbA1c tests should be performed routinely in all patients with diabetes as it strongly predicts diabetes complications.

Patients of T1D depend on insulin injections or pumps (insulin cannot be ingested as a pill) as primary treatment to manage the condition and prevent further complications. Insulin analogues with rapid absorption and long-lasting effects are effective and convenient to use. Planned meals consisting of healthy foods should also be part of the treatment. Parental participation is critical as this condition is common in children and young adults who may not be willing or able to manage the disease alone.

Initial treatment of T2D involves lifestyle modification similar to those suggested for the prevention of diabetes. Recommendations include weight loss or maintenance of a healthy weight, a high quality diet low in saturated and trans fat and high in complex carbohydrates, smoking cessation, and a physical activity routine consisting of 150 min/week of moderate-intensity or 75 min/week of vigorous aerobic physical activity as well as muscle-strengthening activities involving all major muscle groups 2 or more days per week. Professional nutritional counseling and meal planning is often advised. These lifestyle therapies provide significant benefits even when drug treatment is given, particularly in controlling other co-morbidities that may exacerbate diabetes.

There are six different classes of drug therapies for T2D; each one works in a different way to lower blood glucose levels. The most commonly prescribed medication is metmorfin, which lowers the amount of glucose produced by the liver and helps muscle cells absorb glucose. Other common drug types include sulfonylureas, which help the pancreas make insulin, and thiazolidinediones, which helps insulin work better in muscle and fat cells and reduces glucose production in the liver. Rezulin, a thiazolidinedione, has been discontinued because of serious adverse effects on liver function, and other drugs in this class, such as Avandia, have been associated with an increased risk for heart failure but are still effective and commonly prescribed. Medications can be prescribed alone or in combination. As diabetes is often accompanied by comorbidities, possible drug interactions must be considered. Finally, unregulated blood glucose in T2D patients may require insulin injections.

Other clinical tests should be performed to monitor risk factors as well as potential complications. These may include laboratory tests for blood lipids, blood pressure measurements, liver and thyroid function tests, and urinary measures. Due to the possibility of complications, diabetes patients may be followed by specialists in eye and foot care and in renal and digestive diseases, a dentist, a registered dietician, mental health counselors, and other specialists.

Although the ADA recommends that a person with diabetes receive comprehensive evaluation, immigrants are less likely than US-born individuals with diabetes to adhere to any one of seven diabetes care recommendations, in general. Specifically, they are less likely to report having received an influenza vaccination. There are similar reports of poorer diabetes control among immigrants in other countries.

Besides clinical treatments for the patient, diabetes mellitus should be prevented and controlled through other approaches. These may include community programs and interventions (particularly those targeting modifiable risk factors), continued education for clinical staff, support for caregivers, research on the causes and best treatment and clinical practices, and policy, legislation and system changes to improve insurance coverage and quality of care, among other initiatives.

Special Considerations for Immigrant and Minority Populations

Immigrants and racial and ethnic groups have disproportional prevalence and mortality rates for diabetes. The fundamental causes for such are varied, from genetic variation, to nutrition transition (changing from traditional dietary patterns to a Western-type diet), to disparities in risk factors and socioeconomic barriers for prevention and treatment. For example, foreign-born individuals with diabetes tend to be younger, have lower education levels and income, and are more likely to have public or no insurance compared with US-born individuals with diabetes. The impact of rural to urban migration can also affect lifestyle behaviors and thus, diabetes risk. For immigrants, diabetes prevention and control strategies should start soon after arriving to the USA.

Cultural norms and values should be taken into account when working with immigrant and minority populations with respect to prevention and control of diabetes. For example, issues like cultural perceptions of body weight, dietary customs, medical beliefs, language barriers, and citizenship status, among others, should be considered.

Dietary Patterns

Odilia I. Bermudez
Department of Public Health and Community Medicine, Tufts University School of Medicine, Boston, MA, USA

Introduction

With the American population becoming more and more diverse, dietary patterns of minority groups, constantly reshaped by new waves of immigrants, are also becoming more "Americanized" and rapidly adopted by the general population.

Immigrants of multiethnic backgrounds are a common scenario in the United States. While the proportion of non-Hispanic Whites will decline in the period 2000–2050, other major ethnic groups, including African Americans, Hispanics, and Asian and Pacific Islanders, will all increase substantially. New immigrants from all over the world contribute to those changes in magnitude and diversity of the American population.

Americans from racial and ethnic minority groups account for more than one third of the total population, according to estimates from the US Census Bureau. Hispanics, the fastest growing group account for more than 15% of the total US population; non-Hispanic Blacks represent about 13.5%, while Asians, the second fastest growing group, account for about 5% of the total population. Each one of these groups has very distinct food patterns, modulated by their culture, traditions, and socio-ecological factors.

In this section, we present a succinct review of concepts and explanatory factors about dietary patterns and discuss some of the main characteristics of those patterns as associated with specific ethnic groups. We briefly discuss the interactions between dietary patterns, health and disease in US immigrant communities and describe some indicators commonly applied to assess food patterns quality in terms of their contribution to good nutrition and health.

Conceptualization of Dietary Patterns

We define *Dietary Patterns* as the set of norms, rules, and principles that population groups have established to provide nourishment, healing, and comfort to its members, through the provision and consumption of foods and beverages in a variety of combinations. Dietary Patterns include not only the eating of the food, but all those activities around the acquisition and preparation of the food, as well as the cooking practices and the norms that dictate how food is distributed and shared at the internal of family or social groups.

Food patterns are established under the influence of several factors. The physical environment, the direct observation of the effects of foods, single or in combination with other food ingredients, the association of foods with life cycles and with climate phenomena, all contribute to modulate and define eating behaviors of population groups.

Dietary patterns develop slowly and are deeply inculcated in the social and cultural traditions of people. Those patterns are highly affected by cultural influences, as people define their preferences, choices, perceptions, beliefs, and attitudes about foods on the basis of their ethnic traditions and values. The dynamic constructs that define dietary patterns facilitate the modification and redefinition of those patterns as result of the interaction of people from different cultures and ethnicities.

Dietary Patterns of Immigrant Communities

Traditional food-related practices and food ways are deeply ingrained in the lives of immigrant communities, as those food-related practices are integral part of the identities of immigrants to the United States. The preservation of the dietary patterns, cultural foods, and eating behaviors are important sources of comfort in an environment that is new and sometimes intimidating to them. Immigrants maintain their attachment to their food systems as mechanisms of cohesion.

Foods have multiple connotations for people from any ethnic origin, including Americans from the general population. In addition to be means of maintaining their cultural identity, foods satisfy several needs: biological, as providers of nutrients and food components essentials for life; health, as foods ensure health and wellness; social as foods contribute to maintaining social structures; and religious because foods are associated with religious activities and some foods are considered sacred for certain cultures. Nutrition and social researchers had studied the relation between food and social structures and had determined that foods contribute to the maintenance of traditions and serve multiple roles including expressions of hospitality, goodwill, prestige, and status.

There are several ways to classify foods. One commonly accepted identified five food classification systems developed by different cultures: (a) food versus no-food, or what is edible or not; (b) sacred vs. profane foods; (c) food as medicine; (d) social foods; and (e) foods of opposing categories, such as the hot-cold system developed by some Hispanic groups, or the yin (cold)-yang (hot) Chinese principles. Therefore, when working with immigrant communities, it is important to identify their main food patterns and the interpretations they assign to the various foods they are attached to if changes or modifications to those food patterns are considered as part of the actions to be recommended for those groups.

Dietary Patterns and Acculturation of Immigrant Groups

Economic, political, or educational factors are usually the motivators of the immigration process. Rarely are the immigration causes motivated by food- or nutrition-related factors. However, foodways are invariably affected by the insertion of immigrant groups into a new, host culture.

New immigrants into the United States confront the realities of adjusting their traditional lifestyles to the American culture. They need to adjust to differences in language, values, traditions, and food habits. They may also experience changes in their social status and their social and family networks. How profound those changes could be is influenced by the geographic region and place where immigrants choose to live. Those that join already established communities of their own ethnic groups will benefit from the resources and support from their own peers, which include a better chance to maintain their dietary patterns.

Independently of where immigrants establish their residence, they will soon become immersed in the host culture and will initiate the process of acculturation by adapting norms, traditions, and cultural elements of the host American culture, and, at the same time, will preserve cultural elements of their own culture. Resources and opportunities influence their acculturation process, which is multidimensional and dynamic. A dietary acculturation also occurs with the incorporation of new foods and eating practices. The immigrant culture also contributes to the host culture their ethnic foods, which enrich the multiethnic and multicultural characteristics of the American foodways. Classic examples include the “Americanization” of tacos, tortillas, enchiladas, pizza, spaghetti in tomato sauce, and many dishes from the Chinese cuisine.

Dietary patterns are impacted by the acculturation process. The access to new foods or the lack of access to traditional foods, along with the socioeconomic demands of their new lives, affect the food choices made by immigrants, although different ethnic groups adjust their foodways differently. For example, more acculturated Hispanic immigrants, particularly those from Mexico, tend to decrease the quality of their diets (e.g., more fat and less fruit and vegetable intakes) as compared to those less acculturated. However, in the case of mainland Puerto Ricans, more acculturation is associated with better diet quality.

Past experiences with foods also affect the foodways of immigrants and slow the acculturation process. Groups that experienced severe food deprivation, hunger, and famine in their homeland (e.g., Cambodians during the Khmer Rouge period) feel the need to stockpile and consume their traditional foods, those that they were deprived of, even though this overconsumption may be deleterious for their health. These groups tend to maintain their traditional food patterns longer that other groups with less traumatic past experiences.

The age of the new immigrants also influences the acculturation process and the preservation of their foodways. For example, older immigrants, compared to younger counterparts, require longer periods of time to acculturate and are more likely to maintain their traditional food choices. Older individuals have developed strong attachments to their traditional foods. They had long before their arrival into the US defined their core foods, with the assignation of social, religious, and health-related meanings and obtain high levels of comfort and social acceptance from their foods. Moreover, they are seen by their younger peers and family networks as the gatekeepers of the foodways and cultural practices, which reaffirms their identity and cultural values.

Dietary Patterns and Health of Immigrants

In addition to acculturation, dietary patterns of immigrants are affected by the interaction of biological, social, economic, and cultural factors, which, at the same time, could affect their patterns of health and disease.

The easy and cheaper access to food, a more diverse combination of foods, frequent snacking and larger portion sizes, along with decreases in their levels of physical activity and increases in the economic power of immigrants are factors that have been associated with changes in their eating patterns. These same factors are also associated with higher prevalence of obesity and chronic diseases like type 2 diabetes, cardiovascular disease, hypertension, some types of cancers, and others.

The linkages between dietary patterns and health need to be considered when assisting newcomers to the United States, in order to avoid disease and promote health. Therefore, it is important to study the health benefits and nutritional characteristics of those dietary patterns, as this type of information is needed to protect immigrant populations. To examine the contributions of dietary patterns to the maintenance and promotion of good health, there is a need to collect and interpret data about: (a) food patterns and food components of immigrant groups associated with good health; (b) foods that contribute key nutrients; (c) immigrant groups at risk for disease due to insufficient or excessive consumption of certain food groups; and (d) food patterns associated with extreme, deleterious eating practices.

Assessment of the Nutritional Quality of Dietary Patterns of Immigrants

The study of food patterns and their nutritional components (e.g., proteins, vitamins, and minerals) are needed for the identification of the interactions and synergistic effects of foods on health and for health promotion. Several approaches had been used to examine dietary patterns and to identify groups of people with dietary patterns that, in addition to identifying them as cultural or ethnic groups, also provide insight into the health benefits of such patterns. Using appropriate methodologies for the identification of food patterns permitted the description of healthy dietary patterns such as the dietary pattern of Mediterranean groups (“Mediterranean diet”) which is considered health protective because of its high content of fruits, vegetables, and whole grains. A food pattern named “Western pattern,” adopted by some groups of Americans, has been associated with the development of chronic diseases including cardiovascular disease, diabetes, cancer, and obesity. Assessment of dietary patterns of elderly Caribbean Hispanics (mainly Puerto Ricans and Dominicans) that migrated from their homelands to the US Northeast revealed that their “traditional food pattern,” characterized by high amounts of rice, root crops and fats, and low amounts of fruits and vegetables, was associated with higher risk for obesity and with low acculturation status.

Immigrants that come from countries and regions with easy access to a variety of traditional foods may be able to maintain good nutrition and health, as compared to those that immigrated from countries and regions where access to food was limited. Dietary patterns that include a large variety of foods tend to be healthier and more nutritious than those with a limited number of foods. This is because food variety is associated with positive health and nutrition outcomes, such as lower mortality and reduced risk for obesity and for chronic diseases like type 2 diabetes, coronary heart disease, and some types of cancer.

There are several approaches for estimating food variety. Simple counts of the number of foods consumed in a day are applied to estimate food variety scores, with the assumption that the larger the number of foods, the better the chances that the evaluated food patterns provide the nutritional components needed for good health and nutrition and for the prevention of diseases. This approach is too simple because some of the dietary patterns may include foods of low quality or with high amount of simple sugars and unhealthy fats. Therefore, when measuring food quality it is advisable to consider, in addition to the number of food items, the distribution and health value of the food included in those dietary patterns. The identification of the type and quality of the foods eaten by immigrant groups is needed when nutrition and health providers guide them in the maintenance of their health and nutrition in ethnically and culturally appropriate manners.

Final Considerations

Foodways are important aspects of the cultural heritage of immigrants, who bring with them unique cultural characteristics. Those immigrants do not come in a vacuum. On the contrary, they bring new and interesting dietary patterns that, through the acculturation process and the new food environment, get constantly reshaped and modified. Those changes are minimal during the first generation of immigrants, as they maintain a strong attachment to their food patterns and their cultural identity. Second and subsequent generations incorporate rapidly new dietary practices, in part due to their desire to be considered active members of their new culture.

Dietary patterns are not static. They change in a complex process and are influenced by various factors as discussed in this section. As immigrants acculturate into the new, host culture, and their socioeconomic status improves, they redefine their food patterns. Subsequent generations will become more "Americanized." Therefore it is important to guide those immigrant groups toward the maintenance of the health-protective traditional dietary patterns, and the incorporation of American food patterns that are also healthy and social and culturally acceptable. Getting the best of two cultures enriches the well-being and promotes health in the American population.

Disability

ROBERT O. MORGAN
School of Public Health, University of Texas, Houston, TX, USA

The definition of "disability" varies by the source and purpose of the definition. The US Census Bureau defines disability through a series of questions identifying long-lasting conditions (>6 months) that affect sensory, physical, mental, or emotional function. Impairment of function is defined as affecting basic life skills (learning, remembering, dressing, bathing, etc.), or engaging in activities outside the home (e.g., working). The statutory definition of "disability" developed for the Americans with Disabilities Act (ADA) is similar, although not identical. Both of these definitions may differ from other definitions of "disability," for example, the definition of "disability" within the US Department of Veterans Affairs (relevant to VA benefits) or as assigned by the US Social Security Administration (relevant to possible Social Security benefits and Medicare eligibility). As such, any consideration of "disability" among an immigrant population needs to be based on a clear understanding of how it is defined within a specific context.

New immigrants to the USA are less likely to report disability than either nonimmigrants or immigrants who have been resident for a longer period of time, even after accounting for demographic differences. This pattern is somewhat replicated in other countries, although data are only available for a few countries. Since one of the primary motivations for immigrating is to seek employment, recent immigrants are less likely to have been disabled prior to immigration. Interestingly, disabled immigrants are more likely to be employed and to report higher salaries than the nonimmigrant disabled in the USA. Nonetheless, similar factors are related to a higher risk for disability in both immigrant and nonimmigrant populations, including both lower incomes and lower educational levels.

The factors that affect adjustment to disability among immigrants are similar to those that affect adjustment to being in a new society. These include factors that help buffer an individual's transition to new circumstances, such as higher self-esteem and/or self-efficacy, younger age, and marriage and/or social support, as well as factors that impede an individual's ability to adjust, such as perceived societal discrimination. Immigrants with disabilities are thus at a substantially increased risk for poor assimilation into their new societies.

Disabled individuals, in general, use far more medical and support services than nondisabled individuals. This includes more physician visits, more frequent use of therapist or social work services, and a higher likelihood of having a personal attendant. Among the disabled population, immigrants are as likely to use medical and support services as nonimmigrants. Further, access to medical and support services for disabled individuals is affected by many of the same factors as for those who are not disabled, insurance coverage being a key example. As a result, differences in these factors between immigrants and nonimmigrants results in disabled immigrants being at a significantly higher risk for poor access to care.

Within the USA, immigrants generally have a lower rate of health insurance coverage than nonimmigrants, in part due to a lower rate of coverage through employer-based insurance. The eligibility of immigrants, both disabled and nondisabled, for Medicaid, the Childrens' Health Insurance Program (CHIP), and Supplemental Security Income (SSI), and by extension for Medicare, was significantly reduced by the Personal Responsibility and Work Opportunity Reconciliation Act in 1996. Eligibility for some immigrant groups, for example, "qualified aliens," is not restricted. This group includes immigrants with a variety of qualifying characteristics, such as lawful permanent residents, veterans, individuals who have contributed 40 quarters of Social Security coverage, and refugees and asylees. In addition, some immigrants cannot be eligible for coverage for 5 years from the date they enter the country as a qualified alien. Individuals who do not meet "qualified alien" status are generally barred from receiving any federal means-tested public benefit. This significantly limits health care access for disabled immigrants. For Medicare, this primarily affects immigrants who formerly might have been eligible through qualification for SSI benefits. Immigrants may still be eligible for Medicare if they are diagnosed with end-stage renal disease (ESRD; permanent kidney failure requiring dialysis or transplant), although immigrants who have not lived in the USA for 5 continuous years would need to contact the Social Security Administration to determine eligibility. Individuals eligible for Medicare due to ESRD can be less than 65 years old. It should be noted that laws and coverage for immigrants vary widely by state, with some states providing state or locally funded medical care to some or all immigrants. Health care coverage in other countries varies widely depending on the health insurance systems of those countries.

Disasters

Marisa O. Ensor
Department of Anthropology, The University of Tennessee, Program on Disasters, Displacement and Human Rights, Center for the Study of Youth and Political Conflict, Knoxville, TN, USA

The total number of humanitarian disasters has quadrupled in the last 2 decades. The number of people being affected by them is also increasing as a result of overall population growth, poverty, marginalization, conflict, and the movement of displaced populations to marginal areas.

It is currently recognized that while the most immediate causes of disasters are natural phenomena, their consequences are not. Rather, their impact is the result of human agency framed by structural social conditions (e.g., poverty, inequality, and environmentally unsound practices) and people's level of vulnerability (e.g., their capacity to anticipate, cope with, mitigate, and recover from the impact of a hazard). Illustrative of this approach are the *International Disaster Response Law Guidelines* established by the International Federation of Red Cross and Red Crescent Societies, which define a disaster as "a serious disruption of the functioning of society, which poses a significant, widespread threat to human life, health, property or the environment, whether arising from accident, nature or human activity, whether developing suddenly or as the result of long-term processes, but excluding armed conflict." Similarly, the Interagency Standing Committee's *Operational Guidelines on Human Rights and Natural Disasters* defines disasters as "the consequences of events triggered by natural hazards that overwhelm local response capacity and seriously affect the social and economic development of a region."

The negative impacts caused by disasters may include loss of home, community, and livelihood; sex- and gender-based violence; trafficking or recruitment of children into fighting forces; discrimination in the provision of aid; loss of documentation; forced relocation; and issues of property restitution, in addition to death, injury, and illness.

The health dimensions of disasters are twofold. On the one hand, serious health conditions often emerge, or are exacerbated, in the aftermath of a disaster. On the other hand, pandemics and other large-scale public health concerns can be understood as constituting a form of disaster in themselves.

Health Issues in Times of Disaster

Conditions of chronic disease are common features of the social and environmental vulnerability that frequently frames disasters. In addition to their immediate consequences, disasters may also have significant secondary public health repercussions resulting from relocation into overcrowded and unsanitary shelters and resettlement schemes, widespread flooding and exposure to stagnant waters, and the destruction of crops and other food sources.

Lapses in food security in the aftermath of a disaster are at the heart of nutrition and other public health problems. Although casualty rates may stabilize during the post-disaster phase, undernutrition is most likely to develop over the long term among affected populations. Generalized food shortages may be the result of crop losses and the destruction of agricultural land. And even when household supplies appear to be adequate, women, children, the elderly, and other marginalized groups may face an increased risk of food deficiencies or deprivation if practices of food distribution and consumption are discriminatory. Disenfranchised groups' access to other health care needs may also be compromised.

Women

In times of crisis, the already disadvantaged status that women occupy in many societies is likely to be exacerbated and become more conspicuous. Following a disaster, women may find themselves either alone or heading households with diminished resources. Efforts to meet the household's economic needs under difficult circumstances increase women's and girls' (and often boys') vulnerability to sexual exploitation. So does the risk that they will be pressured to participate in "survival sex" – a strategy in which people engage in sex in exchange for needed resources such as food or medicine.

Increases in domestic violence have also been reported in the aftermath of disasters. An extremely damaging form of female disempowerment, domestic violence may increase the risk of HIV infection, especially when it takes the form of sexual abuse. Furthermore, violence, or fear of violence, may act as a significant barrier to women negotiating condom use or requesting fidelity from their partners.

Reproductive health care needs – emergency birth control supplies, early contraception pills, birth control methods, condoms, and skilled health care providers to address obstetrical emergencies – must be made available in disaster relief operations. Culturally appropriate information regarding prevention of STDs, including HIV/AIDS is also important.

Children

Efforts to address the particular needs of children in disaster situations, especially those from mental health or psychological perspectives, have focused primarily on "traumatized victims" who exhibit problematic responses. Other approaches, however, have noted that many youngsters appear to cope well with stress, displaying outstanding resilience to disaster-induced changes.

Findings of young people's remarkable adaptive capacity notwithstanding, children and adolescents do have particular anatomical, physiological, and psychological characteristics associated with their stage of development that may make them more vulnerable to certain health risks than adults. Thus, their vulnerability to disaster-induced health hazards may also be higher. Cases of anemia and micronutrient deficiencies, for instance, are typically more severe in children, as are growth abnormalities associated with malnutrition, including low weight-for-height and low height-for-age. As was the case with women, separated children and those heading households are also more vulnerable to sexual exploitation and resorting to "survival sex."

The Elderly and Persons with Disabilities

While clearly not all senior citizens are frail, dependent, or in need of special assistance, steps must be taken to provide adequate support to those who are. Similarly, persons with disabilities may have particular requirements that must be considered in all disaster management interventions. For instance, it is necessary to ensure that warning systems are recognizable to them and that adequate rescue measures are in place. Additionally, provisions must be made to guarantee that assistive devices and required medication are available, and to ensure that temporary shelters and housing are accessible to those with restricted mobility. At the same time, special attention should be given to the prevention of contagious and infectious diseases among the affected population, particularly among those displaced by the disaster.

Pandemics as Disasters

Like classic "natural" disasters (those provoked by hurricanes, earthquakes, or tsunamis, for instance), pandemics originate in the conjuncture of a human population and a potentially destructive agent. Indeed, threats of pandemics – such as bovine spongiform encephalopathy or "mad cow disease" in 2000, severe acute respiratory syndrome (SARS) in 2005, and, most recently, H1NI or "swine flu" – have been categorized as humanitarian disasters by the international community. While recognizing that HIV/AIDS constitutes a pandemic of enormous proportions, discussions regarding whether it should be considered as a "natural disaster" have been characterized by bitter disagreement. The disastrous effects of this epidemic on the affected population and its clear links with many other dimensions of disasters are, however, undeniable.

Conclusions

The increasing incidence and intensity of humanitarian disasters around the world underscores the need to pay closer attention to the context-specific nature of public health in post-disaster situations. Heightened levels of food insecurity and malnutrition, unavailability of essential necessities such as food – including appropriate food for people based on religious/cultural restrictions – and clean water, lack of adequate sanitation facilities, and the diminished ability of overburdened health care systems to provide for or even reach the most vulnerable groups should be concerns of the highest priority.

There is a need to formulate strategies that address peoples' health needs both before and after catastrophes, prioritizing context-specific protection measures in all phases of disaster preparedness, response, and early recovery. These measures should be guided by a clear understanding of the factors that foster positive adaptation and resilience, facilitating the design of more effective disaster management programs.

Discrimination

Hilary Robertson-Hickling[1], Frederick W. Hickling[2]

Discrimination and Immigrant Mental Health

Discrimination is a social behavior whereby one particular group of people is treated less favorably than others because of their race, color, nationality, or ethnic or national origin. Most countries recognize two kinds of racial discrimination: direct and indirect. Direct discrimination occurs when race, color, nationality or ethnic or national origin is used as an explicit reason for discriminating. Indirect discrimination occurs when rules, regulations, or procedures operating have the effect of discriminating against certain groups of people. Discrimination is not only common in the developed countries in North America and Europe but also in post-slavery and postcolonial countries where legacies of discrimination have been institutionalized.

The World Health Organization (WHO) defines health as "a state of complete physical, mental and social wellbeing and not merely the absence of disease or infirmity." The Ottawa Charter for Health Promotion articulated a series of prerequisites for acceptable social practices. These include equal opportunity for all, social justice, sustainable resources, income, food, education, shelter, a stable economic system, and peace. Reports from many countries indicate persistent and entrenched inequality in the mental health provisions for women, the working class, old people, and immigrant populations. In the case of immigrant populations, they are frequently subject to racial discrimination. Racial discrimination exists in a variety of national contexts as well as in a variety of social settings. This form of discrimination is the one that is most frequently highlighted as the consequences seem to be the most long lasting and injurious to the long-term health and well-being particularly of immigrant populations of color in White societies. There is distinction that has been made by social scientists about direct or indirect discrimination. The former tends to result in intentional harm being done.

There are various forms of discrimination of which racial discrimination is the concept most frequently used to explain problems of ethnic inequality in Europe and Euro-America. Discrimination is not only visible, but it is also invisible and can take very subtle forms. There is need to clarify the concepts and the contexts in which it takes place. The concept can be applied at the individual, institutional, and structural levels. There is also still need to distinguish the theoretical and methodological differences between structural and institutional discrimination. Structural discrimination refers to institutional structures that discriminate against those who are ethnically and otherwise different from those who form the majority ethnic group in society. Institutional discrimination takes place through the development of policies routines and standards that permit those individuals who hold such power as to be gatekeepers in these institutions. These two kinds of discrimination are sometimes described as a single entity by some researchers while others view them as separate, especially as regards the question of intentionality and unintentionality.

The institutional character of most forms of discrimination is often found in markets and health and social care in which there are established rules and procedures. In addition, there are the cultural elements such as stereotypes. The Macpherson Commission defined institutional racism in England as "…collective failure of an organization to provide an appropriate and professional service to people because of their color, culture or ethnic origin…" It can be seen or detected in processes, attitudes, and behavior which amount to discrimination through unwitting prejudices, ignorance, thoughtlessness, and racist stereotyping, which disadvantages minority ethnic groups. Racism should not be conceived of as a unitary concept but one that has many elements – the institutional, the social, and the cognitive. Strategies to address racism must be conceived and implemented at several different levels.

The WHO links the inequalities on mental health, explaining that the chronic stress of struggling with material disadvantages is intensified to a considerable degree by doing so in an unequal society. Chronic stress affects individuals through the neuroendocrine, cardiovascular, and immune systems, which may be accompanied by health-damaging behaviors, violence, anger and despair related to occupational insecurity, poverty, debts, poor housing, exclusion, and other indicators of low status. All of these kinds of discrimination have a negative impact on the health and well-being of immigrant populations who experience considerable discrimination and disadvantage especially in accessing mental health care. There continue to be glaring inequalities in the provision of health care for these populations. Although there has been the collection of data on health inequalities, there continues to be methodological and conceptual problems that result in inadequate, or culturally inappropriate services developed. Considerable research has been done on Black and minority ethnic communities in Britain where Fernando in 2009 identified the following discriminant mental health ethnic issues. Black and ethnic minorities are more often:

- Diagnosed as schizophrenic
- Compulsorily detained under a Mental Health Act
- Admitted as "offender patients"
- Held by Police under Section 136 of Mental Health Act
- Transferred to locked wards
- Not referred for psychotherapy
- Given high doses of medication
- Sent to psychiatrists by Courts

In the Criminal Justice System, Black people are overrepresented in the UK prison population, where 17% of the male prisoners in England and Wales are from ethnic minority groups, constituting 6% of the general population. The rates of imprisonment for Blacks were eight times higher than for Whites. Of Blacks over the age of 21, 51% were serving sentences of over 4 years, as compared to 35% of Whites. In the Mental Health Services, Black and ethnic minorities (compared to the "White" majority communities) are more often diagnosed as schizophrenic, and compulsorily detained under the Mental Health Act. In addition, they are transferred to locked wards from open wards, are admitted to hospital as "offender patients," and held by police under Section 136 of the Mental Health Act (a section of the UK Mental Health Act that authorizes a police officer to remove a person from a public place).

They are not referred for psychotherapy, and they are given high doses of medication and sent to psychiatrists by the courts. In the education and schooling system, there were a large number of permanent exclusions of Black pupils of compulsory school age. African-Caribbean children were excluded four times more commonly than White children. These statistics show an overrepresentation of Black people in some of the major institutions such as prison and mental hospital; and underrepresentation in terms of scholastic and economic achievement. Between 1948 and 1973, approximately 555,000 persons of Caribbean birth migrated to Britain, the majority before the 1962 Immigration Act effectively cut off further migration.

Not only is there stigma against these immigrant populations but also there is stigma about the seeking of psychological and psychiatric care because of the history of oppressive and racist services provided and the role of psychiatry and psychiatrists. In fact, there have seen significant antistigma campaigns in many countries to address the problem.

There is also a problem about the pathways to care for the immigrant populations. Where the police are the pathway to mental health care for these populations, many problems exist. Quite often there have been public outcries to the manner in which mentally ill persons have been treated by the police or the mental health care system and these have resulted in commissions of enquiry. The issue of pathways to care is part of a much larger problem, which relates to the theories of social epidemiology. The discussions about inequalities in health care run more deeply into the structure of opportunity in the society, wealth, and poverty. What are the causes of health or well-being and why are some ethnic groups ill and poor? Matters of social and economic justice and relative power or powerlessness then enter the discourse that is fraught with difficulties.

Discrimination on the basis of ethnicity, religion, immigrant status, or gender represents considerable infringements of human rights in the entire European and Euro-American world. Many Europeans and Euro-Americans have considerable difficulty acknowledging this, and hence, efforts to address these issues have been more symbolic than real.

Disease Prevention

Nanette V. L. Lee[1], John P. Elder[2]
[1]Public Health/Health Behavior, San Diego State University & University of California, San Diego, CA, USA
[2]Graduate School of Public Health, San Diego State University, San Diego, CA, USA

Although immigrants arrive in the USA with better-than-average health, this advantage wanes with increasing years of residence and succeeding generations. Screening services, routine health examinations, and adequate access to care are all essential prevention tools for newly arrived immigrants. Disease prevention occurs in three stages: primary prevention (keeping healthy people free from disease), secondary prevention (screening for early detection of disease), and tertiary prevention (preventing disability as a result of a disease). Although chronic disease prevention is the higher health priority for Americans or others from Western/industrialized countries, immigrants to these countries may suffer from both these and infectious diseases. This entry is divided into three main topics: infectious disease prevention, chronic disease prevention, and barriers to disease prevention. Subdivisions within infectious and chronic disease prevention categories are primary, secondary, and tertiary modes of prevention.

Infectious Disease: Primary Prevention

Keeping Americans free from preventable disease is a US public health objective. Disease prevention at the primary level keeps healthy people free from illness. "Vertical transmission" of disease occurs during childbirth when a mother passes an infection on to her newborn. "Horizontal transmission" occurs person to person as a result of close contact, sexual intercourse, sharing of infected needles, etc., or through water-, air-, or vector-borne infections. Primary prevention methods include vaccination and education on the modes of disease transmission and susceptibility of at-risk populations.

Immunizations are available for many infectious diseases including hepatitis B virus (HBV). Vaccination for HBV is completed after three separate doses ideally spaced out over 6 months. The Centers for Disease Control and Prevention (CDC) recommends routine testing for persons born where hepatitis B surface antigen (HBsAg) prevalence is greater than or equal to 2%.

Recent surveys with Chinese, Vietnamese, Korean, and Cambodian immigrants reveal a lack of basic knowledge regarding HBV transmission, susceptibility, and treatments. While most Asian immigrants know HBV is transmitted vertically, confusion regarding horizontal transmission exists. Many erroneously believe HBV acquisition occurs by sharing eating utensils and drinking glasses with infected individuals or by eating food prepared by someone with the virus. Even though these groups are at increased risk of acquiring HBV, they routinely fail to be vaccinated for the virus. Although awareness of an existing vaccine is high, many do not understand the complete vaccination process. Ensuring these immigrants receive HBV vaccinations and understand their risks of contracting the illness will limit the number of infected people.

There is an increasing prevalence of HBV among Latino immigrants due to sexual transmission compared to other routes of transmission more commonly seen in Asian immigrants. Latinos are undervaccinated because of the low HBsAg prevalence in most of Latin America. In a recent study assessing hepatitis B seroprevalence and risk behaviors among immigrant men, Latino immigrants were less likely to report prior vaccination for HBV compared to Asian immigrants.

Although infectious diseases such as tuberculosis (TB) and HIV/AIDS do not currently have vaccines, scientists continue to research effective immunization strategies for these diseases. A group of Chinese researchers are evaluating a recombinant strain of Bacille Calmette-Guérin (BCG) to vaccinate against TB, while Canadian researchers are investigating nontraditional biological pathways. Recently, clinical trials of a HIV vaccine were conducted in over 16,000 heterosexual men and women in Thailand. Vaccination did not affect $CD4^+$ counts or viral load, but the research suggests future possibilities for immunization. Until scientists develop effective vaccines, education regarding modes of transmission and susceptibility is essential for primary prevention of these diseases.

Immigrants who use illicit drugs are at greater risk of contracting HIV. Injection drug users from Puerto Rico were found to perform higher risk behaviors upon moving to the mainland USA, even though more services are available compared to those on the island. Risk behaviors included sharing needles and other injection equipment and having unprotected sex. While first-generation Latino immigrants have lower rates of illicit drug use compared to subsequent generations, determinants of drug use among immigrant Latino workers in New Orleans contest these data. Immigrants who arrived after Hurricane Katrina to assist in the rebuilding efforts were exposed to individuals and situations which facilitated the use of crack cocaine. Many immigrants reported both physical availability of the drug and affordable pricing. These immigrants used drugs to relieve stress from inconsistent work opportunities, social isolation, and workers' rights abuses. Oftentimes, drug use was associated with other risky behaviors such as solicitation of prostitutes. These behaviors can lead to increased prevalence of HIV among these groups. Primary prevention efforts to educate and inform immigrants about HIV transmission are necessary to curtail the increase in HIV prevalence among these groups.

Infectious Disease: Secondary Prevention

Medical examinations are required for every US-bound immigrant and refugee. Although refugees are not required to pay for this service, this waiver is not given to immigrants who are not sponsored by the US State Department. The CDC provides oversight and technical guidance for a panel of 400–800 local physicians who provide examinations in foreign countries. A member of the CDC-approved panel completes a form indicating overall health status and medical history, including the presence of TB, syphilis and other communicable diseases, drug abuse, and vaccinations. There is a referral portion for follow-up care.

Just as Asian immigrants are not routinely vaccinated against HBV, they are also not receiving routine HBV screening. Recent data indicate Cambodian and Vietnamese immigrants fail to discuss risk of HBV infection with a physician. Because many Asian countries have high endemic rates of HBV infection, screening immigrants from these areas should be a high priority for secondary prevention of HBV.

In much of the world, immigrants aged 15 and older are screened for TB via a standard posteroanterior chest radiograph. If the chest X-ray suggests possible active TB infection, sputum specimens are obtained over the course of 3 consecutive days. These specimens are stained for acid-fast *Mycobacterium tuberculosis* bacilli. Children younger than 15 years undergo screening for TB if there is a history of TB, signs or symptoms of TB exist, or there is close contact with someone diagnosed with TB. If a potential immigrant to the USA is diagnosed with active TB, therapy must be completed and sputum specimens must come back negative before travel is allowed. When immigrants arrive in the USA with a diagnosis of TB, follow-up evaluations are required. Limiting additional TB infection requires adherence to the CDC guidelines for follow-up care. State and local public health departments need to be responsible for ensuring all those diagnosed with TB receive appropriate treatments.

HIV/AIDS screening is no longer required for incoming immigrants. However, the CDC recommends that anyone who is sexually active participate in HIV screening. In the USA, oral fluid, blood, and urine can all be used for HIV testing, but using blood is most common. Using traditional diagnostic tests, results are usually available in a few days, with positive results requiring confirmatory testing. Rapid diagnostic testing yields results in about 20 min. Door-to-door rapid testing has been determined to be a feasible and accepted method of screening for HIV in Latinos. Since the Latino community is disproportionately affected by HIV infection, community outreach programs that limit barriers to testing should be practiced.

Infectious Disease: Tertiary Prevention

Immigrants are twice as likely as US-born Americans to be uninsured. Lack of insurance can lead to disruptions in care and medication adherence, possibly creating disease-resistant strains of illnesses. Patients lacking continuous care may not receive thorough medical support to achieve recovery and ensure others in close contact do not become infected. Additionally, viral infections can lead to increased risk for certain morbidities.

Carriers of HBV are at risk of developing chronic active hepatitis and cirrhosis as well as hepatocellular cancer (HCC). Asian immigrants have higher rates of chronic HBV infection compared to their American-born counterparts due to high endemic levels of HBV in their home countries. However, they do not report high susceptibility. While they understand HBV infection would change their lives, they are unsure about the consequences of HBV, including the possibility of acquiring liver cancer.

Effective strategies exist for decreasing the mortality from HCC. Patients who are at greatest risk should be selected for antiviral therapy, including those suffering with cirrhosis. Interferon-alpha (IFN-α) functions via antiviral and antiproliferative mechanisms. A newer treatment involves a class of oral nucleos(t)ide analogs. These drugs reduce viral load, but can also lead to development of drug resistance. Because HBV DNA is a marker of viral replication, monitoring is required to ensure effective treatment.

The CDC recommends treatment for active TB last a minimum of 6 months and up to 9 months depending on co-occurring conditions. Patients need to be monitored for side effects to medications, so follow-up treatment needs to occur monthly at minimum. Treatment for latent TB infection (LTBI) follows a similar protocol to that for active TB. Directly observed therapy (DOT) for TB infection has been determined to be the most effective treatment for curing TB. In a study comparing DOT treatment to non-DOT treatment in Vietnamese TB patients, those participating in DOT treatment had higher rates of completion and lower rates of relapse. Ensuring immigrant patients return to clinics and maintain treatment will limit drug-resistant strains of illnesses.

Opportunistic diseases that increase mortality from AIDS need to be prevented. Adherence to antiretroviral therapy (ART) is key to maintaining $CD4^+$ counts >200 cells/μL. If $CD4^+$ counts fall below 200 cells/μL, drug therapy against *Pneumocystis pneumonia* (PCP) must be initiated. If the patient responds to ART, drug therapy can be decreased. Patients with a history of PCP must maintain drug therapy for life. Once a patient is infected with HIV, tests should be performed to detect latent infection with *Toxoplasma gondii* and LTBI. Additionally, patients should be educated on ways to prevent *Cryptosporidium*, bacterial, and fungal infections.

Female HIV-positive African immigrants describe unfamiliarity with the US health care system as a barrier to maintaining medication adherence. Social workers indicate that male African immigrants often go untreated due to inability to come to the clinic because they work multiple jobs. Understanding cultural and economic issues relating to treatment can inform public health interventions and increase tertiary prevention among these populations.

Chronic Disease: Primary Prevention

Similar to native-born Americans, the three most common chronic diseases affecting immigrants are heart disease, diabetes, and cancer. Risk factors for heart disease include smoking, low levels of physical activity, obesity, hypertension, and hyperlipidemia. Ethnicity (Asian American, Hispanic/Latino, Pacific Islander, African American, Native American or Alaskan), history of gestational diabetes or cardiovascular disease, clinical conditions associated with insulin resistance, diagnosis with polycystic ovarian syndrome (women only), and advancing age are additional risk factors for diabetes. Along with the risk factors for heart disease, the risk of developing cancer increases with excessive exposure to UV rays and other radioactivity, certain carcinogenic chemicals (including those found in cigarettes), and hormones (estrogen and its derivatives), or from viral or bacterial infection such as HBV, HIV, human papilloma virus, or *Heliobacter pylori*. Excessive alcohol consumption is also a risk factor for many cancers.

Obesity, hypertension, and hyperlipidemia may be caused by high levels of dietary fat and low levels of vegetable and fruit consumption. The 2005 Dietary Guidelines for Americans (DGAs) recommend that people following a 2,000-calorie diet eat four servings of fruits and five servings of vegetables daily. Additionally, 30 min of daily moderate intensity physical activity is advised.

Although they know eating fruits and vegetables decrease the risk of heart disease, Chinese immigrants do not meet the 2005 DGAs. Additionally, they fail to meet physical activity guidelines. However, recent immigrants are more likely to be physically active compared to those who live in the USA for longer periods of time since immigration. Compared to women, men have lower fruit and vegetable intakes and are greater consumers of tobacco. Interestingly, Chinese immigrants do not identify tobacco use as a risk factor for heart disease. Failure to identify risks specific to immigrant groups can result in higher rates of chronic disease.

Female Vietnamese immigrants report greater physical activity with age, although the majority do not meet physical activity guidelines. Smoking prevalence increases with years of residence, while fruit and vegetable consumption decreases. Contrary to most data on acculturation, women who had less English proficiency consumed fewer fruits and vegetables than women who spoke English well. This could be the result of structural barriers such as reliable transportation or proximity to a grocer who supplies easily recognized fruits and vegetables.

Latino immigrants interviewed about diabetes acquisition do not know how diet affects etiology of the disease. It is understood that if one eats unhealthy foods, illnesses will develop, and diabetes is one of those illnesses. Traumatic incidents are also seen to result in great emotional imbalance, causing illnesses to surface. Similar to Latino beliefs regarding cancer, diabetes is deemed a naturally occurring illness that is within the human body, and certain factors can trigger that illness to surface.

American smoking rates are less than those of many foreign countries including China, the Philippines, and Korea. Tobacco companies' market research on Asian Americans indicates that brands popular in their home countries are not necessarily favored in the USA. Some of these reasons include feelings that a particular brand may represent exploitation in the homeland, or brands available in the USA are for higher status smokers. Tobacco companies aggressively market to immigrants regardless of their economic level, attempting to maintain their tobacco-use norms. For example, recent data show that the longer Chinese immigrants reside in the USA, the lower prevalence of cigarette smoking. Countering the industry by intervening with these and other new immigrants is necessary to reduce smoking prevalence.

Major tobacco companies make concerted efforts to understand emerging immigrant markets. They assess the rates of smoking in newly arrived immigrants, comparing rates in diverse areas and concentrated neighborhoods. Based upon this market research, and using assimilation as a proxy for smoking, Marlboro is the brand preferred by less-assimilated Hispanics. As Hispanics adapt and identify more with American culture, Camel is the favored brand. Many companies target border communities to increase smoking rates similar to those found in the home country.

Although Latino immigrants are less likely to use cigarettes, marijuana, or LSD compared to White European immigrants, they have higher rates of intermittent smoking. Furthermore, Latino immigrants who are characterized as light smokers tend to underreport the number of cigarettes consumed. Although Latino immigrants who prefer to answer questionnaires about illicit drug and tobacco use in Spanish are less likely to engage in these behaviors, accurate smoking rates may not be assessed. Because of this, it is important to address the risks of any level of tobacco consumption.

In general, Latino immigrants use alcohol less frequently than their US counterparts. However, alcohol use is associated with economic stress among Mexican migrant men in California. Stress related to finding and keeping steady employment, along with labor discrimination, resulted in increased alcohol use. Similar to findings among Mexican immigrants working in New Orleans, lack of supportive community services to constructively manage stressors can lead to alcohol and drug abuse.

Chronic Disease: Secondary Prevention

Secondary disease prevention begins with ascertaining disease status as early as possible. For many chronic conditions, early detection can result in reduced morbidity and mortality from complications of the illness. According to the American Heart Association, adults should receive blood pressure screenings every 1–2 years. The National Cholesterol Education Program guidelines include having a cholesterol check every 5 years upon reaching 20 years of age, with more frequent checks at 45 and beyond. According to the American Cancer Society, colorectal cancer screening (flexible sigmoidoscopy, double-contrast barium enema, or virtual colonoscopy) should be performed every 5 years beginning at 50 years of age. Colonoscopy can be performed every decade. If a patient is unable to have one of the previous exams, annual fecal occult blood tests (FOBT) or the equivalent should be performed. Women should receive mammograms with clinical breast exams annually upon reaching 40 years of age. Women aged 20–30 should receive a clinical breast exam every 3 years. Pap testing should be performed every 1–3 years if aged 21 years or older, or earlier if sexually active. The Agency for Healthcare Research and Quality states bone density scans should be performed upon reaching 65 years of age.

Screening practices for cardiovascular risks among Asian immigrants indicate areas of improvement. In a study assessing heart disease prevention practices, nearly all the Chinese participants received blood pressure screening, but many did not receive cholesterol screening. Although most Vietnamese participants received blood pressure screening in the past 2 years, many reported not having a cholesterol check in the past 5 years.

Recommended cancer screenings do not always occur. Demographic predictors of cancer screening among Filipina and Korean women indicate that screening adherence is higher with increased years of US residence and with having regular checkups when no symptoms are present. Filipina immigrants are not meeting screening guidelines for cervical, breast, and colon cancers. Compared to Filipinas, Korean women receive fewer mammograms, but more colorectal screenings. Among persons of Mexican origin, limited English proficiency (LEP) contributes to lack of colorectal screening because patients do not receive recommendations or do not know they need the exam. Without a regular physician, screening does not occur. Latino immigrants from Dominican Republic, Puerto Rico, and Columbia indicate colorectal cancer results from consequences of an unhealthy diet (including excess fat intake and constipation) and anal sex. If people feel like they are at lower risk because they do not participate in these behaviors or if there is perceived stigma related to certain behaviors, they may not seek out screening.

Chronic Disease: Tertiary Prevention

Upon diagnosis with a chronic illness, strategies exist to reduce the risk of suffering from comorbidities and hospitalization. Lifestyle changes can often improve health status and potentially decrease dependence on medication. Ensuring adequate follow-up care and maintaining scheduled appointments and communication with health care professionals can improve prognoses.

Diabetics are at increased risk of developing heart disease, stroke, kidney disease, and neuropathies. Smoking increases these risks. Diabetes progression can be slowed by making lifestyle changes such as weight loss, increasing exercise, consuming more fruits and vegetables, and smoking cessation. In order to prevent accompanying diseases, diabetics should follow various health recommendations including semiannual glycosylated hemoglobin (HbA1C) testing and dental exams. Annual eye examinations, urine creatinine screening, and foot examinations should also be performed. Diabetics should maintain HbA1c at 7% or lower, blood pressure below 130/80 mmHg, total cholesterol below 200 mg/dL with low-density lipoprotein cholesterol (LDL-C) below 100 mg/dL, and triglycerides below 150 mg/dL.

Immigrants who suffer from diabetes require additional information regarding comorbidities. Research examining diabetic Koreans' perceived risk of coronary heart disease indicates the same or less perceived risk compared to the general population. In a group of type 2 diabetic Koreans, more than half had uncontrolled blood pressure and higher than recommended LDL-C. In a similar study with diabetic Mexican immigrants along the Texas–Mexico border, the majority were hypertensive and nearly half had hyperlipidemia. Maintaining appropriate cholesterol and blood pressure levels can limit the development of heart disease, stroke, and neuropathies. Routine discussions about limiting these risks should be discussed with a health care provider at every doctor's visit.

Cancer sufferers can improve prognoses by adhering to chemotherapy and radiation treatments as prescribed by the doctor. Maintaining adjuvant treatment during remission can limit potential relapse. Female Mexican immigrants identified economic worries and the lack of money prevented the purchase of tamoxifen or other adjuvant treatment. This financial distress increases anxiety about not maintaining prescribed treatment, but without insurance coverage, many cannot afford medications and therapy. Improving access to care during remission will decrease relapse rates and limit stress resulting from fear of becoming sick again.

Sufferers from cardiovascular disease can limit disability and hospitalization by ensuring proper diet and exercise recommendations. Smoking cessation and stress reduction improve health outcomes. Medication adherence also limits complications. Four behavioral predictors that determine hypertensive medication nonadherence among Chinese immigrants include lower perceived susceptibility, greater perceived benefit of Chinese herbs, less perceived benefit of Western medical treatments, and longer residence in the USA. Ensuring adequate treatment among immigrant populations requires health care provider knowledge regarding cultural practices and barriers to medication adherence. Lack of insurance and the resulting inability to cover treatment costs lead many immigrants to discontinue treatment early.

Barriers to Disease Prevention

Financial, cultural, and language issues are a few barriers to disease prevention. Although immigrants arrive to the USA from different countries, many experience the same barriers. Cultural barriers to prevention may reinforce structural barriers such as shortage of health services and long travel distances to receive care. Additional structural barriers include lack of financial resources and unavailability of culturally competent care providers. Effective ways to reduce these barriers include increasing access to usual care while maintaining continuity of coverage. Additionally, cultural and linguistically appropriate preventive care provision can ensure ideal delivery of information and services.

Regardless of country of origin, many immigrants report similar barriers to cancer screening. Concerns regarding modesty and potential loss of virginity are salient among Filipino and Korean female immigrants. Immigration status and cost of screening prevent Latinas from receiving Pap smears and mammograms. Latinos are more likely to receive screening for colorectal cancer if a physician recommends the procedure. Length of residence in the USA, older age, and Medicaid coverage also affect screening rates. Korean and

Latino immigrants express fatalistic attitudes regarding cancer acquisition and prognoses. Cancer is considered to be a natural process resulting from imbalance in social, emotional, or dietary well-being. Prayer is a source of healing, as are traditional herbs. Latinos may seek out *Curanderos* (traditional healers) for treatment.

Limited English proficiency (LEP) patients may suffer from poorer quality of care due to physician-oriented behavior driven by communication difficulties. Fewer visits, fewer contacts, and visits of shorter duration can all lead to reduced quality. LEP patients have greater difficulty with filling prescriptions, asking their health care provider questions about health issues, and explaining symptoms. These patients also report less empathy from health care providers.

Lung cancer is a leading cause of cancer-related deaths among Filipinos. Predictors of smoking cessation among male Filipino immigrants include living with and socializing with nonsmokers. A key component could be the idea of *pakikisama*, a feeling of social acceptance and friendship among Filipinos. If one socializes with smokers and refuses a cigarette, this can disrupt *pakikisama*, and lead to confrontation. Recognizing this social dilemma and developing intervention materials to address it will ensure successful tobacco cessation programs.

Chinese immigrants identify several benefits and barriers to performing physical activity. Physical activity improves bodily processes such as digestion, circulation, and sleep. Missing from the description, however, is its effect on prevention of specific diseases. Barriers to performing physical activity include lack of time, weather and safety concerns, financial constraints, and lack of organized services for Chinese people. Specific cultural barriers are feelings that elders should not engage in vigorous physical activity. Identifying cultural norms and expectations for immigrants is essential to understanding and addressing perceived benefits and barriers.

Stigma regarding HIV infection affects many immigrant groups, preventing them from seeking screening or treatment for existing infection. In order to address barriers of treatment adherence in female African HIV-positive patients, clinic workers will provide medications in unlabeled bottles or give medications to another person for safekeeping. Workers also train the women to negotiate condom use with their partners without divulging their HIV status. In male Latino populations, men may have sex with other men (MSM) but self-identify as heterosexual. Failure to acknowledge this risky behavior may prevent HIV screening and delay treatment of HIV infection.

Inaccurate beliefs about causes of preventable illnesses, low priority for prevention, limited knowledge about preventive screening services, and delaying screening until initial symptoms occur rather than making it a part of routine care all contribute to limited use of prevention services among immigrants. To overcome barriers to preventive care, health care providers can hire bilingual staff, interpreters who speak patients' languages, translate materials into other languages, and document plans for providing LEP services in clinics and hospitals. Development of ESL (English as a Second Language) classes to educate these populations will reduce inaccurate knowledge regarding transmission, improve screening rates, and limit hospitalization.

Disordered Eating

Nan M. Sussman
Department of Psychology, College of Staten Island
and Graduate Center, City University of New York
(CUNY), Staten Island, NY, USA

Eating disorders (ED) are generally defined in psychiatric terms as intense disturbances in the perception of body shape and poor body image, resulting in restrictive or binge eating/purging patterns. Two main disorders are anorexia nervosa, in which the individual has an intense fear of gaining weight and engages in near-starvation behaviors, and bulimia, in which the individual has recurrent episodes of excessive eating followed by compensatory behavior (e.g., vomiting, use of laxatives, excessive exercise). Severe forms of the disorder can result in death.

Idealized and normally unattainable body types of extreme thinness appear to be at the core of the syndrome. Although every culture has a normative body type related to attractiveness, associated eating disorders had been found predominantly in Western countries. Current literature had conceptualized ED as culture-bound syndromes with more than seven million Americans and 1.15 million English, predominantly women, suffering from these syndromes. High rates of disordered eating are also found in Canada and Australia with lower rates in Europe. Until recently, eating disorders rarely occurred in Asia, Latin America, and Africa. However, as cultures around the world have become exposed to the West and the thinness ideal, primarily through media (movies, television, magazines, Internet), eating disorders have begun to emerge, chiefly among young women. Hong Kong, for example, has seen an increase in disordered eating related to fat phobia, and women in Korea report similar risks for ED as do Americans. It has also been suggested that local variables, apart from Westernization, such as Confucian beliefs and the value placed on physical appearance, may account for the increase in ED in Asian countries. For example, filial piety, the Confucian principle in which the child unconditionally obeys the parent, results in less individuated children. Self-starvation may be one attempt to assert personal control and independence from the family. Parental pressure to be thin is weak as traditional Chinese belief holds that body fat is a sign of health and wealth.

As worldwide immigration has reached historical highs with movement patterns from Asian, African, and Latin American countries to Western ones, the question has been raised as to the effects of immigration on women's body image and risks for eating disorders. Immigration involves more than geographic transitions. Immigrants undergo a process of cultural and identity transitions in which their attitudes, beliefs, values, and behaviors change as they adapt to their new country. This process is known as acculturation, and it has been suggested that high levels of acculturation to a Western country may serve as a risk factor for poor body image and disordered eating. Further, researchers speculated that there may be cultural differences in susceptibility to these syndromes, with some cultures of origin providing buffers against the onslaught of thinness images in the Western settlement countries.

Immigration to the USA

The majority of the research on disordered eating in immigrants has examined immigrants to the USA and will be summarized here by country of origin. Asian-born (Hong Kong, Japan, Taiwan) immigrants formed a large category of study participants. However, studies examining levels of acculturation found mixed results. Some found that high acculturation to the USA was related to lower body satisfaction, but also lower levels of eating disorders. Other research found high acculturation was related to greater body perfectionism and higher ED. Yet other studies, with South Asian, Chinese, and Korean women, found that acculturation had no association with wanting to be thin, worrying about having fat on the body, or other negative attitudes.

Immigrants from Central and South America comprise the largest immigrant group in the USA, with Mexicans forming the majority. Research results again are inconsistent as to the link between body dissatisfaction and ED and regarding the role of acculturation. Several studies found no association between level of acculturation and risks for ED.

A clearer pattern has emerged among Russian and Eastern European immigrants. High acculturation following acculturative stress has been linked to both body dissatisfaction and higher ED attitudes and behaviors. A clear but opposite trend suggests that maintenance of ethnic neighborhoods are a buffer against ED for both Iranian and Caribbean immigrants. The latter, despite having a larger body ideal than the USA, report high body satisfaction and low levels of ED.

Immigration to the UK

Japanese-born and native-born women living in the UK reported similar relationships between emotional eating and bulimic attitudes, but this association was not found among Japanese women living in Japan. Similarly, in two studies, Pakistani-British women reported higher risks for ED and higher prevalence of bulimia than did women living in Pakistan. Examining the factor of acculturation, several studies among South Asian women found conflicts with parents over interpersonal relationships. Higher acculturation was associated with higher ED risk. Japanese immigrants had more risks for ED among women with traditional identity also suggesting that family conflict may contribute to ED. Similar to the study on Caribbean women in the USA, Kenyan immigrants positively perceived large body shapes.

Immigration to Canada

Among second-generation Italian and Greek immigrants, greater family conflicts, higher levels of perfectionism, and internalization of the thin ideal predicted risk for ED. A study of diverse immigrants found concerns with dieting increased with generation status suggesting that new immigrants were initially insulated from Western body norms.

Immigration to Australia and New Zealand

High levels of ED attitudes were found among Chinese female immigrants who either had high acculturation and high pressure to be thin from father or friends or had low acculturation and high levels of parental care. Among Chinese immigrants to New Zealand, positive appraisal of perfectionism served as a buffer between acculturation and ED.

In summary, there is a complex relationship between home culture, level of acculturation, family relationships, residential living patterns, and other demographic variables affecting clinical dissatisfaction with one's body and disordered eating among immigrant populations. Methodological problems plague this research area and the inconsistent use of scales and other assessments impede rigorous comparisons or the ability to integrate the literature. Clinicians should not assume that disordered eating is absent from immigrant communities but rather an array of variables influence the presence of the syndrome.

Disordered Gambling

Erica Marshall, Debi LaPlante
Division of Addictions, Cambridge Health Alliance,
Medford, MA, USA

Gambling consists of *any activity that involves risking something of value on the outcome of an event (e.g., lotteries, bingo, slot machines, sporting events, card games, and more), when the probability of that outcome is less than certain.* For most individuals, gambling is a form of recreation, but for some people it can lead to negative consequences, such as poor mental and physical health, financial difficulties, and degraded social relationships. Recent studies have estimated the rate of gambling-related problems (i.e., experiencing some negative gambling-related consequences) in the adult US population to be 2–3%, whereas the most recent US national studies suggest that less than 1% suffer from the most serious form of disordered gambling, pathological gambling (PG). Currently, one can make a diagnosis of PG using professional diagnostic instruments, such as the *Diagnostic and Statistical Manual of Mental Disorders (DSM)*. The DSM criteria for PG include, but are not limited to: feeling restless, irritable, or anxious when trying to stop and/or cut down on gambling; trying to keep family or friends from knowing how much one gambled; and, having such financial trouble as a result of gambling that one had to get help with living expenses from family, friends, or welfare.

Although the available scientific literature is extremely limited, researchers and other key stakeholders are concerned that members of a number of special populations (e.g., elderly, youth, minorities, immigrants, casino employees) might be at increased risk for gambling-related problems. Researchers suspect that immigration and disordered gambling are related, possibly as a result of the stress of the immigration process on individuals, cultural differences in gambling acceptance and participation, and increased access to gambling opportunities postimmigration.

To date, most studies have considered the prevalence of gambling and gambling-related problems among immigrant populations. The research related to gambling participation has yielded mixed results. Some studies have found increased gambling prevalence among immigrants compared to nonimmigrants (i.e., immigrants from Hong Kong and South East Asia to Canada), although this association is not universal for all immigrant groups. Researchers have also found, in what echoes the findings of unpublished community-based surveys, that the longer the immigrants (i.e., Asian immigrants in Canada and Mexican immigrants in the United States) reported living in their new country, the greater the likelihood that they engaged in gambling activities.

Studies of gambling-related problems among immigrant populations suggest that immigrants should continue to be a population of interest. Studies of gamblers in Norway and Denmark show that, in general, immigrants were more likely to be at-risk for developing gambling problems than nonimmigrants. However, estimates of gambling-related problems and PG among specific immigrant groups vary widely. One study of South East Asian (i.e., Cambodian, Laotian, and Vietnamese) immigrants to the United States found that 12% had probable subclinical gambling-related problems (i.e., South Oaks Gambling Screen (SOGS) scores of 3–4) and 58% met criteria for probable PG (i.e., SOGS scores of 5 or more). A similar study of Cambodian immigrants to the United States found 3.5% had probable subclinical gambling-related problems and 10.4% met SOGS criteria for probable PG.

Despite the availability of some immigrant-focused disordered gambling research, there remain significant gaps in knowledge. The current literature related to immigrant populations is very small, and many studies rely on anecdotal evidence for community interventions and policy decisions. Additionally, most studies are cross-sectional in nature, and many rely on convenience sampling methods and have very small sample sizes. These methods lead to results that might not generalize to wider immigrant communities and cannot provide information on the temporal relationship between immigration and gambling behavior problems. Similarly, research is needed to assess the impact of cultural beliefs and traditions on disordered gambling among immigrants, as well as on treatment seeking and treatment success. Studies indicate that treatments that are culturally competent can aid the recovery of immigrants with gambling-related problems.

Looking to the future, the experiences of immigrants dealing with gambling problems will improve as research fills in the current gaps in understanding for these populations. Prevention and intervention efforts are needed that address the generally poor access that immigrant groups have to both mental and somatic health services, the cultural and language barriers that isolate immigrants and the stigma of seeking help in some cultural groups. Refinement of the knowledge and treatment of disordered gambling for immigrants has the potential to greatly improve the health of individuals and their communities.

Displaced Populations

Jaina Amin
Department of Psychiatry, University Hospitals Case Medical Center, Cleveland, OH, USA

Introduction

The displacement of a group of people can have many long-standing effects. Various forms of population displacement include voluntary forms, i.e., immigration, or involuntary forms, i.e., gentrification of neighborhoods or by the forces of mother nature or political unrest.

While immigrants may choose to leave their countries of origin under seemingly voluntary conditions, they are still leaving behind their homelands and families to move to another country. Thus, when they move and do not have any social support in the new country they have a harder time adjusting. They may suffer from depressive symptoms related to the change in their environment and their living situation, and lack of social support in the new country.

Gentrification of neighborhoods has been thought of a way to revitalize an impoverished area by bringing in a more affluent population. Housing costs increase thus bringing in a more affluent class that can afford these increased prices, and this forces out the lower economic individuals, effectively displacing them because they cannot pay the rent. As more affluent individuals move into the area, more services to cater to the affluent lifestyle move into the area, furthering the displacement of the lower economic individuals. Not all of these displacements are voluntary or friendly. Atkinson notes that 1 in 10 tenants are harassed each year to leave their homes, and 2% of the evicted reported that "other ways" of persuasion were used. These methods of persuasion can lead to emotional symptoms of anger, anxiety, or even posttraumatic stress disorder in severe cases; also there is the emotional component of leaving a home that may have been in a family for generations.

Refugees have similar stories in that they may be leaving behind a home country, city, or village that generations of their families have lived in. Refugees flee their countries to save their lives. They run from war and persecution, often losing beloved family members along the way. People who are displaced within their own country are called internally displaced persons. Not only are they experiencing the loss of their home, either through natural disaster or wars, but they have the added stress of the traumas they encounter before and during the displacement. Math and colleagues found that there was higher psychiatric morbidity in individuals displaced from their countries at 5.2% in comparison to the non-displaced individuals who had psychiatric morbidity of 2.8%. They found that in both the displaced and non-displaced individuals, there was an even distribution of depression and PTSD symptoms. However, interestingly they noted that in the displaced population there was more frequent panic disorder, anxiety disorder, and somatic disorders. Math et al. also found that women were more likely to experience problems with mental health problems after experiencing the tsunami. The World Health Organization noted that in times of war, women and children tend to become victims of exploitation.

It is important to consider the adjustment when dealing with a person who has been displaced from their country of origin. Assessing if that individual expresses feelings of being welcomed in the new culture will support these individuals acclimating with the dominant culture without problems. Individuals who feel isolated will have a harder time trusting people, feeling comfortable; all of these factors can lead to potential increase in emotional distress.

Divorce

Beatrice Gabriela Ioan
Department of Legal Medicine, Medical Deontology and Bioethics, University of Medicine and Pharmacy "Gr.T.Popa", Iasi, Romania

Divorce is the legal termination of a marriage through judicial proceedings. Although it has been said that the divorce rate is increasing, it has actually decreased or remained stable in many countries. For example, data indicate that in 1980, the US divorce rate was 7.9 per 1,000 persons aged 15–64 years, but the rate had decreased to 5.2 persons per 1,000 by 2008. The divorce rate has remained relatively stable in some countries, such as the UK and Denmark, but has increased in Japan, from 1.8 per 1,000 persons in 1980 to 3.1 persons per 1,000 in 2008. Ireland and Montenegro continue to have some of the lowest rates of divorce.

The legalization of divorce and the transition in some legal systems from a fault-based system of divorce (i.e., one partner asks for divorce because of the other's misconduct related to marriage) to one of no-fault divorce (i.e., divorce can be requested without claiming partner's misconduct during the marriage) and unilateral divorce (the ability of a partner to obtain divorce without the other partner's consent) may have led to an increased divorce rate. Although the introduction of these more lenient laws may have led to an immediate increase in the divorce rate, this increase has generally not been maintained over time.

The underlying reasons for divorce and the increased leniency of divorce laws reflect changes in societal attitudes. At one time, most people divorced due to their partner's specific/concrete negative behaviors such as alcohol consumption, or lack of support. Now, many divorces are premised on more abstract reasons, such as different or conflicting life styles or one or both of the partners' desire for increased freedom.

The reasons underlying divorce also vary by gender. Studies show that women often divorce because they feel unloved or underestimated, while men divorce more often because they feel neglected or because they believe their values and interests are incompatible with those of their partners.

Studies indicate that the primary risk factors for divorce in heterosexual couples include marriage at a younger age, low socioeconomic status, lower educational level, great age difference, and sociocultural differences between spouses. The importance of low education may decrease as the duration of marriage increases. Some of the inequalities that exist between spouses, such as a difference in income, may have a protective effect on marriage.

A study conducted in Norway and Sweden found that the risk of divorce is significantly higher in same-sex registered partnership than in heterosexual marriages. (A registered partnership is a legally recognized civil status that, in Norway and Sweden, functions essentially the same as a heterosexual marriage.) The investigators reported that the rate of divorce is about 50% higher in registered partnerships between men than in heterosexual marriages.

Among the same-sex partnerships, the risk of divorce is twice as high in partnerships between women compared to partnerships between men. The investigators hypothesized that the increased risk of divorce among same-sex registered partnerships may be due to lower exposure to normative social pressure for lifetime marriage and the lack of shared responsibilities for raising and educating children.

Studies indicate that international migration is associated with higher divorce rates than those prevailing in the migrants' countries of origin. The reasons and the moment for divorce vary and largely depend on the immigrants' cultural background, their level of acculturation, the new socioeconomic environment, and the social and legal attitudes toward divorce in host countries. Divorce may occur shortly after immigration as a consequence of several factors. These include the emigration of partners at different moments in time, involvement of the first migrating partner in a new relationship in the host country; one of the partners being a "tied migrant" (i.e., a person who immigrates depending on her/his partner), tensions caused by the wife's increasing income, more permissive divorce legislation in the host country. Immigrants may also divorce after a period of residence in the USA due to their assimilation of the more permissive attitudes of the new host society toward divorce, disagreements about returning to their country of origin, and the realization by the marital partners that they are no longer suitable for each other in the host country.

For example, a number of studies conducted with immigrants from Mexico and other Central American countries in the USA found that their divorce rate after migration was higher than the rate in their home countries. A qualitative study conducted with Puerto Rican immigrants in the USA showed that the longer a couple resided on the US mainland, the more likely the partners were to divorce, this association being stronger in informal partners than in married couples.

Research on divorce among Korean-Americans shows a much higher divorce rate than in their country of origin. One of the most frequent reasons for divorce among Korean-American women is the high rate of wife abuse, usually motivated by the patriarchal family structure, the emphasis placed on family harmony, and social discrimination of women in the country of origin. Another important reason is the extensive involvement of Korean-American women in the labor market (estimated at about 60%) and the women's increased economic role in the family, causing confusion and conflict due to disruption of traditional family roles, namely, the dominant role of men and their role as the financial supporter of the family. Given the women's involvement in the labor market they have a dual role: they must raise children and take care of the house but also fulfill their obligations at the workplace. This dual responsibility places a disproportionate burden on them, generating fatigue and marital conflicts. The ease of divorce and the ease of finding a job may have contributed greatly to women's decision to divorce.

A study involving a community of Hmong immigrants in the USA shows that the contact with American culture has induced some changes in their attitudes and opinions on marriage and divorce. They are confused when asked about the acceptability of divorce, as they come from a society and culture that are strongly opposed to divorce. They are, however, less inclined to believe that in case of divorce children belong to father, this being the case in their home country.

Doctors Without Borders

Nuria Homedes
School of Public Health, University of Texas,
El Paso, TX, USA

Médecins Sans Frontières (MSF) – Doctors without Borders – is an international humanitarian aid organization that was founded in 1971 by a small group of French doctors and journalists, headed by Bernard Kouchner who had worked in Biafra during the 1967–1970 Nigerian Civil War. The founders were frustrated with the neutrality that characterized the attitude of the Red Cross during the Nigerian-Biafra conflict and felt the need to create an organization that would provide aid and emphasize and defend the victims' rights.

MSF's values are aligned with the principles of the Declaration of Human Rights of the United Nations, and its mission is to get involved and alleviate the suffering of people. A particular focus of intervention is when there are medical needs that result from violence, torture, warfare, persecution, oppression, natural disasters, epidemics, abandonment, exile, or exodus. MSF defends peoples' right to medical care regardless of race, religion, creed, or political affiliation, and in their view this right supersedes the sovereignty of the state. If necessary, MSF often enters conflict areas to help all victims without the government's permission. Consequently, human rights violations witnessed by its staff are exposed.

MSF believes that denouncing and speaking out about atrocities will raise awareness, educate the public and decision makers, evoke indignation, and eventually promote policy changes that will prevent humanitarian crises. To achieve this goal MSF documents its activities, has partnered with other organizations with a similar mission, and has a strong relationship with mass media (including renowned newspapers, Internet, listservs, speaker's bureau). Most of its publications (reports, documentaries, and videos) are freely available on the

Internet. MSF has also published more than 100 articles in academic peer-reviewed journals.

There are about 27,000 MSF-committed individuals (including doctors, nurses, logisticians, water and sanitation experts, pharmacists, administrators) operating in almost 70 countries and supported by 19 associate organizations distributed around the world (Australia, Austria, Belgium, Canada, Denmark, France, Germany, Greece, Holland, Hong Kong, Italy, Japan, Luxembourg, Norway, Spain, Sweden, Switzerland, United Kingdom, and United States). Each one of these organizations has its own board and a certain degree of independence. The vast majority of MSF aid workers are from the communities where the crisis is occurring, and because they tend to be in remote areas they often capture events that go unnoticed by the established media outlets. In December of each year, MSF publishes a report that describes the top ten humanitarian crises its staff has witnessed.

Eighty-nine percent of MSF's funding comes from private sources, which allows MSF to operate independently of any political, military, or religious agendas. In 2006, MSF had more than three million individual donors and private funders worldwide, and an annual budget over half a billion dollars.

More than half of MSF's programs include the provision of medical care to those affected by armed conflict or internal instability who reside in refugee camps and shelters.

Substantial programmatic effort is devoted to groups of people who experience difficulties accessing health care, even if they reside in stable and economically developed societies. The latter group includes street children, migrants, minorities, displaced people, prisoners, unemployed, drug users, sex workers, and people infected with tuberculosis or HIV/AIDs.

Between 1975 and 1979, millions of Cambodians migrated to Thailand to avoid the Khmer Rouge and MSF set up its first refugee camps in Thailand, and in 1979 they sailed to the China Sea to provide medical services to boat refugees. MSF has provided assistance to victims in many countries including Lebanon, Sudan, Ethiopia, El Salvador, Liberia, Somalia, Mozambique, Bosnia, Herzegovina, Kosovo, Rwanda, Chechnya, Colombia, Haiti, Chad, Democratic Republic of Congo, Ivory Coast, Zaire, Tanzania, Sierra Leone, and India (Kashmir).

For over 15 years MSF has been working with a network of countries (Belgium, France, Greece, Italy, Sweden, The Netherlands, Spain, Switzerland, Malta, and Morocco) on projects related to immigration in Europe, where many immigrants face detention, appalling living conditions and lack of access to health care. MSF has been urging policy makers in Europe to respect the life and dignity of migrants and asylum seekers and improve their access to basic services, including shelter and health care. A key support service has been providing medical and psychological care to those who have survived the journey. MSF also assists migrants in their countries of origin (Somalia, Afghanistan, Democratic Republic of Congo, and Nigeria) and at different stages of their journey. These journeys are often arduous and beleaguered with exposures to communicable and water-borne diseases, violence, and abuse. Unaccompanied minors and women are increasingly among those making the journey and are at increased risk of poor health outcomes.

MSF received the Seoul Peace Prize in 1996 and the Nobel Peace Prize in 1999. These awards recognize the crucial role of MSF in providing access to health care and protecting the human rights of immigrant populations.

Domestic Violence

Sherif Soliman
Department of Psychiatry, Case Western Reserve University School of Medicine, Cleveland, OH, USA

On September 7, 1987, 28-year-old Jian Wan Chen was beaten to death with a claw hammer in her Brooklyn apartment. The man who delivered the eight blows was not a masked intruder, but her husband, Dong Lu Chen. Mr. Chen killed his wife after she admitted to having an extramarital affair. At trial, a defense expert testified that Chinese men commonly threatened to kill unfaithful spouses, out of a sense of inadequacy, but were prevented from doing so by family and friends, whom Chen did not have access to as an immigrant. As a result of this "cultural defense," Mr. Chen's charge was reduced to second degree manslaughter. The judge sentenced Chen to probation for 5 years, the minimum sentence for this offense.

While the last three decades have seen significant efforts to combat domestic violence, domestic violence in immigrants has largely been ignored until the past decade. Whether due to the many barriers they face in accessing services or, as in the Chen case, the dismissal of violence as culturally normal, immigrant women have not received the same protection from domestic violence that native born women are afforded. This entry will review some of the barriers that immigrant victims of domestic violence face in seeking protection and will offer an overview of some available legal remedies.

In deciding to seek help from the authorities in the USA, immigrant women often face disapproving family and friends, fears about the police, and the fear of legal sanction or even deportation. In some cultures, women are taught to play a submissive role, even in the face of abuse. These attitudes are almost always reinforced by the abuser and possibly by his family. The abuser may try to shame the victim's family by spreading rumors about her in close-knit, traditional cultures. Fears of causing the family to break up, of being an inadequate spouse, of being seen as an undesirable partner by other men, or of losing her children are also prominent. Prior traumatic experiences with authority figures in their country of origin also may play a role in preventing women from seeking assistance. Some women have been subject to rape, beatings, and other atrocities by authorities in their countries of origin which will make them fearful of police. For example, former Iraqi dictator Saddam Hussein built "rape rooms."

Once the woman has decided to seek the assistance of the authorities, she will likely encounter language and cultural barriers. In a study of 230 Latina victims of domestic violence, Orloff and colleagues found that only a third of women who called the police were interviewed by Spanish-speaking officers, though nearly all of the women spoke little or no English. Police officers did not interview the victim in one third of the cases, speaking instead with the alleged perpetrator or witnesses. Orloff and colleagues observed that police sometimes use the victim's children or the alleged perpetrator to translate. This can lead to inaccurate information being conveyed and may inflame an already volatile conflict. Police officers sometimes fail to act out of a belief that violence is part of the victim's culture. Therefore, these victims are, in effect, denied the protection that the law would normally afford because of cultural stereotypes.

Even after they are no longer involved in the abusive relationships, immigrant victims face additional barriers. In 1986, Congress passed the Immigration Marriage Fraud Amendment, which mandated that foreign nationals who came to the USA to join their spouses be married for at least 2 years. If the couple was married less than 2 years at the time of immigration, the immigrant spouse was granted conditional residency status until they had been married for 2 years or more. This was intended to combat "sham marriages," or marriages entered into in order to obtain citizenship or permanent residency status. However, it had the consequence of trapping battered immigrant women in abusive relationships for up to 2 years.

Congress attempted to alleviate this problem in 1990 with the passage of the Violence Against Women Act

(VAWA). VAWA included limited relief for battered immigrants. First, it included a Battered Spouse Waiver. Second, it allowed battered women to file a self-petition alleging battery. Third, it established a defense to removal based upon battery or extreme cruelty. A detailed review of the requirements for relief under VAWA is beyond the scope of this entry, but suffice it to say it allows for limited relief and establishes stringent standards for women seeking relief.

Personal protection orders are also available to immigrant victims of domestic violence. Orloff and colleagues recommended including provisions specific to the immigrant's situation in the order. For example, courts may order the batterer not to take the children outside the USA or may order him to surrender the documents the victim needs to complete immigration or social service applications. Thus, protection orders can serve the dual purpose of helping provided for the victim's physical safety while empowering her legally and economically.

Immigrant victims of domestic violence face unique barriers to protection including cultural stereotypes, language barriers, and legal barriers. While VAWA and personal protection orders provide some relief, more protections are needed. Future efforts should focus on bridging the barriers or culture, language, and law so that we can give these victims the same protection afforded other victims of domestic violence.

Dowry

Jaina Amin
Department of Psychiatry, University Hospitals Case Medical Center, Cleveland, OH, USA

There are many customs in marriages across the world; one of them is the giving of a dowry. Europe, South Asia, and Africa have a strong history of giving dowries. Dowries can be cash, gold, goods, or estate. Dowries are given to the groom's family by the bride's family. Historically, this was to ensure that the daughter received some inheritance from her father's estate, as she was not entitled to it upon his death. Dowries are also seen as the wife's financial contribution to the marriage. In some societies a woman's dowry is given back to her if her husband dies, or is given to her children if she dies.

While giving of the dowry started as a well-intentioned tradition, to help the newly wedded bride have some contribution in her new home, over the years it has become a dangerous policy. In India the practice of bride burning has become more prevalent. The husband's family asks the bride's family for more money after their marriage, and when they do not get the extra demand goods they will pour kerosene on the bride and set her on fire. Burning the bride can more easily be passed off as a kitchen accident (compared with poisoning or strangling). Despite the Indian Government's passage of a dowry prohibition act in 1961, Pratap noted that police statistics showed a 15-fold increase in dowry-related deaths from 400 a year in the mid-1980s to more than 5,800 a year in 1995. This increase in the number of cases can be related to the fact that some women are speaking up and reporting this abuse. However, Pratap also notes that police and activists still feel that they are actually only seeing a third of the actual violence secondary to dowry extortions.

Other cultures receive dowries differently. In the Thai culture the prospective groom approaches the bride's family to give a sin sot aka bride's price, to her parents, either on the day of the engagement or wedding. Traditionally, this is a compensation to the parents for losing a set of working hands.

Giving of a dowry has become such a financial burden on families that there are many elective abortions once the sex of the fetus is determined to be female. India banned sex determining tests in the Pre-Natal Diagnostics Techniques (Regulation and Prevention of Misuse) Legislation in 1994. India's 2001 census showed there were only 933 women for every 1,000 men.

The giving of dowries is still practiced in rural, non-educated villages in India, despite government banning of this practice. Continued focus on the bridal abuse and education of the rural public to change this cultural norm will be the only way to eliminate this practice.

Drug Abuse

BEATRICE GABRIELA IOAN
Department of Legal Medicine, Medical Deontology and Bioethics, University of Medicine and Pharmacy "Gr. T. Popa", Iasi, Romania

In the American psychiatric manual, the *Diagnostic and Statistical Manual of Mental Disorders IV*, the term *drug abuse* was replaced with *substance abuse* and, for diagnosis purposes, it is necessary to identify as a maladaptive pattern of substance use resulting in a clinically significant damage or distress manifested by one or more of the following problems occurred over a period of 12 months: inability to fulfill major job tasks, school or home tasks (e.g., repeated absences or reduced work efficiency, absence or expulsion from school, child or home neglect caused by the consumption of a substance); repeated consumption of a substance, in situations where it is physically hazardous (e.g., car driving or machine operation); repeated legal problems arising from the substance consumption (e.g., arrests); and continuous consumption of a substance despite social or interpersonal problems caused or exacerbated by persistent or recurrent substance effects (e.g., domestic violence, physical aggression). In addition, the symptoms have never met the dependence criteria for a substance of the same category.

Drug abuse and addiction are complex phenomena, related to personality, drug, social, and cultural factors. Research conducted in groups of immigrants in the USA and Europe showed that drug abuse issues include: motivation, prevalence, consumption patterns, the significance of drug use, and addressability by specialized medical treatment.

Motivation of Drug Abuse Among Immigrants

The motivation for drug abuse among immigrants is a mix of past, present, and future situations, being often difficult to determine which of these prevails. By giving up their country of origin and by choosing to live in another country, an emigrant must identify the most appropriate coping strategies, drug abuse being often the consequence of choosing ineffective strategies.

Many immigrants are marked by negative experiences from their country of origin, such as armed conflicts, imprisonment, torture, loss of property, or death of close persons. Such experiences may induce posttraumatic stress syndrome, which is commonly associated with drug and alcohol abuse. These are supplemented by the stress caused by immigration, especially the hazards associated with illegal immigration or obligation to spend some time in refugee camps.

The difficult bureaucratic process at the arrival in the host country is a stressor because it induces fear and uncertainty by separation from the family and lack of power. Beside the mandatory bureaucratic procedures faced by the immigrants when entering the new country, they also meet a number of problems such as: stress caused by the new culture, language barriers, discrimination, and financial and social difficulties.

The phenomenon of acculturation, generated by the assimilation of a new culture, the adjustment to the life in a new country with different culture and customs from their homeland often leads to frustration of both first- and second-generation immigrants. Besides cultural differences between home and immigration country, immigrants have to face language barriers that impede their social integration and find a job appropriate to their training. In addition they may be forced to make compromises such as accepting jobs below their education to enable them to meet immediate financial needs especially at the beginning of their life in the host country. Immigrants' frustrations may originate both in society and the family of origin. For example, immigrating to a country with higher living standards and professional opportunities than in the country of origin, parents may have high expectations from children, which the latter cannot reach, thus inducing a strong emotional stress, which leads them to attempt to mitigate the psychological impact of personal failure by abuse of alcohol and drugs. Studies conducted in Sweden, France, and Germany showed that drug abuse among young immigrants is mainly the result of social integration difficulties.

Immigration places a variety of stressors on the individual, their impact on health being conditioned on the one hand by the magnitude of stress, and on the other by personal and social resources that the individual has to cope with stress. The cumulative exposure to major stressors increases the risk of drug abuse and depressive disorders or anxiety. If during the process of acculturation the stress experienced exceeds the individual's abilities to cope and if the individual considers that he/she cannot control the stress, this person may engage in acts of rebellion, delinquency, and drug abuse. Marginalized individuals feel the strongest stress and have the highest risk of drug abuse. It is possible that immigrants are not prepared for the challenges and stressors induced by immigration, these aspects being often underestimated.

Prevalence of Drug Abuse Among Immigrants

A paradoxical aspect when alcohol and drug abuse is recorded both among new and acculturated immigrants is that among the latter, drug and alcohol abuse prevalence is higher and increases as the length of stay in the host country increases. Among Asian immigrants in the USA and, in particular, the second-generation of immigrants (those born in the USA) there has been noticed a more frequent abuse of alcohol and drugs, often as an attempt to escape from family pressure and confrontations related to those parents who have a lower degree of acculturation, and who are largely confined to the culture of their country of origin, thus leading to conflicts between generations.

Studies show that acculturated US Hispanics reported much higher rates of illegal drug use than non-acculturated Hispanics. The greater the length of the Hispanic immigrants' residence in the USA, the more likely they are to engage in drug abuse, particularly tobacco and alcohol. In particular, among Mexican immigrants in the USA there is a higher prevalence of drug abuse and addiction in those born in the USA, compared to the new immigrants. This difference may be attributed to the fact that Hispanic culture has a protective effect against drug abuse, and the significant loss of cultural values by acculturation increases the prevalence of this phenomenon. Low acculturation and greater family support have a protective effect, acting as a buffer against the impact of social stress and/or limiting the exposure to social stressors.

Exposure to American culture increases opportunities for drug use in peer groups, in addition to familiarizing them with the rules or norms of drug abuse. As the young immigrants are acculturated, removing the language barrier, they may communicate more easily with those who have access to the drug environment.

Although the phenomenon of increasing prevalence of drug abuse in direct proportion to the degree of acculturation is supported by a series of research, there are few data indicating the time frame in which immigrants become acculturated and resort to drug abuse.

Patterns of Drug Abuse Among Immigrants

Cultural factors in home countries have a major influence on patterns of alcohol and drug abuse among immigrants, and the type of drug consumed. Abuse of alcohol and drugs is to immigrants a continuation of standards, values, and traditions of home countries, as demonstrated by a series of studies. In the Netherlands, opium trafficking networks, closed in the 1970s with market penetration of illegal heroin, have been reopened by Iranian immigrants who used to consume opium in the country of immigration, thus continuing the home country custom. Alcohol abuse is a problem among immigrants in Europe and usually addictive patterns of home are reflected in addictive disorders related to alcohol in the first generation of immigrants. The strongest predictor of current consumption of opium in South East Asian immigrants in the USA is the opium addiction in the home countries. The same pattern, represented by continuation of drug consumption in the immigration country, was identified among new immigrants arrived in the USA from Cuba, Ethiopia, and Palestine.

Significance of Drug Abuse

The significance of drug abuse in communities of immigrants depends on cultural and religious factors of the home countries, in turn causing the community's response to drug abuse and the degree of addressability to specialized treatment programs. For example, the members of South Asian communities are less involved in drug abuse due to their cultural and religious constraints, so that while alcohol consumption in these communities is quite high, opiate abuse is low. Asian addicts have a higher degree of adherence to their families compared with non-Hispanic White addicts, which facilitates recovery and achieving abstinence. Typically, the Asian immigrant communities use consumption denial techniques because either it is deemed harmless, or the consumption is considered negligible, because it is assumed that young Asians do not use drugs. Denial of the abuse of alcohol and illegal drugs in Asian communities is based on a number of cultural beliefs and the great diversity of ways in which abuse is perceived in different Asian countries. In general, it is considered that the abuse of alcohol and drugs places blame and shame on the individuals and their families, so that Asian families prefer to solve such problems from within the family. In some Asian countries it is considered that alcohol is harmless if it does not induce behaviors that bring shame on the family, and is therefore acceptable for solving personal problems. In other countries, to refuse a drink from a person in a higher position, such as an older relative, may be considered offensive. It is possible that Asians have a particular perception of alcoholism, in that they consider it a sequel of chronic alcohol consumption instead of loss of control over consumption, which may lead them to consider medical intervention useless.

Access to Specialized Medical Treatment

Immigrants use drug-addiction treatment services less than the native population. In the USA, for example, where Asians represent about 4% of the population, less than 1% of addicted enrolled in specialized treatment programs are Asians.

Low access to treatment programs is determined on the one hand by economic and sociopolitical barriers, represented by unfamiliarity with the system, ignorance of how to access these services, unawareness of the existence of such services, or erroneous belief that the treatment programs are intended solely for the native population, and on the other hand by cultural barriers represented mainly by the fact that drug abuse is not considered a problem in the culture from where the individual originates. In addition, community stigma and fear of deportation due to the illegal drug consumption may limit the access to treatment facilities. Therefore, low rate of use of specialized medical services is not due to low prevalence of drug abuse in immigrant communities but to low access to such services. However, studies showed that new immigrants are more receptive to health education and more worried about alcohol abuse, sexually transmitted diseases, and mental health problems than those who are already acculturated.

Drug abuse is largely linked to the transmission of HIV/AIDS worldwide. There are several risk factors for this association: the sharing of contaminated injection needles (UNODC reported that 13.2 million people use injectable drugs, and about 10% of HIV cases are caused by the use of injectable drugs), risky sexual behavior in individuals who were under the influence of drugs (drug abuse can lead to impaired reasoning and decision making), which increases the prevalence of sexually transmitted infections; acceptance of risky sexual behaviors by non-injectable drug users in order to obtain money for drug procurement; and HIV transmission to children born by drug-addicted and HIV-infected mothers. Research showed that retention in drug treatment programs is positively correlated with reduced risk behaviors for HIV transmission and it reduces the rates of HIV seroconversion. Therefore, treatment for drug abuse is an important and effective strategy to prevent HIV infection. As a consequence, the best way to increase access of immigrants to such services must be identified. A study on the use of services for drug-addiction treatment by Asian immigrants in the USA has shown that the key to Asian immigrants increased access and retention in the specialized medical programs is the provision of services in their native language and training of the medical staff for the purposes of sensitivity to their cultural traditions and the problems they face through immigration in a foreign country.

Drug Use

Mihaela-Catalina Vicol
Department of Bioethics, University of Medicine and Pharmacy "Gr. T. Popa", Iasi, Romania

Drug use represents a major problem in the world. The European Monitoring Centre for Drugs and Drug Addiction (EMCDDA) showed that in 2006, 65 million adults have consumed cannabis at least once (20% of the adult population), 10 million adults have consumed amphetamine at least once (3% of the adult population), and 8.5 million adults have consumed ecstasy at least once (2.6% from the adult population). In addition, in Europe there are approximately 7,000–8,000 drug-related deaths per year, comprising almost 3% of all adult population under-40 deaths. Since 2000, many European Union countries have reported a drop in drug-related deaths. However, during 2004–2005, this tendency has not been maintained and the number grew significantly. Alarmingly, the percentage of youth who died in relation to drug use has grown.

The incidence and prevalence of drug use in the United States is also growing. According to the National Institute in Drug Abuse's (NIDA) comparative statistics, in 2004, 7.9% of the population aged 12 and over was using drugs. The consequences of drug use are felt upon several levels. At the medical level, the prejudices are enormous upon both physical and psychological health, with short-term and long-term implications. At the social level, drug use often leads to job loss and loss of friends. It may also involve antisocial activities, including robbery and crimes of violence. At the educational level, drug use may foster a model for children, so that they may become the next drug users.

There are several categories of populations identified as more vulnerable to drug use. According to the EMCDDA 2003 Report, social exclusion, defined as "a combination of lack of economic resources, social isolation, and limited access to social and civil rights," is a key factor in drug use. This underscores the dual relationship between drug use and social exclusion. These elements interact in the following manner: drug use can lead to social exclusion and social exclusion can lead to drug use. Populations considered vulnerable for social exclusion and, so, for drug use are: immigrants, prisoners, the homeless, sex workers, and vulnerable young people.

Immigrants are particularly susceptible to drug use for a number of reasons. Some immigrants are undergoing a process of psychological distress regardless of the degree of self-motivation or self-preparation for the process of migration or of the circumstances. The migration process may involve experiences that could be traumatizing and could place the immigrant at risk for drug use/abuse. The phases of the migration process including premigration, departure, transition, and adaptation may foster experiences such as removal from friends, family, birth place, the feeling of being lost, anxiety, and the feeling of not belonging anywhere. Immigrants may cope with the stresses caused by the mismatch between their hopes and expectations and the realities of life in their new home by using drugs or alcohol. The background of immigrants such as traumatic experiences like war or torture may be related to subsequent drug use. Also the new country's social attitude toward them plays an important role in making immigrants vulnerable for drug use, such as marginalization and lack of social support. Immigrants' illegal status, their low income, and reduced access to healthcare system may foster not only drug use, but also it may assure the continuity of the process, without the possibility of treatment. The World Health Organization Report of 1996 points out that the consumption of drugs such as tranquilizers and antidepressants among young immigrants in Europe is growing.

To stress the importance of the phenomenon upon immigrants and also to examine the impact upon their health, immigrants' drug use has been compared in different countries to the native population's drug use. One study describes drug use in Russian immigrants in Israel. Before 1989, drug use in Israel was more common among people having origins in Morocco and Tunisia, their drug of choice being heroin. The drug user's typical profile was age between 18 and 30, low economic status, and low level of education. Since 1989, there has been an increase in immigrants from the former Soviet Union in Israel. With this phenomenon, the drug user's typical profile changed to be mainly Russian in origin. The drug administration pathway is now mainly intravenous injection, and in 20% of cases it involves women.

Drug use has an impact on immigrants' health. Intravenous injection brings HIV and hepatitis risk. Risk related to overdose death also grows.

Other findings are reported in Greece. In this country two "waves" of immigrants have been registered, the first one dominated by Albanians in the early 1990s, and the second one after 1995 from the Balkan region and Middle East, including Pakistan, Iran, Iraq, and the former Soviet Union. From 1993 to 2001 there was a significant growth in drug-related deaths in which foreign-born persons were involved. A study of drug use among immigrants in Greece describes some interesting findings. There was no difference between the natives and foreign-born population in preferred drug (heroin), but there was a significant difference regarding the administration pathway. Natives used the inhalant and the oral methods, while the immigrants used the intramuscular injection with more persons using the same needle and syringe. Immigrants were initiated into drug using at an older age than the native-born population, and those immigrants advanced faster than the native-born population in the intramuscular drug use. Compared to native-born citizens (13.7%), more immigrants had been registered without even having knowledge of the risks of taking and the consequences of AIDS infection (26.4%) through using the intravenous administration of drugs with the same syringe and needle. Another significant difference is lower use of the healthcare system among immigrant groups compared to natives.

A study of immigrants in the Netherlands showed that the preferred drug was a morphine type drug. Male and female immigrants from Turkey along with female immigrants from Morocco had a lower risk of first administration than male immigrants from the Dutch Antilles and Surinam and female immigrants from Germany.

Another study conducted by the Department Of Health And Human Services Substance Abuse and Mental Health Services Administration (SAMHSA) on immigrants and substance use (1999–2001) revealed that during the past month marijuana use was lower among foreign-born individuals living in the United States (1.7%) than among US-born persons aged 18 or older (5.1%). For adult immigrants, rates of substance use were generally higher among males than among females, and rates were higher among immigrants who had been in the United States for fewer than 5 years than among those who had been in the United States for 5 years or more. Prevalence rates also were generally higher among immigrants aged 18–25 compared with persons aged 26–49 or those aged 50 or older. Some differences have been observed on the different kinds of immigrants in the USA. For example, past month marijuana use rates were higher among immigrants from Mexico (0.9%), Puerto Rico (2.0%), El Salvador (1.4%), and Jamaica (5.5%) compared with immigrants from Cuba (0.2%). Foreign-born US residents from Mexico (2.3%), Puerto Rico (4.7%), and Jamaica (6.4%) had higher past year marijuana use rates than those from Cuba (0.8%) or El Salvador (1.8%). The prevalence rates for any illicit drug use for both the past month and past year were higher among persons immigrating from Puerto Rico (7.7% and 13.6%, respectively) when compared with past month and past year rates for persons from Mexico (2.2% and 5.5%), Cuba (0.5% and 2.6%), or Colombia (2.1% and 4.9%).

These studies draw attention to several facts regarding immigrants and drug use. First, the growing number of immigrants contributes to the proportion of drug users. Second, though most of the time, the drugs of preference are similar among native-born and immigrant populations, the administration pathways may differ, with consequences on immigrants' health in relation to their habit of sharing needles and multipersons syringe usage. If there is reduced access to information about diseases like AIDS or hepatitis and reduced access to healthcare, the potential for serious health consequences are encountered. Last, but not least, immigrants represent a vulnerable population on drug using for many reasons and special supports should be developed.

E

East Asians

Christopher J. Lockey
Division of Public Psychiatry, Oregon Health and Science University, Portland, OR, USA

East Asian immigrants are among the fastest growing minorities in the USA. This is a heterogeneous population that includes people who have been represented in the USA for generations. The US census reports that between 1980 and 1990 the total number of East Asian immigrants living in the USA grew from 960,000 to 1,800,000. (For the purposes of this paper, East Asia includes China (with Hong Kong, Macao, and Taiwan), Japan, and Korea (north and south).) This was 10% of the total US immigrant population of 19.8 million in 1990. In 2000, the number had more than doubled to 4.3 million, representing 42% of the total Asian immigrant population and 1.5% of the total US population. The Chinese percentage of East Asian immigrants grew to 56%, followed by Koreans 25% and Japanese 19%.

In part because of data collected on average income and education, East Asian immigrants are stereotyped as socioeconomically successful. In reality, this is a diverse group that varies in terms of educational and economic status, and in degrees of assimilation. For example, although the average income of Asian immigrant families is higher than the US average, the poverty rate of all Asian immigrants in 1999 was 12.6% compared to the US average of 12.4%, and unemployment was higher. The largest group of East Asian immigrants – those from China – had a poverty rate of 13.5%. In comparison, the poverty rate of Japanese immigrants was 9.7%.

In moving to another country and part of the world, immigrants face logistical, social, employment, educational, and political challenges. Given the diverse gender and family role expectations in the USA, conflicts within marriages and families develop. This is exacerbated by loss of direct contact with family members and support networks in native countries. They also face higher unemployment and job discrimination, and often have to accept jobs that do not suit their experience and education. The reasons for emigrating from their countries vary and include political persecution. These stresses along with the stress of navigating a fractured and complicated system of health care can significantly impact health and well-being.

Health care workers should be familiar with health issues facing East Asian immigrants. The countries from which East Asians immigrate have different approaches to health care. Korea and Japan have universal health care though their systems reach that goal differently. Both have single systems, government funded and administered, but Japan has multiple insurance plans from which citizens can choose. Except for Taiwan, China does not have universal coverage. These differ from the US system in which employer-based insurance is common, multiple private insurance carriers exist, and a substantial percentage of the population lacks insurance.

Since 1945 East Asian health care has been influenced heavily by Western medicine; however, traditional practices continue to play a role. For example, most Chinese immigrants believe that herbal medicines are the most effective treatment for high blood pressure. A study done at Stanford Medical Center showed that 100% of Chinese immigrants use self-prescribed traditional Chinese medicine at least once during the year. Forty-three percent of those self-prescribe weekly and only 5% reported that their regular physicians asked about it. Affluent immigrants were more likely to have health insurance and use Western medicine instead of traditional practices.

Along with traditional practices, it is important for health care workers to know that within this population,

Sana Loue & Martha Sajatovic (eds.), *Encyclopedia of Immigrant Health*, DOI 10.1007/978-1-4419-5659-0,

medical decisions are often made in the context of social and family concerns. The focus is on family and social groups rather than the individual. For example, because native foods are often central in an immigrant population, symptoms of diabetes and its treatment strategies can challenge dynamics about nutritional practices and family role. Studies demonstrate that social support can be critical for successful health care visits and treatment adherence.

There are unique mental health, medical, and genetic problems in East Asian immigrant populations. Psychiatric symptoms are likely to manifest as physical complaints such as fatigue and upset stomach, and may be overlooked by primary health care practitioners. Depression is prevalent in older immigrants and is linked to numerous factors including the strength of family relationships and English proficiency. Degree of acculturation has been shown to be inversely associated with level of mental distress. For example, the more an individual is assimilated into US culture, the less impact a negative life event will have on his or her mental health.

East Asian immigrants are less likely than the general US population to seek psychiatric services for mild to moderate mental illness and overall, mental health services tend to be underutilized. Although they are just as likely to seek services for severe mental illness, their suicide rates are substantially higher than their US-born counterparts. Interestingly, children of East Asian immigrants are just as likely to seek psychiatric services as the general US population. Studies show that barriers to mental health access include language barriers, financial limitations, lack of knowledge, and perceived stigma.

Although East Asian immigrants have lower rates of smoking, drinking, obesity, and have healthier diets, Chinese and Japanese immigrants have a lower life expectancy than their US-born counterparts. Although there are little data to explain these findings, there are data about mortality rates from cancer. Japanese and Chinese immigrants have different mortality rates from cancer than their US counterparts. Mortality rates from lung, stomach, cervical, and liver cancers are higher whereas mortality rates from prostate and breast cancers are lower. In Japanese immigrants, the incidence of stomach and rectal cancer is higher than the general US population, and in Chinese immigrants the incidence of nasopharyngeal is higher. A study in Canada showed that Asian immigrants are less likely to get Pap smear screens in part because of lack of necessity and time.

There are infectious diseases that are more common in Asian populations than in the general US population. For example, hepatitis B, parasitism, and tuberculosis are all more common in Asian immigrants than in the USA.

The risks of disability and chronic disease increase with the amount of time East Asian immigrants are in the USA. With economic development, nutritional changes and a more sedentary lifestyle, diabetes and obesity rates have increased. This has put more at risk for heart and kidney problems and cancer. A recent study showed that Japanese immigrants with similar levels of obesity to their Japanese counterparts are 2–3 times more likely to develop diabetes. This suggests that mainstream US diet may contribute directly to diabetes and coronary artery disease in Japanese immigrants.

Some of the more prevalent genetic disorders are the blood disorders called beta and alpha-thalassemia, and hemoglobin E. These cause the formation of abnormal blood cells and are found in South Asian and Chinese immigrants. Other disorders include glucose-6-phosphate dehydrogenase deficiency (primarily male disorder that causes blood cell breakdown) and lactose intolerance. A study found that 76–92% of the adult Chinese population is lactose intolerant. In areas of the USA with a high concentration of Asian immigrants, the incidence of the diseases caused by these disorders is higher and it is important to counsel couples who are considering having children.

These are some of the important health issues facing East Asian immigrants. Health care workers in countries with East Asian immigrants should be aware of the cultural and social traditions and unique health care concerns of this population particularly if they are recent or older immigrants. Being familiar with this and the cultural barriers to accessing health care services will help ensure safe and effective care of a rapidly growing minority.

Eastern Europe

Amy N. Sharpton
Department of Veterans Affairs, Louis Stokes DVA
Medical Center Cleveland, Brecksville, OH, USA

History

The distinction between Eastern and Western Europe can be traced to the history of the Roman Republic. As the Roman Empire grew, a cultural and linguistic separation appeared between the mainly Greek-speaking eastern provinces and the Latin-speaking western territories. This cultural and linguistic division was reinforced by the political division of the Roman Empire and was buttressed by a number of events during Late Antiquity and the Middle Ages. In particular, the Great Schism that formally divided Eastern and Western Christianity enhanced the cultural and religious distinctiveness between Eastern and Western Europe.

Boundaries

Rarely are the boundaries of global regions defined by objective geographical criteria; more often the margins fluctuate with expert opinion and context. Currently, there are a variety of ways in which Eastern Europe is defined; most characterizations are aligned with a particular cultural or political position. Current descriptions lack precision, with growing debate even among political scientists. The United Nations Statistics Division records Eastern Europe as comprising the nations of Bulgaria, Czech Republic, Hungary, Poland, Romania, the Russian Federation, Slovakia, and the Slavic republics of Belarus, Moldova, and Ukraine. Frequently, the term "Eastern Europe" is used to refer to all European countries that were governed previously by communist regimes. This territory is known collectively as the Eastern Bloc, in reference to the concept of an "Iron Curtain" separating Western Europe and Soviet-controlled Eastern Europe throughout the period of the Cold War. Prior to German reunification, East Germany was usually included as an Eastern European country.

Geography

Eastern Europe features many steppe, forest, lake, and tundra regions, as well as a humid continental-type climate with cool summers. Generally, the region is considered to be bordered by the Baltic and Barents Sea on the north; the Adriatic, Black, and Caspian Seas and the Caucasus Mountains on the south; and the Ural Mountains on the east. The western area of the region is comprised mostly of glaciated plains. The west central section is dominated by mountains and highlands and with structural basins between the highlands. The eastern section of the region is characterized as a large, relatively flat, stable, geologic plateau. The northeastern portion of Eastern Europe features lakes and glacial ridges. The region is highlighted by a multitude of major rivers, including the Vistula, Danube, Volga, Dnepr, Don, Elbe, Rhône, and Ural.

Ecology

In the recent past, Eastern Europe has been plagued by ecological concerns. In the mid-1990s, the Polish Academy of Sciences described Eastern Europe as the most polluted region in the world. Throughout that decade, many countries in the region began to evaluate their ecological situations and discovered a lack of effective pollution control systems. In some cases, cities were without wastewater treatment systems, allowing raw sewage to flow into the rivers. In some areas, fruits and vegetables grown in the polluted soils were feared to be toxic to humans and portions of rivers no longer supported aquatic life. As a result, environmental rehabilitation was made a priority throughout the region.

Culture

While there is some continuity, the countries of Eastern Europe have their own unique traditions that continue to be observed today. Frequently, these customs originated thousands of years ago when nomads and farmers began to populate the region. The traditions that are practiced today combine ancient pagan rituals relating to the seasons and agricultural cycles with the holidays of Christianity (often Eastern Orthodoxy), and even the festival celebrations of the former Soviet Union.

Economy

Manufacturing is critical to Eastern Europe's economies. The Czech Republic is the leading industrial nation in the western section, while Ukraine, the Ural Mountains, and the land along the Volga River are the major urban-industrial regions in the east. However, many of the former Soviet-controlled nations are dealing with excessive pollution and significant environmental issues due to lax industrial controls that prevailed during the Soviet era. Eastern Europe boasts many commercial forests and agricultural areas, although the growing season in the north is short. The Danube Valley countries produce corn and wheat; by proportion of the total Danube basin area, these countries include Germany (7.5%), Austria (10.3%), Slovakia (5.8%), Hungary (11.7%), Croatia (4.5%), Serbia (10.3%), Bulgaria (5.2%), Moldova (1.6%), Ukraine (3.8%), and Romania (28.9%). Rye, potatoes, and livestock are important commodities as well. Known for years as the "Breadbasket of the Soviet Union," the Ukraine is one of the most important wheat producers in Europe. Eastern Europe's major mineral resources are coal, iron ore, petroleum, natural gas, and bauxite.

Migration

History

At the end of World War II, the Soviet Union occupied most of Eastern Europe and part of Central Europe. Longing for independence, more than 15 million citizens of Soviet-occupied Eastern European states emigrated to the West in the immediate 5 years following World War II. Until the early 1950s, the lines between German occupation zones could be crossed easily; the number of Eastern Europeans applying for political asylum in West Germany was 197,000 in 1950; 165,000 in 1951; 182,000 in 1952; and 331,000 in 1953. As a result of limited resources and space in West Germany, in 1952 the United States responded to a request by President Harry Truman and increased its resettlement admissions quotas under the United States Escapee Program (USEP).

The migration that occurred between 1945 and 1950 represents the largest movement of any European people in modern history. Considering ethnic Germans alone, at least 12 million fled or were expelled from Soviet-occupied territories that would become the Eastern Bloc. It is estimated that at least two million perished during the exodus, with roughly 25% dying from physical force. An additional four million ethnic Germans were prevented from leaving Soviet-occupied Eastern Europe or were deported to remote areas of the Soviet Union.

During the period 1950–1990, most east–west migration stopped as a result of a restrictive Soviet approach to controlling national movement. However, some migration persisted, both within and from the Eastern bloc states. For example, after the Hungarian Revolution of 1956; 171,000 Hungarian refugees crossed the border into Austria and an additional 20,000 refugees crossed into Yugoslavia. Most of the east–west flow that remained took place between East and West Germany, as the lines between

Soviet-occupied eastern Germany and the western-occupied zones could be crossed easily in most places until 1952. More than 3.5 million East Germans emigrated to West Germany before 1961; this flow comprised most of the total net emigration of 4.0 million emigrants from all of Central and Eastern Europe between 1950 and 1959.

On August 13, 1961, construction of the Berlin Wall began, a barrier erected by East Germany that separated East and West Berlin. Thereafter, only 5,000 persons crossed the Berlin Wall between 1961 and 1989, and the total net emigration from Central and Eastern Europe fell even further to 1.9 million between 1960 and 1969 and 1.1 million between 1970 and 1979. The numbers increased to 2.3 million between 1980 and 1989, owing to increased ethnic emigration. In fact, more than 75% of those emigrating from Eastern Bloc countries between 1950 and 1990 did so under agreements for ethnic and religious migration. Examples include emigrants from Bulgaria (ethnic Turks and other Muslims), Poland (ethnic Germans, ethnic Hungarians, and Jews), Romania (ethnic Germans, ethnic Hungarians, Jews), and Yugoslavia (ethnic Turks and other Muslims). The majority of Soviets permitted to emigrate during this period were ethnic Jews.

Recent Migration Trends

The Schengen Agreement, a treaty signed in June 1985, gives citizens of the European Union (EU) member states and their families the right to live and work anywhere within the EU. A large proportion of immigrants in western European states have emigrated from former Eastern bloc states. Geography, language, and culture have helped shape-specific migratory patterns. For example, there are large numbers of Polish expatriates living in the United Kingdom and Ireland, while many Romanians have chosen to settle in Spain and Italy.

Of particular concern in recent migration trends is a high level of human trafficking from some of the Eastern European countries. Central and South Eastern Europe (CEE) are reported frequently as an origin from which are taken victims of human trafficking. As compared globally, four countries rank very high as origin nations. These are, in alphabetical order, Albania, Bulgaria, Lithuania, and Romania. Among countries ranked high are the Czech Republic, Estonia, Hungary, Latvia, Poland, and Slovakia. According to the United Nations, trafficked victims from countries in Central and South Eastern Europe are reported to be trafficked mainly to Western Europe. Germany, Italy, the Netherlands, Greece, the United Kingdom, Belgium, Austria, France, and Spain are reported frequently to be destination countries for victims from the CEE. Poland, Bosnia and Herzegovina, and the Czech Republic are countries within the region that are reported to be destinations for those trafficked from countries in Central and South Eastern Europe.

Brain Drain

Switzerland's Federal Office for Migration reports that Eastern bloc countries are seriously affected by this ostensible brain drain – as over the past decade Bulgaria has lost to emigration approximately 20% of its educated residents. Even more staggering are figures from Armenia, from which it is estimated that 30–40% of the population emigrated over the same 10 year period.

Migration Policy

Free movement of EU nationals is an important aspect of regional migration policy and has resulted in significant political tensions between some EU countries. For instance, tensions have arisen between Italy and Romania, as Italy has expressed the intention of restricting free movement – contrary to treaty obligations and the jurisprudence of the European Court of Justice.

Education

Carolyn Leung Rubin[1], Phitsamay Uy[2]
[1]Tufts Medical Center, Boston, MA, USA
[2]Graduate School of Education, University of Massachusetts-Lowell, Lowell, MA, USA

Toward the end of the twentieth century, globalization has changed the face of cities and towns across the world. The racial and ethnic compositions of today's schools also reflect changing demographics. For example, in Europe, the largest immigrant student group is Turkish and in the United States, the largest immigrant group is students from Mexico. With the massive movement of people and resources across the globe, immigrant scholars are examining how receiving nations view the new immigrant students and in turn how they prepare them to be successful global citizens.

Here, we will discuss the major education issues facing school administrators and teachers who teach immigrant students. Because educational systems vary greatly across nations, we will not be able to do justice in explaining the intricacies of each country. Instead we will discuss the major educational issues shared by all receiving nations and then highlight those issues in the United States which has the highest immigration rate of all countries.

Major Education Issues

Schools around the world face common educational challenges related to language access, the achievement gap, teacher preparation, and curriculum development. In the past, publicly funded schools were seen as the mechanism by which immigrants could shed their native language and acculturate to the styles and habits of the receiving country. Issues of language proficiency, different cultural models of communication, and different parenting styles are a few of the issues that teachers and administrators struggle with daily. Research has also shown variable differences in educational outcomes between immigrant students and their middle-class native counterparts.

In addition despite their good intentions, many teachers are not equipped with the cultural sensitivity and background experience to effectively teach immigrant children. In fact, some research has found that teachers hold stereotypical beliefs of immigrant children and they have little understanding of how racism and discrimination impact them. Asian American children, for example, are seen as the "model minority." Children from this background may be assumed to be good in math and science and assumed to not have problems in school. Ignorance of student backgrounds can translate into a "color-blind" philosophy that, in essence, serves to deny a student's cultural heritage.

Another factor that may influence student outcomes is the family's migration experience. Children of immigrants have varying migration patterns. These demographic differences between past and present immigrants have several implications for schools and education. Today's immigrants are more likely to have global and transnational identities and lives. These immigrants tend to maintain an active connection to their country of origin. They frequently travel back and forth between the receiving country and their native country, and many send remittances back to their country of origin. Because of these patterns, children may miss long periods of school as they travel with their families. Some parents stay in their native country, but send their children to the United States and other developed countries to provide their children with better educational opportunities.

Because immigrants are part of a transnational workforce, families may move from town to town in search of better economic opportunities. Moving from town to town causes a disruption in their children's education. Under these circumstances, children can be transferred from school to school. Frequently, their records do not immediately follow them and these children are, in essence, getting an incomplete education for that year. This can also make it difficult for children to make lasting bonds with teachers and peers, relationships that have been shown to have a positive impact on educational outcomes.

Immigrant communities are extremely heterogeneous, though they share common characteristics. When working with immigrant children, it is important to understand their specific background and life circumstance especially since these diverse factors impact their academic careers. Immigrant populations span the range on different indicators of quality of life, economic, and educational achievement.

The receiving context in which immigrant children find themselves also has a significant relationship on their school experience. Immigrant children can find themselves in ethnic enclaves or in communities where they are one of few immigrant families. The schools, however, in either type of community may not be equipped to handle immigrant students. They may lack the linguistic and cultural resources to provide support and help.

Immigrant scholars have pointed to generational status as a strong indicator of academic achievement. Generational status is connected to age and education background prior to coming to the host country. Combined, these two indicators influence academic success. Many 1.5 generation children (i.e., children who immigrate at a young age) may have had schooling in their home country, but that education could have been disrupted by war and time spent in the refugee camps. Similarly, an immigrant child who arrives as a teenager may have had only an elementary school education from their native country. Oftentimes, the quality of education the immigrant students receive in their country of birth varies greatly from the quality of education of their host country.

For undocumented children, the challenges are many as well. They face all the challenges of other immigrant children and they have the added fear of deportation of themselves and their families. Though schools are not legally required to ask for status, this fear can permeate students' lives. These challenges are exacerbated by the fact that undocumented children cannot always access social services designated for the community without proper documentation.

The US Educational System

Public School Enrollment

Due to post-1965 immigration patterns, Latin Americans and Asian Americans are the two fastest growing ethnic groups in the United States. Between 1990 and 2000, the US Latino population grew by 58%, from 22 to 35 million. Since 1990, there has been a 72% increase in Asian American residents in the United States (US Census Bureau 2002). This increase in immigration from Latin America and Asia has affected public school enrollment. For example, in 2006, about 49 million students were enrolled in public elementary and secondary schools compared to the 30 million enrolled in 1990 (i.e., a 63% change). Of the 49 million students, 34 million were enrolled in prekindergarten (pre-K) through grade 8, and 15 million were enrolled in grades 9 through 12. Of this population, 56% of the students are White compared to the 15% Black, 21% Latino, 4% Asian and Pacific Islander, 1% Native American Indian, and 4% Multiracial.

Linguistic Access/Bilingual Education/ESL

Language access is one of the most important issues for immigrant children. According to the US Department of Education, there are 5.5 million English language learners (ELL) in the US public school system. The number one language spoken by English language learners is Spanish, followed by Vietnamese and Hmong. English language learners face many barriers to attaining educational success. Because many of their parents are not proficient in English, these children do not have assistance with homework, school projects, and communicating with school personnel. Because of this, immigrant children depend on their teachers, yet not all teachers are qualified to teach ELL students. Less than 3% of teachers instructing ELL learners have a degree in English as a Second Language or a degree in Bilingual Education. Oftentimes, ELL students find themselves misdiagnosed as special education students. Their limited English proficiency is categorized as a learning disability and they are placed in special education. Not only do ELL students face the rigor of learning the English language but they also face the challenge of learning the academic subject matter. Only 8% of ELL students receive extensive instruction designed to meet their learning needs. This translates into less than 10 hours per week of academic content. Research from the National Center of Educational Statistics shows that in order for ELL students to understand content they must have at least 25% of instructional time in their native language.

One policy challenge of teaching immigrant students is how to teach these students English and academic subject areas. While immigrant students are found across the United States, there is no one accepted way of teaching ELL students. There are a variety of methods including English as a Second Language, transitional bilingual education, two-way bilingual education, English immersion, and pull-out. How to teach ELL students is a contested battle. During the 1990s, residents of California, Arizona, and Massachusetts voted for state initiatives to end bilingual education.

Culturally Relevant Pedagogy

Many teachers are not prepared to teach a largely multicultural student population. The less teachers understand students' backgrounds, the lower the students' outcomes. Only 56% of teachers have taken a multicultural education course. Oftentimes, multicultural education takes the form of "heroes and holidays," which while important, can be a superficial way to address issues of diversity in the classroom. Instead of using "heroes and holidays," teachers can use interdisciplinary lesson planning and thematic learning in the curriculum. In other words, multicultural education is not taught in certain months but infused throughout the year-long curriculum. For example, a teacher using culturally relevant pedagogy for immigrant children must find examples from students' own culture and connect it to the content learning inside the classroom.

This strategy also helps immigrant children see school as a safe space for them to learn and grow. Too often, immigrant children feel a disconnect between their home culture and their school culture. For example, Lao children may grow up in a family where they are not expected to look teachers in the eye or question the teacher's authority. This cultural norm goes against the prevailing school practices that encourage students to speak out in class and seek help. Sometimes teachers misinterpret the silence as lack of comprehension of material. Teachers must learn about the culture that students come from in order to provide appropriate support.

Teachers who buy into the philosophy of "colorblind" deny the immigrant student's ethnic identity. In doing so, they are not capitalizing on the richness of culture that a student can bring into the classroom. They silence the child's voice when they do not connect their home life to their school life, sending a message that their home culture is not as important as what they are learning in school.

Gendered Experiences

Over the years, patterns of gender differences have been observed in educational outcomes and engagement of immigrant students in the US school system. Some immigrant children come from cultures that are patriarchal and where women have fewer opportunities than in the United States. While there are examples of strong women in their native country, many girls find increased opportunities through schooling in the United States and other developed countries. In the United States, most immigrant parents are hopeful and supportive of their daughters' academic pursuits. Coupled with the support of their parents, many females with higher aspirations and expectations have been able to achieve academically. These girls view school as a means to getting a better job and future.

In contrast, while girls may express their femininity through good behavior at school, boys sometimes prove their masculinity through defiance of authority and school culture. Boys are often characterized as "antagonistic" and "oppositional" by school personnel. With fewer opportunities to learning, boys see a lack of connection between school and work. Other factors such as gender role socialization and previous life experiences also predict education attainment. For example, early incarceration for boys and early childbearing for girls become negative turning points in their life trajectory.

Access to Higher Education

Immigrant young adults face challenges to accessing higher education. Many immigrant students from low-income backgrounds cannot afford higher education. Additionally, undocumented immigrants are not considered in-state residents and must pay out-of-state tuition. They are not eligible for any state or federal financial aid. In some states, though, the DREAM

(Development, Relief and Education for Alien Minors) Act has made higher education possible for countless immigrant children. The purpose of this legislation is to help immigrant children realize the American Dream by providing access to education. In states like California, Texas, and New York, undocumented immigrants became eligible to attend state-run higher education institutions and pay in-state tuition. They also received access to state and federal grants and loans, many private scholarships and work-study. Upon successful completion of college, these students are automatically eligible for citizenship.

Filling out the Free Application for Federal Student Aid (FAFSA) proves to be a huge deterrent to higher education for many immigrant students. Many do not know about the FAFSA or do not have family members who can help them fill out this form. Because they are unaware of financial aid, they may elect to go to a community college because it is more affordable.

Another problem facing immigrant students once they gain access to higher education is their academic readiness. Due to the inappropriate academic preparation, immigrant students do not find themselves competitive for universities. Many schools in low-income neighborhoods do not offer honors, advanced placement, or elective courses. Without taking these kinds of college preparatory classes, immigrant students sometimes find themselves at a competitive disadvantage when they apply for college.

The Achievement Gap

Contemporary discussions of the “achievement gap” in the United States are at the forefront of education debates, but it can be difficult to have, as there is not a universal way to talk about who is actually dropping out of school. The National Center for Education Statistics uses three definitions, that is, event rate (percentage of students who drop out in a single year), status rate (percentage of students in a given age range who drop out), and cohort rate (percentage of a single group of students who drop out over time). Given limitations in all these rates, the actual drop-out number may be even higher and are inconsistent across schools and states.

Early studies of immigrant children indicated that these children are performing as well, if not better, than their native-born counterparts. Immigrant children showed comparable rates of attending college as well as high school graduation. These perceptions, however, mask both inter-group differences and more recent trends in education. Dropout rates can differ within groups by gender, ethnicity, and nativity (see Table 1).

Education. Table 1 Number of status dropout rates of 16–24-year-olds by gender, nativity, and race/ethnicity

		Total	Native	Foreign born
Whites	Male	6.8	6.8	6.3
	Female	5.3	5.4	4.4
Blacks	Male	13.9	14.3	8.7
	Female	8.9	9.1	6.6
Hispanic	Male	23.7	13.3	38.9
	Female	15.7	9.6	28.0
Asian	Male	3.0	2.6	3.5
	Female	2.9	1.8	4.0
Pacific Islander	Male	9.5	8.0	13.5
	Female	5.6	2.5	10.8
American Indian/ Alaskan native	Male	16.2	16.3	[a]
	Female	14.3	14.4	[a]
Multiracial	Male	8.4	8.8	3.5
	Female	6.7	6.9	4.2

[a]No data is available

Source: National Center for Education Statistics, Institute for Education Science, 2007 Current Population Survey.

Standardized testing indicates that there is an achievement gap between White students and students of color. National statistics show that one-third of all high school students drop out of high school before their senior year. The actual number may be even higher, given that some students drop out in middle school. A higher percentage of boys than girls drop out of high school and this pattern is found across racial/ethnic groups.

Almost 24% of Hispanic students drop out of school. Of this group, there are large differences between native-born and foreign-born Hispanic students as well as males and females. Dropout rates for Hispanic female students born in the United States are approximately 10% whereas Hispanic male students born in the United States have a 13% dropout rates. These figures are larger for foreign-born Hispanic students (i.e., approximately 28% and 29%, respectively). These numbers still, however, may not capture the full picture because of various factors (e.g., lack of disaggregated data, inconsistent data collection, and time of dropout.)

These dropouts are disproportionately students of color, primarily from Black, Latino, and working-class immigrant backgrounds. Fifty-five percent of all Hispanics over the age of 25 have completed high school compared to the national average of 82%. Hispanic students typically find themselves concentrated in low-income, urban areas in schools without the proper resources to provide them with equal educational opportunity.

The Role of Parent and Family Engagement

Because family engagement is seen as a key strategy of school reform, it is important to understand the context for immigrant parent and family engagement in education. One in five children in the US public school system has at least one foreign-born parent. Because today's immigrants are increasingly from working-class backgrounds, the education experience of parents in their native country is often limited. Foreign-born parents may bring different cultural beliefs about schools than do native-born parents. Foreign-born parents may expect that the classroom teacher be the experts on their children's education. Parents repeatedly defer to teachers on academic decision-making and see their role as providing for their children's basic needs and helping to preserve the student's cultural heritage. As such, parents do not always challenge teachers or actively participate in parent–teacher meetings. At the same time, immigrant parents can have high expectations for their children. They want their children to achieve more than they have and achieve upward mobility in society. This expectation fuels their "immigrant optimism," a belief that they can come to this country, work hard, and achieve a better life than they had in their home country. This immigrant optimism is prevalent in the first-generation, but less so in the second- and third-generation immigrant students. As a result, we can see decreasing academic motivation in later generations of immigrant children.

While the first generation often has "immigrant optimism," with each successive generation, immigrant children become more aware of racism and discrimination in the school system. Some of these children of immigrants will actively resist assimilation and assume an oppositional stance toward schools and teachers.

Immigrant children find themselves acting as cultural brokers for their families. They may shoulder the burden and responsibility of being the family translators when parents are not fluent English speakers. Sometimes they have to miss school in order to go with their parents to a doctor's appointment or the utility company to provide the translation.

Because of different messages that they receive at home and at school, immigrant children face a disconnect between their home culture and the school culture. Immigrant children may adopt one identity at school and a different one at home. In essence, they are forced to "code-switch" between these different spheres. These students are navigating multiple systems and multiple cultures and they experience more pressure than their native-born counterparts. Schools should take this into account when teaching immigrant children.

Health and Education

Many low-income immigrant children come to school with basic health needs such as poor vision and poor dental care. Frequently, parents without health insurance are not able to get their children annual exams and some use the emergency room for primary care services. Students with poor vision often complain of headaches and cannot see the white board in the classroom.

Mental health issues are habitually overlooked in the immigrant population and not made a priority. Some immigrant children and/or their families have experienced trauma in the migration process and are in need of specialists who can address posttraumatic stress disorder (PTSD). Children coming to school with PTSD may appear silent and withdrawn in school and will not engage with teachers or their peers until they feel safe. Oftentimes, silence is interpreted as complacency by teachers and these children do not get the attention that they need. Parents and caretakers who struggle with PTSD are sometimes unwilling to come to the school because they fear and/or have anxieties interacting with authority figures.

Chronic health conditions such as asthma, diabetes, attention deficit hyperactivity disorder, and hepatitis B impact immigrant children in schools. For low-income families, they struggle to manage these diseases in the face of no health insurance. Unmanaged, these chronic diseases can lead to high absenteeism among immigrant children.

Conclusion

This is not a comprehensive or exhaustive list of the issues facing immigrant children in our schools. Immigrant communities are found all over the world and represent a spectrum of nationalities, languages, ethnicities, and religions. The reference list included goes into more detail about specific immigrant populations. Educators can also find resources in the local communities. Ethnic, faith-based, and service organizations can be a valuable resource as cultural brokers in helping to build bridges between schools and communities. Schools can also find resources from the immigrant community (e.g., service providers, college students) who can help with translation.

While providing broad strokes here to introduce issues of immigrant children in schools, educators and health providers must make an effort to get to know immigrant children and their families in order to understand their specific experience. In order to provide the appropriate services, they should develop relationships with service providers, religious figures, and community members who will help provide a better understanding of their student's unique learning needs and community context.

Ellis Island

Amy N. Sharpton
Department of Veterans Affairs, Louis Stokes DVA
Medical Center Cleveland, Brecksville, OH, USA

From 1892 to 1954, over 12 million immigrants entered the United States through Ellis Island, a small island in the upper bay of New York Harbor. Lying within the shadow of the Statue of Liberty, the island is situated just off the New Jersey coast. Well before it was designated as the site of one of the first Federal immigration stations by President Benjamin Harrison in 1890, Ellis Island had acquired a rich and varied history. The local Indian tribes had called it “Kioshk” or Gull Island. Due to plentiful oyster beds and shad runs, it was known as Oyster Island for many years during the Dutch and English colonial periods. By the time Samuel Ellis became the island’s private owner in the 1770s, the island had been called Kioshk, Oyster, Dyre, Bucking, and Anderson’s Island. The Federal government purchased Ellis Island from New York State in 1808; it was approved for inclusion in the new harbor defense system, and fortification construction began – including a parapet for three tiers of circular guns. In honor of a brave officer killed during the War of 1812, the fort at Ellis Island was named Fort Gibson.

Prior to 1890, rather than the Federal government, the individual states oversaw immigration into the United States. From 1855 to 1890, Castle Garden in the Battery served as the New York State immigration station, where approximately 8 million immigrants, mostly from Northern and Western Europe, passed through it. In the latter half of the nineteenth century, it became apparent that Castle Garden was not equipped to handle the increasing numbers of immigrants arriving yearly. The federal government intervened, constructing a new federally operated immigration station on Ellis Island. On January 1, 1892, Annie Moore, a 15-year-old Irish girl, accompanied by her two brothers, was the very first immigrant to be processed at Ellis Island. However, after 5 years of operation, the station burned down, and the Treasury Department ordered the immigration facility be replaced quickly, stipulating that all future structures built on Ellis Island be made fireproof. On December 17, 1900, the new main building was opened and 2,251 immigrants were received that day.

Unless they were sick or had legal problems, those who sailed first or second class were not required to undergo the inspection process at Ellis Island. It was thought that if they could afford such a ticket, they were less likely, due to medical or legal reasons, to become a public charge in America. Passengers who traveled “steerage” or third class would arrive at the Hudson or East River Piers and were transported by ferry or barge to Ellis Island for medical and legal inspection. For those whose papers were in order and were in reasonably good health, the Ellis Island inspection process would last approximately 3–5 h. The inspections took place in the Registry Room (or Great Hall), where doctors would scan briefly every immigrant for obvious physical ailments. The two agencies responsible for processing immigrants at Ellis Island were the US Public Health Service (USPHS) and the Bureau of Immigration, later known as the Immigration and Naturalization Service (INS).

The island became known as a place of hope for many – and a place of tears for some. The two main reasons an immigrant would not be allowed entry into the United States were if a doctor diagnosed him or her with a contagious disease or if a legal inspector thought the immigrant was likely to become a public charge or an illegal contract laborer. Approximately 20% of immigrants stayed overnight in dormitory rooms until their cases were cleared. The hospital on Ellis Island opened in 1902, and grew to 22 medical buildings, sprawling onto two islands adjacent to Ellis Island. The hospital served as America’s first line of defense against contagious disease. Thousands of immigrant patients were separated from family, detained in the hospital, and healed from illness before becoming citizens. Three hundred and fifty babies were born in the hospital, many being named after the doctors and nurses who helped deliver them. Sadly, in an era before antibiotics, ten times that many immigrants died on Ellis Island – 3,500 were buried in pauper graves around New York City.

During World War I, immigration to the United States decreased, and numerous suspected enemy aliens were kept in custody at Ellis Island. Between 1918 and 1919, along with the Army Medical

Department, the US Navy commandeered the island complex for the duration of the war. Detained suspected enemy aliens were transferred from Ellis Island to other locations. During this time, inspection of arriving immigrants was conducted regularly on board ship or at the docks. At the end of World War I, as a big "Red Scare" took hold across America, thousands of suspected alien radicals were interned at Ellis Island, and hundreds were later deported – especially if they had any association with an organization that advocated revolution against the federal government. When Ellis Island reopened as an immigration receiving station in 1920, 225, 206 immigrants were processed that year.

With the passage of the Quota Laws in 1921, and the National Origins Act in 1924, Ellis Island was no longer primarily an inspection station but rather a detention facility, whereby many persons were brought and detained for various periods of time. Ellis Island served primarily as a detention center during World War II, when by 1946 approximately 7,000 aliens and citizens were detained there. In November 1954, the last detainee, a Norwegian merchant seaman named Arne Peterssen, was released and Ellis Island officially closed. Changes in immigration laws, new modes of transportation, and rising operating costs, all played a role in its closure.

Emergency Services

Amyna H. Sabir
Pediatric Emergency Medicine, Rainbow Babies and Children's Hospital, Cleveland, OH, USA

The core components of a country's or local community's emergency services include police, fire, and medical services. Extending from these are more specialized services including but not limited to military, coast guard, cave rescue, bomb disposal, poison control, animal control, public utilities, and chemical decontamination team. All emergency services deal with extraordinary and life-threatening situations in society. Because emergency service providers are confronted with situations that are outside of daily human living, they are directed by rigid codes to ensure effective teamwork and give a high level of expected performance. All emergency service providers share an ultimate goal to help and protect those that cannot protect themselves.

Police Service

The main function of the police is to enforce the law. This encompasses responding to emergency situations and to implementing injury prevention measures while upholding the human rights of all persons. Today, the majority of their tasks include maintaining patrols, responding to call-outs, directing traffic at emergency scenes, providing first aid at emergency scenes, investigating crimes, and arresting criminals. Policing first became a profession in 1829, London, England under Sir Robert Peel. Then and for the rest of the 1800s, it was a very political institution. During this time, the police in the USA were authorized and funded by local municipalities and were strongly connected to the local social and political scene. The organizational style was a very quasi-militant, or "do as your told" style. Their main tasks were to fight crime, riot control, and maintain order, mostly all on foot patrol. The organization was in the control of White politicians with little to no attention paid to communities of racial minorities and low socioeconomic status. The reform era, from the 1930s to 1970s came from a great desire for change in the organization toward professionalization. This occurred via a pioneer, August Vollmer, the first police chief of Berkeley, California, who emphasized education and training. During this time, women made advances in the profession. They began as matrons in the police organization with the primary focus of ensuring the proper care of children. In the early 1900s, they began to occupy positions as policewomen as well. Yet, there were still differences in their tasks, salaries, promotion requirements, and expectations. The demands on the local police departments to serve the community increased with no increase in budget. There was also a need for a stronger relationship between the community and the police. The community era from the 1980s to the present has been the best solution. The focus was on problems solving with the residents of the community. Outcomes are measured by quality of life in the neighborhoods, problem-solving solutions, citizen satisfaction, and crime rate. Today the citizen police relationship is improved with residents of a community taking more responsibility for the problems of their area.

Internationally, the police forces in less developed countries can be weak and ineffective. They still may be managed by a political administration that changes frequently with each election or militant change in power. Often, the "do as I say" style of command still prevails. In war-torn areas of the world, there is a shift in their responsibilities to more dangerous tasks. In Sri Lanka where there have been major natural disasters and a prolonged tribal war, the police force is pushed to manage disasters, fighting among citizens, sick and injured people, stranded children, criminal activities, ransom demands, and apprehending suspicious persons. In many circumstances, the force and control of other human beings is necessary to maintain order in a society. This fine line of control can and does lead to the abuse of privileges in some countries. Therefore, limitations are set on how to use force against citizens. While most police departments are set up regionally as local or municipal authorities, national or federal governments may also hire policemen. Additionally, trained police officers or military authority may be utilized to perform any of the duties listed above. Since they are constantly forced to handle potentially dangerous situations such as apprehending criminals, and emergency responses such as industrial fires, explosions, terrorist bombings, hostage-taking incidents, delicate rescue operations, it is clear why police officers have a higher injury and fatality rate than other occupations. In an emergency situation, the police are in the best positions to take control and coordinate the rescue as well as the safety of those at and around the scene including other emergency service providers.

Fire Service

Equally as dangerous of a service but in a different way is the fire service, also called the fire department, or fire brigade. This service is mainly responsible for extinguishing fires, and rescue work. Originally, the fire service began as private agency whose main focus was to minimize property damage from fires only for those who had insurance. It soon became clear that this was a valuable resource for all citizens. Most countries have developed a public fire response department. Like police, firefighters have many tasks such as, operating water pumps feeding high-pressure hoses, positioning ladders to deliver water, rescuing victims, administering first aid, ventilating smoke-filled areas, and minimizing property damage. Many firefighters are also trained as emergency medical technicians (EMTs) and paramedics. Their everyday line of work involves performing dangerous operations rapidly, and under intense pressure. For this venture, they must be physically fit and psychologically sound of mind. To coordinate all their activities and ensure teamwork, firefighters are directed by a superior officer. Similarly, different firefighting teams in any given area need to be coordinated, especially in disaster situations. Southern California had noted an increase in brush fires in dry hot weather. Because of the many agencies in the area, better coordination was needed to efficiently perform their duties. An oversight agency was formed that grew to coordinate more than just fire emergencies. FIRESCOPE (Firefighting RESources of California

Organized for Potential Emergencies) resolves issues of terminologies between agencies, coordinates modular expansion of services, multi-agency, multi-jurisdictional command conflict. With these other duties, and many agencies performing different duties, an oversight committee or superior officer is needed be most effective and efficient.

As with police officers, firefighter's duties change depending on the needs of the community. In Tokyo, firefighters provide emergency medical services more than cleanup of hazardous materials, rescue, and even firefighting. The trend in New Zealand, Ireland, and the United Kingdom is of increasing incidents attended by Fire Brigade but declining percentages of those cases as fire emergencies. They are spending more time in other duties unrelated to fires. Even in Berlin in 1994, the percentage of emergency medical services provided was close to 70% where firefighting incidents was only 5%. The fire brigade has many more tasks than is initially obvious by the name.

Medical Service

Emergency Medical Services (EMS) is the delivery of unscheduled care, usually in high patient census settings, for a wide variety of medical and surgical problems. It encompasses everything from emergency to primary care. Emergency medical services provide patient education, coordinating specialty care, resuscitation, management of critical care, toxicology, trauma, injury care, and prehospital and disaster response. It also covers preventive efforts for injury and violence. Commonly, however, EMS refers to the prehospital care of patients with traumatic injuries or serious illness. EMS is the conglomeration of autonomous and highly interdependent agencies.

The use of an ambulance dates back as early as the Larrey. This was a horse drawn, "flying ambulance" that was used to carry surgeons and medical supplies into the field of battle to help the wounded in the Napoleonic Wars. The Rucker Wagon was used in the American Civil Wars. This remained the standard until 1869 when Bellevue Hospital in New York began the first city-based ambulance service. In 1965, a commercial hospital in Cincinnati, Ohio was the first to develop a hospital-based ambulance service.

Since emergencies occur outside a hospital setting, a complex system of prehospital services requires coordinated resources. Providers have to be notified that an accident has occurred, before the necessary resources are brought to the scene where rapid evaluation and initial care is given. The patient then is safely and rapidly transported to a hospital for definitive care.

World Medical Service

Globally, there are two types of very different EMS systems. The Anglo-American system is made of skilled emergency departments and prehospital emergency medical services utilizing paramedics. The Franco-German system is a highly developed prehospital emergency physician service.

The type and quality of services are most influenced by a country's economic development and the funding that the government has committed to health care. Most countries provide most services in urban areas where the density of the population is located and almost all the tertiary hospitals. Many countries have a private fee-for-service health care system with any combination of private physicians, private hospitals, and private ambulance services. Although this is unavailable to the socioeconomically disadvantaged, they may provide advanced surgeries and better technology. Clearly, they are better funded, despite only serving a smaller portion of the population.

The World Bank designates four levels of national development based on a country's economic and health care development. Among the high economic tier regions, such as the USA, Japan, Europe, and Australia, there is a complex medical system. However, the health care even in Japan has a very limited EMS system where providers have minimal to no training. The middle level is divided into an upper and lower middle economic development. Under this umbrella are South and Central Americas, the Middle East, and Asia. In many of these areas where there is urbanization but unsophisticated EMS system, injuries are often the cause of premature death. For example, in some areas of Egypt, mortality rate is as high as 25% of road traffic injuries and is only expected to rise. Among the least developed areas including Sub-Saharan Africa, South Asia, part of Central America, there are high infectious rates and infant mortality. Developing countries often rely on primary health care workers to provide a needed cost-effective service.

The role of the Emergency Care Physician also varies based on the country's development and therefore health care need. In developed countries, emergency physicians coordinate emergency care, resuscitate, and provide toxicology expertise, trauma care, and much more. In middle spectrum developed countries, emergency physicians are limited to providing an advanced level of care including critical care and resuscitation, as well as injury care and prevention. Undeveloped countries have a lot of task shifting. It is vital for general practitioners to learn some emergency skills as well as to manage large volumes when and where an Emergency Department or prehospital service is not financially sustainable.

As is evident, developing countries do not have the finances for expensive prehospital equipment and training. Their goals are still delegated to improving the Primary Health Care system. Generally, they have urban centers with large population hubs and rural hard-to-reach communities. Transport in these rural areas would be inefficient and expensive. A long transport time will decrease survival. In this situation, the benefit would not be worth the expense that would be better served improving other areas of the health care system.

Underdeveloped countries may have a more informal system with no planned response, care, or transport. There may be no prehospital system in which a victim may rely on family and friends or a complete stranger to bring them to medical care. A rudimentary system may be provided by other services such as fire, police, or even taxi drivers. Here, the emphasis is on transport, not on care. Some countries offer basic first aid training to these transporters. Although rudimentary, this may be adequate and even more efficient in some countries. Multiple studies have shown that basic first aid training to these "first responders" improves patient morbidity and mortality. The level of hospital-based emergency care also affects the prehospital system. If there is no nearby emergency facility to transport the patient, then a prehospital system would be futile.

A more formal system has services of designated responders to care for and transport sick and injured patients. The system is incomplete if it does not provide access to all patients all the time. There may not be enough resources for 24 h/day coverage. Some areas of a nation may not have the resources while a wealthier area may. A system is universal when the services are accessible to any person at any time, regardless of the ability to pay. Many formal systems incorporate a dial-in-number, or access number that provides a dispatcher and emergency instructions to caller until help arrives.

The level of training of the transporter varies. These nonphysician caregivers treat patients based on preestablished protocols and direct telecommunication with a physician. The transporter may be a physician, nurse, or just the driver. In the Franco-German model, specially trained physicians in emergency or anesthesia ride in the ambulance and provide stabilizing care. Some of the patients cared for in this model may not need a hospital-based Emergency Department because they may be admitted to a ward directly from the scene.

The prehospital providers' ability to care for a patient is also dependent on the equipment they are able to carry. In Chennai, India vehicles only carry O_2 tanks. In the USA a basic transport vehicle will always be stocked with a backboard, cervical collar, splints, and bandages. Most places have a mix of providers, supplies, and funded agencies or within an agency.

United States Medical Service

In the USA, the level of prehospital care is optimized at a more complex level. Coordination and cooperation is key to running a functional system. EMS in the USA is fairly new. The Emergency Medical System took flight almost 100 years after the first city-based system, when a report was published on Accidental Death and Disabilities, describing the hazardous conditions of EMS care. In response, public and private organizations poured funds into improving the systems for prehospital care.

There are many designs to the EMS systems. The local community it serves decides the type of design. The regional system is assisted more than directed by a state administration. EMS agencies are relatively autonomous organizations but have a high degree of interdependency. In a crowded urban area, there may be multiple agencies of different types and levels. There are many challenges to coordinate multiple agencies of different types. Agencies in a region can be of different types, private, public, hospital based, or typically, a combination of these forms. This combination impacts whether the funding is federally provided, fee-for-service, locally provided, or from multiple sources. It also affects who is dispatched to notify the agency and medical director directed to medically support the providers. Coordination is best achieved at a local/regional level.

Once the call is received, either a Basic Life Support (BLS) or ALS (Advanced Life Support) squad must respond. BLS squads are not able to perform complex interventions. They have the ability to provide an oral or nasal airway, bag mask ventilation, cardiopulmonary resuscitation (CPR) including the use of AEDs (automated external defibrillators), hemorrhage control, and fracture and spine immobilization. Many squads can also facilitate childbirth. The ALS squad is more comprehensive. The responder's training is more advanced. They can provide advanced airways, intravenous line, and certain medications including anaphylactic dose epinephrine, cardiac monitoring, and manual defibrillation. First Responders are typically the first to respond to the scene of an accident because of their proximity. They are fire, police, and/or volunteers who will assess a scene, provide any life-saving interventions as well as CPR, basic airways, c-spine immobilizations, control of hemorrhage and cardiac defibrillation until EMTs arrive. These responders do not have the ability to transport the patient. Use of these providers and squads is locally determined based on a multitude of factors.

Conclusion

From police, to fire, and medical, the three core high-risk emergency services, though independent with unique tasks, have much overlap and interdependence that requires much coordination. With the safety of the people that they serve as their primary concern, the different disciplines and agencies within a discipline come together to work effectively as one team. Immigrants, often lacking access to health care, delaying needed care, and living in hazardous and threatening conditions are likely users of emergency services. Emergency service providers need to be aware of the life circumstances of this vulnerable population as they deliver services to protect the health and safety of the entire population.

Emic

KRISTI NINNEMANN
Department of Anthropology, Case Western Reserve University, Cleveland, OH, USA

The term *emic* originates in linguistics, and is used regularly within the fields of anthropology and other social and behavioral sciences. The word emic can be used to describe perspectives, constructs, data, or methodology, and in all uses serves a descriptor of positionality. Sometimes referred to as the insider's view, emic perspectives strive to recognize and understand the meaning of a concept from within the cultural framework in which it is being observed. An emic approach attempts to assess and convey conceptual schemes, categories, and/or culture in terms of members' own indigenous and meaningful criteria. Intensive longitudinal, qualitative, and ethnographic methods are touted generally as the most effective means of gleaning an emic perspective of cultural phenomena.

Emic is often discussed in opposition to *etic*, a term that denotes assessment and/or evaluation of schemes, categories, and/or culture from the perspective of an observer, or outsider. An etic perspective strives to be neutral or culturally objective, whereas emic views attempt to represent subjective experience and cultural understanding. In addition to the insider/outsider contrast, the emic/etic comparison has been described further as focal/global, particular/universal, and first-order versus second-order conceptualization.

The terms *emic* and *etic* were coined by the linguistic anthropologist Kenneth Pike, and were derived from an analogy with the terms *phonemic* and *phonetic*. Pike suggests that, just as there are two perspectives that can be used in the study of a language's sound system, there are two perspectives that can be used in the study of a society's cultural system. In both cases, it is possible to take the point of view of either the insider or the outsider. Pike contends furthermore that the emic perspective focuses on the intrinsic cultural distinctions that are meaningful to the members of a given society (e.g., whether the natural world is distinguished from the supernatural realm in the worldview of the culture) in the same way that phonemic analysis focuses on the intrinsic phonological distinctions that are meaningful to speakers of a given language (e.g., whether the phones/b/and/v/make a contrast in meaning in a minimal pair in the language). The native members of a culture are the sole judges of the validity of an emic description. Similarly, the native speakers of a language are the sole judges of the accuracy of a phonemic identification.

The etic perspective, again according to Pike, relies upon the extrinsic concepts and categories that have meaning for scientific observers (e.g., per capita energy consumption) in the same way that phonetic analysis relies upon the extrinsic concepts and categories that are meaningful to linguistic analysts (e.g., dental fricatives). Scientists are the sole judges of the validity of an etic account, just as linguists are the sole judges of the accuracy of a phonetic transcription.

The binary of emic and etic is not without debate. Although the terms are discussed often in opposition to one another, critics argue that neither term is absolute. All emic interpretations are informed by whoever is making the observations, and all etic interpretations are rooted within some type of cultural context. As such, it has been suggested that emic and etic be considered as points along a continuum rather than discrete entities.

Emigration

Amy N. Sharpton
Department of Veterans Affairs, Louis Stokes DVA
Medical Center Cleveland, Brecksville, OH, USA

Introduction

Human migration is the physical movement by humans from one area to another. Throughout history, the migration of populations has continued under both voluntary and involuntary conditions. *Emigration* is defined as leaving one's native country, or country of origin, and settling in another. It is related to immigration, but from the perspective of the sending country. Human movement before the establishment of or within political boundaries falls under the general term migration. Persons make the choice to emigrate based on a variety of motivations including religious, political, and economic. For others, their motivation is personal in nature, for example, marriage or the desire to reside in a different climate. It should be noted that emigration differs significantly from involuntary or forced migration.

Forced migration is defined as the coerced movement of persons away from their home or home region. It is suggestive of violent coercion, and it is used interchangeably with the term forced displacement. Two examples of forced migration are population transfer and ethnic cleansing. Sanctioned by state policy or international authority, population transfer is the movement of a large group from one region to another; frequently, this action is based on ethnicity or religion. Ethnic cleansing refers to the policy of one ethnic or religious group to remove, by violent and terror-invoking means, the civilian population of another ethnic or religious group.

In the eighteenth, nineteenth, and twentieth centuries, with the hope of finding a more prosperous future, millions of Europe's poor immigrated to the United States, Canada, Brazil, and other locales. These waves of mass emigration affected greatly the future cultures and economies of the sending and receiving countries. The choice to emigrate can be based on incentives that attract persons away from their country of origin (pull factors), or they can be based on circumstances within the country of origin that encourage persons to leave (push factors).

Pull and Push Factors

Pull factors are incentives that make more enticing the prospect of emigrating. Some pull factors seen frequently include increased or better job opportunities, higher wages, better social programs, better schools, better opportunities for acquiring land/farms for self and children, increased political freedoms, to build a religious community, travel prepaid by relatives, and to join relatives who have moved already. Push factors are situations within the country of origin that encourage persons to exit the country. Push factors seen frequently include lack of employment opportunities or upward mobility, lack of political or religious rights, oppressive legal/political conditions, discord with other cultural groups, and shortage of farmland.

Modern Trends in Migration

According to the World Migration Report 2010, produced by the International Organization for Migration, in 2010 the number of international migrants was estimated at 214 million. If the average rate of growth holds steady over the next 20 years as was witnessed in the previous 20 years, the number of international migrants could reach 405 million by 2050. While the impetus of some modern migration includes factors such as political unrest, wars, and natural disasters, modern migration largely is economically motivated. For example, there are great disparities across countries in the world in terms of the wages that can be earned for similar work. Also, for some jobs in high-wage countries, at times there is a shortage of appropriately qualified citizens to fill these positions. Some countries, such as Great Britain and Australia, operate point systems that give lawful immigration visas to noncitizens who are qualified to fill the shortage. Noncitizens have an economic incentive to obtain in their own country the necessary skills and then apply for, migrate, and fill the job vacancy.

Migration that is motivated by economic disparities is seen within the European Union, where legal barriers to migration have been lifted between member countries. Countries that have higher prevailing wages, such as France, Germany, Italy, and Great Britain, are net recipients of immigration from countries with a lower prevailing wage, such as Greece, Hungary, Lithuania, Poland, and Romania. Some contemporary economic migration occurs, even as the migrant becomes an illegal resident of the host country. These emigrants will be at a clear disadvantage in the employment market. Examples include illegal immigrants who cross from Mexico into the United States, from Mozambique into South Africa, from Bulgaria and Turkey into Greece, and from North Africa into Spain and Italy.

Consequences of Migration

The consequences of migration can be subdivided into three categories: demographic consequences, social consequences, and economic consequences.

Demographic consequences include changes in the numbers of people within a region, as well as in how the people are concentrated or distributed. Public policy must address then the best ways to assist individuals, communities, and regions as new immigrants enter and settle an area. Social consequences of migration include the bringing together of different people, which can lead to conflicts; however, it has the potential also to establish understanding between diverse groups of people. The economic consequences of migration depend upon the "quality" (skills, age, educational attainment, health, etc.) of the migrants and the economic needs of the sending and host countries. Emigration is beneficial to overpopulated areas; it reduces pressure on the land. However, in underpopulated areas, emigration may slow development.

Emotions

Loren M. Post
Department of Psychology, Case Western Reserve University, Cleveland, OH, USA

Anger, disgust, joy, sadness, fear, and surprise are basic human emotions. Emotions have different components with each component having different functions. Emotions have a cognitive component used in the evaluation of objects and events, a motivational component used in the preparation and direction of action, a facial and vocal expression component used in the communication of reaction and behavioral intention, and a subjective feeling component used in the monitoring of internal state and individual–environment interaction.

Cross-cultural research suggests that there are both universal and differential aspects of emotions. For example, facial expressions associated with the basic human emotions appear to be universal, while cultural differences exist among various aspects of emotion, such as managing emotional expressions, labeling and understanding emotions, and coping with emotions. For instance, people from different cultures may differ in their evaluation of events that would be associated with anger and of the behavioral responses that would warrant the emotional description of "angry." The existing cultural differences in emotions are likely to affect immigrants.

Upon entering a new culture, immigrants face many challenges. One such challenge may be adjusting to cultural differences in emotions. Recognition of cultural differences in emotions and emotional expression is important to immigrant health, as miscommunication and misunderstanding can result in significant negative consequences. For instance, a misunderstanding of culturally appropriate emotional expression can affect the formation of successful relationships with people. Thus, this entry will focus on emotions in relation to immigrant health by examining the role of culture in emotion components. Additionally, this entry will touch on the importance of recognizing cultural differences in emotions and emotional expression when diagnosing and treating mental disorders among immigrants.

It should be noted that research studies often attempt to study culture, which may be defined as a set of dynamic values and beliefs influenced by one's social and psychological world, by means of ethnicity. Although often necessary in conducting research, the method is limited in that it incorrectly implies that people of a certain ethnicity all share the same culture.

The question, "to what extent are emotions universal or cultural in nature," is useful when considering emotions and emotional expression among immigrants. Many studies provide evidence for cultural differences and similarities in emotion components. Within a cognitive model of emotions, as proposed by Mesquita and Frijda, the elicitation and manifestation of emotions are considered to involve the following components: (1) *antecedent events*, that is, events that precede the emotion; (2) *event coding*, that is, categorizing the event as a certain event type, such as humiliation or bereavement; (3) *appraisal*, that is, perceiving the event with respect to its implications, such as evaluating whether the event was caused by someone else or the self; (4) *physiological reaction patterns*, that is, the bodily reactions involved in emotions; (5) *action readiness*, that is, an impulse to act, such as the impulse to protect oneself from a danger when afraid; (6) *emotional behavior*, that is, overt behavior patterns often resulting from action tendencies; and (7) *regulation*, that is, monitoring and modulating emotional reactions to emotionally evocative events. Of these components, cultural differences in regulation processes, antecedent event types, appraisal tendencies, and behavioral generation (the process by means of which behaviors are selected from a person's emotional behavior repertoire) form major sources of cross-cultural emotion differences.

In considering regulation processes, there are cultural differences in both emotional suppression (inhibiting or avoiding emotions) and emotional enhancement (fully expressing or exaggerating emotions). Cultures have different display rules, which are rules that dictate the appropriateness of display of emotions depending on the social situation. In adapting and adjusting to a new culture, immigrants may not be fully aware of the culture's display rules and, thus, may offend or be offended by people of the host culture. For example, a woman who has migrated from China (where the display of anger is often considered to be inappropriate) to the USA may have difficulty managing conflict situations in which people from the host culture are more likely to freely express anger.

In considering antecedent event types, studies suggest that there are cultural differences in emotion antecedents (e.g., differences in events that elicit joy). For example, in one study, Japanese individuals reported anger in relation to interactions with strangers much more often than European and American individuals, while American individuals reported more anger in the context of relationships than European and Japanese individuals. Thus, there may be cross-cultural variation in emotional sensitivity to various antecedent events. Therefore, immigrants may find themselves in a new culture where they are expected to have specific emotions in a certain situation that are in conflict with the emotions that they generally experience in such situation.

There are also cross-cultural differences in appraisal tendencies. As part of the cognitive model of emotions, appraisal involves the evaluation of events in terms of their relevance for an individual's well-being and coping options. There is evidence of cultural differences in appraisal propensities that lead to the same situations being associated with different emotions. For instance, the high frequency of guilt among the Japanese may be linked to a tendency to blame themselves for negative events. Therefore, if a man from a culture where self-blame is less prevalent were to migrate to Japan, his tendency to attribute blame to external factors in a negative situation may lead to interpersonal conflict and misunderstanding.

Cultural differences in behavior generation are affected by the cultural availability and expected effectiveness of the various emotional behavior patterns. For example, the Balinese often react to frightening events by falling asleep, which interestingly is a culture-specific extension of the universal action tendency of avoidance of feared events or objects. Falling asleep is a culturally accepted way of both expressing and concealing fear that may not be recognized or understood by immigrants. There is the possibility that certain cultural behaviors may not even be part of an immigrant's emotional behavior repertoire, leaving immigrants with the task of learning new behavior patterns in order to effectively interact with others.

Ethnicity may also be a source of the observed cultural differences in emotions. There is evidence for ethnic differences in emotions and emotional expression. For instance, a study examining ethnic variation in trait emotions and levels of emotional conflict tactics found that Russian/Ukrainian immigrants and US-born European Americans reported more negative emotion (i.e., sadness, shame, fear, and anger) and less positive emotion (i.e., joy and interest) than either US-born African Americans or Jamaican immigrants.

Similarly, Russian/Ukrainian immigrants and US-born European Americans reported greater use of emotional expression during conflict than either US-born African Americans or Jamaican immigrants. However, there were significant differences within the two major racial groups. Russian/Ukrainian immigrants reported greater levels of guilt and less joy than all other groups, including US-born European Americans. US-born African Americans reported significantly less guilt than all other groups, including Jamaican immigrants, and greater contempt than Jamaican immigrants. Taken together, different ethnic groups (both of the same race and from the same country) appear to be associated with different emotional climates. Thus, there is the possibility that differences in emotions are also a function of ethnicity.

Yet, the ethnic differences may relate to societal standards that influence emotion and the cultural values different ethnic group members place on emotions and emotional expression, such as the cultural display rules previously described. For instance, in a classic study, American and Japanese individuals viewed highly stressful films in two conditions (alone and with an experimenter) while being videotaped. Both American and Japanese individuals showed the same emotions in their faces when viewing the films alone. However, when in the presence of an experimenter, Americans continued to show their facial signs of negative emotions, while Japanese individuals were more likely to mask their negative feelings with smiles. Thus, these results demonstrate cultural differences in display rules. In considering subjective aspects of emotional responses, a study compared Chinese Americans' (involving a culture that values emotional control and moderation) and Mexican Americans' (involving a culture that values open expression of emotion) emotional responses to a startling noise. The results showed that Chinese Americans, in line with proposed cultural values, reported experiencing less positive and negative emotion than Mexican Americans. Thus, rather than viewing these variations in basic emotions as a result of ethnicity, it may be more useful to consider the cultural influence on the perceived value of emotions and emotional expression. Therefore, upon entering a new culture, it is important for immigrants and people of the host culture to understand each other's cultural beliefs and values of emotion in order to avoid reliance on ethnic stereotypes. Yet, learning, understanding, and adapting to a new culture's implicit set of rules can be quite difficult for immigrants. Many times, new cultural beliefs and values do not perfectly map onto those held by immigrants.

A misunderstanding of cultural differences in emotions and emotional expression can affect communication between immigrants and people of the host culture. Intercultural communication often involves uncertainty and ambiguity concerning the ground rules of communication and interaction. When emotional behaviors do not conform to expectations, conflict and misunderstanding may arise. People's stereotypic ways of thinking may then be aroused and ultimately lead to negative value judgments and associated negative emotions about the misunderstanding and cultural differences.

One theoretical framework proposed by Matsumoto, Hirayama, and LeRoux, informed by the literature on stress and coping, suggests that immigrants will be more likely to have successful adjustment if they learn how to regulate their emotions so that they can engage in clear thinking about intercultural conflicts and misunderstandings. Once emotions are properly regulated, immigrants can engage in learning about the new culture and understand the intentions and behaviors that brought about conflict in the first place from a different cultural perspective. Because intercultural contact and change are significant life events that are inherently stressful, emotion regulation is a psychological skill that can help immigrants deal with life in a new and different environment. Indeed, research suggests that immigrants with better emotion regulation have less depression, anxiety, culture shock, and homesickness, and higher levels of happiness, well-being, marital satisfaction, language proficiency, and income.

There is the possibility that cultural differences in emotions are also a function of personality traits. A study examined cultural differences in emotion regulation as indirectly affected by individual differences in personality traits (i.e., neuroticism, extraversion, and conscientiousness) between American and Japanese individuals. The study found that Americans had higher emotion regulation than the Japanese. Additionally, Americans had higher scores on extraversion and conscientiousness, while the Japanese had higher scores on neuroticism. When examined together, the three personality traits demonstrated a complete indirect effect on the country differences in emotion regulation. Thus, personality traits may be one of the factors that account for cultural differences in emotion regulation. There are two ways of interpreting the causal mechanisms between culture and personality that affect emotion regulation. First, personality may be the product of culture and second, genetically based personality traits may shape culture. Further study of the causal links between culture and personality would be useful in better understanding how immigrants can adapt and adjust their emotions in new cultures.

Immigrants face numerous stressors when living in a new cultural environment that may contribute to poor mental health. Recognition of cultural differences in negative emotions is important in accurately diagnosing and treating mental disorders. Although depression and anxiety are prevalent across all cultures, there are cultural differences in symptom presentation. However, despite different ways of reporting distress, the major symptoms of depression are present across different ethnicities.

Cultural differences in the conceptualization of anxiety disorders exist as well. For example, *ataque de nervios* is considered a "culture-bound syndrome," which may occur among Latinos from the Caribbean, characterized by symptoms of trembling, attacks of crying, screaming uncontrollably, and becoming verbally or physically aggressive. Individuals often feel as though their emotions are out of control and that most episodes occur as a direct result of a stressful life event related to family. The cultural differences in the experience and expression of anxiety are distinguished as a culture-specific form of distress.

In terms of clinical considerations, clinicians should not assume automatic differences in emotions and emotional expression based on the ethnicity of their patient. Because research studies often use ethnicity as a proxy for culture, the patient's level of exposure and adherence to his or her culture or cultures and maybe even personality traits should be considered.

Despite the emphasis on culture throughout this entry, one should still question the extent to which culture is accounting for the differences observed in emotions and emotional expression. Various psychosocial factors should be considered when comparing different immigrant groups, such as socioeconomic status and health. An individual's years since immigration and level of acculturation are also important to consider. Factors such as undocumented status, pressures of acculturation, and exposure to anti-immigrant and racial prejudice may over time contribute to immigrants' increased psychiatric vulnerability. For example, a study showed that undocumented Latino immigrants with concerns of deportation were at heightened risk of experiencing negative emotional states, particularly anger. Additionally, even with progress in cross-cultural research, many research studies continue to use Western psychology constructs and related measures that may not be appropriate in investigating emotion among different ethnic and cultural groups. For example, a study demonstrated that the finding that Asian ethnicity and being high on interdependence makes Asians prone to emotional distress may actually be a result of emotional distress measures (e.g., Beck Depression Inventory) that pathologize Asians for being high on interdependence or low on independence.

There do seem to be cultural differences in various aspects of emotion. Cultural differences are often found in the emotion components of regulation processes, antecedent event types, appraisal tendencies, and behavioral generation. Immigrants often face the task of adapting and adjusting to a new culture's emotions. Misunderstandings of cultural differences in emotion components between immigrants and people of the host culture can lead to negative value judgments and associated negative emotions and conflict. Thus, immigrants' general well-being and mental health are positively affected by the recognition, understanding, and acceptance of cultural differences in emotions and emotional expression.

Empathy

Briana L. Root
Department of Psychology, Case Western Reserve University, Cleveland, OH, USA

Empathy is the ability to imagine what another person is experiencing – to view the world through his or her eyes and to walk in his or her shoes. Empathy can entail both cognitive and affective components. For example, imagine witnessing the following scene: a woman is walking down the street and as she passes by a group of people, someone refers to her using a derogatory ethnic slur. Cognitively, experiencing empathy for this woman would involve your ability to take her perspective, to imagine how she is thinking and feeling and to differentiate her likely internal experience from your own reactions to the event. Affective empathy would include your emotional responses to her experience. You may feel emotions that are congruent with what the woman herself is feeling (perhaps you feel fear, indignation, or anger toward the person calling her a name) or your feelings may represent your reaction to the woman's situation (e.g., you sympathize with her distress).

Empathy is generally understood to precede prosocial behavior. The experience of empathy tends to be associated with a benevolent attitude and an urge to help the person perceived to be in distress. Furthermore, those who do act on their impulse to help often experience positive emotions as a result. For example, witnessing the event described above may inspire you to approach the woman in question and to inquire whether she desires assistance. Empathy's link with prosocial behavior, in particular its tendency to reduce levels of aggression and prejudice, makes it relevant to immigrant health. With this in mind, this entry will examine empathy's role in improving attitudes toward immigrant groups, including a particular method used to facilitate empathy. Additionally, this entry will introduce the novel concept of ethnocultural empathy.

Encounters with racism (both at the individual and institutional levels) are stressful and detrimental to an immigrant's psychological well-being. Empathy plays an important role in reducing intergroup aggression and prejudice. Feeling empathy for an immigrant's experience is related to not only increased concern about the welfare of the individual in question but improved attitudes toward the racial, ethnic, or cultural groups to which the immigrant belongs. A powerful method of eliciting such empathy is perspective or role-taking. This practice involves either (1) imagining oneself in the other person's situation in an attempt to perceive as the other does or (2) imagining events similar to the other person's situation happening to oneself. For example, you may try to imagine what the woman may be feeling during such verbal harassment or you may think of what you would feel like if someone made derogatory comments about your ethnicity. Taking the perspective of an immigrant reduces aggression and prejudice at both the individual and group level: (1) It links you with the other person, in effect merging the self and the other, and (2) it increases perceptions of a shared humanity and common destiny; in other words, it increases perceptions of being members of the same overarching group (humanity), whereas before you were separate and dissimilar. Acts of aggression and prejudice tend to be justified by dehumanizing and distancing oneself from the victim. Empathy increases one's awareness of the other's humanity and connects oneself with the other, therefore reducing one's likelihood of both acting aggressively toward the other and endorsing prejudiced attitudes toward the other's group.

The perceived level of similarity between oneself and the other person is a key predictor in one's ability to take the other person's perspective. This tendency to be more empathic to those most like oneself is known as the similarity bias. Perceiving the other person as similar provides the basis for perspective-taking which then fosters empathy. The role perceived similarity plays in fostering empathy raises important considerations for how racial or ethnic cultural differences may impact interpersonal interactions. Immigrants are typically deemed less familiar and less similar to the resident population, and therefore tend to be viewed less favorably. The perceived lack of similarity may lead to reduced perspective-taking and therefore reduced empathy toward immigrants.

Recently, the construct of ethnocultural empathy has been developed to describe and measure individuals' experience of empathy for those from dissimilar racial and ethnic cultural groups. Ethnocultural empathy therefore relates to the ability of members of the resident culture to empathize with immigrants. Ethnocultural empathy is comprised of four factors: (1) empathic expression toward members of other ethnic groups (e.g., feeling disturbed upon hearing others make racist statements or jokes about ethnic groups different from your own), (2) awareness of society's view and treatment of different ethnic groups (e.g., awareness of how the media portrays different ethnic groups), (3) acceptance and understanding of ethnic group behavior (e.g., reporting little irritation or impatience when people from dissimilar ethnic backgrounds speak a language different than your own), and (4) the propensity and ability to understand the perspective of members of different ethnic groups (e.g., the ease with which you relate to and the degree of understanding you have for members of different ethnic groups).

It is important to remember that empathy is teachable. Empathy for immigrants therefore can be encouraged and enhanced by utilizing the methods detailed above. Encouraging perspective-taking in consideration of an immigrant's emotional experience not only seems to increase perceptions of similarity between individuals previously viewed as dissimilar, but it tends to increase empathy and favorable attitudes toward the individual immigrant and the immigrant's respective groups as well.

Employment

Loveth Adenuga
Family Medicine Research Division, Case Western Reserve University School of Medicine, Cleveland Heights, OH, USA

Introduction

Employment is defined as the work or occupation for which one is often paid. Employment is vital to society because it keeps money in circulation. For example, when an individual works, they receive payment or compensation. They then use the compensation to purchase goods or services, which indirectly compensates the person or company from whom they purchase the goods. High unemployment rates are usually indirectly linked to low consumer spending. Employment can come with many benefits, including health insurance and discounts on various goods and services. Those who may not benefit from employment are those who are injured, sick, or too young to work.

Employment rates for the last 40 years have shown to be fairly capricious in major international economies. From 2007 to 2009, a recession hit the international marketplace that affected millions of people around the world. The 2007–2009 recession (or the Great Recession) hit several economies, making the employment rate decline globally. The Great Recession hit the global economy as a result of the housing market collapse in the US economy. The US economic crisis started developing in early 2007, and grew into a full-blown financial crisis later that year. Even though the economic downturn took place in the United States, a ripple effect impacted the whole world.

US Employment Decline

In 2007, the employment–population ratio was 63% in the United States. In 2009, it dropped to 59.3% – a seemingly small drop. This decline in employment saw an increase in unemployment and by 2009 the unemployment rate had reached 9.3%, which was more than double the unemployment rate in 2007, of 4.6%. This means that by 2009, approximately 14,265,000 people were unemployed in the United States, compared to the 7,078,000 that were unemployed in 2007.

The manufacturing industry saw the largest number of unemployed workers, with 1,890,000 employees out of work. The second largest industry for unemployment was the retail industry with 1,844,000 employees out of work. Men were unemployed in larger numbers, with 8,453,000 men and 5,811,000 women out of work in 2009.

Global Employment Impact

United States suffered a devastating decline in employment between 2007 and 2009. Between 2007 and 2009, some nations did not suffer more than a 1% unemployment increase and some countries, such as Germany and the Netherlands, increased their employment–population ratios.

In the United Kingdom, the recession and subsequent decrease in employment–population ratio effected Eastern European immigration and the government saw a smaller group of migrant workers come to the United Kingdom. They also saw a decrease in international students, which affected the funding for higher UK education. The decrease was not so large, however, that the United Kingdom's economy suffered a major deficit. In fact, the proportion of the country's working-age population that was employed decreased by 1.4% between 2007 and 2009, a percentage significantly less than the United States.

Employment of Men and Women

Unemployment rates between men and women are very different, and a common trend seen among the majority of the global economies is that men have a higher unemployment rate than women. In the United States between 2007 and 2009, the male unemployment rate rose from 4.7% to 10.3%, while women saw less of a sharp increase – 8.1% from 4.5% (2010). In the United Kingdom, men saw an increase from 5.7% to 8.7%, while women experienced a significantly lesser unemployment rate at 6.5%, a 1.5% increase from 2007 (2010). With this increase in unemployed men, women became a prominent presence in the workforce, with some women becoming the sole providers for their households. These rates have greatly affected the number of individuals that are covered by health insurance since insurance is linked to employment.

Employment and Unemployment Among Minorities and Immigrants

Among minorities, African American men were unemployed in the largest numbers, with 1,448,000 (17.5%) unemployed in 2009. African American women also exceeded the unemployment rates of other minorities, with 1,159,000 (12.4%) unemployed in 2009. Hispanics were the second largest group of unemployed among minorities.

Unemployment among minorities can be more devastating than among the majority population because of the risk of discrimination. Although illegal, minorities face discrimination in the workforce, and can be subjected to unlawful termination at any time in their employment. Such illegal actions may be exacerbated in a financial crisis. Among immigrants, employment is vital to survival because the compensation they receive from work may be the only financial help they can get. Their relatives may be poor and unable to help them, or they may be the ones who are supporting their extended families. Among undocumented immigrants, their employment status may put them at risk for deportation. For many minorities and immigrants alike, employment is the only way they and their family will have access to health care.

There has been significant backlash in recent years from native US citizens regarding the risk of immigrants taking the jobs of native workers. It is believed that this is linked to the increase of unemployment rates among the US population. The other school of thought on this issue believes that although immigrants may be aggressive job seekers and acquire a lot of work, the work they do is unskilled and in the secondary labor market, a key economic support in the marketplace.

Conclusion

Although the economy has improved, employers are still very hesitant to hire new employees in the United States, and the unemployed find it difficult to get work. They either find themselves overqualified for a job, or completely discouraged at the possibility of never finding work again. With this sustained unemployment comes the termination of insurance and health benefits, which will cause millions of Americans to go into debt or poverty.

Immigrants are especially at risk of falling into debt or poverty due to unemployment and lack of health benefits. Undocumented immigrants without employment are at very high risk of poor living conditions and denial of health care. It is difficult for an undocumented immigrant to receive health care in the United States without subsequently being deported. Immigrants who are legally present may also have difficulty receiving health care such as Medicaid and will have to meet certain qualifications in order to receive care.

The social benefits of employment are also important, as the compensation that an individual receives from employment will be used to socialize and build relationships with others. Further, employment fuels the operation of countries and sustains the standard of living for the population. As a social dynamic and economic driver, employment is crucial to survival for all populations and serves as an indicator of the prosperity of nations.

End-of-Life Care

Moon Choi
Department of Epidemiology and Community Health,
Virginia Commonwealth University School of
Medicine, Richmond, VA, USA

Definition and Practice

Patients with a terminal illness can decide whether they want aggressive treatment that might prolong their life or whether they prefer to stop treatment, which could help them traverse the dying process more comfortably. End-of-life care refers to a broad spectrum of care given to terminally ill patients, focusing on making patients comfortable.

Many healthcare professionals can be involved in providing end-of-life care, depending on the patient's needs: for example, doctors and nurses, counselors, social workers, therapists, and spiritual care coordinators. In most cases, healthcare professionals work in teams to deliver end-of-life care to patients and their families in hospitals, nursing homes, hospice, and their homes.

The end-of-life care team takes a holistic approach, which means helping patients and their families with the medical, psychological, and spiritual issues surrounding the dying process. Terminally ill patients often receive medications and treatments to control symptoms such as pain, vomiting, or coughing. Patients can choose to decline life-sustaining procedures such as cardiopulmonary resuscitation (CPR), artificial breathing, or artificial feeding. Counseling is available if patients are anxious or scared. End-of-life care also helps patients to plan ahead, such as completing advance directives.

End-of-Life Care in the USA

In the USA, studies funded by the Agency for Healthcare Research and Quality (AHRQ) showed that patients who talked with their families or physicians about their preference for end-of-life care had less fear and anxiety, felt that they had more ability to influence and direct their medical care, believed that their physicians had a better understanding of their wishes, and indicated a greater understanding and comfort level than they had before the discussion. However, less than 50% of the severely or terminally ill patients in existing studies had an advance directive in their medical record. Furthermore, only 12% of patients with an advance directive had received input from their physician in its development. These reports suggest that many patients have not participated in effective advance care planning. In addition, the majority of people who die in the USA (80–85%) are Medicare beneficiaries age 65 years and older and most die from chronic conditions such as heart disease, cerebrovascular disease, chronic obstructive pulmonary disease (COPD), diabetes, Alzheimer's disease, and renal failure. Thus, patients with chronic illness also need advance planning.

Immigrants and End-of-Life Care

Predicting what treatments patients will want at the end of life is complicated by the patient's age, the nature of the illness, the ability of medicine to sustain life, and the emotions families endure when their loved ones are sick and possibly dying. Conspicuously, "cultural factors" strongly influence patients' decisions about end-of-life care. The following points of cultural diversity need to be considered in providing end-of-life care to immigrants: (1) emphasis on individualism versus collectivism, (2) definition of family (extended, nuclear, or non-blood kinship), (3) common views of gender roles, childrearing practices, and care of older adults, (4) views of marriage and relationships, (5) communication patterns (direct vs. indirect; relative emphasis on nonverbal communication; meanings of nonverbal gestures), (6) common religious and spiritual-belief systems, (7) views of physicians, (8) views of suffering, and (9) views of the afterlife. Ethnic minorities exhibit greater variability in their preferences for health care as compared with Whites of European descent. Although stereotyping should be avoided, certain styles of communication and decision-making may be more common in some cultures.

Many studies have found significantly lower rates of advance directive completion among Hispanics and

Asians. Among Hispanics, a view of collective family responsibility may lead to the lack of acceptance of advance directives. A consensus-oriented decision-making approach rather than formally appointing a specific family member to be in charge may often be more acceptable in this population. Among Asians, filial piety may influence adult children to decide aggressive treatment for their elderly parents. Elderly Asian parents may experience a reciprocal obligation to continue living for the emotional well-being of their adult children.

The American Academy of Family Physicians (AAFP) has published cultural proficiency guidelines and policy and advocacy statements about diversity in AAFP educational activities. Notably, sensitivity to cultural diversity is integrated within the AAFP's policy statement on ethical principles for end-of-life care. Specifically, the policy states: "Care at the end of life should recognize, assess, and address the psychological, social, spiritual/religious issues, and cultural taboos realizing that different cultures may require significantly different approaches."

Needs for end-of-life care would increase and become diverse because of changing demographics in the USA, which are associated with increasing life expectancy, more immigrants, changes in the ethnic make-up, and retirement of the baby boomers. Health professionals need to be prepared to timely provide accurate information to patients with a terminal illness and their families while considering the patients' cultural background, thus giving patients more choices to meet their healthcare needs.

End-Stage Renal Disease

SHARMEELA SAHA
Department of Internal Medicine, University Hospitals Case Medical Center, Cleveland, OH, USA

End-Stage Renal Disease and Common Associated Health Problems

End-Stage Renal Disease (ESRD) refers to the irreversible decline of kidney function that is not compatible with life. Generally people are diagnosed with chronic kidney disease which may progress to end-stage renal disease. The rate of progression varies and depends on numerous factors including other comorbidities and the type and etiology of the chronic kidney disease. It is important to make the diagnosis of kidney disease as early as possible and to be referred to a nephrologist, a doctor who specializes in kidney disease. People with ESRD suffer from other conditions secondary to their kidney failure. The kidneys are also involved in production of red blood cells in the body due to kidney cells synthesizing a hormone called erythropoietin. Patients with ESRD often become anemic, or have low blood counts. They may need to get iron replacement because iron is necessary to make red blood cells in addition to getting erythropoietin injections periodically.

Bone disease and mineral/electrolyte disorders can also occur among individuals with ESRD. Bone disease is usually from secondary hyperparathyroidism, in long-term dialysis patients. Osteitis fibrosa, a hyperparathyroid bone disease, involves increased bone breakdown and eventually bone marrow fibrosis. Another common problem is having high blood levels of phosphorous or potassium (mineral and electrolytes). To tackle these issues, doctors prescribe medications that are known as phosphorous binders to aid in the removal of the dietary consumption of phosphorous. High-phosphorus-containing foods include meat products and whole grains. It is also important to follow a low potassium and low phosphorous diet. Foods high in potassium include oranges, bananas, kidney beans, apricots, potatoes, and spinach.

Malnutrition is also a very common problem in people with ESRD. Dialysis patients are often malnourished because of poor appetite. In addition, they often do not consume enough protein and calories to maintain their weight. All the causes of the malnutrition seen in the ESRD populations are not known, but another factor may be the destructive metabolic stress of hemodialysis itself.

The number one cause of death in the ESRD populations is cardiovascular disease. It is essential to maintain normal blood pressure and lipid control. Often patients on dialysis achieve adequate control on dialysis and do not need to take blood pressure medications.

Renal Replacement Therapy

Fortunately, there are multiple modalities that allow prolonging life for patients with kidney disease, such as hemodialysis, peritoneal dialysis, and kidney transplant. Dialysis helps both maintain fluid and electrolyte balance in the body. Patients will develop severe volume overload and electrolyte abnormalities that quickly lead to death if they do not have dialysis. When patients are without renal replacement therapy, they may experience symptoms such as weight gain and difficulty breathing from the excess fluid buildup in their bodies and nausea, vomiting, anorexia, and fatigue from the accumulation of toxins that their own failed kidneys cannot clear.

Hemodialysis is the process of exchanging solutes from the blood via diffusion and removal of excess water by a pressure gradient. Two needles are inserted into an access site, one needle allows blood to leave the body and go through a dialysis membrane and the other needle allows the clean blood to return to the body. Most people get dialysis at a dialysis center three times per week. The incidence of dialysis is highest in Taiwan and the United States.

Peritoneal dialysis involves infusing a dextrose, or sugar, and electrolyte solution into the peritoneal cavity of the abdomen. After a period of time the fluid is drained out of the body through a single peritoneal dialysis catheter. People can choose to do exchanges throughout the day on their own or only at night with the help of a machine.

Dialysis Access

To start dialysis, one needs a way to connect the body to whatever method of renal replacement therapy that is being used. For hemodialysis, one needs an arteriovenous fistula, an artificial graft, or a temporary dialysis catheter. Temporary catheters can be used for a few days to months but often get infected and have to be removed. Grafts are made from foreign material but also have a large risk for infection and do not last long. Fistulas are made up of one's blood vessels by connecting an artery and vein. Sometimes, patients cannot have a fistula placed because their own blood vessels are not large enough to make the fistula. Grafts are usable more quickly than fistulas and need to be placed about 1 to 2 months before starting renal replacement therapy, but fistulas must be made 2–6 months prior to the initial dialysis.

For peritoneal dialysis, a catheter is placed through the abdominal wall into the peritoneal space. Once the catheter is externalized, or opened outside the skin to be available to use, a nephrologist waits about a week before starting peritoneal dialysis. Peritonitis, or the infection of the peritoneal fluid in the abdomen, is a common complication of peritonitis as well as exit site infections involving the peritoneal dialysis catheter.

Kidney Transplant

Kidney transplant is a favorable option for patients with ESRD because with current immunosuppressive therapy the transplanted kidney can last more than a decade. Transplanted kidneys can come from deceased or living donors. The process of finding an acceptable kidney is complex and includes assessing blood type compatibility, HLA (human leukocyte antigen) tissue typing, and antibody crossmatching. Complications of kidney transplantation include acute and chronic rejection as well as infections. Immunosuppressive therapy also has a number of side effects including toxicity to the kidney themselves over time as well as low blood counts, high blood pressure, and central nervous system damage.

Health Care Costs

Patients with ESRD have astronomical health care costs. In the United States, Medicare ERSD program pays for the majority of dialysis patients, a cost of about $40,000 per year on dialysis. Renal transplant is more economical in the long term with the initial cost of transplant about $40,000 and $10,000 annually for the following years of a functioning transplant.

Undocumented Immigrants in the United States

Immigrants who reside in a nation without legal permission make up a large part of the population in many countries. In the United States, it has been estimated that there are over 11 million illegal immigrants. It is difficult to know how many people suffer from ESRD, but it has been suggested that about 5,500 undocumented immigrants have ESRD.

Chronic dialysis is not paid for by the federal government in the United States, and states have varying policies on maintenance dialysis reimbursement. Examples of states that provide chronic dialysis include North Carolina, California, Arizona, and New York. Unfortunately, most states have only emergency dialysis funding for undocumented immigrants, and therefore, ESRD patients may have to be admitted to the hospital emergently for a series of treatments. Consequently, these patients have temporary catheters which, as discussed earlier, have higher rates of infection placed repeatedly for access. The Renal Physicians Association in the United States has stated that patients with ESRD should have access to federal funding for their renal health, and furthermore, that nephrologists should honor the confidentiality characteristic of the patient and physician relationship and not be expected to inform legal authorities regarding undocumented immigrants. Patients without access to nephrologists and chronic renal care often have higher blood pressures and more difficult transitions to dialysis. Providing health care to undocumented immigrants poses an ethical and financial dilemma that plagues many countries.

English as a Second Language

Elizabeth Chacko
Department of Geography, The George Washington University, Washington, DC, USA

English is the dominant or only official language in Australia, Canada, and the United States, the three largest immigrant-receiving nations in the world today. Approximately, 22% of Australia's population is foreign-born; the corresponding figures for Canada and the United States are 20% and 13%, respectively. Most immigrants to these countries come from developing countries in Latin America, Asia, the Middle East, the Caribbean, and Africa, where languages and cultures often differ significantly from those of the host countries. Immigrants who are not proficient in English face the challenge of learning to speak, read, and write in English as a Second Language (ESL). In the United States alone, there are 1.8 million who are limited English proficient (LEP). The inability to communicate effectively in the host country's language can be a barrier to integration into the host society and has health implications as immigrants who are LEP may have problems in understanding health care options and in accessing health care.

Inability to communicate in a country's official language is a marker of risk for poor health. Language and nativity were found to play an important role in access to health care among United States Hispanics (Latinos) who are the largest immigrant group in the United States. LEP Latinos were found to not use or be aware of local public health programs and other health resources. In addition to language barriers, isolation in new communities was also found to be a problem in accessing health care. An Australian study found that the social integration of non-Western immigrants was associated with good mental health. It is important to note that isolation and LEP can be mutually reinforcing. In the United States, 60% of legal immigrants who were eligible for citizenship but did not become citizens were LEP. In a country such as the United States where immigration status affects access to health care, acquiring citizenship can be a critical qualification in maintaining good health.

English medical terminologies are difficult to understand for someone for whom English is a second language. Most ESL patients feel that they could describe their symptoms and experience of illness better in their primary language and also understand the diagnosis and their physician's instructions better in their mother tongue. But there is often patient–physician language discordance as it is usually difficult to find same-language physicians. Interpreter services help to some extent to ease the communication gap between immigrants with ESL and their physicians. However, these services are not always available to all populations due to the great number of languages spoken by immigrants, high costs, and lack of adequate numbers of interpreters.

Language ability can also influence the use of preventive care. In the Canadian context, where 80% of Chinese Canadians are foreign-born, English ability was positively associated with mammography adherence among Chinese immigrants. Another Canadian study found that there was a significant association between poor English proficiency and self-reported poor health among women immigrants.

While all countries have English language health education materials and media campaigns, providing language access and assistance to limited English proficient (LEP) immigrants is a critical step to ensuring good health. Assistance can involve providing information in the immigrants' native languages and through ESL classes that are available for adults and through each country's public school systems. ESL classes can help individuals with limited English attain proficiency so that they can more fully participate in the host country, be aware of, and be able to access its health care systems more effectively.

Environmental Exposure

Bettina Rausa
Salk Institute for Biological Studies, La Jolla,
CA, USA

Environmental exposure has significant impacts on human health. Exposure to environmental pollution, produced primarily by humans, can cause health problems ranging from minor skin irritations to sudden death. The largest sources of environmental exposure that have the greatest impact on human health include polluted air, water, and land. Migrants are exposed to additional environmental factors such as weather, travel conditions, and duress or coercion both during their migration process and after reaching their country or location destiny.

Air Pollution

Polluted air, both outdoor and indoor, harms human health in a number of ways. It can cause respiratory diseases like asthma, lung cancer, allergies, and chronic bronchitis – all of which are contributors to premature death. Breathing polluted air has serious consequences for women who are pregnant as it may cause complications during pregnancy, premature birth, low birth weight, and various physical and neurological problems in newborns. Pollutants in the air can also cause harm to humans by settling onto vegetation and in water ways – both of which end up in the food chain. Specific outdoor air pollutants that are known to trigger health hazards for humans include carbon monoxide, lead, nitrogen dioxide, ozone, particulate matter, and sulfur dioxide. The primary sources of these pollutants are factories, power plants, motor vehicles, and waste burning activities. Indoor air pollution is generated from activities such as cooking and heating with solid fuels on open fires or traditional wood burning stoves which result in high levels of smoke inhalation – especially in poorly ventilated homes. Poor ventilation is often due to substandard construction or lack of air conditioning systems. Indoor smoke from sources like fireplaces and other wood, gas burning activities, and tobacco smoke contains a range of health-damaging pollutants including small particles/particulate matter that can settle inside the lungs and carbon monoxide which can cause significant levels of toxicity of the central nervous system and cardio vascular system, and can even cause death.

Water Pollution

In 2000, a water quality survey conducted in the USA showed that over 30% of streams, 48% of lakes, and more than 20% of estuaries were polluted. The survey also found that almost 20% of water systems that serve over three million people were in violation of basic health standards. Contaminants found in drinking water that threaten human health include microbes from human and animal waste, chemical pollutants including pesticides and volatile organic compounds, metals such as arsenic and lead, and even chemical byproducts created by the very processes used to disinfect drinking water, like chlorine. The adverse health effects caused by these contaminants range from gastrointestinal illness to cancer and developmental problems. People who are most likely to be exposed to contaminated water include those who do not have access to proper sewer systems, who live near factories, landfills, hazardous waste sites, and large farms, and those whose water supply comes from shallow wells or surface water sources. Children are especially at risk because they consume more water and breathe more air than adults in comparison to their body composition and therefore take in more harmful toxins compared to their body weight.

Land Pollution

Land pollution includes the use of chemical additives in soil and on vegetation for agricultural purposes such as fertilizers and pesticides. It can also be caused by mineral exploitation, and industrial and urban waste dumping. Hundreds of millions of metric tons of solid waste are put in landfills every year. In industrialized nations, many open dump sites have been replaced by more sanitary landfills which provide better aesthetic control of the sites; but in less developed countries, open dump sites are still common practice. Even when dump sites are redesigned to control the noxious smells, fumes, and rodent infestations, industrial waste, often of unknown content, is commingled with domestic waste which leaks into the soil and ground water and contaminate water supplies.

Pesticides

The use of pesticides poses particular concerns because many people are exposed to them on a daily basis via sources such as food, water, and air. Pesticides are particularly dangerous because many of those used in commercial farming are not biodegradable. Pesticides are bio-accumulative, that is, they are retained in the body of the consuming organism and passed along the food chain.

People who live in or near agricultural areas are at much higher risk for adverse health problems caused by pesticides because their exposures are significantly higher. Pesticides are made up of various chemicals that are used to kill insects, molds, and other organisms that can destroy crops; they are used on lawns and inside buildings to control insect and rodent infestations. Even low levels of human exposure can be toxic; some of the most common effects on human health include skin rashes, burning eyes, cough, nausea, vomiting, diarrhea, sweating, twitching, and difficulty breathing. Humans exposed to pesticides are also at greater risk for certain types of cancer including lymphoma, prostate cancer, and childhood cancers. Women who are pregnant and are exposed to pesticides are at higher risk for miscarriages or giving birth to a child with birth defects.

Environmental Exposure and Immigrant Health

The World Health Organization estimates that roughly one-quarter of the diseases facing humankind today occur because of prolonged exposure to environmental pollution. Many of these diseases, however, are not easily detected and may be acquired during childhood only to manifest into serious health problems later in adulthood. Poor and improper waste management, for example, poses a great challenge to the well-being of individuals living in urban areas, particularly those living adjacent to dumpsites. To emphasize the link between environmental pollution and public health, the United Nations Environment Program commissioned a pilot study of the Dandora municipal waste dumping site in Nairobi, Kenya. Analysis of soil and water samples found heavy metals, polychlorinated biphenyls (also known as PCBs which were banned by the USA and the Stockholm Convention on Persistent Organic Pollutants) and pesticides – all known to have adverse affects on human health.

The health problems discovered among children living in Dandora included skin disorders and skin cancer; respiratory abnormalities including bacterial infections, chronic bronchitis, and asthma; abdominal and intestinal problems including liver cancer, kidney, and renal failure; dental disorders (dental carries and pain); ear infections; skeletal muscular pain; central nervous system impairments such as neurological damage, nerve damage, and headaches; eye infections, blood disorders like anemia; and other diseases such as malaria, chicken pox, septic wounds, congenital abnormalities, cardiovascular diseases, and lung cancer.

There is a shortage of information regarding the impacts of environmental exposure in immigrant communities around the world. Immigrant communities, like other marginalized communities, comprise vulnerable populations that are often exposed to a variety of environmental and occupational health hazards. Immigrant communities generally experience higher rates of poverty and health disparities which are typically the result of both inadequate access to health care and lack of culturally appropriate health care and information. Immigrants who do not have legal immigration status are especially vulnerable. For example, in the USA, various laws have been passed to ensure that immigrants who do not have legal immigration status are denied access to health care and restricted access even to legal immigrants. The Personal Responsibility and Work Opportunity and Reconciliations Act of 1996 denies most legal immigrants nonemergency federal health care benefits, also known as the Medicaid program. The Illegal Immigration Reform and Immigrant Responsibility Act, also passed in 1996, further denies most immigrants the option of applying for federal public benefits for the first 5 years of legal residency in the USA and makes immigrants who lack legal immigration status ineligible for any federal, state, and local public benefits.

There is little research about the risks of environmental exposure incurred specifically by immigrant populations; however, several studies have been conducted of populations living near sources of pollution, the vast majority of which are minority groups, low-income and subsistence level households, and other marginalized groups. Immigrants worldwide are found in these communities. In Massachusetts, the neighborhood of Boston Chinatown is populated primarily by first-generation Asian immigrants, and it is the only community in Boston that is located at the juncture of two major highways that account for 250,000 vehicles/day. The noise and air pollution caused by this level of motor vehicle traffic have been linked to elevated blood pressure, cholesterol levels, and impairment of reading and language skills in children. Components of vehicle exhaust and particulate matter have been associated with a variety of acute and chronic conditions including headaches, eye conditions, and asthma.

A Swedish study conducted in the county of Scania found that four of the five cities surveyed had immigrant populations that were more likely to be exposed to air pollution from various sources, primarily vehicle traffic related. Studies in England and Wales found that solid waste and other polluting facilities were disproportionally located in more economically deprived areas. A national study in France looked at eight different hazardous sites, including industrial, nuclear, incinerators, and waste management facilities and found that the towns with the highest proportion of immigrants hosted more of these hazardous sites. In Hungary, 15% of the 767 Roma colonies (three million people) are located within 1 km of illegal waste disposal sites including asbestos. Eleven percent of Roma colonies are within 1 km of animal carcass disposal sites. In fact, Roma are exposed to some of the worst environmentally polluted areas throughout Europe as they are often pushed to the farthest outskirts of cities and towns, away from access to clean water and other sanitation services, but near garbage dump sites and flood plains. In all of these circumstances, irregular immigrants, or those without legal documentation regarding their immigration status, bear the highest cost in terms of exposure. Their options for housing and jobs are extremely limited and as such, they are often confined to environments with the highest risks to human health.

A fair amount of research can be found regarding Latino immigrants, primarily from Mexico, living in the USA and their environmental exposure. In addition to working in and living near agricultural areas where exposure to agricultural chemicals such as pesticides is very high, Latino migrants in the USA also tend to live in industrial areas where pollutants are constantly discharged into the air by factories and heavy motor vehicle traffic. In addition, the highest numbers of abandoned hazardous waste sites which have been designated by the US Environmental Protection Agency (EPA) for cleanup, also known as Superfund sites, are located in states that also have the highest number of Latino immigrants. Those states are, in order of the largest number of immigrants: California, which has 37 Superfund sites, Arizona with two Superfund sites, New Mexico with 5; Florida with 24, Texas with 25, and New York with 49. Although there is a federal mandate to clean up these highly hazardous sites, the program has been underfunded and cleanup work is slow.

The US–Mexico border region is characterized by a particularly serious environmental hazard for many Latinos living in these mostly impoverished areas: polluted water supplies. Pollutants in drinking water in southern and western US states along the Mexican border are known to cause sudden and deadly illnesses. Parasites, bacteria, and viruses in contaminated water can cause diarrhea, abdominal cramps, weight loss, fever, chills, vomiting, dehydration, bloating, headaches, jaundice, and muscle pain. At even higher risk for serious and fatal diseases are individuals with weakened immune systems.

The children of immigrant farm laborers are at particular risk for environmental hazards because they breathe more air, drink more water, and consume more food in comparison to their body weight than adults. Although they may not work in the fields, because they reside near them and because their parents work in them, children are exposed to pesticides at home from their parents' clothing and from dust tracked in the house, at school, and on playgrounds. The toxic chemicals in pesticides pose serious risks to children's health but few studies have examined the neurological impact of pesticides on children of Latino migrant farm laborers. A study of children living near agricultural areas in Mexico, however, revealed high incidents of diminished stamina and coordination, memory impairment, and alarming differences in drawing recognizable representations of people and objects. In fact, the drawings were incomprehensible compared to the drawings of children of the same age who were not exposed to pesticides. There is also evidence that demonstrates the associations between parental or infant exposures to pesticides and childhood brain tumors, leukemia, non-Hodgkin's lymphoma (cancer of the lymphatic system), sarcoma (cancer in the connective tissues like bones, cartilage, and fat), and Wilm's tumor (childhood kidney cancer).

Much of the world's human migration occurs from rural to urban areas, especially within countries. The World Health Organization estimates that over three billion people live in cities and the United Nations Population Division estimates that within 30 years, nearly two- thirds of the world's population will live in cities. Most of this growth will occur in Asia and Africa; in fact, Asian cities already have more urban populations than North America and Europe combined. Growing urban areas attract migrants from impoverished rural areas, and many of the world's poorest migrants end up in slums where the environmental conditions coupled with inadequate facilities are a danger to human health. In the Southeast Asia Regions (SEA), four cities alone are home to 15 million slum dwellers (Delhi, Dhaka, Kolkata, and Mumbai). Slums are characterized by extreme poverty, lack of clean water and water supplies in general, lack of solid waste management, electricity, sanitation, and other basic services. Garbage often accumulates in huge quantities. Dwellings are often simple structures made of flimsy materials and poor construction. This makes them absolutely vulnerable to natural and man-made disasters such as landslides, earthquakes, floods, and fire. There is also a lack of security, making poverty stricken slum populations subject to crime and violence. Climate change will contribute to the unhealthy and dangerous living conditions of slum residents by causing flooding in coastal cities, heat stress, and exposure to new disease vectors. The stress of living in slums coupled with weakened social support systems that are characteristic of big cities creates further challenges in the areas of mental health.

The migration journey itself can expose humans to harsh environmental factors. Images of "boat people" have been witnessed around the world: people fleeing war-torn Vietnam, Cambodia, and Laos in the late 1970s and early 1980s; Cubans taking on the treacherous journey to cross the Atlantic to reach the USA; and refugees from the former Yugoslavia and surrounding countries fleeing war and genocide in desperate attempts to reach the Italian shores, are among just a few. One of the more closely studied groups of people who go through extraordinary efforts to migrate are those crossing the US–Mexico border on foot. Several factors make this a very treacherous journey. First, it can take several days of constant walking. Border and immigration enforcement efforts have pushed migrants to cross the border in the most desolate and dangerous terrain areas of desert and mountain passes. A study supported by the American Civil Liberties Union (ACLU) and Mexico's National Commission of Human Rights in 2009 estimates that at up to 5,600 individuals died crossing the border in the last 15 years, although there are no official records because many of those who die are either never found or not officially counted by border or other government agencies. The number of deaths has increased yearly since enforcement efforts have increased. Incidentally, the number of unauthorized immigrants into the USA from Mexico has grown from 8.4 million in 2000 to 11.9 million in 2008, despite the stepped up border enforcement.

Environmental exposures of migrants crossing the US–Mexico border on foot include extreme weather temperatures which can lead to organ failure and death. Some people die quickly due to the environmental stress, especially if they have pre-existing health problems. Migrants who have died in the desert areas that make up the border region also show signs of blunt trauma from falling on the prolific desert cacti and rocks. The heat generated from the desert sand can also burn through inadequate shoes, causing severe blistering of the feet, making it impossible to walk. People usually make this journey in groups and if they are not able to keep up the pace, they are often left behind in desolate, treacherous, and harsh terrain with no access to water, food, or shelter. Humanitarian organizations that go into the desert to provide lifesaving services to these migrants report treating individuals suffering from hypothermia, heat exhaustion, abrasions, snake bites, skeletal trauma, dehydration, severe sunburn, nausea and vomiting, miscarriages, and exhaustion. Migrants also drown in various rivers, canals, and other waterways that are used to cross the border, including the ocean.

More and more migrants are crossing into the USA via the Pacific Ocean and Texas Gulf because physical barriers have been erected along various canals in California, Arizona, and Texas to prevent undocumented migration. To cross the border via the Pacific Ocean, people must swim quite far from shore in order to not be detected by law enforcement monitoring this section of the border. Motor vehicle accidents are also big contributors to injury and death of migrants. Vehicles used to smuggle migrants into the USA are often poorly maintained and severely overloaded. They may reach dangerously high levels of speed if being chased by law enforcement. Migrants also suffer violence and abuse at the hands of their smugglers, as do many clandestine groups of people who migrate illegally, including the millions who are trafficked every year all over the world. Homicide and assault are not uncommon for unauthorized US–Mexico border crossers as smuggling networks are often tied to other criminal enterprises including drug and arms smuggling. And finally, natural disasters such as the enormous fires in California in 2003 and 2007 may result in injury or death. During these fires, law enforcement reported the apprehension of 200 individuals, some having suffered burns requiring hospitalization, and five who died in the fires.

Women are also especially vulnerable to sexual exploitation and violence during and after the migration process. The ACLU study reports that women are often offered "security" by their smugglers and others involved in the smuggling of humans across the border in exchange for sex. Women who refuse may be beaten and/or raped. All of these women are at risk for injury, pregnancy, and sexually transmitted diseases. Upon reaching their country or region of destination, or wherever traffickers decide, women are often easily exploited by working in unregulated sectors of the labor market, and most especially in the sex industry. Some estimates indicate that up to 80% of all trafficked persons are women and girls.

Environmental Health

David M. Gute[1], Samuel C. Levine[2]
[1]Civil and Environmental Engineering, Tufts University, Medford, MA, USA
[2]Community Health, Tufts University, Medford, MA, USA

This entry will describe the impact of environmental influences on the health status of immigrant populations. The health of populations is influenced by a variety of factors which reflect genetic inheritance, behavioral attributes, access to and quality of health care, as well as environmental influences. (For a seminal distillation of these factors please see Marc LaLonde's – A New Perspective on the Health of Canadians as published in 1981). Before we begin to explore this issue we need to address two important issues: the first of these is the definition of "environmental influences or factors" and the second is the consideration of "the act of immigration as a putative factor in the maintenance of health and the development of disease." This second issue has been examined via classical sequential cross-sectional studies following populations as they pass through different locations (For an example see the 1974 work of Kagan et al. which tracked the experience of populations in Japan, Hawaii, and California).

Definition of Environmental Health

The definition of environmental influences is sometimes broad; LaLonde in his already referenced work includes a wide variety of factors. Traditional environmental health is comprised of contaminants in the ambient environment that affect the health of populations. Other writers take a more restrictive view and hold that environmental exposures are inherently defined as involuntary exposures. Steenland and Savitz use the illustrative example concerning the burden imposed by tobacco consumption as being compartmentalized into personal behavior (active smoking) in contrast to secondhand smoke being characterized as an involuntary environmental exposure. This interpretation is lent further credence by the evolution of the term "Environmental Tobacco Smoke." With the approach of considering environmental exposures to be largely those that are imposed and of an involuntary nature we will explore the literature with regards to what is known regarding the putative impacts of such exposures on immigrant populations.

First, a word regarding the act of immigration per se. Many commentators have written about factors associated with immigration that complicate the interpretation of health status data from such populations. An early paper on this subject by Kasl and Berkman highlighted the powerful self-selection factors found in immigrant populations. These include the varied and hard to measure responses to changes in environment. Kasl et al. went further to point out that the screening of immigrant populations may occur as a result of international travel and entry into new occupations, thus "improving" the health status of these new arrivals. From this it follows that the very act of immigration needs to be thought about distinctly from environmental influences.

Healthy Immigrant Effect

One question to consider at the outset is the "healthy" immigrant issue. This holds that powerful selection factors may influence which individuals in fact immigrate**.** The health care utilization experience of recent arrivals tracks differently according to geographical and access to medical care contexts. Eamranond and Hu also note that Spain, which features relatively easy access to health care coverage for immigrant populations, reports a lower rate of health care utilization among immigrants than among native born residents. The Canadian experience, again reflecting the structural advantages of a health care system featuring universal access, finds persistent advantage to immigrant populations for chronic conditions versus comparisons to native born counterparts as noted by McDonald and Kennedy in their work. It is noted that some of these advantages erode with added years in Canada.

There are alternative hypotheses which are brought forward to explain the so-called "healthy immigrant." These range from a twist on the hygiene hypothesis which holds that early stimulation of the immune system yields greater resistance to disease later in life to the protective elements of cultural differences in terms of social support and people rich networks.

Other broad factors help determine and influence the health of populations such as recent immigrants including diet, access to beneficial exercise, and use of drugs and alcohol. It is not the place of this entry to decide this question. It is however important to remain aware of alternative explanations surrounding the health experience of immigrant populations.

Micro Versus Macro Environment

One may hypothesize that immigrants have a less robust control of both their "micro" and "macro" environments. This potentiates the likelihood that immigrants may be subject to more concentrated exposures and possibly for longer duration to environmental contaminants than native born populations. Documenting such realities is still very much a work in progress. This is one of the most striking results of consulting the extant literature with regards to the subject of this entry: the paucity of published research on the etiological importance of environmental sources on the health of immigrants. This lack of descriptive research is particularly challenging for the crafting of interventions with regards to immigrant populations given their heterogeneity when assessing various characteristics at the subgroup level. Some works, such as that of Kandula et al, recognize that such differences as framed by variables such as country of birth are critical to planning and evaluating the need for specific public health interventions which address immigrant health needs.

The pollutants most associated with the immigrant experience are a relatively small set of well-known environmental toxicants. Pollutants with documented differential impact on immigrants include lead (Pb), pesticide exposures (in residential settings such as public housing as well as in occupational sources such as the agricultural industry sector which can affect workers but also contiguous environments), as well as a developing literature with regards to air pollutants.

Internal Migration

Another issue of concern is the internal migration pressures which produce steady flows of migrants from the rural hinterlands to urban centers. These populations often encounter similar disadvantageous living situations similar to those which confront immigrants who cross national borders. A great proportion of this internal migration is fueled by the prospects of better employment, education, and social advancement. Marmot in a 2009 World Health Organization report assessing the social determinants of health cautions that inequities between rural and urban areas need to be addressed in a meaningful way, so that internal migrants are more adequately prepared for and received in urban environments.

It must be stated that internal migration imposes its own set of pressures on affected populations. Often times the shift from agrarian, rural settings to urban environments can be just as jarring as a journey of many time zones and across wide oceans. What is certain, however, is that a set of transcultural factors have contributed to a global trend favoring urbanization which has caused the growth of the "mega city," particularly in low and middle income nations. Such mega cities (Djakarta, Mexico City, Sao Paulo, Ibadan) are more often than not found in emerging economies that often bear the economic and developmental pressures already alluded to. Such pressures produce higher density in both the urban and peri-urban city scapes, more competition for existing housing stocks, greater unmet needs in terms of water distribution systems and sanitation infrastructure such as sewers and latrines, all played out in an environment which often places the migrant and immigrant having to navigate this complicated landscape in a similar manner. For in-depth coverage of this phenomenon please consult the activities and research trajectory of the UN-HABITAT organization.

The pressures exerted by urban life are not solely operating in the province of low income nations. A brief case is presented here which chronicles the difficulties and opportunities faced by immigrants in the metropolitan area of New York City (NYC). The reader should be aware that issues within the traditional province of environmental health (air, water, soil, noise, climate) exert strong influences on population health and are of growing importance in both research and practice.

Case Study: New York City

According to the Department of Homeland Security, sixty percent of all legal immigrants in the US live in 6 states, and 75 live in 10 (Department of Home Land Security, 2009). In 2010, 5 metropolitan areas accounted for 40% of all new legal permanent residents). This concentration of immigrant populations is a common trend worldwide. New York City (NYC) is a prime example of a place where immigrants face different environmental exposures, risks, and challenges than their native counterparts.

As of 2006, 37% of all NYC residents were foreign born. Many are new arrivals – between 1990 and 2007, 1.5 million immigrants moved to NYC. Lerner et al. discovered that these immigrants are more at risk for lead poisoning, pesticide exposure, residence in low rent apartments, the development of asthma, childhood obesity, and the development of behavioral issues.

For immigrants in New York, the home can be a significant source of exposure to environmental hazards. Over half the immigrant population pays 30% or more of their annual income on housing. This proportion is even higher in the poorest of immigrant populations. Immigrant housing is often overcrowded and in poor condition, with insects, rodent infestations, and poor air quality. These deficient housing conditions may contribute to asthma and lead poisoning, with children being at particular risk. In addition, cleaning agents and pesticides used in the house, and available for sale in neighborhoods, place residents at additional risk. Unfortunately, with a lack of affordable housing being constructed, and the tendency for immigrants to move into neighborhoods of their own ethnicity, the issue of poor housing may continue to exist for NYC immigrants.

The broader immigrant neighborhoods and communities produce additional exposure and risk. As stated earlier the sale of chemicals, cleaning agents, and pesticides on the street is common, especially in Hispanic communities. (Hispanic communities contain one-third of immigrant children living in NYC). While these physical risks are clearly present, many non-tangible exposures also exist in these environments. The stress of living in a new environment, especially one of poor life quality, may have a negative effect on residents' psychological state. A Milano Graduate School publication chronicles how immigrant children suffered a disproportionate amount of anxiety and psychological trauma from the September 11 attack and the Flight 547 crash in Queens. In addition, the presence of violence and crime in these immigrant neighborhoods may have a negative effect on resident mental health. Because of language limitations (15% of immigrant families do not have a member over the age of 14 who can speak English), these neighborhoods are often inescapable, lacking social and economic mobility for residents.

It is easy to focus on specific, quantifiable exposures concerning the environmental health of a population. However, the environmental context of an immigrant is much broader than chemical or biological exposure. In the case of New York City, the biggest changes in environment from native countries are the ones more difficult to measure – lifestyle, environmental stress, access to native foods, and culture. Thomas R. Frieden, Commissioner of the NYC Department of Health, acknowledged this in writing that immigrant health is negatively affected in the USA by new environmental influences, extending to differential levels of concentrated tobacco marketing and exposure to unhealthy diet.

The NYC immigrant population is a pertinent example of how sudden and severe changes in context and culture can exert strong effects on mental health, and put immigrants at increased risk for chronic disease such as heart disease, diabetes, and obesity. Combined with the lack of access to care and primary prevention in the New York City foreign born community, this may pose a serious threat to health status. These complications can sometimes produce varied outcomes in heterogeneous populations exposed to the same stimuli.

The differential responses to the tragedies of September 11 and the Flight 547 crash serve as an example of a similar environmental exposure affecting native and foreign born populations differently. Immigrants responded with increased rates of posttraumatic stress disorder, depression, prescription drug use, and less health care utilization. Lack of primary care physicians may have contributed to this difference, and the lack of primary care in the immigrant population may have exacerbated the difference in reaction to these disasters. The difference in response to the same event, however, indicates that outcomes from individual exposures are complicated by the host factors found in the exposed populations. In the case of environmental health, immigrants in New York City appear to have intangible differences form their native born counterparts.

Difference in risk, exposure, and response exist within the broader heterogeneous immigrant population. Some variability makes sense – new immigrants will find jobs and homes most often through the social networks of family and friends, creating communities of singular ethnicity, and particular hazards. However, because of the multitude of immigrant communities represented in NYC, this variance presents a problem when considering interventions. Variance within a single immigrant community exists too. Immigrant children are especially at risk for exposure, as they have even less control over their environment than adults of the same population. This underscores the importance of the active study of children and adolescents as sensitive or susceptible populations as seen in the National Children's Study.

New York City provides an example of a great amount of available data on the immigrant health experience in contrast to the often marked paucity of information pertaining to immigrant health. The past decade has shown an increase in concern and study of immigrant health, and acknowledgment of the disparities that exist across ethnicity, age, and gender. In this regard, New York City serves as an example of the potential benefits achieved as a result of successful research and dissemination of information pertaining to immigrant health.

Being a city of considerable size, population, diversity, and disparity, it is not surprising that a number of risks and exposures exist in New York City. What is instructive here is the disproportionate risk and exposure that immigrants, especially immigrant children, bear. It is also clear that given the demographic importance of the immigrant populations in New York City that interventions mounted to improve immigrant health also raise the health status of the remaining (US born) population.

Resistance to Environmental Stressors

The ability for communities and populations to exhibit resistance to environmental stressors and other provocations has captured much recent attention under the broad term of resilience. Resilience has been calibrated in global populations as well as in populations faced with the challenge of natural disasters and other broad scale environmental stressors. The particular definition of resilience involves both substance and context. Almedom and Glandon write that the ability of populations to respond to changes, exposures, or stimuli in an effective and competent manner fall under the concept of resilience. Given the heterogeneity of host factors found in immigrant populations it is reasonable to assume that research probing resilience in different immigrant populations will be a topic of growing importance. In short, why are certain populations less prone to the deleterious impacts of environmental factors?

The impact of the acute heat wave which occurred in the summer of 1995 in Chicago, Illinois is of use in this consideration. Some of the impact resulted from characteristics of the host populations but also as a result of the capacities and efficacy of social and civic institutions (such as police and fire departments as well as departments of social service). One result which emerged from Klinenberg's book on the subject is that although Latinos comprised about 25% of the city population and are disproportionately poor and sick, this population accounted for only 2% of the heat related deaths. Initial commentary regarding this protective effect posited that Latinos benefited from intact social networks. Klinenberg, however, interpreted this result as the influence of the concentrated density and vitality of the neighborhoods selectively populated by Latinos, in contrast to neighborhoods subject to the corrosive influences of abandonment and more commonly inhabited by African Americans. In the end, Klinenberg's analysis demonstrates that fragility of a diverse set of social institutions set in motion events that caused excess heat related mortality. Lessons were learned and policy modifications were instituted as borne out by the result of a similar 1999 heat wave in Chicago. During this more recent heat wave, while still causing excess heat related deaths; the final toll was less than one-quarter of that recorded in 1995. The core responses featured public health warnings, access to air conditioned public spaces, door-to-door checks mounted by police and public safety staff of vulnerable individuals, and other measures at the population level.

Factors Associated with the Built Environment

Such successful policy and programmatic responses also find analogs in more traditional ambient environmental interventions being pursued globally. One salient example is the recent reductions in air pollution achieved in Mexico City, Mexico. These reductions have been achieved by the initiation of a variety of engineering controls (introduction of low sulfur fuels) and behavioral modifications (reductions in car use). In the USA attention has turned to the influence of the built environment in terms of creating positive influences on population health. In the September 2003 special issue of the *American Journal of Public Health*, immigrant populations were identified as one of the at risk populations relative to the built environment because of primarily poor housing stock and other environmental stressors such as unsafe pedestrian environments, and greater exposure to air and water borne contaminants.

This differential impact is one that will be seen in many built and ambient environmental factors as we move forward in time. The impacts of climate change are widely believed by many analysts to impose disproportionate burden on the global poor but also upon those living in high risk areas which are more prone to the ravages of flood, drought, and other extreme weather events. This brings into sharp relief the proposition that immigrants will potentially be adversely affected through an extension of factors which drive environmental justice inequities in the USA and elsewhere. A case can be built that supports the notion that the strength of these sociopolitical forces will only intensify as immigrants will likely be subjected to often hostile immigration policies and a skeptical response on the part of native born populations faced with uncertainties which stretch from globalization to the halting recovery from a worldwide recession.

Ultimately, ensuring environmental health for immigrants improves the environmental health of all. This will require improvements in *physical* and *social* infrastructure. The physical infrastructure is the world of better housing stock, mass transit to lower air pollution burdens, better water and sanitation systems. This can be paired with social infrastructure such as improvements in population-based risk factors which are affected by behavioral changes in diet, exercise, smoking cessation, etc. Equally important is the interplay between the built environment and personal risk factor reduction. The nexus (particularly the influence of perceptions of safety and access on physical activity) of these factors will likely form an agenda item of increasing importance for environmental health specialists and land use planners in the future.

Additive Effect of Environmental Exposures

The consideration of the impact of multiple environmental stressors upon the health status of populations has spurred attempts to arrive at estimates of the possibly additive, synergistic, or perhaps antagonistic relationship between and among such stressors. The concept of cumulative risk speaks to the marshaling of either quantitative or qualitative data to express such additional risks imposed upon specific geographic locations. This comes into sharpest focus when regulatory authorities are attempting to site a new source of environmental stress in a given place. This prompts questions relating to other place-based risks to which this population is exposed, and whether the new risk skews this cumulative risk to “unacceptable” levels.

Johnson, in an innovative design implemented in Detroit, Michigan, attempted to separate the risk for developing asthma into a set of host factors as well as an aggregate risk score called the environmental risk index (ERI) for each household. The ERI did not attempt to characterize the ambient environment but rather concentrated upon factors associated with the design, construction, and condition of the dwellings inhabited by the study participants. Johnson and her coauthors found that immigrant populations, in terms of asthma, are appropriate populations to view the combined impact of culture and environment. The complexities of managing asthma as a medical condition also were found to increase the importance of English fluency, and birth in the USA was associated with improved health outcomes. The prevalence of asthma was highest among moderately acculturated immigrants compared with new immigrants. This suggests along with the work of other investigators already cited that “Western” risk factors begin to predominate for Arab-Americans as the population becomes more established. Brugge and colleagues found that such differences in terms of the distribution of asthma among native and foreign-born populations at the community level in Boston are not always obvious or straightforward. This research team urged further work at the neighborhood level while recognizing the difficulties that they faced in recruiting a sample of sufficient power to answer the hypotheses of interest.

Two main themes are of interest in this consideration of the impact of environmental factors on the health of immigrants. The first is the relative paucity of either descriptive or analytical information regarding the distribution of environmental exposures across these populations as well as a need for clear identification of the impact of these factors on health status.

Given that there is growing momentum in the interest of global researchers on the immigrant experience, perhaps this knowledge gap will be addressed in the relative near term. This is especially important to achieve given the second theme that emerges from a consideration of immigrant health status relative to environmental exposures. This second theme concerns the heterogeneity that is consistently displayed in the distribution and magnitude of risk factors found within immigrant subgroups. It is critically important to comprehend such differences in the mounting of successful public health interventions.

Assessing Immigrant Environmental Health

Certain systemic realities are important to comprehend when assessing the environmental factors which affect the health status of immigrant populations. These include, as summarized by Eamranond and Hu, restrictions on access to health services in such countries as the USA, the often xenophobic social environments found in many countries which impedes the ability of the immigrant population to trust the institutions of the host country, and a wide array of host factors that are quite different between newly arriving immigrant populations and native born populations.

Thus researchers and program planners are faced with specific methodological differences in gathering valid data on immigrant populations. Kasl et al. offers some salient recommendations concerning how such studies should be implemented. He urges the formation of three cohorts: pre-migrants, nonmigrants, and host country residents, within which frequent characterization of both health status and psychosocial factors are performed. Kasl suggests further that the measured environmental exposures should include the physical, social, and behavioral aspects of the studied populations. Such analyses would be carried out in a rigorous manner that reflects to the extent possible sensitive measures of adaptive responses to stress and other potentially harmful stimuli.

The rigor of such recommendations is challenging to implement but also illuminating in the quest to unravel the impacts of both immigration and the environment. In the end, if environmental conditions are improved to the benefit of immigrants, the health status of the overall population will surely benefit as well.

Environmental Justice

Penn Loh
Department of Urban & Environmental Policy and Planning, Tufts University, Medford, MA, USA

Environmental justice is a concept born out of the struggles of lower-income communities and communities of color against disproportionate environmental burdens. The grassroots environmental justice movement in the USA grew in the 1980s from the recognition that the incidence of hazardous and polluting sites was higher in communities with fewer economic resources and political power. The environmental justice movement unites African Americans and Native Americans with immigrants of color, in particular Latinos and Asian Americans, but also immigrants from the Caribbean, Africa, and the Middle East. The movement redefined the environment as where people "live work, and play" and criticized the mainstream environmental movement for not adequately addressing environmental issues as experienced by people of color and the poor. An early instance of the use of the term "environmental racism" occurred in 1982 in the fight against the siting of a toxic landfill by a predominantly African American community in Warren County, North Carolina. In this case, a national faith-based organization, the United Church of Christ, supported the grassroots environmental efforts explicitly in terms of civil rights.

Through the 1980s and into the 1990s, numerous studies documented the disproportionate incidence of polluting facilities in poor and minority communities. The landmark 1987 report Toxic Waste and Race by the United Church of Christ found that race was the most significant indicator of the location of commercial hazardous waste facilities across the country and that three of every five Black and Hispanic Americans lived in a community with uncontrolled toxic waste sites. In a 1993 study reviewing 64 empirical studies of environmental disparities by income and race, Goldman found that all but one showed disparities by race and/or income. In 1999, the Institute of Medicine found that while the exposure of low-income communities and communities of color to environmental health risks and their disparate health status has been well documented in the literature, there have been gaps in research that establishes the direct link between exposure and illnesses.

The environmental justice movement coalesced nationally in the early 1990s. The 1991 National People of Color Environmental Leadership Summit in Washington, DC drew more than 500 delegates representing African Americans, Latino Americans, Asian Americans, and Native Americans from all 50 states as well as several other countries. Summit participants adopted 17 Principles of Environmental Justice, which are widely viewed as the guiding principles of the movement. The national momentum generated by the Summit led to President Clinton's 1994 Executive Order 12898, "Federal Actions to Address Environmental Justice in Minority and Low-Income Populations." This order required all federal agencies to ensure that they do not discriminate in their environmental and public health programs.

Immigrants and Environmental Justice

Immigrant communities, especially Latino, Caribbean, and Asian, are well represented in the environmental justice movement and share many of the characteristics of other environmental justice communities. In their 2001 book *From the Ground Up*, Cole and Foster include the farmworker movement of the 1960s as one of the foundations of the environmental justice movement. For example, the United Farm Workers, led by Cesar Chavez, organized to ban the use of hazardous pesticides.

In addition to the effects of racial discrimination and poverty, immigrant communities face additional challenges that can place them at risk for environmental injustice and exposure to environmental health risks. These factors include lack of proficiency with the English language, lower educational attainment, legal status, lack of access to health care, and specific cultural practices. The workplace is a significant factor in environmental health risks for immigrants. Certain industries, such as agriculture and janitorial services, have high percentages of immigrant workers who face various occupational safety and health hazards. The urban and rural communities in which immigrants live also present environmental injustices. The remainder of this entry will review the health impacts of environmental injustice on various immigrant communities where they work and where they live. Examples are drawn primarily from the experience of Latino and Asian immigrant communities, though other immigrants from Africa, the Caribbean, and the Middle East experience similar conditions.

Where Immigrants Work

Immigrant workers face environmental hazards in both urban and rural contexts. For example, Latino immigrants still comprise a large majority of the farmworkers in the USA. In the fields, workers are exposed to pesticides and often are not provided with the proper training or equipment to safely use these products. Workers can then bring these residues back home, where their families and children can also face exposure.

In cities, Latina and Asian workers, predominantly women, make up a large portion of the workers in the textile and garment industry. In these factories, they are exposed to poor ventilation, fire hazards, and chemicals such as formaldehyde and other dye preservatives. Likewise, Latina and Asian workers are concentrated in the microelectronics manufacturing industry. For example, in Silicon Valley, 70–80% of the production workforce are Latinas and Asians. In the "clean rooms" for manufacturing chips and assembling circuit boards, workers are exposed to numerous toxic chemicals. Studies have documented high rates of occupational illnesses, including respiratory disorders, miscarriages, birth defects, and cancer.

Where Immigrants Live

Rural Latino communities, where many farmworkers live, can also host a disproportionate burden of polluting facilities. For example, in the early 1990s, in California, the state's three Class 1 toxic waste sites were located in three majority Latino towns – Kettleman City, Buttonwillow, and Westmorland. In Kettleman City, residents won a historic battle against the siting of a toxic waste incinerator in 1993, after winning a court case in which the judge determined that the residents (who were 40% monolingual Spanish speakers) were not meaningfully involved in the public process because of lack of Spanish translation.

More than 1.5 million Latinos in the USA live in *colonias* along the US–Mexico border. These unincorporated communities often have substandard housing and lack access to potable water and sewage treatment, leading to risk of waterborne diseases such as giardiasis, hepatitis, and cholera.

In urban areas, Latinos also face environmental injustice. About 66% of Latinos live in areas where the air quality does not meet federal Clean Air Act standards. Air pollution from automobiles, factories, and power plants contribute to risks for asthma, cancer, and other diseases. Though nationally Latinos have a lower asthma rate than Whites or African Americans, there are areas where Latino asthma rates have been found to be much higher. For example in New York City, Latinos have the highest rates of adult asthma (6.4%) of all ethnic groups, compared to 3.5% for Whites and 4.6% for African Americans.

Latinos and Asians in urban communities have also had to deal with polluting facilities and the cleanup and redevelopment of toxic waste sites. In Chicago's Little Village neighborhood, home to the largest Mexican

American population in the USA outside of East Los Angeles, residents have led a successful struggle to remediate a Superfund site, which had hosted an asphalt plant for over 70 years. The same community is surrounded by two power plants that contribute to about 2,800 asthma attacks and 40 premature deaths each year.

Asian immigrant neighborhoods also host disproportionately high numbers of polluting facilities and contaminated sites. For example, Laotian refugees have settled in large numbers in Richmond California in the San Francisco Bay area. Richmond, a city of over 100,000, is comprised of 36% African Americans, 26% Latinos, and 12% Asian. Richmond is host to over 350 industrial facilities. In July 1993, the accidental release of concentrated sulfuric acid by the General Chemical plant sent more than 20,000 residents to the hospital.

Housing conditions for lower-income immigrant communities can also present environmental hazards. Lead paint in older homes contributes to lead poisoning. To the extent that Latino and Asian immigrants are also of lower income, they have less access to lead free housing. Latino children are twice as likely to have elevated blood lead levels as White children.

The transportation system in urban communities also poses health threats to immigrants. Not only is a large portion of air pollution from transportation sources, but many times transportation facilities and heavily trafficked roads are located in immigrant neighborhoods. For example, five of the six transit bus depots in Manhattan are located in Northern Manhattan, which are predominantly lower-income African American and Latino communities. In densely populated neighborhoods, such as Chinatowns in many cities, high levels of traffic and congestion contribute to pedestrian accidents and injuries.

How Immigrants Live

Cultural practices also contribute to environmental health risks, such as lead and mercury exposure. In Latino communities, these practices include consumption of lead in candy imported from Mexico and eating food cooked or served in pottery with lead glazes. Some Mexican folk remedies, such as the lead-based *greta* or *azarcón* and mercury-based *azogue*, are used to treat indigestion. Commonly used cosmetic products used by Latinos have also been found to contain high levels of mercury.

Immigrant fishing and gardening practices combined with lack of English proficiency also contribute to consumption of contaminated fish and vegetables. Immigrant families often come from places where they practiced subsistence gardening and fishing. In the USA, many immigrants continue these practices, in part because of economic necessity. In Richmond California, two Laotian families were growing vegetables on an abandoned battery factory, which exposed them to lead. Warning signs were posted in only English and Spanish.

Immigrant anglers often depend on the fish they catch to feed their families. They are often fishing in polluted waters, where fish can be contaminated with mercury and other toxic chemicals. Oftentimes, state advisories warning anglers of contaminated fish are posted only in English.

Environmental Tobacco Smoke

BRANDEN E. YEE
Department of Anesthesiology, University of Rochester
Strong Memorial Hospital, Rochester, NY, USA

Second-hand smoke, or environmental tobacco smoke (ETS), is smoke that fills enclosed spaces when people burn tobacco products. No amount of ETS is considered safe, and people are potentially exposed to ETS thousands of times per day – from tobacco smoke in the home, automobiles, public places, the workplace, even to exposure in conversations with peers who recently smoked. Linked to various chronic conditions, ETS has emerged as a significant health risk in America and is a particular threat to immigrant populations. Due to its inextricable link to tobacco use, which has a long history engrained in American culture, ETS remains a prominent health issue in the USA, which is difficult to combat.

Tobacco has been around for thousands of years. While small amounts of nicotine were found in human remains and pipes in the ancient world, there was no evidence of routine use of tobacco for several thousands of years later. Tobacco was introduced to Europe as Columbus and other explorers made voyages to the Americas and disseminated it throughout the world as intercontinental sea-passage and trading arose. As smoking tobacco continued to spread in popularity throughout the globe, manufacturing companies of tobacco products were established and smoking tobacco products like cigarettes and cigars became increasingly commonplace. By 1901, yearly sales in the USA totaled 3.5 billion cigarettes and 6 million cigars, and 4 of 5 American men smoked at least 1 cigarette every day. Due to the worldwide popularity of tobacco use, many immigrants who entered the USA in the 1900s were already smokers or started smoking as they assimilated into American culture. The smoking industry continued to prosper and grow through advertisements to men, women, and minorities. Without knowledge of tobacco's negative effects, smoking became a well-incorporated component of American culture, practiced daily in homes, workplaces, and public places.

Not until the twentieth century did the health problems associated with tobacco and tobacco smoke exposure become more widely documented. Risks of tobacco smoke came to light in the USA in 1964 with the Surgeon General's report on "Smoking and Health." This report drew attention to the various negative health outcomes associated with using tobacco products. The report also suggested that cigarette smoking was responsible for a 70% increase in the mortality rate of smokers compared to nonsmokers as well as increased incidences of lung cancers, chronic lung conditions, and heart disease. For the most part, the 1964 report focused on the health risks of active smoking and did not present the effects of tobacco smoke on the nonsmoker. Only briefly touching on the indirect consequences of ETS by highlighting the notion that smoking during pregnancy could affect the fetus and often results in newborns of lower birth weight, the 1964 report did not fully delve into the extensive dangers of tobacco smoke, many of which were still being investigated.

The report was effective in beginning to change the perception of active tobacco smoking. Prior to the report, less than half of those polled believed smoking to cause cancer, while in the 4 years after dissemination of the report, more than three-quarters of those polled believed smoking to cause cancer. While many people began to view smoking more negatively, it also became apparent that eliminating tobacco smoke and its burden on the health of Americans was more complicated than simply highlighting these risks. Addiction, culture, and social habits emerged as complicating factors in the battle against tobacco use.

Despite the 1964 findings, many people continued to use tobacco products. Through chemical addiction to the product and targeted advertising toward minorities, the tobacco industry continued to prosper. In the 1970s, tobacco companies specifically targeted American immigrant populations using cigarette smoking as an American marker of high social status. The companies used tactics to appeal to immigrants of varying degrees of assimilation and even advertising to populations of future immigrants in their countries of origins.

While the concept of the negative health ramifications of smoking on the individual smoker was taking hold, more than 20 years passed by before the Surgeon General released a new report warning that tobacco smoke affects more than just the individual using the cigarette. In 1986, the Surgeon General released a report titled "The Health Consequences of Involuntary Smoking," which identified chronic diseases that result from individuals' exposure to ETS. It concretely cemented research findings and set forth a new understanding of tobacco use. The report detailed the chemical composition of tobacco smoke and the health outcomes associated with toxicity from exposure to it, even as a nonsmoker. Furthermore, the report implicates the necessity for further governmental regulation to protect and prevent further disease burden from ETS. The report reframed smoking as more of a community issue than an individual problem.

From the Surgeon General's reports, and other tobacco research, we currently know that tobacco smoke contains over 4,000 known chemicals; at least 250 are known to be harmful and more than 50 of them are known to cause cancer in humans. Collectively, tobacco products cause 600,000 premature deaths a year, 50,000 of which are a result of heart disease or lung cancer brought about by ETS. The International Labour Organization estimates that ETS continues to be a problem, as approximately 200,000 workers die every year due to ETS within the workplace. The WHO estimates that around 700 million children, or almost half of the world's children, breathe air polluted by tobacco smoke, and thus are subject to the health risks associated with ETS. Children exposed to ETS are 1.5–2 times more likely to start smoking themselves.

Tobacco smoke exposure is now known to cause health problems with several organ systems, including the lungs and heart, as well as have a high incidence of varying types of cancers. Pulmonary complications arising from tobacco smoke exposure range from long-term and irreversible problems like chronic obstructive pulmonary disease, to short term and reversible problems such as reactivity of the airways or impairment of motility of tiny hairs within the airways, called cilia, that filter out dust and other particulate matter. Chronic exposure to ETS can also lead to problems with breathing such as airway obstruction and impairment of an individual's ability to breathe without medications. Long-term ETS exposure can also increase the risk of development of lung cancers, many of which can be terminal.

While chronic exposure to ETS can lead to significant long-term pulmonary morbidity, even exposures of short periods of time can negatively affect an individual. Environmental tobacco smoke can trigger or exacerbate breathing problems in individuals with underlying medical conditions such as asthma. Particulate matter within ETS can irritate the lungs and make breathing more difficult or even cause an asthma attack in which the airways spasm, a potentially life-threatening scenario. Even for those without underlying respiratory issues, ETS can cause problems, as acute exposures can impair the proper function of airways causing breathing problems such as coughing, chest tightness, or wheezing.

In addition to pulmonary complications, ETS is a risk factor for cardiovascular disease. Tobacco smoke exposure can lead to atherosclerosis, or hardening of arteries, throughout the body causing problems that range from high blood pressure to coronary artery disease. Hardened arteries are less flexible and can manifest as high blood pressure, which may require pharmacologic interventions. Additionally, atherosclerosis in the periphery, such as the arteries in the legs, might lead to pain in the legs called claudication. When atherosclerosis occurs within the arteries of the heart, patients can experience chest pains and shortness of breath with exertion, or even heart attacks or death. Atherosclerosis of the arteries that supply blood to the brain can lead to mini-strokes called transient ischemic attacks (TIAs) or even debilitating strokes that might lead to one-sided weakness, an inability to speak, or death.

Not only has tobacco smoke exposure been linked to pulmonary and cardiac complications, but tobacco products are linked to several types of cancers. In addition to lung cancer, which has been linked to tobacco smoke exposure regardless of primary or environmental level, recent research has even suggested that ETS has a role in the development of breast cancer, nasal sinus cancer, and nasopharyngeal cancer in adults, as well as leukemia, lymphoma, and brain tumors in children.

As the health perils of ETS have become more apparent, the need for policies limiting ETS to nonsmokers has become warranted. The first in the line of limitations was a banning of smoking within public places. Recognizing that ETS places employees at significant health risk on a daily basis, the ban of smoking within office-based settings was one major step in eliminating ETS. Bars and restaurants in many states have followed suit, yet some states continue to allow smoking in public places. While smoking bans were the first step toward eliminating ETS, it is still very present in homes, especially those of disadvantaged populations.

Although restrictions of tobacco marketing increased within the USA, the 1980s and 1990s represented a time of increased marketing in developing countries including the rapidly developing Asian market. The marketing was clearly successful, as Marlboro was fighting with Coca-Cola to be the number one brand worldwide during this time. Although the damning health risks of ETS continue to mount, the tobacco industry continues to adapt its marketing strategies to enable continued growth and brand recognition.

The tobacco industry continues to prosper by using the same marketing tactics that made tobacco hugely popular within the USA. Philip Morris International (PMI) launched high tar and nicotine tobacco products in Indonesia. The higher tar and nicotine cigarettes are marketed as a rugged man's variant of the type of cigarette most frequently smoked by Indonesians and introduced them to the Marlboro brand. As the notion of harm from tobacco smoking has become more globally prevalent, the tobacco industry has also recycled marketing of filtered cigarettes or low tar products to 20 markets throughout the world (including Brazil, Ukraine, and Russia), despite the finding of a US federal district court that such a claim is fraudulent. The tobacco industry has also looked to marketing its products to youths by aligning itself with musical performances and concerts geared toward young people.

As the tobacco industry continues to expand its marketing to other countries, there will remain barriers to further progress in the prevention and elimination of ETS. Within the global setting, perhaps the largest obstacle to the reduction of tobacco product usage and ETS is the lack of knowledge and regulatory bodies limiting ETS to nonsmokers. Within the US immigrant population, multiple limitations exist to further reduction of tobacco use and ETS. These include, but are not limited to, the social acceptability of smoking in one's prior country, lack of health services, stress and coping mechanisms developed by immigrants of specific cultures, communication barriers to the harms of tobacco products and ETS, and socioeconomic status.

Epidemiological Paradox

Erin R. Hamilton
Department of Sociology, University of California at Davis, Davis, CA, USA

The epidemiologic paradox describes a set of research findings showing that some groups of Hispanic immigrants to the United States have rates of mortality and health outcomes that are similar to native-born, non-Hispanic Whites and better than native-born, non-Hispanic Blacks. This pattern contradicts the standard social science model of racial and ethnic differences in health and mortality. This model understands elevated health risks and mortality levels of African Americans relative to Whites to be due to socioeconomic disadvantage and discrimination, which in turn influence a variety of proximate risk factors for health, including health behaviors, access to and quality of health care, and stress. Given this framework, and the fact that Hispanic immigrant groups are relatively socioeconomically disadvantaged in the United States, with particularly high levels of poverty and low levels of education, their health and mortality in comparison to other major racial and ethnic groups in the United States are paradoxical.

The epidemiologic paradox has been documented most clearly for Mexican-origin immigrants, the largest national origin immigrant group in the United States. Because Cubans are a relatively advantaged group, their good health outcomes in comparison to other groups are not considered paradoxical; because Puerto Ricans are a relatively disadvantaged group, their poor health outcomes in comparison to other groups are consistent with the social science model of racial and ethnic differences in health. A variety of health outcomes have been used to document the paradox, but most research has focused on infant birth weight and mortality and adult mortality.

Three explanations have been offered for the paradox. Although these explanations are distinct, they are not incompatible, and they have all found support in empirical research studies. The first involves data issues. Mortality rates may be downwardly biased by the incorrect reporting of racial identity on death certificates, namely, Hispanic deaths may be incorrectly counted as White or Black deaths. More importantly, Hispanic immigrant deaths may go unrecorded in US vital statistics data because of the selective return migration of the sickly and/or elderly to their countries of origin, which has been called the salmon bias. Analyses of Medicare data that exclude return migrants show that conventional estimates of Hispanic mortality rates are too low, but the paradox pattern in Mexican immigrant adult mortality rates is still observed even when accounting for this source of bias. The paradox pattern has also been shown in Mexican immigrant infant mortality rates as early as 1 hour following the birth of the child, when return migration to Mexico is practically impossible.

The second explanation argues that immigrant culture protects immigrant health by proscribing certain health behaviors – in particular, the use of tobacco and alcohol, especially among women – and emphasizing kin and co-ethnic networks as sources of support. Studies have shown that immigrant health deteriorates over time in the United States, suggesting a process of unhealthy acculturation to US norms and behaviors. Across all racial and ethnic groups in the United States, immigrants have lower mortality than their native-born counterparts, which is consistent with the idea of unhealthy acculturation, although cross-sectional differences may reflect differences in the composition of immigrant groups arriving at different points in time, rather than a process that unfolds over time. Regression to the mean has been posed as an alternative explanation for native-immigrant differences. The culture argument is also limited by the fact that nonmigrants in sending countries are not equally protected – in other words, immigrants' health is not only better than that of those they encounter in their country of destination, but also better than the health of those they leave behind, who are presumably protected by the same culture.

This last pattern suggests the third and final explanation for the immigrant health paradox, which is that immigrants are a selectively healthy group. Most simply, the idea is that healthy people will be more likely to migrate than unhealthy people. Immigrants are likely also selected on a number of unmeasured characteristics that positively affect health, such as a sense of efficacy (or control over destiny), tolerance for risk, and a positive outlook. An ideal test of this hypothesis requires data on emigrants and nonmigrants in the sending community. Unique pooled origin-destination data on infant mortality among Puerto Ricans shows a clear pattern of selective migration in which recent Puerto Rican migrants to the United States have a lower risk of infant mortality than either women on the island or women who migrated to the mainland several years earlier. A recent study of households in Mexico, however, showed small and largely insignificant differences in the health of emigrants and nonmigrants.

Epilepsy

José F. Téllez-Zenteno
Division of Neurology, Department of Medicine, Royal University Hospital, University of Saskatchewan, Saskatoon, SK, Canada

Epilepsy is a common chronic neurological disorder characterized by recurrent unprovoked seizures. Seizures are transient signs and/or symptoms of abnormal, excessive, or synchronous neuronal activity in the brain. In primary practice, epilepsy ranks as the second most commonly reported neurological condition worldwide. Epilepsy affects quality-of-life in patients and their caregivers and can result in high societal costs through loss of work productivity and high medical care expenditures.

Epidemiology of Epilepsy

The prevalence of epilepsy in developed countries ranges from 4 to 10 cases per 1,000. Studies in developing and tropical countries have reported higher prevalence rates of epilepsy, ranging from 14 to 57 cases per 1,000 persons, for example, in Panama, Ecuador, Colombia and Venezuela. The median incidence rate of epilepsy in developed countries ranges between approximately 25 and 50 per 100,000 person-years while in developing countries it ranges from approximately 30 to 115 per 100,000 person-years. The reason for the high reported rates in developed countries is probably related to methodological aspects of the studies, but in some regions in the world, specific infectious causes such as neurocysticercosis (a parasitic illness) are endemic.

In developed countries, the incidence of epilepsy tends to exhibit a U-shaped curve with the highest rates in children and in the elderly. This same pattern has not been found in developing countries, where the incidence of epilepsy appears to peak in early adulthood.

SMR (Standard Mortality Ratio) in epilepsy ranges between 1.2 and 9.3 and depends on study methods and population. It should be noted that most data on mortality in epilepsy is derived from industrialized countries. Overall the information that proves that mortality is increased in patients with epilepsy versus different type of controls is very solid and comes from well-designed controlled studies.

A study in the Canadian population showed that the prevalence of epilepsy was higher in Whites and nonimmigrants compared with immigrants. Possible explanations for the lower prevalence of epilepsy in Canadian immigrants may be that people with epilepsy are less likely to migrate for health-related, personal, or regulatory reasons.

Given that the incidence and prevalence of epilepsy in developing countries is high compared with developed countries, it is possible that patients without epilepsy who start living in a developed country may decrease their risk to develop epilepsy by changing their environment and avoiding exposure to some factors such as potential infectious causes of epilepsy.

Types of Epilepsy

Seizure types are classified first according to the source of the seizure within the brain. Seizures could be localized (partial or focal-onset seizures) or generalized seizures. Partial seizures are further divided on the extent to which consciousness is affected and the localization. If the level of consciousness is not affected during the seizure, they are classified as simple partial seizures; when consciousness is affected they are called complex partial seizures. Partial seizures can also be localized in different parts of the brain, such as seizures originating in the temporal, parietal, occipital, or frontal lobes of the brain. A partial seizure may spread within the brain, a process known as secondary generalization. Generalized seizures are divided according to the effect on the body but all involve loss of consciousness. These include seizures of various types including absence (petit mal), myoclonic, clonic, tonic, tonic–clonic (grand mal), and atonic seizures.

Causes of Epilepsy

Different causes of epilepsy have been described in some age groups. During the neonatal period and early infancy the most common causes include CNS infections, hypoxic brain injury (due to lack of oxygen supply to the brain), diverse encephalopathies (generalized brain dysfunction), trauma, congenital CNS (central nervous system) abnormalities, and metabolic disorders. During late infancy and early childhood, febrile (fever-related) seizures are common, but also other causes like CNS infections and trauma. In addition, during childhood there are well-defined epilepsy syndromes.

During adolescence and adulthood, CNS lesions and idiopathic epilepsies (epilepsy of unknown cause) are less common. Some causes that are frequent in this age group are trauma, brain tumors, illicit drug use, and alcohol withdrawal. In older adults, cerebrovascular disease is the most common cause. Other causes include CNS tumors, trauma, and degenerative diseases such as Alzheimer's.

In some regions of the world, particularly in resource-poor countries, epilepsy may be related to infection such as malaria, neurocysticercosis, paragonomiasis, and toxocariasis. Overall neurocysticercosis (brain infection due to parasitic infection) has been recognized as the most frequent cause of seizures around the world.

The cause of epilepsy is an important consideration for immigrants, especially for those migrating from developing to developed countries. Some causes of epilepsy, such as neurocysticercosis, that are highly prevalent in developing countries are now recognized in developed countries. An example of this situation is the occurrence of several cases of neurocysticercosis in the south of the United States, clearly related with the migration of Mexicans and other people from Latin America where neurocysticercosis is an endemic disease and the most common cause of seizures.

Epilepsy Diagnosis

Physicians have to confirm the diagnosis of epilepsy, in order to provide adequate treatment for patients. Conditions that can mimic seizures are syncope (sudden drop in blood pressure leading to loss of consciousness), pseudoseizures (seizures that have psychological origin), migraine, and less frequently transient ischemic attacks (sudden, brief stroke-like phenomena). The initial evaluation includes a detailed neurological examination, routine EEG (electro encephalogram/ brain-wave recording), and brain imaging (CT or

MRI). Potential candidates for epilepsy surgery will require other tests such as positron emission tomography (PET), single photon emission computed tomography (SPECT) single intracarotid sodium amobarbital test (Wada test), functional MRI, or magnetoencephalography (MEG) as supplementary tests. Some patients will require an invasive investigation to localize the seizure onset and focus via a procedure that involves placing electrodes on top of the brain. Brain mapping using electrocorticography is another procedure used in the process of invasive epilepsy testing in some patients. Immigrants with epilepsy who have the opportunity to arrive to developed countries may benefit from availability of such advanced diagnostic tests, in addition to highly trained specialists.

Treatment

Epilepsy is usually treated with medications. An accurate differentiation between generalized and partial seizures is important in determining the best treatment for the patients. In many cases anticonvulsant medications will be lifelong and can be associated with major effects on quality-of-life. The choice among anticonvulsants and their effectiveness differs by epilepsy syndrome. For many years few anticonvulsants were available for patients. Currently there are close to 20 medications available to treat patients with epilepsy and most of them appeared after 1990. The medications available for use in patients with epilepsy are carbamazepine, clonazepam, ethosuximide, felbamate, fosphenytoin, gabapentin, lacosamide, lamotrigine, levetiracetam, oxcarbazepine, phenobarbital, phenytoin, pregabalin, primidone, tiagabine, topiramate, valproic acid, and zonisamide. Medications released after 1990 are called the second generation of antiseizure medications and the most commonly used treatments are lamotrigine, topiramate, and levetiracetam. Compared with the first generation of anti-epileptic drugs, the second generation has a similar efficacy to control seizures, although the side effects profile may be better.

The main goals of epilepsy treatment are to decrease the frequency and severity of seizures and to avoid side effects. Many patients can be treated adequately with one anti-seizure medication (monotherapy), although some will require the use of two or more medications to control seizures (polypharmacy). It is very important to measure serum levels of epilepsy medication to evaluate adherence (compliance), to determine drug interactions, and to correlate potential side effects in patients. Children or adults with cognitive problems may benefit from routine screening of drug levels.

In many developing countries only two or three medications are available to treat seizures. The benefits of antiepileptic drugs for immigrants with epilepsy that arrive to developed countries and have access to a wider array of epilepsy treatments are significant. The term refractory or intractable epilepsy is used when a person with epilepsy cannot be brought under control after two adequate trials of different drugs. A classical study of patients with previously untreated epilepsy demonstrated that 47% achieved control of seizures with the use of their first single drug and 14% became seizure free during treatment with a second or third drug.

Epilepsy surgery could be an option for patients whose seizures remain resistant to treatment with antiepileptic drugs. The best candidates for epilepsy surgery are patients with focal abnormalities that can be located and therefore removed. The goal for these procedures is total control of epileptic seizures, and many patients will require anticonvulsant medications after surgery.

The main goal of the evaluation for epilepsy surgery is the location of the epileptic abnormality, in order to determine if surgery will affect normal brain function. The most common surgeries are the resection of lesions such as tumors, arterial-venous malformations (abnormality of blood vessels in the brain), and other lesions that are closely related with epileptogenic areas.

The most common type of intractable epilepsy is temporal lobe epilepsy, and the most common procedure is the anterior temporal lobectomy, which includes the resection (removal) of the whole temporal brain region or other related surgical treatments. Surgery for temporal lobe epilepsy is effective, durable, and results in decreased health care costs. Approximately 60–70% of patients are seizure free after surgery for temporal epilepsy.

Epilepsy surgery in developing countries is compromised. The lack of equipment, specialists, and advanced therapies impedes the possibility for many patients to have epilepsy surgery. A significant advantage of immigrants with epilepsy coming to a developed country is the possibility of having much-needed epilepsy surgery. However, some immigrant groups may not have health insurance or may not live in areas where specialized epilepsy surgery care is available. These immigrants may continue to have negative outcomes due to lack of health care access.

Other Epilepsy Treatments

The ketogenic (high fat, low carbohydrate) diet has been used mainly in some children with severe, medically intractable epilepsy. The mechanism of action is unknown, but its efficacy is well recognized for patients with intractable general epilepsy during childhood.

Electrical brain stimulation has also been used extensively in recent years to treat patients with epilepsy. Vagus nerve stimulation (VNS) is given with a computerized electrical device similar in size, shape, and implant location to a heart pacemaker. The device is connected to the vagus nerve in the neck producing stimulation in the brain. All the evidence suggests that 50% of patients experience improvement in seizure frequency and also there is improvement in severity. The success rate is not as good as epilepsy surgery, but it becomes a good alternative for patients who decline epilepsy surgery, patients that failed to respond to epilepsy surgery because of different reasons, and patients who are not candidates for epilepsy surgery.

Deep brain stimulation is another treatment for epilepsy. Other therapies such as the use of the Gamma Knife or other devices used in radiosurgery are currently under investigation as alternatives for treatment in some patients.

While all of these newer therapies such as vagus nerve stimulation, deep brain stimulation, and ketogenic diet are promising, most of them are not available in many developing countries. All of them require highly trained specialists and expensive equipment.

Ethiopia

Bobby Singh
School of Medicine, San Francisco Veterans Affairs Medical Center, University of California, San Francisco, CA, USA

Tenasystillin! This short greeting, the most common one in Ethiopia, is roughly translated as "May God grant you health," and speaks volumes about the importance of good health and well-being to Ethiopians. However, health in Ethiopia and among its diasporas is better understood in the context of Ethiopia's history, geography, culture, and other relevant factors. Although a comprehensive discussion of such factors is beyond the scope of this chapter, a brief overview is presented below in the hope that it will give the readers a better understanding of the important health-related successes and challenges faced by Ethiopian immigrants and emigrants.

Background

Ethiopia, formerly known as Abyssinia and now officially called the Federal Democratic Republic of Ethiopia, is located in a region of northeast Africa (the Horn of Africa). It is a land-locked country that shares its borders with Eritrea, Djibouti, Somaliland, Somalia, Kenya, and Sudan. As of 2009 estimates, Ethiopia's population is approximately 85 million, with more than three million people living in the capital of Ethiopia, Addis Ababa, which is located in the center of the country. In terms of size, Ethiopia is roughly one-and-a-half times the size of the US state of Texas or slightly smaller than France and Spain combined. The Ethiopian landscape is quite varied. Prominent features include the Afar desert in the northeast to various mountain ranges, for example, Simien Mountains in the west and Bale Mountains in the southeast. Rift Valley bisects the Ethiopian Highlands from a northeast to southwest direction. Ethiopia's geography plays a significant role in the prevalence of various medical illnesses in certain parts of the country. For instance, in the highlands, malaria typically follows the end of the rains, whereas it is endemic in the lower areas.

Administratively, Ethiopia is divided into nine regional states and two city administrations. As many as 80 different ethnic/linguistic groups make up the population of Ethiopia, with the major groups being the Oromo, Amhara, Tigrai, Sidamo, Gurage, and Somali. By some estimates, over 80 languages are spoken in Ethiopia, with the most significant being Amharigna (Amharic), Tigrigna, Oromifa (Oromigna), Somali, and English. The main religions in Ethiopia are Christianity (∼50–60%) and Islam (∼33%). The latter is mostly concentrated in the eastern part of the country.

Ethiopia is one of the oldest independent countries, not only in Africa, but also in the world. With the exception of a brief Italian occupation from 1936 to 1941, it has maintained its independence for centuries. Emperor Haile Selassie, who had ruled Ethiopia from 1930, was deposed in 1974 by a military junta, the Derg. A social state was established by the Derg, which was toppled in 1991 by the Ethiopian People's Revolutionary Democratic Front. Four years later Ethiopia's first multiparty elections were held, and Meles Zenawi was elected the Prime Minister. In 1993, with the help of the United Nations, a referendum on Eritrean independence was held. Due to overwhelming support, Eritrean independence was declared in May 1993. Five years later, a border war with Eritrea broke out, which lasted until 2000.

A broad overview of health in Ethiopia requires taking into consideration current trends related to population and health. Based on 2009 estimates, Ethiopia is one of the ten fastest growing countries in the world, with a population growth rate of approximately 3.2%. It also has one of the highest birth rates in the world with 43.66 births/1,000 population and a total fertility rate of 6.12 children born/woman; both of these indicators are among the top ten in the world. On the other end, the death rate is about 11.55 deaths/1,000 population and the net migration rate is −0.02 migrant(s)/1,000 population.

Regarding migration, due to various issues like famines, lack of economic opportunities, and political instability, many Ethiopians left their homeland and settled in neighboring countries, as well as many faraway lands, especially the United States, Canada, Europe, and Israel. More recently, many Ethiopians have started to return and it is expected that the repatriation of Ethiopian refugees residing in Sudan will continue for several years. Furthermore, Ethiopia itself also served as a haven for many refugees from the surrounding countries, most of whom were escaping similar problems in their own lands. The number of refugees in Ethiopia is estimated to be approximately 100,000 with Sudan being the single largest country of origin for the refugees (about 67,000). Somalia and Eritrea are also major sources of refugees to Ethiopia. As with Ethiopian emigrants, many refugees are also starting to return to their homes. It is estimated that the number of internally displaced persons in Ethiopia is at least twice the number of refugees. This is the result of the abovementioned border war with Eritrea, as well as ethnic clashes in various regions. Not surprisingly, access to health care among refugees and internally displaced persons tends to be lower than the general population, and metrics of health in these populations – rarely available – tend to be among the lowest.

As with the native population, travelers and immigrants to Ethiopia are the beneficiaries of recent improvements in Ethiopia's public health system, while still having to contend with its current limitations. To fully appreciate the recent public health advances in Ethiopia, it is helpful to consider its history. The foundations of the public health system in Ethiopia were laid in the early 1940s and in 1947 the Ministry of Public Health was officially established. As recently as 1953, there was not a single Ethiopian physician in the country, and all physicians were foreigners (estimated to be about 80 at that time). To respond to this challenge, the government devised a formal public health policy in the early 1960s with the aid of the World Health Organization (WHO). Ethiopia's public health system has made huge strides in the last 50 years or so, though certain aspects remain underdeveloped. These are discussed in more detail below.

Public Health Successes in Ethiopia

The current public health approach in Ethiopia is based on the Health Sector Development Programme (HSDP), which consists of a 20-year health development approach, broken down into 5-year programs. The goals of these programs, among others, include further developing preventive health care, increasing access to health care for rural populations, increasing health care capacity, and a greater cooperation between government and other entities, such as nongovernmental organizations and the private sector.

One feature of HSDP that has had remarkable success is the Health Service Extension Programme (HSEP), which was started in 2003. Under the HSEP, two female health extension workers in each "kebele" (the smallest administrative unit covering a population of approximately 5,000) perform outreach work, focusing on four aspects of public health: hygiene and sanitation, disease prevention and control, family health services, and health education and communication. To date, approximately 25,000 workers have been trained and deployed. Although the initial goal of achieving universal primary health care coverage by the year 2008 with the HSEP was not met, the coverage of publicly funded health care arose from 61% in 2003 to 87% in 2007. Furthermore, Tewodros Adhanom, Ethiopia's Minister of Health, stated in 2008 that Ethiopia is expected to achieve universal primary care by 2010.

Given the limited scope of this chapter, an overview of public health challenges facing Ethiopia can be given via a discussion of Millennium Development Goals (MDGs). MDGs consist of 8 international development goals that all 192 UN member states have agreed to achieve by the year 2015. As three of the eight MDGs are directly related to health – child health, maternal health, and disease control – progress in achieving these goals, or lack thereof, is often helpful in monitoring certain aspects of public health. More specifically, MDG4 aims to reduce child mortality, with a target of reducing under-five mortality rates by two-thirds over the period 1990–2015. MDG5 aims to reduce the maternal mortality ratio (MMR) by three quarters over the period 1990–2015. MDG6 aims to have two targets achieved by 2015: (1) to have halted, and begun to reverse, the spread of HIV/AIDS; and (2) to have halted, and begun to reverse, the incidence of malaria and other major diseases.

Based on the last national major health survey done in Ethiopia in 2005, under-five mortality rate declined from 204 to 123/1,000 live births between 1990 and 2005. This is significantly better than the rate achieved by Sub-Saharan Africa as a whole, where the mortality rate declined from 184 to 158/1,000 live births. Likewise, the infant mortality rate in Ethiopia also declined from 122 to 77/1,000 live births in 2005. Though this remains high in comparison to some other countries – for instance, the rate in the United States is 6.22 and in Japan it is 2.79 – this downward trend is much steeper (better) than the decrease observed in Sub-Saharan Africa (99/1,000 live births). Often the measles immunization rate is used to measure progress toward MDG4. In Ethiopia, the coverage rates arose from 38% in 1990 to 72% in 2007, versus from 56% to 72% in Sub-Saharan Africa. Overall, under-five mortality rate decline appears to be on task for achieving MDG4.

Regarding MDG5 of reducing MMR, based on local surveys (national survey results not available) it is estimated that MMR was 1,400 deaths/100,000 live births in 1990. Based on the national health survey of 2000, MMR was 871 deaths/100,000 live births. This had been reduced to 673 deaths/100,000 live births per 2005 national survey. In Sub-Saharan Africa, there was negligible progress during this time and in 2005 the rate was 900 deaths/100,000 live births. Other indicators of maternal health, such as prenatal coverage and the percentage of deliveries assisted by a skilled attendant, also improved in Ethiopia during this time, though not so in Sub-Saharan Africa. Overall, MMR appears to be declining, as a firm conclusion cannot be based due to lack of national survey data from 1990 and due to various statistical issues with the other data.

Regarding the HIV/AIDS aspect of MDG6, HIV prevalence had remained stable at around 2% over the last 5 years – the average for Sub-Saharan Africa is approximately 6%. The number of people with HIV/AIDS who are receiving antiretroviral therapy increased from 3,880 in 2004 to 109,930 in 2007. This coverage rate is estimated to be 41%, which is higher than the coverage rate of Sub-Saharan Africa (30%). The TB case detection rate increased from 15% in 1995 to 34% in 2007. This is substantially lower than the average detection rate in Sub-Saharan Africa (48%) and international standards (70%). Likewise, the TB treatment success rate increased from 61% in 1995 to 84% in 2007. This compares favorably to the treatment success rate in Sub-Saharan Africa (76%) and is nearly the same as the international standard of 85%. Regarding malaria, a substantial reduction in malaria morbidity and mortality was observed in Ethiopia. Overall, there appears to be good progress regarding controlling HIV/AIDS and malaria, though TB detection rates remain below international standards.

Public Health Challenges

In terms of health-related indicators, Ethiopia has made substantial progress on many fronts, though many daunting challenges still remain. Poverty remains a significant challenge for Ethiopia as it is one of the poorest countries in the world. According to the United Nations Development Program (UNDP) Human Poverty Index, Ethiopia ranks 99 out of 103, with 45% of the people living below the poverty line. In 2000, the WHO estimated that "As a proportion of GDP, Ethiopia's public sector spending on health between 1990 and 1996 (1.2%) was at the 25th percentile of African countries, and below average for lowest-income Africa. . .In real terms, this translates into less than US$ 2 per capita. . ." More recent data indicates that per capita spending has been increased, though it remains less than US$ 5. By some estimates, a basic package of health services costs approximately US$ 13, a substantially higher sum. Not surprisingly, Ethiopia continues to face significant public health challenges, including having one of the lowest rates of supervised deliveries in Africa, low contraceptive prevalence, and some of the highest rates of malnutrition and fertility in Africa. According to 1995 estimates, about 75% of the population suffered from preventable communicable diseases and malnutrition. Life expectancy at birth for the total population is 55.41 years, which is among the lowest in the world. The majority of the population continues to reside in the rural areas, which poses significant challenges for public health outreach efforts, especially given the limited transportation infrastructure. Regarding MDG-related specific health care challenges, although service coverage has increased over time, improvements have not been uniform. For instance, routinely scheduled services, such as immunizations, have improved significantly more than those that rely on 24-h availability of clinical services, such as skilled care at birth, which is considered the single most important factor in reducing maternal mortality. As mentioned above, TB control also remains a significant challenge. According to WHO, Ethiopia is one of the top three in Africa with regard to incident cases of TB. Due to inadequate infrastructure, a dearth of health personnel, and limited health education and awareness in the community, the TB detection rate in Ethiopia remains inadequate to meet the target for TB control. Despite improvement in HIV/AIDS related care, prevention of mother-to-child transmission of HIV/AIDS in Ethiopia is only 10%.

Although the nonphysician health care workforce has increased significantly, Ethiopia continues to have one of the lowest physicians-to-population ratio. As per WHO, Ethiopia is estimated to have fewer than 0.03 physicians/1,000 population overall, which places it among the bottom. Given that physician coverage in rural areas tends to be much lower than urban areas, this ratio is likely to be much worse in certain settings. Furthermore, the health care workforce itself is not immune to the illnesses and diseases prevalent in the population. Recent data from Ethiopia, Kenya, Malawi, Mozambique, and Zimbabwe show that 43% of deaths or medical retirement of health workers were known or suspected to be caused by HIV/AIDS, and 37% were known or suspected to be due to tuberculosis.

Other challenges include a high female illiteracy rate (75%), poor access to sanitation (10% of the population has access to safe sanitation), and poor access to safe water (27% of the population has access to safe water). Many of these factors affect both natives and immigrants equally. For instance, many major infectious diseases pose a potentially high risk for those who immigrate to Ethiopia. HIV/AIDS certainly has a significant presence in the country as mentioned above. In Ethiopia, the primary mode of HIV transmission is heterosexual contact. As such, women are more vulnerable to infection than men, with urban women at highest risk. In rural areas the difference between genders appears to be negligible. Other subpopulations at higher risk for HIV infection include people in prostitution, police officers, and members of the military. Food- or waterborne diseases, such as bacterial and protozoal diarrhea, hepatitis A and E, and typhoid fever, also occur commonly. Malaria remains a significant concern, particularly for immigrants and travelers to certain parts of Ethiopia. Other infectious diseases that require precaution are meningococcal meningitis, rabies, and schistosomiasis.

Health Among the Ethiopian Diaspora

Due to the widespread emigration of Ethiopians to various regions of the world and the lack of large, high-quality studies of the medical problems facing them, there are significant challenges in drawing overall conclusions that are applicable to all groups. However, information is available regarding Ethiopians living in certain places, which does allow for some meaningful observations. Ethiopian immigration to the United States, for the most part, is a relatively recent phenomenon, essentially starting in the early 1980s. The Refugee Act of 1980 was the first formal policy the United States adopted toward the African refugees. Soon after, Ethiopians started to voluntarily arrive to the United States and, along with Eritreans, formed the largest refugee group until 1999. Migration data indicates that approximately 65% of the immigrants are male. Most immigrants identify themselves as Christians, are from urban areas of Ethiopia, and are from Amharic-speaking linguistic groups. Different sources give various estimates of the number of Ethiopians living in the United States, though the most reliable estimate is 350,000–500,000. The largest number of Ethiopians live in Washington, D.C., with Los Angeles, New York City, Dallas, Houston, and the San Francisco Bay area also housing a significant number. In general, Ethiopians living abroad have better access to health care than their native counterparts, though it should be kept in mind that most Ethiopian immigrants still lack access to a primary care physician.

Overall, Ethiopian immigrants, especially those who are new immigrants, tend to have similar medical problems as seen in other similar immigrant and refugee groups. A study that examined the global health status of Ethiopian immigrants living in Boston and Washington, D.C. found that 72% of the studied sample had a positive PPD test (a test used to detect tuberculosis), though only 1% had active tuberculosis. These rates were consistent with those found in Ethiopia at that time. Other significant laboratory abnormalities included intestinal parasites (about 37%), anemia (about 15%), eosinophilia (14%), positive syphilis serology (7.5%), and hepatitis B surface antigenemia (9.4%). Much of these data are comparable to that collected in Ethiopia.

HIV/AIDS remains a significant concern among Ethiopian immigrants, much like it is for the Ethiopians in Ethiopia. Although the data are limited, Ethiopian and Eritrean immigrants seem to have the highest reported cases of AIDS among all African immigrant groups in the United States. As HIV/AIDS data for African immigrants is included with African Americans, it is difficult to obtain such data pertaining only to Ethiopian immigrants residing in the United States. A study conducted in California regarding HIV/AIDS related attitudes and behaviors among Ethiopian immigrants found that there is a general awareness of HIV/AIDS among Ethiopian immigrants, though they have limited insight into their own HIV risk behaviors. On the plus side, most Ethiopian immigrants are aware of the risks of blood contact and sexual modes of HIV transmission. However, a number of them also incorrectly believed casual contact, kissing, and sharing eating utensils can cause HIV transmission. Furthermore, overall, they determine whether someone is at high risk for HIV by appearance and social standing.

A significant number of Ethiopian immigrants believe that HIV/AIDS in the United States is a disease of prostitutes, drug users, and homosexuals. Most believe that HIV/AIDS in heterosexuals is a problem only in Africa and would not affect them in the United States. Like in many parts of Ethiopia, Ethiopian immigrants who test HIV positive in the United States tend to keep it a secret from family and friends for fear of stigma and isolation. Ethiopian immigrant women generally are not able to ask men about their sexual history or about using condoms; this places them at a potentially higher risk for HIV transmission. Due to the prevalence of gonorrhea and syphilis in Ethiopia most immigrants tend to be aware of these sexually transmitted infections. However, their knowledge of other sexually transmitted infections is limited. As a group, the Ethiopian male immigrants report engaging in high-risk behaviors, including, not using condoms, having multiple sexual partners, and consuming alcohol.

Needless to say, immigration is a major life stress event, and overall it has been associated with an increased likelihood of being diagnosed with a mental health problem. Although mental health can be difficult to study across cultures, some studies of Ethiopian immigrants have been conducted and have revealed important information. A study of Ethiopian immigrants in Canada found that over the course of a year 85% of the studied population used one or more type of health services. However, only 12.5% of individuals with a mental disorder (defined as depression, anxiety, and/or posttraumatic stress disorder) received services from formal health care providers. Furthermore, a metaanalysis of 7,000 refugees, many of whom were Ethiopians, found that "refugees resettled in western countries could be about ten times more likely to have posttraumatic stress disorder than age-matched general populations in those countries." Due to the nature of this study, it is not possible to conclude with certainty that this specific conclusion is applicable to the Ethiopian immigrants. However, there are much data indicating that the rates of posttraumatic stress disorder, and often depression and anxiety as well, among immigrants are higher than the general population. At least one study, conducted in Israel, has found higher rates of suicide among the population of the Ethiopian immigrants in Israel, in comparison to other immigrant groups there.

Traditional Medicine and Beliefs

Although space constraints do not allow a detailed discussion of traditional medicine and medical beliefs among Ethiopians, and thus, Ethiopian immigrants, it is important to note that cultural beliefs and norms play a huge role in their lives. For example, much like in many Asian cultures, the concept of patient autonomy and the patient's "right to know" is a limited one. In fact, among Ethiopian immigrants it is not unusual for the family to withhold certain information from the patient. When it comes to disclosing bad news, the priority is not to necessarily disclose the information rapidly or promptly, but rather, in "an appropriate" time, place, and manner. So, for instance, unless it requires immediate attention, tragic news is often not told in the evening and is often deferred to the morning when the recipient of the news may be surrounded by friends and family. Furthermore, results of tests and other medical information are often disclosed not to the patient first, but the family, who in turn may give the information to the patient. Denial may be employed frequently by patients and their families so as to minimize the distress from an imminent death. Likewise, it is not unusual that at times Ethiopian immigrants may even expect their Western physicians to withhold certain information or to only partially disclose information so as to not undercut a patient's hope or will to fight the illness.

Other traditional beliefs that many Ethiopian immigrants carry with them to their new home countries include the concept of health being a state of equilibrium within the body and between the body and the outside. This equilibrium is delicate and can be disturbed by numerous factors, for example, excessive heat or cold, the sun, worms, and eating or drinking too much. For example, many Ethiopian immigrants believe that when the sun strikes a part of the body that is sweating or unclean, *mitch* ("sunstroke") can develop, which manifests as irritation or rash. Many Ethiopians also believe that the heart regulates other organs in the body by producing heat that radiates throughout the body, and prolonged excess of cardiac activity can cause *lib dekam* or "tired heart," which manifests as chronic fatigue.

In part of Ethiopia, a large number of children (as high as 80–90%) have had their uvulas removed due to the belief that if a sore throat develops and the baby still has his or her uvula, the baby will suffocate. As this procedure is often done without sterile conditions – by a traditional healer, using scissors, horsehair, or a special knife – it is possible for the baby to develop tetanus, meningitis, or sepsis. In the Gondar region, in response to eye disease, eyebrows are often cut vertically and blood is allowed to flow into the eyeballs as a treatment. There have been documented cases of Ethiopian immigrants refusing transparent bottles for their babies. This is due to the Ethiopian belief that some people carry *buda* or the "evil eye" and they can poison a substance by looking at it. Therefore, a translucent bottle is preferred to guard against this. Multiple sources have also documented that Ethiopians generally prefer injections to tablets. There also exist some traditional beliefs around pregnancy. For instance, many Ethiopians believe that a woman can be pregnant for more than 9 months and that during menopause, a woman can have a pregnancy that "turns to bone." Amharic Ethiopians especially believe that the stomach does not digest on its own but instead houses Ascaris worms whose job is to transform food into waste.

Touching upon two issues discussed above, HIV/AIDS and mental health, two traditional beliefs are important. In Ethiopia, sexually transmitted infections are often attributed to other factors besides sexual intercourse. This includes contagion from a female dog, urinating facing the full moon, or urinating on a hot stone or where a female dog recently urinated. Many also believe that these infections are cured by drinking sheep fat, cactus milk, by having multiple sexual partners (to "weaken" the disease), washing lesions with the blood of a goat, or drinking one's urine. Needless to say, some of these beliefs can unfortunately delay appropriate treatment, exacerbate the symptoms, and lead to further transmission. Mental illness is often attributed to evil spirits and often treated with holy water and exorcism. Spirit possession or *zar* occurs more often in women than men, and the possessed individual often presents in a manner which would be often considered psychotic in Western countries. *Zar* can be appeased by bribery (food items, clothes, beads and such), though there is no cure per se.

Finally, the issue of female genital mutilation/circumcision needs to be mentioned as this remains a significant problem among native Ethiopians and is being seen more and more by Western health care providers due to increased contact with Ethiopian immigrants. The underlying belief is that a woman with an intact clitoris is likely to be hyperactive and hypersexual. Though obviously inaccurate, unfortunately this belief is widespread. By some estimates, in certain parts of Ethiopia, the rates of this practice are as high as 90%. Three types of female mutilation/circumcision are practiced in Ethiopia. This includes clitoridectomy, in which the clitoris itself or the hood of the clitoris is removed. Excision involves the removal of the clitoris, as well as a partial or total removal of the labia minora. Infibulation involves excision along with the removal, or scraping, of the inner walls of the labia majora. The two sides are joined together, leaving a hole smaller than a grain of corn for the voiding of urine and the passing of menses. Various parts of Ethiopia practice these different procedures.

In the southern region of Ethiopia, as well as some other parts, female genital mutilation/circumcision is not practiced. Though no firm data are available as to how often this practice is still being carried out by immigrants in their adopted countries, at least one study indicates that most Ethiopian women in Israel have undergone this practice. More and more Western health care providers are recognizing that this practice is still being performed outside Ethiopia and are speaking against it. However, a small minority has argued that since many immigrant parents insist on this practice taking place, it is better for these types of procedures to be done by Western providers, using sterile conditions and anesthesia, so as to minimize pain, risk of infections, and other potential complications. Others, however, have strongly argued against Western providers playing any role in these types of procedures, and there has been a push to prosecute parents who force this procedure upon their children.

Conclusion

Ethiopia is an ancient country with a rich past and potentially a very bright future. At present, it faces some big public health challenges, while it continues to make significant gains at the same time. Emigrants to Ethiopia are certain to be drawn into Ethiopia's tug of war with HIV/AIDS, malnutrition, poverty, maternal and child health, access to clean water and sanitation, and so on. At the same time, they have the historical opportunity to watch Ethiopia advance on many fronts, as detailed above, which have improved, and will continue to improve, the lives of its people and raise standards of living to new heights. Likewise, the Ethiopian diaspora is part of a historical and exciting trend in the world, where migrations of people to lands thousands of miles away from their native land is happening at an unprecedented scale. No doubt Ethiopian immigrants have much to offer to the lands where they settle, bringing with them the incredible diversity of their culture. However, as with any other group of people, not all of their beliefs and behaviors are ideal, and many are or will be in conflict with the mores and values of their adopted lands. The difficult, but also rewarding, task of reconciling various belief systems has already begun, though it remains to be seen how – or even if – it will ever end.

Ethnic Cleansing

Daniel J. O'Shea
HIV, STD and Hepatitis Branch, Public Health
Services, County of San Diego, San Diego, CA, USA

Ethnic cleansing is the attempt to eliminate an unwanted ethnic group or groups from a society within a geographic area with the intent of creating ethnic homogeneity. This may occur through forced migration, deportation, or forcible displacement of persons belonging to a particular ethnic group(s). The term is also used broadly to describe all forms of ethnically motivated violence, inclusive of murder, rape, and torture. Ethnic cleansing may encompass removal of all physical remnants of the targeted group through destruction of monuments, cemeteries, houses of worship, and other edifices. Some definitions are broader in scope to also include genocide, the deliberate and systematic destruction of a racial, political, or cultural group. In that case, ethnic cleansing may be considered a continuum ranging from forced emigration and population exchange to deportation and genocide.

Others consider genocide distinctly separate or different, but related in that ethnic cleansing can lead to genocide, with mass murder used to "cleanse" the land of a particular ethnic group. The intent of the perpetrator should be used to distinguish the two: for genocide, the goal is the destruction of the unwanted ethnic, racial, religious, or political group; for ethnic cleansing, the goal is ethnically homogeneous lands. On the other hand, in 1992, the U.N. General Assembly declared ethnic cleansing to be "a form of genocide."

A literal translation of the Serbo-Croatian phrase *etnicko ciscenje*, the term “ethnic cleansing” first became widely used in the 1990s to describe the brutal treatment and mass killings of various ethnic civilian groups, including Bosniacs (Bosnian Muslims), Serbs, and ethnic Albanians, in wars that erupted in areas of the former Yugoslavia: Bosnia, Herzegovina, the Krajina region of Croatia, and the Serbian province of Kosovo. The term was also used in 1999 to describe violent treatment by Indonesian militants of the people of East Timor after the latter voted for independence, and during the 1990s for Russian military operations against Chechen separatists, leading Chechens to flee their homeland.

Scholars disagree about whether ethnic cleansing originated in the twentieth century with the rise of powerful nation-states driven by nationalism and racist ideologies combined with advanced technology and communications. However, there are countless examples of historical efforts prior to the twentieth century aimed at genocide and forced migration around the world, wrought upon those of the “wrong” ethnicity, religion, nationality, or political belief. These date back as far as the ninth and seventh centuries B.C. with the forced resettlement of millions of people by the Assyrians. Other historic examples are: the mass execution of Danes by the English in 1002; removal of Germans from Czech territories in the Middle Ages, and of Jews from Spain in the fifteenth century; and the forced displacement of Native Americans by White settlers in North America in the eighteenth and nineteenth centuries. In this century, examples include massacres of Armenians by the Turks in 1915–1916; the Nazi Holocaust of European Jews in the 1930s and 1940s; the displacement of 15.4 million people fleeing or displaced within Europe in the 1945–1950 postwar period, including the expulsion of Germans from Poland and Czechoslovakia; the Soviet Union’s deportation of ethnic minorities from the Caucasus and Crimea during the 1940s; the forced migrations and mass killings in the former Yugoslavia and Rwanda in the 1990s, creating the largest wave of refugees and displaced persons since 1945; and, more recently, the displacement of a massive population in the Darfur province of Sudan.

Survivors of ethnic cleansing experience high rates of posttraumatic stress disorder, depression, and other forms of mental illness, while long-term psychological effects have yet to be studied. Women in particular were frequently targeted for especially vicious treatment, methodical rape and enslavement, in part because they were considered the biological and cultural “carriers” of the next generation of their ethnic group. Women and children were often left defenseless when men left to join resistance groups.

Two ad hoc international tribunals were created by the United Nations Security Council in the 1990s to investigate allegations of war crimes and crimes against humanity, including ethnic cleansing, and to prosecute violations of international humanitarian law in the former Yugoslavia and in Rwanda. The International Criminal Court (ICC) was established in July 2002 as a permanent tribunal to prosecute individuals for genocide, crimes against humanity, war crimes, and the crime of aggression. Genocide, crimes against humanity, and war crimes all constitute “ethnic cleansing” within the ICC’s jurisdiction.

Despite continuing controversies over its definition, the concept of ethnic cleansing is well established in international law. Even so, mechanisms to effectively prevent and deal with ethnic cleansing have yet to be developed and implemented.

Ethnic Enclaves

Michelle A. Johnson
School of Social Welfare, University of Kansas,
Lawrence, KS, USA

Global economic trends, local immigration policies, and immigrant preferences have contributed to the widespread emergence of ethnic enclaves in diverse geographic settings. The study of ethnic enclaves has a long history in the USA, which experienced its first great wave of immigration in the early twentieth century. These settings have been studied primarily from the perspectives of economic and community development as a mode of incorporation for immigrant adaptation to new societies. Ethnic enclaves are complex environments with interlocking economic, physical, social, and institutional dimensions that may have implications for immigrant health.

From an economic perspective, ethnic enclaves may offer employment to immigrants, which may be particularly beneficial in providing a livelihood for those who may be undocumented or lack the language skills of the host culture. Enclaves can also provide access to credit, employment information, and "on-the-job" training in lieu of specific educational requirements. Conversely, a lack of documentation, language skill, and educational background can lead to exploitation in enclave settings such as low wages, poor benefits, and hazardous labor conditions. Such conditions are typically related to poor health.

Access to ethnic specific markets in thriving enclave settings may allow residents to maintain the diets and health practices of their culture of origin. Ethnic enclaves are often located in communities of low-income. Disinvestment in ethnic enclaves may contribute to a loss of jobs and businesses that cater to the ethnic economy. This process may, in some cases, produce food deserts, prompting shifts in dietary habits that are associated with poorer nutrition.

The physical design of an ethnic enclave may also influence health behaviors such as walking outdoors, running, and bicycling. Whereas lower neighborhood crime rates have been associated with greater physical activity and social interaction among residents, immigrants who reside in ethnic enclaves with higher crime rates may experience greater victimization, isolation, and reluctance to participate in outdoor activities. Residents in communities plagued with crime are also less likely to seek needed health care services.

The collective resources available to residents from social networks are known as forms of social capital. Social networks typically include family members, friends, and other acquaintances inside and outside of neighborhoods of residence. Forms of social capital that may be present within ethnic enclaves include the psychosocial resources that support newcomers in their adaptation to the host culture and may buffer them from some forms of discrimination. Social capital may include benefits that are provided collectively by the ethnic enclave such as its resilience or political power to bring health resources into a neighborhood. Social control is a form of social capital reflected in the values that discourage or promote the health behaviors of enclave residents. Cultural capital may provide residents with a sense of community and access to traditions and practices that may support health.

While a vast and complex system of institutions delivers health and social services to immigrants and refugees, disparities have been observed in the access and utilization of health and mental health services among immigrants when compared to their native-born counterparts. An ethnic enclave's institutions may influence the accessibility, availability, and acceptability of health and mental health care as well as the presence of traditional healers. For example, mainstream organizations such as hospitals may tailor their services to serve specific immigrant populations within ethnic enclaves, while barriers within mainstream services may give rise to private and/or self-help organizations that are formed and led by community members. In general, the more institutionally complete the enclave setting, the more likely immigrants will be to meet their health-related needs despite barriers.

As in all neighborhoods, health is also shaped by the quality and accessibility of basic services such as police and fire protection, sanitation, parks and recreation, and schools. Churches, social clubs, and neighborhood associations provide services as well as opportunities for residents to participate in community life, which can be particularly beneficial for immigrant newcomers.

The study of immigrant health dynamics within ethnic enclave settings is growing as interest in the roles of ethnicity and geography in social disparities in health is accelerating. To date, research suggests that the relationships between ethnic enclaves and immigrant health vary by ethnic group, neighborhood quality, the characteristics of residents, and the health indicator under consideration. Additional research will be necessary to create more responsive health care systems and stronger health infrastructure for immigrant populations in diverse enclave settings.

Ethnic Group

- ► Ethnic minority group

Ethnic Identity

Camila Godoy Delgado
Department of Psychology, Suffolk University, Boston, MA, USA

Ethnic identity refers to an individual's sense of belonging to a socially constructed group that shares a common culture, race, language, religion, and/or place of origin. It includes the individual's beliefs and attitudes toward that group that can change with time and context. Developing a positive ethnic identity is of fundamental importance to the psychological well-being of all minority individuals. For immigrants in particular, leaving their country to settle in another poses particular challenges concerning the extent to which they can or wish to maintain their original heritage and how much they can or wish to adopt the new cultural practices, values, and identities of their host culture. An immigrant's ethnic identity is oftentimes multifaceted (i.e., incorporates multiple ethnic identities) and reflects the qualities of their acculturation experiences, as well as their own psychological adjustment to their new environments.

The term ethnic identity surfaced in the 1800s as scientists became interested in understanding the psychological aspects of migration to and from Europe. At the turn of the twentieth century, it was believed that globalization would lessen the impact of ethnic identity, but it in fact did exactly the opposite. Ethnic identity reemerged during the civil rights movement as a way to explain the psychological struggles of African-Americans in the USA. With the surge of immigration to the USA and Europe especially, it also became an important tool for discerning the complexities of an immigrant's adjustment. Today, ethnic identity affords sociologists, anthropologists, and psychologists worldwide such a tool for the more than 200 million people living in a country other than the one in which they were born, for their native-born children and subsequent generations, and for the problems of prejudice and discrimination that persist in our societies. Scholars such as Jean Phinney, John W. Berry, Rubén Rumbaut, and Alejandro Portes have made great contributions to our conceptualization of ethnic identity among immigrants and have urged practitioners, researchers, educators, and policy makers to consider its implications in their work.

Ethnic Identity Development

Ethnic identity includes components such as self-identification (labeling of one's ethnicity), pride (sense of belonging to an ethnic group), knowledge (understanding of ethnicity and the group), satisfaction (attitudes toward one's group), and value (degree of importance of ethnic identity). Importantly, each of these changes from early childhood to adolescence and into adulthood. Frances Aboud has demonstrated that children learn to self-identify with a particular ethnic group between the ages of 4 and 7. At around 8–10 years old, they begin to understand that ethnicity stays the same over time. As a child's cognitive abilities grow, so too do they begin to appreciate ethnicity concretely (e.g., through food and language) and behaviorally (e.g., through actions and customs).

It is not until adolescence that ethnicity is conceptualized as something abstract and changeable through time and context. Jean Phinney highlights these differences between age groups and further posits that ethnic identity formation occurs in stages predominantly during adolescence. In childhood, ethnic identity is acquired from the influences of family rather than through personal exploration (i.e., foreclosed ethnic identity). Adolescence, characterized by identity formation, often includes ethnic identity confusion and discovery as well (i.e., moratorium stage). As adolescents continue learning about their ethnic group and its role as a separate subgroup to the larger majority, they begin to more clearly understand and accept their own ethnicity (i.e., achieved stage).

These identity components and the process of ethnic identity formation are influenced by the social and cultural contexts of development. For children, the family, school, community, and larger society all directly affect the attitudes and feelings toward their ethnic group. When a family is warm and supportive, feelings toward their ethnic group tend to be stronger and more positive. Importantly, family customs, gender role expectations, and language maintenance take place within the larger society, further shaping ethnic identity in youth. If messages from school, neighbors, and the media contradict or negatively portray characteristics of their ethnic group, children and adolescents are likely to experience greater conflict in their ethnic identity resolution. An example of many Dominican-Americans in the USA described in the work of Cynthia García Coll and Amy Marks highlights this influence of the larger society. Dominican-Americans are characterized by strong family ties, high maintenance of cultural traditions, and high levels of ethnic pride. Dominican-American children develop a secure sense of belonging to their ethnic group as a result. In adolescence, however, many Dominican-Americans with darker skin color and Afro-Dominican features are ascribed as being "Black" by community members around them (e.g., police). The negative racial stereotyping and discrimination that occurs as a consequence makes them less likely to label themselves American and more likely to retain their original language and customs. For many second-generation Dominican-Americans especially, this creates profound psychological struggles in their attempt to integrate into mainstream North American culture. These difficulties foster a susceptibility to mental health issues such as depression, anxiety, and suicidal ideation.

Ethnic Identity and Acculturation

The term ethnic identity has often been used interchangeably with acculturation, but it is best understood as an aspect of an immigrant's acculturation process. In John W. Berry's work, acculturation is described as the process of psychological change that occurs when one cultural group comes into sustained contact with another. Explained in this way, there are two components to consider: the retention of one's culture of origin and the adoption of the culture and customs of the new society. Inherent to the bidirectional interplay between these two aspects of acculturation is the ethnic and national (i.e., pertaining to the larger society) identity of an individual. It is important to note that the process of acculturation does not entail a choice between an ethnic or national identity, but rather involves a complex interaction between the two that results in an independent resolution of each; that is, an individual can identify strongly or weakly with either their ethnic or national identities or both.

These psychological adaptations and subsequent ethnic identity changes take place within the larger social structures of the immigrant's receiving community. Sociologists such as Minh Zhou and Alejandro Portes have argued that an immigrant's skin color, geographic location, and residential accessibility to upward mobility ladders are among the many contextual factors that contribute to an immigrant's adaptation and ethnic identity formation. Countries differ in their immigration laws, in the degree to which they historically welcome immigrants, and in the cultural background of the immigrants they prefer. Within specific countries, there are also large differences between and within cities regarding existing community resources, economic and educational supports, and social capital available to receive immigrants from particular regions or cultures. In addition, the neighborhood characteristics of the immigrant's location including foreign-born concentration, socioeconomic status of residents, crime rates, and institutional resources of the area also impact the quality of an individual's acculturation experience and ethnic identity formation. For example, cities such as Miami in the USA are particularly welcoming of Hispanics where they comprise nearly 68% of the population, nearly all of whom identify Spanish as their first language, and half of whom are Cuban. Cubans have also benefited from immigration policies and financial incentives that have facilitated their adjustment compared to Haitian-Americans in the area. Nevertheless, being Cuban in Coral Gables (per capita income of approximately U$60,000) has its marked advantages to being Cuban in Hialeah (per capita income of nearly U$13,000). Cubans in Coral Gables are more likely to have a strong, positive ethnic and national identity as a result.

In sum, the social contexts that support retention of an ethnic identity are more likely to foster a strong ethnic and national identity (i.e., integration). Others that generally discourage or alienate specific immigrant populations are more likely to promote strong ethnic identities and weak national identities (i.e., separation) or weak ethnic identities and strong national identities (i.e., assimilation). Researchers have consistently shown that integrated individuals (i.e., individuals that possess a strong ethnic and national identity) fare better on measures of mental health, behavioral, and academic outcomes.

Ethnic Identity and Well-Being

The complexities of forming, maintaining, and reconciling ethnic identities within these social structures can, and oftentimes do, have a direct impact on immigrant individuals' physical and mental health outcomes. For example, most US immigrants, by way of being a racial or ethnic minority, have experienced discrimination, stigmatization, or stereotyping at some point in their lives, whether overtly (e.g., through physical or verbal threats) or subtly (e.g., through exclusion or microaggressions). Oppositional identity theorists contend that many such individuals, for whom neither minority nor majority social norms are easily adopted, will instead form oppositional identities. Oppositional identities may involve dress, language, or behaviors that are not consistent with either an ethnic or national orientation. For example, adolescents may be conflicted with doing well in school lest they be perceived as "acting white." In turn, they may resort to hiding such behaviors or revert to putting forth less effort in school, withdrawing from peers or negatively affecting their academic performance and upward mobility possibilities in such a way. Oppositional identities often lead to declines in grades, increased behavioral problems, and decreased self-acceptance.

Numerous studies have also demonstrated that having a weak, negative ethnic identity is associated with poorer self-esteem. Social identity theorists Henri Tajfel and John Turner suggest people naturally aim at having a positive social identity that enhances one's self-esteem. Often, being perceived positively involves a choice between the ingroup versus outgroup. Immigrants who may be viewed negatively by the larger society are frequently conflicted by this choice. They may be able to sustain a strong ethnic identity, overcome the difficulties of belonging to the outgroup, and ultimately possess a higher self-esteem and resiliency. They may also internalize the devaluation of their outgroup and choose to adopt the ingroup or majority identity instead. Many such individuals later feel as though there is a degree to which they never completely belonged and experience self-esteem issues regardless. Another option still involves internalizing the devaluation of their outgroup, sustaining a high ethnic identity all the same, and generally maintaining a low self-esteem due to the taxing nature of such psychological struggles. While this does not include all positions an immigrant may take and their potential outcomes, it does provide a sense for the relationship between ethnic identity and self-esteem. Importantly, an achieved ethnic identity includes positive feelings toward one's group. These positive feelings alone are often the source of the personal strength and high self-esteem needed for many resilient ethnic and racial minorities.

Research has generally shown that having a strong, positive ethnic identity is related to more positive academic outcomes, fewer behavioral and mental health issues, and protection from risky health behaviors such as substance use, drug use, and smoking. Beginning in childhood, individuals exhibit more positive coping styles and positive peer relationships when ethnic identity is strongest. It further moderates the negative impact of ethnic and racial discrimination. For immigrant youth in particular, having a secure ethnic identity is of utmost importance throughout the course of their adjustment to a new neighborhood, school, language, and customs. Social adjustment and academic achievement is also highest for second-generation immigrants when they identify strongly with their ethnic group. Individuals particularly at risk for physical and mental health disorders are those for whom conflicts are twofold; that is, they boast weak ethnic identities and are female, Black, homosexual, or poor. A strong support network in these cases is crucial.

Bicultural and Multicultural Ethnic Identities

Historically, research considering ethnic identity aimed to explain how and why an individual identifies with a particular group at the expense of a majority or national identity. Such research further argued that attempting to merge both an ethnic and national identity leads to "culture shock." Today it is understood that forming ethnic or national identities can co-occur; that is, individuals can possess a strong sense of belonging to both their ethnic and national group and engage in exploration of each simultaneously. Such "biculturalism" involves identifying with and being competent in two or more cultures. Recent studies on bicultural individuals suggest they oftentimes fare better than their monocultural peers in measures of self-esteem, anxiety, and academic outcomes. Some researchers describe the related cognitive skills needed for biculturalism as "frame switching," which involves moving between two sets of cultural interpretive frames, including the different languages, customs, and values of each, in response to socio-environmental cues.

In sum, whether an immigrant experiences his or her ethnic identities as a culmination of multiple ethnic selves (multicultural), a balance between two ethnic identities (bicultural), or a competition between the traditional ethnic identity and the new national identity, it is clear that forming and maintaining ethnic identities is a complex process that involves the bidirectional influence of context and culture on the individual. Environmental factors such as poverty, discrimination, and language difficulties can be rather easily ameliorated through a warm and supportive family, effectively redirecting ethnic identity from a weak resolve to a strong and secure sense of belonging. As such, the role of ethnic identity on the health and development of immigrants can be profound. Future research is needed to further investigate how gender, age at migration, and generation of the immigrant shape immigrants' ethnic identities. Studies that more comprehensively capture ethnic identity development across the life-span and incorporate person-environment interactional models will go a long way toward enhancing our understanding of ethnic identity in a world where the well-being of immigrants is becoming increasingly important to our societies.

Ethnic Minority Group

Parikshit Deshmukh
Department of Psychiatry, University Hospitals Case
Medical Center, Case Western Reserve University
School of Medicine, Cleveland, OH, USA

Introduction

"Ethnic minority group" can be defined as any sociological group based on common ethnicity of its members. The group typically constitutes a minor part of political voting of the total population of any particular society at any particular point of time. Ethnicity, in particular, can be defined as social identity that is associated with shared behaviors and patterns. The factors affecting these patterns include, but are not limited to race, skin color, religious affiliation, language, type of clothing, eating habits, pattern of social interaction, and health behaviors. These patterns collectively give unique features to the group. Other commonalities (including genotype and phenotype) and preferences for certain common geographic area for residence make these groups even more unique.

Ethnic Identity of a Member as a Basis of Ethnic Minority Group

Although the concept of "ethnic identity" of a member of ethnic minority group remains vague, Tajfel has defined it as "that part of individual self concept which derives from (his) knowledge of (his) membership of social group (or groups) together with value and emotional significance attached to that membership." However, in order to explain this concept comprehensively, various components have been taken into account. These components are self-categorization (identifying oneself as a member of particular social group), commitment and attachment (strong personal involvement in the group), exploration (seeking information and experiences about one's ethnicity), ethnic behavior (speaking language and eating food, etc.), in-group attitudes (positive attitude such as pride and good feeling about one's group or negative attitude such as wish to belong to another group), ethnic values and beliefs, importance of group membership, and ethnic identity in relation to national identity.

Types of Ethnic Minority Groups

The categorization of ethnic minority groups can be extensive, but, for example, in the USA, per the census, it has been broadly classified into Latino, African American, Asian, American Indian, Alaska Native population, Native Hawaiian, and Pacific Islander. However, it should not be confused with racial group or nationality of origin which happens frequently. Applying genetic meaning to defining ethnic group would equate it with race and would not take cultural components into account. In order to appropriately use the terminology of "ethnic group," one must account for genetic as well as cultural dimensions.

Importance of the Concept of Ethnic Minority Group in Health Care

The discussion about "ethnic minority group" in the health care sector is important due to the variations in occurrences and presentations of various medical diseases in various "ethnic minority groups" and the disparities in the health care they receive as compared to general population, despite their significant number in the US society. Health disparities are defined as diseases, disorders, and conditions that disproportionately afflict individuals who are members of racial, ethnic minority, underserved, and other vulnerable groups.

This disparity was perhaps first best mentioned in 1985 in the landmark document, *Report of the*

Secretary's Task Force on Black and Minority Health. It was then that attention to the burning problem of this disparity was achieved. This report highlighted that the ethnic minority populations suffered disproportionately from heart disease, stroke, cirrhosis, diabetes, infant mortality, unintentional injuries, and homicide.

Despite numerous federal, state, and local initiatives implemented to address these and other health-related disparities in ethnic minority populations, the differences in occurrences of various illnesses and injuries remain prevalent. History clearly suggests that the advances have been taken to provide uniform health care and to mitigate this disparity based on ethnic and racial differences. However, Bach argues that US ethnic minority communities might be receiving lower quality of care due to differences in their primary health care providers or differences in the site of care. The same review also discusses the current disparity in surgical procedure number and quality outcome due to race and ethnic variables. In particular, groups such as African Americans and other marginalized groups, suffer higher rates of morbidity and mortality from just about every major cause of death, including cardiovascular disease, cancer, diabetes, and HIV/AIDS.

Culturally Competent Care as a Solution for Disparity in Health Care Among Ethnic Minority Groups

As this disparity is now well supported in literature, the term "culturally competent care" has been well emphasized. This includes achieving awareness about cultural differences among different "ethnic minority groups," gaining knowledge (collecting information about patient's race, ethnicity, and spoken and written languages), and acquiring skills and abilities (provision of language access services, and support from organizations for cultural competence) to work among these groups. Despite the evidences about the advances in this direction, need for further efforts in education, practice, research, policy, and advocacy exists to mitigate this disparity and provide better health care to different ethnic minority groups. Moreover, as these groups are in minority and not well represented at higher authority level, better awareness and collaborative efforts are essential to assure the same health care level to them as compared to general population.

Ethnicity

Katandria Love Johnson
University of North Texas Health Science Center at Fort Worth, Primary Care Research Institute, Fort Worth, TX, USA

Historical Background and Definition

There are several ways to define ethnicity. This term can be used to describe how an individual identifies his or herself in relation to a particular race or culture. It is how one is self-labeled when assigning group affiliation. Ethnicity also explains the way of life of a distinct group of people, based on a set of shared values and customs. This term is a construct that changes depending on how the situation develops and its context. Such contexts include religion, language, culture, kinship, and nationality.

An ethnic group comprises those who share common religious, cultural, or life-style practices, which make them unique from another ethnic group. Ethnic affiliation determines how one lives and self-conceptualizes in the context of society. Specific cultural traits related to an ethnic group are usually related to the native language, food, and clothing, which develop from time spent in isolation and cultural differences. It is through geographical location and social isolation that ethnicity is maintained. For example, many immigrants who come to the USA maintain their cultural distinctiveness in food and language while assimilating with the host country. This type of ethnic stability is found in parts of a country where certain ethnicities have isolated themselves to a specific locale and promote sales and purchase of native food and goods with restaurants and other businesses for that ethnic group.

Ethnicity or Race?

The terms "race" and "ethnicity" are not always clearly distinct. As a result, these terms have been utilized interchangeably and inappropriately in the literature. For example, ethnicity was a term used from the mid-fourteenth century until the mid-nineteenth century to describe racial characteristics. During World War II, this term was utilized to describe Jewish, Italian, and Irish immigrants. Since the 1960s, "ethnicity" has become a popular term in the field of social anthropology to denote group relationships and classification of people.

Ethnicity can be viewed as how an individual is part of a distinct group of people while race is oriented toward how one is categorically different than another group. Unlike race, which distinguishes populations based on physical characteristics, ethnicity describes a social group that shares a common history, cultural identity, and geographical location, regardless of racial difference. For example, a Hispanic or Latino is considered to be an individual from Cuban, Mexican, Spaniard, South or Central American, or other Spanish culture or origin. Some ethnic groups base their identity on affiliations within ethnic groups. In this instance, the most important and binding component of one's attachment to a group of people is the belief that that group of persons is unique and whose cultural bond is shared. Members within the group define the group characteristics and ownership. This definition of ethnicity also focuses on the personal feelings of the individual about their ethnicity within that ethnic group. In turn, one's affiliation with that ethnic group is typically to serve the needs of the individual. Such affiliations allow the individual to collaborate with members within their group or compete in society.

The concept of ethnicity is unidimensional whereas race is multidimensional. When one speaks of ethnicity, the reference is strictly linked to a single genealogy or ancestry. This link can be real or presumed by the members associating themselves with a particular racial group. Race is a social construct utilized to categorize people based on skin color, ancestry, or country of origin, which can be multiple genealogies or ancestries. In addition, race is related to biological, genetic, religious, and linguistic similarities; however, ethnicity does not include the two latter traits. Time is the major factor by which ethnicity is defined, in that religion and language are two phenomena that develop and evolve with time. In both cases, the two terms can be considered social constructs. A final note with respect to race is its distinction resting on physical features to include skin color, facial features, and traits that are considered similar among races.

Dimensions of Ethnicity

Primordialism and Circumstantialism

The viewpoint of primordialism supports the notion that human beings desire to be a part of similar groups of people whose way of life reflects theirs. Changes within ethnic groups are gradual, seek a place of social acceptance, and have time-enduring cultural practices. Primordialism holds that ethnicity is not based on the pros and cons of financial loss and gains but rather feelings, and that it is a state of being which is unchangeable, fixed, and based on community interests. Circumstantialism, on the other hand, is diametrically opposed to the viewpoints of primordialism in that ethnicity is viewed as fluid and experientially organized. Circumstantial ethnic identity is based on political, economic, and social status driven by history circumstances and inequality whereas instrumental ethnic identity is linked to nature, socialization, and biology otherwise inherited.

Instrumental and Symbolic Ethnicity

One might also conceive of ethnicity as being formed based on political and social bonds between members of the same ethnic group. Such bonds include marriage, friendship, kinship, ritual beliefs, and practices. In turn, these social contracts evolve into informal political groups that set out to accomplish goals and objectives that strengthen the ethnic socioeconomic infrastructure, which is an instrumental perspective.

The process of ethnic identification is usually in a self-identifying format whereby which the individual determines which group or groups with which they relate most closely, such as Hispanic or Latino. Noyoo identified two components of ethnicity: instrumental and symbolic. The former term is derived by deprivation from material goods while the latter refers to individuals' ability to maintain their cultural identity. For example, a Hispanic who immigrates to the USA may not have access to traditional goods and services provided by the host country; however, the immigrant may still have access to his or her cultural festivities celebrated annually in his or her native country through community-sponsored events.

Expounding on symbolic ethnicity, this term can be defined by how groups of people base their identity on their cultural differences. Years of social and political conflict have created a rift between some ethnic subgroups. As an example, two African groups, the Hutus and the Tutsis, were segregated into majority and minority ethnic groups based on their occupations. Regardless of their shared language and physical appearance, the Belgian governing body that led to the colonization of Rwanda also created political competition between these groups. Even though these two African groups were similar in that they shared a culture, their occupational assignments brought about ethnic isolation and cultural differences among the Rwandans.

If we apply the concepts of symbolic ethnicity to the Rwandans, one could say that such ethnic conflicts have led to liberalization and democratization certain parts of Africa. This situation can potentially destroy civil society, thereby decreasing a country's life span. Finally, ethnicity can also be viewed as a way by which individuals accumulate wealth or political power. This perspective views ethnicity as a strategy to access resources within society to include gainful employment and an education.

Language and Culture

Immigrants may arrive to a country whose language and culture may differ from theirs. In addition to learning to navigate through a different socioeconomic and educational system, management within the healthcare system prompts a different kind of knowledge in terms of the linguistic and cultural norms the immigrant may need to remain a healthy member of society. Ethnically diverse groups must either know the language and culture or interpreters and translators must be available during every day communications within the educational, business, and medical contexts. Because ethnic diversity is wide and varied, the dialect of the interpretation or translation may be different from that of the immigrant's native country. Ethnic differences among immigrants may signal differences in understandings about the origins and treatments of specific diseases and differing opinions regarding non-Westernized medical treatment such as alternative or herbal medicine. The extent to which immigrants retain such beliefs may be associated with the length of time spent living and adapting to the norms of the host country while maintaining or decreasing ethnically based social norms.

Acculturation

Once understood as operating unidirectionally, we have come to understand that acculturation may occur bidirectionally. An individual from another country may assimilate with the cultural norms and customs of the host country, while also retaining the language, norms, and customs of his or her country of origin. The extent to which immigrants adopt the culture of their new country or retain the culture of their country of origin varies across individuals and across immigrant groups, and also varies depending upon the particular aspect of the culture. For instance, an individual may become completely bilingual, but may not adopt the value system of the receiving country. In some instances, the immigrant may integrate both paths into his or her lifestyle, which leads to a variety of relationships and social contexts in which the individual is accepting of and accepted by both ethnic groups.

Recent research has shown that acculturation directly affects Hispanics' ability to assess their own health and seek out health care services. On the other end of the spectrum, a Hispanic paradox exists in that some literature points to poorer health outcomes for highly acculturated Hispanics. More recent research contradicts this notion and purports that less acculturated Hispanics tend to rate their health as fair or poor. Nevertheless, ethnicity and the immigrants' association with the ethnic norms of the host country appear to affect, whether negatively or positively, health outcomes of individuals who have been exposed to more than one culture.

Knowledge of the different models of acculturation is important to understand ethnic identity. It can be described from a bidimensional model as a means to describe differences in ethnic identity. Integration within the culture of the host country can be considered biculturalism while assimilation describes the one who chooses to identify only with that of the host country. The greatest sense of social isolation may come from the immigrant who does not assimilate with either culture. In any case, ethnic identity with the new society can be considered a form of nationalism.

Census and Nationalism

Every 10 years, the USA conducts a census to quantify all citizens based on various social, economic, biological and psychological factors. This process of recording and publishing information is utilized to allot government funds to medical, educational and other public institutions and social services. In this context, ethnicity is a term that catalogues the various groups of people that live in the census of those living in the USA. The US Census identifies race as what the individual self-identifies or reports. The individual is grouped based on the person's own concept of culture and society. Races are considered to be any of the following: White, Black or African American, American Indian or Alaska Native, Asian Indian, Chinese, Filipino, Japanese, Korean, Vietnamese, Native Hawaiian, Guamanian or Chamorro, Samoan or Pacific Islander. The term Hispanic, which was once considered a race, has been removed from census and has been replaced with the following ethnicities: Hispanic, Latin or Spanish origin. Unlike the USA, countries such as France and Switzerland do not collect ethnicity information from its residents. On the other hand, countries like India catalogue ethnicity based on the native language of that group; this society is based on a caste system whereby occupations are linked and fixed to a family's pre-existing socioeconomic status.

Nationalism and ethnicity are closely related in that these terms are characteristically ethnic. Nationalism is an expression of multi-ethnic beliefs and ideas that share civil rights versus cultural origins. In that regard, some immigrants may be unsure of how they may classify themselves as between nation and ethnicity. For example, Mexicans living in the USA belong to an ethnic group (Hispanic or Latino), but also belong to the country of Mexico, regardless of whether they return to their native city. Nationalism can be viewed as the basis of multiculturalism within the host country, if the country's policies promote such concordance. Policies that promote integration can create a sense of psychosocial and physical well being for immigrants migrating to that host country. For example, the USA has set a precedent for the variety of immigrants it allows to migrate and live as refugees. In all, integration within society is closely tied to state and national institutions that promote biculturalism rather than total assimilation to the values and norms of the host country.

Immigrant Health

Health is often viewed as a sense of well-being from a mental, physical, and social standpoint, without illness present. Depending on one's ethnic group and immigration status, health may be considered a right or a privilege. In any instance, health is what affords one to a become productive member in society, facilitating access to employment and, thereby, an adequate standard of living. Immigrants arriving to the USA from developing countries sometimes find that their new host country offers certain health care services not traditionally accessible in their country. This accessibility, in turn, places that group at reduced risk for specific diseases or debilitating ailments that could compromise their ability to earn or maintain a living. In this context, ethnicity is a sociopolitical means to enforce federal laws promoting equal access to such services, decrease disparities in public services for specific minority groups, increase employment opportunities, and address environmental risks affecting certain ethnically diverse populations.

In the USA and other countries, ethnic diversity affects the development of economic growth, particularly service and health industry. Research has shown that immigrants who navigate through a healthcare system different from that of their host country, who have low or poor health literacy rates, or who have limited linguistic ability in the language of the host country are more likely present with poor health outcomes. The lack of healthcare services for this population can be attributed to several additional factors, including socioeconomic status, education, and cultural barriers. Such factors are directly linked to the institutions that are available to these ethnic groups and the amount of fiscal funds targeted for designated ethnic populations.

Ethnic Identity and Psychosocial Health

Immigrant attitudes, characteristics, and reactions of the society within the host country often arise in response to the interaction of ethnic identity, immigration, and well-being. This interaction is moderated by individual characteristics of the ethnic group, specifically their attitudes about whether to assimilate with the cultural norms of the host country or retain those of their native culture. This decision will be driven by how accepting the immigrant feels in the host country and whether pluralism, i.e., the acceptance of multiple cultures and ethnic groups, is accepted among the native ethnic group. Positive outcomes usually result from an ethnic identity that is encouraged by a supportive community. On the other hand, social pressures to assimilate may lead the immigrant to form a new national identity while negative attitudes toward assimilation foster solidarity toward the native cultural group.

Ethnic identity within the host country is determined by a number of factors. First, the psychological status of the immigrant pre-arrival to the USA will directly affect the perceptions of negativity and stereotypes within the host country. Second, the level of security of ethnic identity will generate psychological well-being of the immigrant, among the acculturating groups and resolution of within group conflicts. Confident feelings about one's ethnicity are prerequisite for the immigrant's valuation of his or her ethnic group and affirmation of his or her affiliation with it. Third, an individual's ethnic self-conceptualization may differ from the ethnic identity ascribed to him or her by others. Conceptualizations by the immigrant and by others may fluctuate with time and situational factors.

Ethnic identity is developed and maintained by one's self-esteem, psychological stability, and physical health within one or more cultural groups. When an immigrant arrives to the host country, ethnic stability cannot come without adaptation. If the migrated individual relates positively to the values and norms of the host country, he or she tends to develop a strong identity with the host country while maintaining that of his or her native origin. Furthermore, a secure sense of identity of self enables an immigrant to address conflict within and outside his or her ethnic group while maintaining positive relationships and a sense of solidarity within such groups.

Several moderating factors affect ethnic identity immigrants that are transitioning to another country. These factors include age, generational status, and sex. The tendency is for young women to be more accepting of assimilation toward Westernized culture as it may provide females with increased rights and liberties. Older female immigrants may remain in the home and maintain practices of their native country. So identity and adaption to the host country are also closely linked to the generation and point at which immigration took place. New immigrants tend to have a strong sense of affiliation with their native culture and country with degrees of adaptation occurring over time. The degree to which adaptation occurs will depend on a variety of chronological and sequential factors including ethnic identity level with the native country, socioeconomic status, and education that enable to immigrant to choose instead of be forced to conform to the norms and values of the host country.

Summary

Immigration brings about the intersection of race, culture, and ethnicity. Individuals may decide to leave their country and travel to another for several reasons, which are not limited to schooling, job access, and relatives who reside in the host country. Movement abroad may occur in the hope of creating a better socioeconomic lifestyle for themselves and their families. Individuals who immigrate tend to be healthy enough to look for work or study abroad when they arrive to the host country. In contrast, some immigrants may arrive with preexisting medical conditions, which may worsen in the absence of adequate working and living conditions and healthcare access. Such conditions can be genetically linked to their ethnic group such as the Auschwitz BRCA1 cancer gene.

Ethnic groups have differing ways of coping with the stressors of life. In many instances, the lack of social support from immediate family or friends who already reside in the host country may predispose some immigrants to illness. This combination of social, working, and living conditions in the host country can lead to increased susceptibility to disease. Furthermore, if the immigrant does not access healthcare for routine checkups, chronic diseases can potentially worsen and compromise the immigrant's ability to work productively. For example, Mexican immigrants tend to maintain a nuclear link with their immediate family and those who have immigrated to the host country. In addition, they may seek out social and health service support from their ethnic group because of the shared beliefs and practices held within that population.

In sum, physical, mental, and spiritual health is requisite for an immigrant to conceptualize his or her ethnic identity and how it ties in with the country of residence. Socioeconomic factors discussed weigh in heavily in terms of individuals' ability to adapt to, isolate from, or assimilate their ethnic background with that of the host country. Historically, the use of the term ethnicity has brought about discriminatory attitudes and social isolation among certain ethnic groups. However, the use of this term to describe an immigrant remains an instrumental part of identification within the USA and international communities.

Ethnocentrism

Ahmed Afzal
Department of Anthropology, School of Natural and Social Sciences, Purchase College, State University of New York, Purchase, NY, USA

Ethnocentrism is a universal ideology that ascribes superiority to the familiar, such as one's own group or culture, and regards other cultures as strange, immoral, or inferior. Ethnocentrism emerges from culturally constructed and historically contingent boundary-making characteristics, such as language and even accent and dialect, physical features, ethnicity, religion, nationality, and territory, that create contexts and situations for in-group favoritism and also shape behaviors, attitudes, and social relations toward other groups and cultures. Empirical evidence from cognitive psychology, however, suggests the persistence of bias in favor of one's own group even though these predispositions are influenced and shaped by culture and social environment. Ethnocentric views, policies, and practices have guided systematic efforts such as religious missionary proselytizing and European colonial domination to bring about changes in the developing world. Research in anthropology and psychology shows the appropriations of ethnocentric ideologies and practices in promoting ethnic conflict and war, and shaping consumer choice and voting practices.

In the contemporary global epoch characterized by the intensified flows of people, ideologies, and forms of knowledge across national and cultural borders and boundaries, health care professionals and researchers who work with immigrant communities increasingly emphasize and consider the material and cultural contexts including social and economic inequalities that shape beliefs and attitudes toward health and nutrition, and sometimes even intervene in situations of health risk and crises. Anne Fadiman's exemplary informal ethnography, *The Spirit Catches You and You Fall Down: A Hmong Child, Her American Doctors and the Collision of Two Cultures*, illustrates a cultural impasse with devastating results when two equally hegemonic forms of knowledge, i.e., Western medicine, and Hmong understanding of disease, illness, and treatment, collide with one another.

The opposite of ethnocentrism is cultural relativism. Cultural relativism is an idea and world view that considers all cultures and groups to be equally cultured because every group's social practices are characterized by order, harmony, and refinement. According to proponents of cultural relativism, traditions, values, and beliefs must be considered within the context of the community or culture in which they are found. Cultural relativism, a foundational concept in anthropology, provides a systematic and theoretical basis for contesting ethnocentrism in public discourse, policy and practices, and in textual and mass mediated representations of non-western cultures and communities. From its beginnings in the late nineteenth century, founding figures in anthropology like Franz Boas have argued for the centrality of cultural relativism in cross-cultural analysis.

Health care professionals and researchers who work with immigrant communities have typically resisted making judgments about cultural practices and beliefs and traditions lest such judgments be construed as ethnocentric. However, health care professionals and researchers increasingly agree that there are limits to cultural relativism, and that the criteria for taking a stand against a cultural practice should be based on whether or not the practice constitutes harm. Researchers today routinely take a stand against war crimes, violence against women and children, female infanticide, authoritarian regimes, and the curtailment of civil liberties and rights in several contexts and situations. In recent years, applied social researchers have provided expert testimony to denounce female circumcision on the grounds that it constitutes a form of torture and as a practice of female subordination under the guise of cultural tradition and religious edict. Rather, applied researchers argue that female circumcision persists due to societal constructions of honor, respectability, and marriage norms. Human rights activists have re-conceptualized female circumcision as female genital mutilation on the grounds that it can lead to chronic infections and fatalities, pain during sexual intercourse, increased difficulties in childbirth, and psychological trauma and stress.

Ethnography

JENNIFER BURRELL, JAMES SHUFORD
Department of Anthropology, University at Albany, The State University of New York (SUNY), Albany, NY, USA

Ethnography is a primary theory and methodology embraced by researchers in the health and social sciences to advance understanding of the actions and choices of people vis-à-vis health, health programs, healthcare access, and risk and decision-making processes involved in prevention, maintenance, and treatment. In the realm of immigrant health, ethnography has become the main vehicle by which researchers assess what health means to individuals and groups, how it is understood, and the kinds of barriers that contribute to persistent disparities and inequalities. One of the central tenets of ethnography is the importance of the particularities of everyday life in relation to larger contexts that influence health and healthcare access. Insisting that daily life often holds the key to crucial scientific breakthroughs, ethnographic approaches have been critical to comprehending the failure of public health programs to "prevent" risky behaviors in intervention programs that target HIV prevention, dietary changes, exercise practices, and harm reduction in substance abuse, among many other examples.

Ethnography is both method and theory, allowing researchers to embrace the subjective meaning of behavior – not just what people do or say they do, but why and how their motivations and behavioral intentions are constructed or shaped. Theoretically, ethnography provides a basis for challenging positivistic approaches to health and immigration, and many schools of thought, from phenomenology to symbolic interactionism to political economy, have nurtured ethnography itself as a body of knowledge. Methodologically, ethnography is empirical and includes in-depth description of everyday life and practices; it has been explained as an art or science that is used to describe others.

Ethnography is conducted through fieldwork that is often long-term, although some researchers are recently drawn to its reduced RAP (Rapid Assessment Methodologies) and RAM (Rapid Assessment Procedures) forms. Researchers, or ethnographers, employ participant observation, meaning that they live in or otherwise experience a research site in order to gain an insider or emic (as opposed to etic, or outsider) perspective with the insistence that data must be understood in relation to lived lives. Through this "insider's" point of view, ethnographers seek to allow meanings and modes of understanding to emerge, rather than imposing them from outside. Taking part in the daily life of research consultants (or "informants"), interviews, life histories, and open-ended questions are among the ways in which data may be collected. This allows people to express their views and ways of thinking without predetermining them. The depth of detail amassed through these practices is sometimes called "thick description," a term coined by Clifford Geertz in his writings on an interpretive theory of culture. The data gathered from ethnography are often referred to as qualitative, as opposed to more quantitative or statistically based methods.

The scale of the ethnographic research focus may often be small, that is, limited to a particular community, group, or even person (in the case of a life history.) However, the descriptive and analytic capacities of ethnography allow for a uniquely holistic research perspective that places these individuals, communities, and groups within larger worlds. As immigration, globalization, and various forms of transnationalism proliferate, ethnography has been crucial to understanding both the universal and the unique issues faced by people throughout the world.

The centrality of participant observation to ethnography requires knowledge of the language, history, and culture of the place and/or group of people to be studied. Therefore the training for ethnographic research and its ideally long-term nature require unusual preparation relative to other research methods. Ethnography also requires that researchers be able to conduct studies "on the ground," outside of university or institutional settings where other kinds of research projects are often situated. Due to the unique ability to take into account and center what people say and think and to understand these holistically, ethnographic methods have grown increasingly popular as researchers seek community participation and local perspectives, and to build long-term collaborative research relationships.

Ethnography and Immigrant Health: Some Insights and Studies

For ethnographers, health and health care are intrinsically linked to social contexts. These social contexts are structured by the inequalities found in daily life and are expressed through health disparities. This is especially true for immigrant health concerns, as immigrants are categorized and classified in ways that directly affect both their health and their access to care. Immigrant health disparities can be seen, then, as the material, empirical evidence for social inequities. Paul Farmer, an anthropologist and physician describes this linkage through the framework of "structural violence." For Farmer, structural violence refers to systematic violence that is attributable indirectly to those who are members of a specified social order. Through the lens of ethnography, immigrant health disparities and the structural violence they are embedded in are expressed not merely through statistical trends, but are witnessed through the conditions of everyday life. As a primarily qualitative methodology, ethnography's strengths can best be illustrated by providing several case studies as examples.

In the USA, a significant percentage of migrants work in agricultural labor and experience particularly acute health care disparities. As a result, migrant farmworkers exemplify the challenges immigrants face in maintaining health and in achieving health care. A study by Seth Holmes of migrant farmworkers in the Central Valley of California illustrates the structural violence experienced through hierarchical categorizations based on ethnicity. Holmes conducted his fieldwork through participant observation while he lived in a shack in a migrant camp. He spent his time each day engaged in picking berries with the farmworkers, interviewing employees and residents, and observing the activities at the local migrant clinic. Taking participant observation to its logical extension, Holmes also migrated from the mountains of Oaxaca, Mexico, with Triqui farmworkers he had come to know, across the US–Mexico border and through the Arizona desert, where they were caught by the Border Patrol. Ultimately the farmworkers continued on to Oregon where they secured false social security cards, and obtained employment on a farm in Washington state.

What Holmes found through his ethnographic fieldwork was that income, difficulty of work, and residence patterns on the farm were all structured according to ethnicity. On the bottom of this structure were the indigenous Mexican Triquis who picked the strawberries, which was the most labor intensive job, requiring them to bend over for long periods of time, causing back problems. They were also required to work while fields were being sprayed with insecticides. The Triquis also made the least amount of money, and lived in the worst housing on the farm, which was the farthest away from the farm headquarters. Unfortunately, Holmes found that the conditions causing health risks for Triqui workers were often not seen by the physicians that treated them. These doctors often blamed their patients for the injuries that they suffered, and failed to recognize the role played by the larger social order and international policies in creating the conditions that led to such injuries.

Ethnography also provides a powerful methodological tool for studying immigrant health in the context of the hospital or clinic. In an ethnographic study of a health clinic in Albuquerque, New Mexico, Sarah

Horton found that inequalities in immigrant health care access are structured by ethnicized and racialized categories of deservingness. Horton's study was based on 2 years of research including 90 hours of participant observation, interviews with the clinic's providers, physician assistants, 4 nurses, 3 clerical workers, social worker, immigrant advocates, and over 30 patients. Horton also conducted follow up interviews with clinic staff for 3 years following the main study.

Horton's study focused on the differential access to health care of Cuban refugees versus Mexican immigrants. While Cubans receive federal assistance for health care due to their refugee status, Mexican migrants must rely on the Medicaid Managed Care plan (MMC) in order to cover health care costs. Horton's thesis was that the policies of MMC introduced a logic of deservingness or moral worth onto the documentation status of its clients. While Cuban immigrant healthcare costs are covered by the federal government, coverage for Mexican migrants is paid from county and state funds. As a result, Mexican migrants are seen as a burden on society. This financial burden interpolated into a discourse of risk and responsibility as a measure of moral worth, and hospital staff and administrators appeared to attribute risk and responsibility based on ethnicity or national origin. Cubans and Mexicans were then seen by the public health system as deserving or undeserving of public benefits, categorizations that are reinforced by the clinic's staff. Horton argued that the end result of this policy of differential access is that it further discourages Mexican migrants from seeking care.

Legal status of migrants is often a significant vector for health inequities as well as a substantial barrier to accessing healthcare. In these cases, ethnographic methods have been central to including the perspectives of immigrants who may otherwise "fall through the cracks" or may be afraid to participate in more qualitative studies where they do not know researchers and have no ongoing links to them. In an ethnographic study of undocumented immigrants in Germany, Heide Castañeda found that the condition of "illegality" itself functioned as a risk factor. A German "Denunciation Law" mandates that unauthorized immigrants be reported to authorities if they seek public social services, and are also not covered by the state for emergency medical care. As a result, any health condition requiring medical care may result in deportation. Despite Germany's restrictionist immigrant policy, nonprofit and nongovernmental clinics have begun to fill in the gaps of health care needs for unauthorized migrants. Castañeda spent over 6 months of participant observation at a German clinic and conducted 61 semi-structured interviews with physicians, staff, unauthorized migrant patients, and local experts on immigrant health issues in Germany. Physicians reported to Castañeda that patients at the clinic arrived "sicker" on average than in a normal practice and often waited to obtain medical treatment, resulting in the exacerbation of their illness. Stress and fear due to illegality and deportability have begun to pose mental health risks unique to unauthorized migrants. Castañeda found that a pattern of "stress narratives" arose as she conducted her research relating directly to issues surrounding migrants' lack of documentation, leading one doctor to refer to the correlation between mental health and illegality as the "illegal syndrome."

In addition to providing insights into the health of immigrants and their access to institutional forms of care, ethnographic methods also provide a window into how immigrants perceive health and health care from an emic (insider) cultural perspective. As more and more hospitals and clinics are beginning to institute "cultural competency" programs as a way to close the cultural gap between patient and provider, ethnography is uniquely suited to inform these programs and policies. Many immigrants' knowledge of health and expectations regarding health care are situated in culturally specific bodies of knowledge. As a result, many immigrants report that doctors "don't know anything," because the patient and doctor are working with different sets of medical frameworks.

In a study of Mexican immigrant health in San Diego, Leo Chavez examined the ways in which traditional Mexican cultural knowledge of health influenced their health care practices in the USA. Chavez, in association with the Center for US-Mexican Studies at the University of California, San Diego, conducted interviews with 2,103 individuals born in Mexico, but living in California. The interviewees were sampled following contacts' networks of social relations. Because many were undocumented, this allowed researchers to establish and maintain the trust and rapport necessary for ethnographic research. Interviews began as structured, closed questions, which were followed by more open-ended interviews in order to obtain more qualitative information. Although a small minority sought traditional medical care from a *curandero*, or traditional healer, approximately a third of the migrants interviewed sought their health care in Mexico. Chavez found that migrants' decision to seek care in Mexico rather than their place of residence was due in part to lower cost in Mexico and language issues in the USA. Migrants' also expressed their dissatisfaction with the quality of care they received in the USA.

Finally, ethnographic methods applied to immigrant health show that assumptions and beliefs about health are not universal and vary from culture to culture. In *The Spirit Catches You and You Fall Down*, Anne Fadiman traced the struggles of the Lees, a Hmong family from Laos who have resettled in California. When their daughter began to show signs of epilepsy, their encounter with the Western medical system was fraught with misunderstandings and clashes between Hmong spiritualism and practices with Western biomedical models. Fadiman's encounter with the Lee family and with the doctors who treated Lia Lee are set against a long-term history of US involvement in Laos, Hmong culture and resettlement in the USA, and immigration and issues associated with it, such as assimilation and discrimination.

The common thread between all of these case studies is the linkage of the phenomenology of reporting lived individual experience within the context of larger sociocultural frameworks. Whether it is Holmes' witnessing the experience of migration, Horton's observations of how clinic discourse both reinforces and is shaped by public policies, or Fadiman's understanding of divergent cultural diagnostic explanations and medical expectations, ethnography strives to provide both a window into the perspective of immigrants themselves as well as contextualizing that emic description within an etic analysis. Ethnography gives both a voice and understanding to the subjective experiences of immigrants as they negotiate their own health and well-being within larger systems of health care. These subjective experiences must not be gathered solely through interviews and reported behavior, but also through observation and participation in order to gain a holistic picture of immigrant health experiences.

Ethnographic research and analysis provide a bridge between the scale of individual lived experience and the scale of social structure in which they are embedded. Health disparities are shaped by social inequalities, and immigrant health in particular is characterized by a greater prevalence of inequality, which makes contextualizing health and health care concerns within social and cultural frameworks of even greater importance. The fine detail of ethnography requires a level of solidarity between the researcher and their subjects, which is facilitated through long-term participant observation. This solidarity, enabled by immersive research methods, results in a knowledge that is "thicker" and richer (albeit often limited in scale to a particular group or site) than would be possible via surveys and statistical analysis alone. As the cultural perspectives and health inequalities of immigrants are particularly salient to immigrant health researchers, ethnography provides a unique methodology and perspective that has the potential to illuminate both the subjective meaning of lived experience as well as the structural frameworks that channel and constrict immigrant health.

Etic

Kristi Ninnemann
Department of Anthropology, Case Western
Reserve University, Cleveland, OH, USA

The term *etic* originates in linguistics, and is regularly used within the field of anthropology as well as other social and behavioral sciences. The word *etic* can be used to describe perspectives, constructs, data, or methodology, and in all uses serves a descriptor of positionality. Sometimes referred to as the outsiders' view, *etic* perspectives provide description and assessment of conceptual schemes, categories, and/or culture based upon external evaluative categories. *Etic* perspectives strive to be culturally neutral and objective.

Etic is often discussed in opposition to *emic*. *Emic*, or insider, perspectives attempt to recognize and understand the meaning of a concept from within the cultural framework in which it is being observed. An *emic* approach attempts to assess and convey conceptual schemes, categories, and/or culture in terms of members' own indigenous and meaningful criteria. *Emic* views attempt to represent subjective experience and cultural understanding. In addition to the insider/outsider contrast, the *etic/emic* comparison has further been described as global/focal, universal/particular, and second-order versus first-order conceptualization.

The binary of *etic* and *emic* is not without debate. Although often discussed in opposition to one another, critics argue that neither term is absolute. All *emic* interpretations are informed by whoever is making the observations, and all *etic* interpretations are rooted within some type of cultural context. As such, it has been suggested that *emic* and *etic* be considered as points along a continuum rather than discrete entities.

Eugenics

Oana C. Stîngă
University of Medicine and Pharmacy “Gr. T. Popa”,
Iasi, Romania

Eugenics seeks to improve a population by selectively breeding so as to increase the prevalence of mental and physical characteristics within that population that are deemed to be desirable.

The basis of the eugenics movement was represented by the belief that heredity is key to improving humans. The foreseeable effect of this movement was improvement of humankind. Genes were to be selected in order to provide future generations only with certain features and the "unfit" were to be removed or doomed to segregation.

Eugenics originates from Great Britain, where Francis Galton coined the term in 1880. Gradually, Galton's theory of heredity gained more and more supporters. Charles Benedict Davenport continued Galton's idea and organized a series of studies which sought to prove that heredity plays a role in human traits as laziness, wanderlust, and pauperism. The most important research carried out by Davenport focused on heredity as it relates to feeblemindedness, insanity, epilepsy, criminality, deaf-mutism, genealogy, immigration, and sterilization. Davenport's book *Heredity in Relation with Eugenics* seeded fear in Americans' minds with respect to the consequences of immigration and the potential for changes in the races as they existed. As genetics became more and more popular among scientists, the members of Galton's Society, including Davenport, tried to envision a method of applying genetic theory in order to improve the human race. The solution identified by the Galton's Society was to control human procreation.

In this context, America's interracial marriages came to eugenists' attention as a source for uncontrolled racial changes and potentially undesirable results. The best solution recommended for these couples was sterilization. In time, ideas and ways of processing race differences were to strengthen the "necessity" for having a purified supreme race.

Initiated in Great Britain and continued in America, the eugenics movement had followers in Europe too. Here, the eugenics movement reached its height during the Nazi regime. In 1939, Hitler authorized the provision of mercy death for the individuals with "lives not worth living."

For Nazis, the cruelty had no limits. Nothing was considered to be too much in order to eliminate the unfit and purify the race. Euthanasia of the ones with lives not worth living was not enough; "greater" plans were to follow. The *Jewish Question* had to be addressed, Gypsies were considered as an issue, mentally ill and sexual and racial pathologies were also placed on the list of "problems." The best solution for all these problems according to Hitler was mass extermination.

Although barely noticed, resistance against the eugenics movement existed. Herbert William Conn from Wesleyan University and Herbert Spencer Jennings, a Johns Hopkins biologist, stated the importance of the environment in human evolution and development. Yet, although they resisted eugenics, they did not entirely reject it. Others, such as T.H. Morgan and Franz Boas, were categorical in their rejection, adding more importance to the human social and behavioral differences. Some scientists underscored the importance of nature and nurture in the developmental process of humankind. Among them, Dewey, Jennings, and Lippman helped public opinion to turn against the eugenics movement. Immigrant communities in the USA opposed eugenics, emphasizing the importance that the environment has on humankind's evolution.

Political backlash against immigrant minorities and restrictive immigration policies have always been present in many European countries and in the USA. Most explanations of the adoption of restrictions on immigration have focused on ethnic competition for material resources and on national political factors.

Brigham reamiend steadfast in his bias against Black Americans, which he premised on theories of heredity, despite research demonstrating that the intelligence of the Black immigrants was not inferior to Whites. Although the scientific evidence contradicted Brigham's ideas, he continued to believe that the ethnic diversity of America constituted a threat to the national welfare.

Eugenics taught humanity a harsh lesson on how science can be used to turn against people. The eugenics movement represented an excuse for exterminating the "unfit" individuals and for removing the "burden" that such people can place on the society's shoulders. It was actually a movement designed to solve societal problems by means of medical methods.

In short, based on real or imagined differences, every immigration law adopted in the USA excludes at least some categories of individuals. The laws adopted between 1789 and 1875 discriminate against every foreign citizen. In 1875, no convicts and no prostitutes were allowed; in 1882, idiots, lunatics, and individuals who could not pay a tax of 50 cents and needed public care were discriminated. From 1882 to 1943, restrictions were imposed on Chinese people. In 1885, restrictions were applied for cheap contract laborers. In 1891, restrictions were imposed on immigrants with contagious diseases, paupers, and polygamists. In 1903, no epileptics, insane persons, beggars, anarchists were allowed. In 1907, no feebleminded children under 16 years of age without their parents and immigrants unable to support themselves due to their physical or mental inability were permitted to live in the USA.

Both the Act of 1924 and the Act of 1952 granted residency based on national origin with a particular discriminative nuance toward Asians. The Immigration Act of 1965 focused on non-European countries and the Third World countries. The criteria of admission were based on skill or for family reunification.

Europe's history was also marked by immigration restrictions. The migration of labor force has continuously increased due to economic reasons. Destination countries include UK, Germany, Spain, Italy, Austria, Holland, Swiss, and Switzerland. To limit the access of immigrants, neighboring countries established agreements that permitted entry of only especially qualified individuals to immigrate.

European Court of Human Rights

Beatrice Gabriela Ioan
Department of Legal Medicine, Medical Deontology and Bioethics, University of Medicine and Pharmacy "Gr. T. Popa", Iasi, Romania

The European Court of Human Rights (ECtHR) is an international Court, which operates within the Council of Europe.

History

In 1950, the Council of Europe drafted the European Convention on Human Rights (Convention for the Protection of Human Rights and Fundamental Freedoms), which entered into force in September 1953, signed by all Member States. The objective of this Convention was to implement the rights set forth in the Universal Declaration of Human Rights 1948, adopted by the United Nations.

ECtHR was established in 1959 under this Convention, in order to monitor the protection of human rights in the signatory countries. ECtHR worked with this structure between 1959 and 1998 when the Member States of the Council of Europe drafted and ratified the Protocol No. 11 to the European Convention on Human Rights. The purposes of this protocol were to simplify the structure of EctHR, to shorten the proceedings and, at the same time, to strengthen the judicial nature of the system, making it compulsory and abolishing the decision-maker role of the Committee of Ministers of the Council of Europe. Under the Protocol No. 11 dated 1998, ECtHR became a permanent legal structure, with full-time judges and allowing direct access to the European citizens.

Organization

The permanent headquarters of ECtHR is at Strasbourg, France, in a building designed in 1994 by the

English architect Richard Rogers and completed in 1995. The Operating Rules of Court provide that some of the meetings can take place in the Member States of the Council.

ECtHR is composed of 47 judges, with no conditions of nationality imposed on them. The judges are selected by the Parliamentary Assembly for a 6-year mandate; they exercise their duties ex officio on an individual basis, without representing any country. The 47 judges are assigned across into the five sections of the Court. Each section has a president, as well as the court. Two of the five presidents of the sections also serve as vice presidents of the Court. All of these functions are assigned for a period of 3 years. Each section chooses a Chamber which consists of the Chairman and six members by rotation. The Court has a Grand Chamber, composed of 17 members: president, vice presidents, presidents of the sections, and judges of the sections, the latter being selected every 9 months.

On June 23, 2008, ECtHR adopted the Resolution on Judicial Ethics, a document stating the principles that must be followed by judges to ensure clarity and transparency of their work: independence from any external authority or influence, impartiality and avoidance of conflicts of interest, integrity (high moral character), diligence and competence, confidentiality and privacy of Court deliberations, freedom of expression of their views, lack of involvement in additional activities (except when they can remain impartial and independent and when their schedule is not affected), rejection of any benefits, gifts, decorations or honors that might affect their independence and impartiality.

Procedural Issues

ECtHR judges individual complaints or complaints of the Member States of the Council of Europe, on violations of the civil and political rights stipulated in the European Convention on Human Rights. The official working languages are English and French.

ECtHR procedure is structured on three levels:

1. The Committees composed of three judges, each elected for 12 months within each section, charged with sorting claims in order to reject them if unfounded
2. The Chambers, consisting of seven judges, who are responsible for rendering decisions on the complaints admitted as founded by the committees
3. The Great Chamber, which consists of 17 judges, who judge the most important complaints

ECtHR decisions are made by the majority of judges present. The Committee of Ministers oversees the compliance of the states and the enforcement of ECtHR decisions. The most serious sanction that can be imposed on a State for the violation of a Court decision is exclusion from the Council of Europe.

In recent years, due to the increased awareness of citizens about their rights, an increased number of complaints have been lodged with the EctHR, leading to an unprecedented overload of cases and delayed decisions. For example, on January 1, 2010, the number of pending applications was 119,300, with 23% more than on January 1, 2009. The number of cases allocated to a judicial formation of the Court (Committee or Chamber) increased by 15% in 2009 compared to 2008 (from 49,850 cases in 2008 to 57,100 cases in 2009).

In 2004, Protocol No. 14 to the European Convention on Human Rights was issued in an attempt to simplify and accelerate the work pace of ECtHR. This Protocol instituted a number of procedural changes, such as:

- The initial selection of cases by a single judge and acceptance only if it finds that plaintiff has suffered “significant disadvantage”
- The analysis of cases for similarity to other cases judged before by ECtHR and their motivation by the failure of a Member State to comply with the ECtHR decision
- The assignment of only three judges to a case
- The potential to bring a member State of the Council of Europe before the ECtHR by the Committee of Ministers if the State fails to comply with the Court’s decision
- The provision by ECtHR of an interpretation of its verdict in order to maximize the likelihood that the State will respect its decision

The European Convention on Human Rights and Fundamental Freedom contains provisions on civil and political rights without stipulating the right to health of citizens. However, the Court has overcome this obstacle by considering the right to health as part of other civil and political rights stipulated by the Convention.

Article 3 of the Convention that prohibits torture or inhumane or degrading treatment or punishment may protect immigrants against expulsion to countries where there is a real risk that they will undergo treatments that could be considered torture or inhumane or degrading treatment or punishment, irrespective of the individual immigration history or her/his criminal record.

The European Court of Human Rights has examined over time a number of cases in which immigrants complained that although they were sick, they were expelled from the host country to their origin country where they could not receive proper medical care. Article 3 in these cases has been tempered in the sense that deportation of a person from a country where he or she could not receive adequate medical treatment was considered violation of the Convention. This issue was raised for the first time in 2004, in *D. v. the United Kingdom*, where the Court ruled that the deportation of a man suffering from end stage AIDS to St. Kitts, where he could not receive proper medical treatment or social support, represents a violation of the Article 3 of the Convention. However, a violation of the Article 3 of the Convention was not found in the case involving the deportation of a person suffering from a nonterminal disease who could benefit from proper medical care in the deportation country.

In *Hukić v. Sweden* (2005), the members of an immigrant family complained about their deportation to Bosnia-Herzegovina because their 5 years old son suffering from Down syndrome could not enjoy the same standard of medical care as in Sweden. The Court decided that "aliens who are deported can not claim the right to remain in a State signatory to the Convention to continue to receive medical, social or other forms of assistance provided by deporting State." This decision took into account the fact that the child's condition was not a fatal one and specialized care, appropriate to that case, was available in Bosnia-Herzegovina.

In *Ndangoya v. Sweden* and in *Amegnigan v. the Netherlands* (2004), the applicants, who were suffering from AIDS, challenged their deportation to their origin countries, Tanzania and Togo, respectively. In these cases, deportation was not considered a breach of Article 3 of the Convention because the disease was not in an advanced stage and the applicants were not deprived of medical care or family support in their countries of origin. Although the circumstances in their countries of origin were not as favorable as those in Sweden and the Netherlands, respectively, this was not decisive to the Court's decision.

European Union

Robert W. Stephens
Rynearson, Suess, Schnurbusch & Champion, L.L.C,
St. Louis, MO, USA

The European Union is an economic and political union between 27 member countries located primarily in Europe. The European Union was officially formed on November 1, 1993, by the Maastricht Treaty. In 2002, Euro notes and coins replaced national currencies in 12 of the member states. At this time, the Euro was used in 16 countries. The 27 member countries that compose the European Union are: Austria, Belgium, Bulgaria, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden, and the United Kingdom. There are currently three official candidate countries: Croatia, Macedonia, and Turkey. Albania, Bosnia and Herzegovina, Iceland, Montenegro, and Serbia are officially recognized as potential candidate countries. Kosovo is also listed as a potential candidate, but the European Union does not list it as an independent country because not all member states recognize it as separate from Serbia.

Each European Union country is free to decide on the health policies best suited to national circumstances and traditions, but they all share common values. These include the right of everyone to the same high standards of public health and equity in access to quality health care. Joint action of the European Union countries adds value when facing potential threats such as epidemics and bioterrorism. The European Union has common standards for safe food and nutrition labeling, the safety of medical equipment, blood products and organs, and the quality of air and water.

The European Union is investing to improve health security of its citizens, promote good health, reduce inequalities, and provide more information and knowledge on health. This money is spent on a wide range of issues, including planning for health emergencies, patient safety, and reducing injuries and accidents. The European Union is also funding to promote better nutrition, safe consumption of alcohol, healthy lifestyles, and healthy aging to combat consumption of tobacco and drugs, to prevent major diseases including HIV/AIDS and tuberculosis, and to exchange knowledge in areas such as gender issues, children's health, and rare diseases.

The European Union determined that improving the environment will improve the health of its citizens. Environmental factors, largely pollution, cause between one quarter and one-third of illness and disease in industrial countries. A strategy within the European Commission's Environment and Health Action Plan is to tackle the links between environmental factors and conditions such as asthma, allergies, respiratory diseases, cancer, and neurodevelopmental disorders, such as autism and speech problems.

The European Union is improving health through research. The European Union is spending six billion euros on health research between 2007 and 2013 under the Seventh Framework Programme for Research and Technological Development (FP7). The money funds research in improvements in health and boosts competitiveness and innovative capacity of Europe's health-related industries and business. The emphasis is on translating basic discoveries into clinical applications, and developing and validating new therapies, as well as health promotion and prevention strategies, better diagnostic tools and medical technologies, and sustainable and efficient health care systems. Priority diseases include those that are cancerous, cardiovascular, infectious, mental and neurological, and specifically those linked to aging.

One of the hallmarks of the European Union health care system is providing access to medical treatment everywhere. European Union citizens can obtain health care wherever they go within the European Union. The European Health Insurance Card makes it easier for travelers to claim their right to health care. This card is available to citizens from the 27 member states, plus citizens of Iceland, Liechtenstein, Norway, and Switzerland. European Union citizens are able to obtain health care if they become ill in another member state, and in some cases, other European countries. With the European health insurance card, European Union citizens have the same access to care in the public sector (doctor, pharmacy, hospital, or clinic) that the inhabitants of the country the individual is visiting receive. If the individual receives care in a country where they are charged for the treatment, the individual will receive compensation after they return to their homeland. Additionally, in certain circumstances, a European Union citizen may obtain treatment in any European Union country of their choice, even if they are not on holiday in that country.

The single European emergency phone number is 112. This phone number can be used in any European Union country to connect to any emergency service. This service can be accessed from fixed phones, including pay phones and mobile phones and is provided by the European Union free of charge. When an individual calls 112, a specially trained operator will answer his or her call. The operator will handle the request directly or connect the individual to the appropriate emergency service. Operators are increasingly able to answer 112 calls in more than one language, which is helpful for individuals calling 112 while abroad.

The presence of illegal immigrants in European Union countries is increasing despite considerable immigration policy efforts over the last years. European Union Member States have responded by strengthening their fight against illegal immigration, with different multilevel measures that include the curtailment or denial of social security rights such as access to publicly funded health care. Access to health care for illegal immigrants is generally limited to situations that are life-threatening or pose a risk to the public health.

Exclusion

Carlo Devillanova
Department of Institutional Analysis and Public Management (IAM), Bocconi University, Milan, Italy

The Universal Declaration of Human Rights (1948, Article 25) states that “everyone has the right to a standard of living adequate for the health and well-being of himself and of his family.” In its broadest sense, health exclusion denotes a situation in which a person or a group persistently fails to attain access to this essential living standard. Two elements are fundamental to the notion of exclusion and its relationship with immigration.

First, the concept has a multidimensional nature. Numerous basic economic, social, cultural, and political factors make up people’s health and well-being, such as housing, education, information, leisure, food, clothing, pollution, and health care. (Effort has been devoted, especially within the European social policy framework, to identify indicators suitable for measuring exclusion.) As a consequence, many features of the integration process of immigrants in the host country can affect their probability of being excluded. One prominent aspect is their success in the labor market and, more generally, the incidence of financial barriers relative to the native population, since income has an enormous influence on life standards.

Second, individuals or groups can be declared excluded only compared to other members of the specific society in which they hold membership. Because exclusion is a relative concept, the notion of exclusion varies across time and place and depends, among other things, on the level of development, culture, and the prevailing institutional arrangements and social policies. For example, in countries where most people lack water sanitation services, lack of access to clean water is not evidence of exclusion.

Consideration of these two elements together (multidimensionality and relativity) produces a very complex picture of the concept of exclusion. Here, the scope of the analysis is restricted by focusing on a specific dimension (access to health care) and a restricted set of countries (advanced economies). Broadly speaking, developed countries are equipped with welfare state institutional arrangements, which explicitly deal with social exclusion in general and, in particular, guarantee coverage against specific health care needs. These public programs encompass both in-kind provision of health care (as in most European countries) and monetary transfers to support private expenditures in health care (either out-of-pocket payments or the purchase of private health insurance, as in the U.S.). For migrants, barriers to accessing public health programs represent a complex picture, where both eligibility criteria and differential take-up rates are relevant.

In general, countries do not intentionally discriminate against naturalized immigrants in their entitlements to access public social programs. In some countries, the eligibility of noncitizens for such benefits is conditioned on the length and category of their residence in that country and on their legal status (documented vs. undocumented). An example of the former type of limitation is the U.S. 1996 Personal Responsibility and Work Opportunity Reconciliation Act, which prohibited the receipt by most noncitizens of most types of public assistance, including Medicaid, during the first 5 years after arrival. The period of residence is relevant to the receipt of benefits in some European countries as well, such as Finland. Most countries prohibit access by undocumented immigrants to most, if not all, types of medical assistance. For example, in the U.S., undocumented immigrants cannot enroll in Medicaid and SCHIP; limitations differ across E.U. countries. However, emergency care and medically necessary health care are often permitted to them. In general, the residence permit/citizenship requirements represent implicit obstacles to access medical care. Often, people living in temporary detention centers face important access problems, too. Rules can also differ for refugees and asylum seekers.

Even if immigrants are eligible for public health care programs, they may be effectively excluded from participation in these programs due to low application rates. Potential barriers that could reduce immigrants' participation in the programs include: lack of information, e.g., knowledge about the availability of the program, application procedures, and other relevant institutional details; language difficulties; geographic barriers; administrative and bureaucratic factors, such as unintended administrative complexities; and differences in culture and social norms, which affect health behaviors. These barriers add to the other possible dimensions of relative deprivation of immigrants, such as poverty, inadequate housing, insecure working conditions, etc.

The above discussion on eligibility criteria and benefit application rates highlights a useful distinction between active and passive exclusion. Some rules, notably immigrants' eligibility restrictions, intentionally exclude a particular group of people from accessing public health assistance. In some cases, such as when administrative complexities exist, the potential exclusionary outcomes are accidental. Because of the interplay between the various dimensions of exclusion, active or passive exclusion in one particular area can bring about unintended and even unforeseeable exclusionary consequences in access to health care. As an example, undocumented immigrants often refrain from contacting authorities due to fear of being reported or arrested. This may increase the informational and bureaucratic barriers they face and reduce their access to hospitals. In this sense, strict rules against illegal immigration can unintentionally reduce undocumented immigrants' application rates for health-related benefits.

Several studies show that inequalities between immigrants and natives and across immigrants from different national origins in both eligibility criteria and application rates negatively affect immigrants' health care utilization, particularly access to prevention programs and delayed care, and health outcomes. Moreover, inequalities in health care utilization tend to persist over time and across generations, even after explicit barriers are removed. This last feature is crucial, as it causes sizeable persistent differences in access to health care across national minorities (ethnic, racial, linguistic).

These facts raise clear equity issues and can undermine social cohesion over time. From a public policy perspective, lack of health care utilization by immigrants can impact the community health, as might occur through increased exposure of citizens to transmissible diseases, and the increased costs associated with delayed interventions or unnecessary presentation for emergency services when regular care cannot be accessed.

Countries can try to address the public health concerns associated with migration inflows by enforcing selection rules on applicant migrants as well. In fact, while the previous discussion focuses on the potential barriers to accessing health care for immigrants already settled in the receiving country, another relevant form of exclusion occurs if potential migrants are precluded from entering into a country on the basis of health-related grounds (as, for example, in Canada). In general, the avowed aim of this kind of selection rules is to prevent the entry into the country of specific communicable disease (the screening procedures may differ across countries of origin) and/or persons likely to become an excessive charge on the public health care system (or, in general, on the welfare system). Both motivations were present, for example, in the U.S. Immigration Act of 1891 and continue to be reflected in current law.

Explanatory Model of Illness

Julia Lechuga
Department of Psychiatry and Behavioral Medicine,
Center for AIDS Intervention Research (CAIR),
Medical College of Wisconsin, Milwaukee, WI, USA

The definition of the term explanatory model of illness underscores the non-universal nature of the manner in which illness is defined and experienced bringing to bear the thesis that illness is a socially constructed experience and not solely the result of purely biological factors. Studies on this topic began with the seminal work of medical anthropologist Arthur Kleinman. The term "explanatory model of illness" attempts to capture the idea that factors outside of the individual, such as culture, influence the way illness is conceptualized and experienced.

In certain societies, medical research and practice has been primarily influenced by germ theory which emphasizes pathogens as causes of disease. Germ theory gave rise to the biomedical model which conceptualizes individuals as physical and chemical beings. The term explanatory model of illness was developed to understand the way disease is experienced in individuals who do not endorse the biomedical model and thus, to quantify the illness experience of individuals who endorse more contextual explanations of disease rather than a purely biological one.

The predominant model of illness in a society influences an individual's disease causal attribution. Certain cultures emphasize social factors such as social stress and interpersonal conflict over etiological agents such as bacteria as causes of disease. For example, individuals from certain rural communities in Latin American prefer folk belief-shaped theories about body functioning. Moreover, some members of highly traditional Asian societies emphasize the role of non-somatic related phenomena such as depletion of energy, socially caused stress, such as disharmony between kin members, or physically caused stress, such as overwork, and disruption of temperature homeostasis, also known as sudden "enfriamiento" or "cooling," in illness manifestation.

Empirical evidence suggests that cross-cultural differences exist in the explanatory models of illness preferred by ethnic minority groups residing in multicultural societies. For example, a study investigated the importance given to various causes of illness by Black, Latino, Asian/Pacific Islander, and non-Hispanic White males and females with an age range of 16–81 years, residing in the United States. Results indicated that members of the minority groups sampled emphasized the importance of supernatural and interpersonal causes as disease explanations when compared to non-Hispanic Whites. Research with older Hispanic adults residing in the United States indicates that the health beliefs of certain members of this population can be described as a complex belief system. For example, health is conceptualized as a state of harmony between three entities: (1) the individual, (2) nature and cosmos, and (3) society. Moreover, experts have termed this complex health belief system Curanderismo. Curanderismo refers to the health practices that exemplify this historically influenced world view about the sources of illness. A study was carried out to investigate the use of folk medicine such as Curanderismo in Mexican-American women, 20–47 years, living in the United States. Findings suggest that 84% had personally received the services of an indigenous/folk/spiritual healer.

Immigrants' preferred way of explaining illness may come in conflict with the way health practitioners of the receiving community explain and treat illness. A lack of appreciation by health care practitioners of the way sociocultural aspects influence illness causal attributions can lead to ethnic health disparities by impacting important predictors of disease outcomes such as adherence to prescribed treatment regimen. In other words, an emphasis on chemical agents as cures may lead health care practitioners of the receiving community to neglect psychosocial and contextual/cultural aspects as potentially curative. A study conducted to investigate the preferred modes of treatment by physicians in a highly Westernized society revealed that biomedical variables alone predicted prescribed treatment regimens in 53% of cases. Experts agree that health care practitioners need to be aware of the potential diversity in explanatory models of illness especially in immigrants from cultures that are far removed from societies that emphasize a purely pharmacological disease treatment. Failure to inquire about disease conceptualization and attribution could negatively impact diagnosis accuracy and treatment effectiveness. Thus, it is recommended that health care practitioners probe the concept of explanatory model of illness in their culturally diverse patient population.

Researchers use different ways to assess cultural differences in preferred explanatory models of illness. For example, qualitative research methods are particularly useful to elicit cultural differences in Illness Representation Models (IRM). An IRM captures the following domains in illness cognitions: (1) the characteristics of the illness and their effect on identity, (2) the causes of the disease, (3) disease duration, (4) disease consequences, and (5) disease chronicity. Research suggests that the various domains of the IRM are influenced by culture and predict the manner in which individuals conceptualize a disease and the strategies used to control and adapt to such illness. An IRM is related to symptom experience, treatment seeking and adherence, and to the general psychological adaptation to the disease. For example, an emphasis on somatic disease attributions, at the expense of other potential environmental or contextual causes, leads to worse symptom management, and ultimately worse disability. On the other hand, emphasis on contextual disease attributions may lead to lower treatment adherence.

An individual's preferred explanatory model of illness has important implications for the adoption of health protective behaviors. Experts suggest that cultural health beliefs about factors that cause illness directly influence the actions that people take to prevent disease. Researchers urge multicultural societies to consider potential diversity in the health beliefs and practices of their population while planning and implementing health care services as certain population segments may embrace alternative health models. Failure to take into account existing cultural differences in illness explanatory models may result in the alienation of those individuals whose explanatory model of illness may differ from the predominant forms of prevention and treatment.

Multicultural communities are unique environments characterized by a continuing renewal of cultural patterns. Such dynamic cultural patterns interact with individual level, social, and geopolitical factors affecting societies at large. Thus, explanatory models of illness may be dynamic too and in constant fluctuation. The different conceptual systems of health illness beliefs influence an individual's exposure to risk, prevention, and care and as such can be important domains for assessing the relationship between cultural adaptation, well-being, and vulnerability to disease. Thus, it becomes important to investigate the extent to which indigenous health cognitions change and how they shape the adoption of health protective behaviors, access, and utilization of health care services.

The preferred explanatory model of illness has implications for the design and delivery of health promotion interventions aimed at culturally diverse individuals residing in multicultural societies. Research suggests that subjective culture influences the communication preferences of individuals regarding message content, source of communication, and channels used in public health interventions. Thus, it becomes important to investigate the influence of culture on explanatory models of illness and its subsequent effect on the communication preferences of culturally diverse individuals regarding preferred messages, sources, and channels for message delivery in health promotion interventions.

Falls

Amy N. Sharpton
Department of Veterans Affairs, Louis Stokes DVA Medical Center Cleveland, Brecksville, OH, USA

A fall is an event that results in an individual coming to rest unintentionally on a lower level. Fall-related injuries can be fatal or nonfatal; however, most are nonfatal. A recent study of childhood falls in the People's Republic of China, for example, reported that for every death due to a fall, there are 4 cases of permanent disability, 13 cases that require hospitalization for more than 10 days, 24 cases that require hospitalization for 1–9 days, and 690 cases that require medical care or that result in missed school or work.

Falls are a chief public health concern worldwide. The World Health Organization (WHO) estimates that 424,000 fatal falls occur each year; falls rank second only to road traffic injuries as the leading cause of unintentional injury death. Notably, 80% of fall-related fatalities occur in low- and middle-income countries; regions of the Western Pacific and Southeast Asia account for more than two-thirds of these deaths; and death rates due to falls are highest among adults over 60 years.

Each year, there are approximately 37.3 million nonfatal falls that are severe enough to require medical attention, resulting in greater than 17 million disability-adjusted life years (DALYs). Originally developed by the WHO, DALY is a measure of overall disease burden. It is expressed as the number of years lost due to ill-health, disability, or early death. Concerning severe yet nonfatal falls, the largest morbidity occurs in the following groups: persons aged 65 years or older, young adults aged 15–29 years, and children aged 15 years or younger. Another potential consequence of a fall, particularly for older people, is the risk for subsequent long-term care and institutionalization.

Risk

Age, gender, and health of the individual can affect the type and severity of injury. Age is a key risk factor for falls. Older people have the highest risk of death or serious injury from a fall, and the risk increases with age. In the United States, for example, 20–30% of older people who fall suffer moderate to severe injuries. Another high-risk group is children. Childhood falls occur largely as a result of their evolving developmental stages, innate curiosity of their surroundings, and increasing levels of independence that coincide with more challenging risk-taking behaviors. The circumstances surrounding a fall are often complex, interacting with poverty, sole parenthood, and particularly hazardous environments.

Both genders are at risk of falls; however, in some countries, it has been noted that males are more likely to die from a fall, while females are more likely to suffer more nonfatal falls. Older women and younger children are more likely to experience a fall and are at increased risk for severe injury. Worldwide, males consistently sustain higher death rates and DALYs lost; possible explanations may include higher levels of risk-taking behaviors and hazards within occupations.

Prevention

It is suggested that fall prevention strategies be comprehensive and multifaceted, where research and public health initiatives are prioritized, variable risk factors are explored, and effective prevention strategies are utilized. Effective fall prevention programs aim to (a) reduce the number of people who fall, (b) reduce the rate of falls, and (c) reduce the severity of injury should a fall occur. For older individuals, fall prevention programs frequently include a number of components to

Sana Loue & Martha Sajatovic (eds.), *Encyclopedia of Immigrant Health*, DOI 10.1007/978-1-4419-5659-0,

identify and modify risk, such as screening within living environments for risks for falls; providing clinical interventions to identify risk factors, such as medication review and modification, treatment of low blood pressure, vitamin D and calcium supplementation, treatment of correctable visual impairment; home assessment and environmental modification for those with known risk factors or a history of falling; prescription of appropriate assistive devices to address physical and sensory impairments; muscle strengthening and balance retraining prescribed by a trained health professional; community-based group programs which may incorporate fall prevention education and Tai Chi-type exercises or dynamic balance and strength training; use of hip protectors for those at risk of a hip fracture due to a fall. Experts suggest that effective interventions for children should include multifaceted community programs; engineering modifications of nursery furniture, playground equipment, and other products; and legislation for the use of window guards. Other promising prevention strategies include use of guard rails/gates, home visitation programs, mass public education campaigns, and training of individuals and communities in appropriate acute pediatric medical care should a fall occur.

Familismo

Maura I. Toro-Morn
Department of Sociology and Anthropology, Illinois State University, Normal, IL, USA

A quality that has come to characterize Hispanics/Latinos across the hemisphere is the notion of *familismo* (familism), defined as a strong orientation and commitment toward the family. *Familismo* is also connected to a high value on marriage, childbearing, and responsibility toward siblings. Family duties, loyalty, and interconnection to family members in both nuclear and extended families are also qualities that accompany the notion of *familismo*. The ideology of familism extends beyond blood kin to include extended families of several generations and godparents (*compadres*), another important cultural practice found among Latino families. Interviews conducted by the National Research Council offer some evidence as to how *familismo* is defined by immigrants and their children. A Mexican immigrant in Raleigh, North Carolina observes "that sometimes families here, White families, are not as united as Hispanics families... We're always famous for having aunts and uncles and relatives .. . ." In contrast, a third-generation Hispanic in Houston, Texas adds "[t]ypically, we have close families. Family is a really big part of our culture." These two quotes point out two critical issues underlying what we know about familismo: It is a quality that distinguishes Hispanic/Latino families from other groups, most principally Whites, and it tends to be passed down from generation to generation.

Historians trace the centrality of the family and its accompanying ideology of familism to the colonization of the Americas by the Spanish and Portuguese. In particular, the institution of marriage created alliances between families to further extend kin interests. In the USA, the development of large extended households is connected to the social and economic conditions that prevailed among Mexican American families in the Southwest before and after the end of the Mexican–American war in 1848. The large extended family offered stability and support in particular for poor and young men and women. In the Southwest, families expanded and contracted baffling census takers through the nineteenth and early decades of the twentieth century.

Familismo is a gendered ideology that helps organize the roles and responsibilities that men and women have toward each other and toward other family members. For example, among many immigrant families in the USA, children are not encouraged to leave the house until they are married. Once grown and married, they are encouraged to live close to parents so that everyone in the family lives close by. Even when children are married, some parents encourage the newly married couple to move in as a strategy to save money and maintain family ties. The notion of *familismo* as a defining quality of Latino families has been inscribed in popular culture by films such as: Gregory Nava's, *My Family* (starring Jimmy Smits, Edward James Olmos, Esai Morales, and Jennifer Morales) from 1995 and the more recent, *Nothing Like the Holidays* from 2008, produced by Alfredo De Villa, starring John Leguizamo, Alfred Molina, Luis Guzman, and other Latino actors.

Research has sought to link the notion of *familismo* to school failure and lack of assimilation among Latino immigrants and their children. Some associate the strong family orientation among Latino immigrants as an impediment to developing and assimilating an ideology based on the needs and desires of the individual. The argument is that strong family ties prevent Latino immigrants from developing individualistic and self-oriented goals needed for success in school. Others have used *familismo* as a cultural practice impeding full acculturation of men and women and therefore a cultural explanation for the high rates of isolation and poverty among Latinos. A distorted notion of *familismo* as applied to men and women posits that Latino families are characterized by strong-minded macho men and submissive and passive women tied together by notions of obligation to each other. The trope of *familismo* has become a convenient label to dehumanize, demonize, and cast off Latino immigrants as culturally incompatible with modernity and post-industrial societies.

Research has also offered alternative ways to understanding how *familismo* becomes a resource for immigrant families across mainland Latino communities. There is evidence that extended-family households continue to prevail among immigrant communities because of different life-course needs. Immigrant families often contain aging parents, children, and other family members in different stages of family formation. Psychologists have found Mexican American and Puerto Rican children are more likely to live with grandparents, thereby providing working parents some reprieve from the huge costs of child care. A question that concerns researchers is: if familism protects children, could low-economic status offset the benefits of living in a large extended family? Evidence suggests that two-parent homes with extended kin often provide resources (emotional, economic, and cultural) that offset the socioeconomic instability found among working class and poor immigrant families. The consensus emerging from some of the research suggests that familism is a value worth keeping, even in the name of rapid acculturation processes among second- and third-generation Hispanic/Latino youths.

If Hispanics/Latinos continue in the path of assimilation and acculturation similar to the one used by European American groups, some researchers suggest that this could place the value of familism in jeopardy. To what extent does the socio-economic mobility and adoption of US cultural norms erode *familismo* as a cultural characteristic of Hispanic/Latino families? Researchers suggest that trends in intermarriage, cohabitation, and divorce rates vary a great deal among the many nationality groups that represent the larger community popularly known as Hispanics/Latinos. Mexicans, for example, tend to have larger families and have been found to be more familistic than other groups. It has been suggested that this is due to the high levels of immigration and residential concentration, factors that help maintain in-group marriage and familism.

Migration is also another factor that could seriously erode notions of familism among some Hispanic/Latino groups. The growing number of immigrant working mothers who leave children in their countries of origin in the care of grandparents and other relatives has raised concerns about the future viability of these transnational families. Transnational mothers are caught in the struggle to survive produced by globalization processes, thereby throwing into relief deeply cherished notions of *familismo*. Further, in the USA, the implementation of more restrictive immigration laws and the recent increase in deportation of men and women without proper documentation foster conditions that threaten immigrant family relations, bonding, and responsibilities.

Family

Marjorie Nigar Edguer
Mandel School of Applied Social Sciences, Case
Western Reserve University, Cleveland, OH, USA

Family as it relates to immigrant health refers to a unit of biologically related individuals in a variety of scenarios: the members of this unit may immigrate to a receiving country together, they may be separated from each other by some members' decision to immigrate to a new country, they may be separated physically but maintain strong ties emotionally or financially. Each of these experiences has different repercussions for the "family" involved. There are many reasons behind family decisions to migrate, including: poverty, war and other destructive situations, oppression and prejudice, or a desire for freedoms not available in the sending country. A common factor in immigration for many families is to provide better lives and more opportunities for their children. Children are usually aware of this motivation, which carries with it expectations for them. Immigrant families often differ from other families in receiving countries: structurally, relationally, and financially. There are many factors that influence outcomes for families following immigration. It is important to consider characteristics of both sending and receiving countries when working with immigrant families, and to look at the interactions between families and the systems of the receiving country, as well as the nature of the family's exit from the sending country.

A structural and relational difference between immigrant and native families, especially in the USA, is that immigrant families are more likely to include extended family members, and have different expectations for family members than native-born families in receiving countries. Immigrant families are likely to have a two-parent household, and often include grandparents or aunts/uncles/cousins or others. Living with extended family members may be a temporary arrangement following immigration, allowing for support during transition, but changing as the family adjusts. In industrialized countries, native-born families are more likely to be "nuclear" families consisting of only parents and children, and may have only a single parent. Extended family members often constitute an important social support for immigrant families, whether they live in the household or in the neighborhood, providing child care, social support, job opportunities, language translation, and financial support. Children and adolescents in immigrant families tend to have significant responsibilities, contributing to the family and home in a multitude of ways. Immigrant families often expected siblings to be caretakers prior to migration, and continue the practice following migration. Sibling caretaking is perceived by immigrant families to have many positives for all involved: children who are caretakers like the authority and responsibility, children who receive care see their older siblings in a positive way, and parents feel that they can trust the care that is being provided, as well as seeing an economic benefit. However, sibling caretaking conflicts with the cultural expectations of most receiving countries, where children are seen as dependents and are not given such high levels of responsibility. In some receiving countries this can lead to allegations of neglect, or cause immigrant families to have punitive interactions with government systems (educational or child protection). It is important to look at the risks and benefits for each family, and to recognize the cultural norms and values that shape the practice.

While extended family provides support, the larger ethnic community of other immigrants from the same sending country also creates networks of resources. When families either immigrate with or find a community of compatriots from their sending country, the network of compatriots supports the family in maintaining its values, structure, and traditions. The network helps to socialize children and reinforce cultural norms. The ethnic community can provide jobs or knowledge about opportunities in the receiving country, help the family to navigate the educational and social support systems, and generally facilitate the family's transition. The experiences of immigrant families that have this extended support are very different from those of families who immigrate without it. Immigrant families are more likely to adopt the language and cultural practices of the receiving country if they are isolated from the support of their ethnic community. But some of these immigrant families will adhere to the culture of their sending country despite their isolation, maintaining the familiar through all the transitions.

It is important to consider how connections to family members in the sending country are maintained for an immigrant family. Most immigrants will have ties to family members that were left behind, often sending money or resources. They may travel between the receiving and sending countries on a regular basis. They may even maintain a residence in their sending country, intending to eventually return. These transnational patterns are becoming more common as it becomes easier for families to travel and migrate. Sometimes parents migrate prior to the immigration of other family members in order to prepare a home for the family in the receiving country. This separation has ramifications for family relationships, as some children feel loss and resentment as a result, even if they cognitively understand the reasons for the parent's absence. During the separation, children may be given more power in the family, causing conflict if the parents attempt to reassert their roles. If there is a marital separation as part of migration, it may cause stress on the marriage. These strains will need to be addressed following reunification. The consequences of these separations and their effects on different populations remain unclear; research continues in this area.

The losses accompanying separations are one form of loss that immigrants experience. Other forms of loss may be pre-, post-, and part of the immigration process. They include traumas and separations prior to immigration, often due to war or oppressive regimes in the sending country; separation from family members and loss of familiar settings, resources, climate, and cultural opportunities due to immigration; and separations that occur following immigration, as well as losses due to adaptation and acculturation to the receiving country. Traumas and separations prior to immigration influence the family's exit from the sending country, as the family may feel compelled to exit, may leave as refugees, or may have to use subterfuge to exit. These affect the resources that the family will have in the receiving country, which affects the overall transition process. The family may worry about family members left behind with no way to maintain contact or be sure of their continued safety. This can consume family members' energy, making it more difficult for them to adjust, and may contribute to differential adjustment within the family. Depending on how trauma is experienced by different family members, this may also contribute to differential adjustment to the receiving country. Families that do not have trauma prior to immigration will still experience the loss of their familiar milieu, and will need to learn which of their skills and assets will be useful in their new setting. Adaptation, acculturation, and assimilation are further losses that impact immigrant families. Because different family members may change at different rates, conflicts may arise as a result of these differences. Some family members may perceive the losses related to adaptation as positive, where others see it as threatening, and others become depressed.

One way that many immigrant families tend to differ from native families is the value placed on collectivism or individualism. Families tend to emigrate from sending countries, such as India, China, or nations in the Middle East or Africa, where collectivism and interdependence are valued. For many there is a cultural conflict between the values of the sending country and those of the receiving countries, such as members of the European Union and North American countries, which often emphasize individualism and autonomy. Collectivism and interdependence stress the importance of social relationships and connections to family members. Many immigrant families are able to support their members in maintaining connections while developing the autonomy that is expected in most receiving countries. Some immigrant families see autonomy as a threat to these relationships; when this happens it can lead to conflict and division within the family. The prioritizing of interdependence is more commonly seen in immigrant families than native families. In addition to these umbrella values, there are specific cultural heritages that influence how family members are socialized and further shape family relationships and dynamics.

Sending and receiving countries often hold differing values with respect to gender roles. Women often gain status and power following immigration, and men may lose power and status if they are unable to work at a level commensurate with their previous status. A specific immigrant group in which the dynamics relating to changes in gender and families have been explored is that of Somali immigrants to the USA. Traditionally Somali families are patriarchal and headed by men, but 25% of Somali families who have immigrated to the USA are headed by women. Extended family support is very important in Somalia, but because these ties have been disrupted by immigration, new networks have been created with other nonfamilial refugees while others struggle in isolation. While extended family provided support premigration, it also was a source of social control, especially for women. In the USA, social control comes from other sources in the community, and is more directed at men. Somali women tend to view the changes in power dynamics more positively than Somali men do, but both are aware that there is an increased strain on marriages.

Despite all of the associated stress, immigration is often seen as a protective factor. Families who immigrate tend to have family members who overcome many obstacles and who are resilient in response to risks that cause problems for nonimmigrants. These protective factors usually do not extend beyond the first or the 1.5 generation, which suggests that the protective factors are related to the experience of immigration. There also appears to be an interaction between the cultures of the sending and receiving countries that affects this protective factor. The children who are most successful following immigration tend to be those who are able to use the resources of both the sending and receiving countries.

Each family needs to be seen in light of all the different resources and experiences they bring to the immigrant transition. Resources include family and community relationships, finances, education, skills, and language. Experiences include traumas and losses, as well as the culture and history of the sending country and reasons for immigration. The systems of the receiving country create the space where all these resources and experiences are used, and depending on how the systems work and what is valued, the family's transition will be more or less successful.

Family Planning

Griselda Chapa
Tulane University, New Orleans, LA, USA

Family planning in the developing world and with immigrant and minority populations in the United States, has a mired history of opposing goals and competing factions. Research physicians defied the Declaration of Helsinki as recently as 1971 in their conduct of experiments with hormonal contraception on unsuspecting women. The Catholic and Evangelical churches have rejected all family planning except periodic abstinence, also known as the rhythm method, and only for married couples. Government agencies have focused on population control while simultaneously expressing concern about women's health, particularly maternal mortality. Women's desires, needs, and rights have rarely been a family planning priority. This has led to inconsistent contraception use, unwanted pregnancies, and clandestine abortions. Populations most affected are those without the resources necessary to access health care services.

Since the latter part of the twentieth century, Hispanics have had the highest fertility in the United States. On average, according to Census data, Hispanic women have 2.3 children compared to 1.8 for non-Hispanic White women and 2.0 for African American women. Hispanic fertility in the Unites States is higher than in various Latin American countries. In the latter, largely due to local government concerns and foreign aids, family planning programs have been aggressive. Hispanic-origin women residing in the United States face multiple obstacles to accessing health care and, as a result, to family planning.

The National Family Planning Program, also known as Title X, was created in 1970 during the Nixon administration. The Title X Family Planning program is administered within the Office of Public Health and Science, Office of Population Affairs (OPA) by the Office of Family Planning (OFP). It is the only federal program in the United States dedicated exclusively to the provision of family planning and related preventive health care. The most recent Title X annual report explains that immigrant populations fear Title X providers will turn them over to (immigration) authorities and, therefore, underutilize available services.

Hispanics are less likely to be privately insured than their non-Hispanic White and African American counterparts. Undocumented Hispanics have very limited access to public insurance. The Personal Responsibility and Work Opportunity Act of 1996 limited federal Medicaid coverage to citizens and legal immigrants. Additionally, in order to qualify for coverage, legal immigrants must have arrived in the United States before 1996 or have resided in the United States for at least 5 years. Hospitals, however, are required to provide emergency medical services to the undocumented, including labor and delivery services. The 2005 Deficit Reduction Act codified new regulations requiring proof of citizenship as a condition for Medicaid eligibility. The one exception applies to low-income women during pregnancy even when they are undocumented.

Beyond regulatory barriers, disparities in family planning mirror disparities in other health services. Discrimination and distrust have affected the relationship between communities and family planning providers. The first large-scale clinical trial of oral contraceptives, or the Pill, was conducted in Puerto Rico in 1956. By 1957, Mexico and Haiti were also testing the Pill. The Food and Drug Administration (FDA) approved the Pill in the United States in 1960, but reports of side effects prompted pharmaceuticals to further fine-tune the Pill's hormonal composition. In 1971, a San Antonio doctor set out to test whether the Pill's side effects were psychological or real.

Mexican women in San Antonio attending a clinic to obtain oral contraceptives were, without their consent, entered into a crossover clinical trial. Half were given placebos and the other half were put on the Pill. In the middle of the trial, the experimental group crossed over to being the control group. Eleven out of 76 women became pregnant and sued the doctor for child support. They lost. The researcher said he had instructed the unsuspecting study participants to use vaginal spermicides to prevent pregnancy if the Pill did not. Vaginal spermicides have a substantial failure rate when used alone (without a condom or diaphragm). The researcher also claimed the subjects would not have been able to understand his study design, thereby excusing his failure to secure their consent.

As early as 1949, just under one fifth, or approximately 20%, of all deliveries in Puerto Rico were followed by sterilization. Currently, Hispanic women are far more likely to be counseled on sterilization than their non-Hispanic White counterparts and sterilization rates reflect this disparity. Recent data indicate that 20% of Hispanic women in their childbearing years are sterilized compared to 16% of non-Hispanic White women.

In the United States, the largest repository of information on family planning is the Centers for Disease Control's National Survey of Family Growth (NSFG). It is a household survey, which has been translated into Spanish. The NSFG attempts to explain trends and group differences in birth rates, contraception, infertility, sexual activity, and marriage. In the first 5 cycles of the survey – 1973, 1976, 1982, 1988, and 1995 – the NSFG was based on samples of women 15–44 years of age. In 2002, the survey was expanded to include a national sample of 4,928 men. Response rates have been approximately 80% in every cycle. NSFG survey results report Hispanic women are more likely to use 3-month injections (Depo Provera) than the Pill compared to non-Hispanic White women, 24% and 69% versus 14% and 87%, respectively. The NSFG documents that Hispanic women are more likely to obtain their birth control from clinics than from private providers. Also, Hispanic women were far more likely to be counseled on family planning when this was not the focus of a medical visit.

One topic not currently discussed in the literature on Hispanics and fertility that has been investigated in anthropology involves the menstrual cycle and what is normal. Research conducted with African Dogon women in Mali in the 1980s found that women had far fewer menstrual cycles than American women did. This is because these women, during their fertile years, were either pregnant or lactating, which was a fairly typical pattern in preindustrialized agrarian societies. Breastfeeding was, and in some areas still is, used for child spacing. However, women must breast-feed between eight and ten times a day to suppress ovulation. This mechanism also suppresses menstrual bleeding. The NSFG documented Hispanic Americans' preference for Depo Provera, which has been associated with decreased menstrual bleeding; this preference may be related to what Hispanic immigrant women or their relatives have experienced as "normal" menstrual cycles. On the other hand, the choice of a quarterly injection over a daily pill may have been influenced by providers who believe Depo Provera is a better choice, that is,, more reliable, for certain populations. Indeed Depo Provera is more reliable than the Pill, and becoming pregnant after stopping Depo Provera takes longer than becoming pregnant after stopping oral contraceptives.

Additional research on Hispanics and family planning was available for approximately the past 50 years. Sociologists and economists have developed theoretical models. They have attempted to explain the Hispanic fertility differential using various hypotheses, which address a wide range of topics from cultural preferences for larger families to the impact of women's work on family planning and fertility. Hospital data, from various Latin American countries, demonstrate women are being hospitalized for complications of induced clandestine abortions as abortion is largely illegal across Latin America. These data contradict the belief that Hispanic women's reproductive choices are affected by either cultural norms or religiosity. Recent applied studies on Hispanics and family planning have been done in health services research. However, much of the applied family planning research on Hispanics has used small clinic samples and, therefore, has studied predominately lower socioeconomic status women. Some of the recent clinic studies have also revealed Hispanic-American women are doing their own abortions.

Much of the early theoretical research on Hispanic fertility focused on Mexican origin individuals as they were the first large Hispanic immigrant subgroup in the United States. The early research on Mexican (and minority) fertility attempted to contrast economic and cultural models to accept one view by ruling out the other. In the 1960s, the work of Goldscheider and Uhlenberg incorporated both economic and cultural components in their Minority Status Hypothesis. This model posits that being a minority has an independent effect on fertility. That is, some "minority" individuals will have fertility levels different from the majority population for no other reason beyond their minority status. This hypothesis does not suggest a direction. Exposure to the majority society, they state, can depress or increase fertility.

Two decades later, Bean and Swicegood explained that three broad approaches to the study of minority fertility emerged from the work of Goldscheider and Uhlenberg. These are the comparative, the intragroup, and the contextual studies. The comparative studies examine minority to majority fertility levels after matching for socioeconomic variables. According to this view, perceptions of discrimination or marginality will not surface until the minority group has become acculturated and partially assimilated. Intragroup studies do not study minority group status directly. They focus on the internal heterogeneity of racial and ethnic groups with regard to individual acculturation and assimilation. This approach intends to tap into dimensions of ethnicity not measured by socioeconomic status. Contextual approaches usually take residential and occupational segregation to be indicators of acculturation and assimilation. These may vary independently of individual socioeconomic characteristics but still affect fertility behavior. For example, a Hispanic-origin individual with a college degree living in a largely Hispanic enclave will keep the traditions and practices of the ethnic enclave. This view contradicts economic models, which suggest upward mobility is associated with taking on the values and norms of the host society.

The value of children, according to economic theory, can be measured by the amount of children – quantity, or by resource intensity – quality. Thus, children are seen as human capital. In agrarian societies, child quantity was more important than child quality. As populations become urban, this tendency is reversed. Economists see children as home-produced assets. “Production” will be affected both directly and indirectly by the wife’s time and the (cost of) available market goods and services. All this is contingent on the level of education of both parents. The more valuable a parent’s time is, as measured by salary for work outside the home, the more expensive a child becomes. This theory may work well for nuclear families and less so for cultures that benefit from the social support (for childcare) made possible by extended families, albeit sometimes non-blood kinships.

Recent research examining fertility and maternal earnings across racial groups found that family size is detrimental to non-Hispanic White women’s earning but not to Hispanic women. These researchers also report that early onset of childbearing was detrimental to Hispanic women’s future earnings but not to their non-Hispanic White counterparts. They attribute this, in part, to the fact that Hispanic women have a high gender ideology and, therefore, are less likely to seek work that does not conform to (Hispanic) female gender roles. This type of work pays less. To their credit, they do discuss the role of discrimination in preventing access to better jobs. However, they did not examine ethnic subgroups of Hispanic immigrant women. There is a vast body of research going back to pre-Colombian times addressing gender roles in Latin America and how these vary by geographic area. Moreover, gender roles are fluid. Aztec deities had the ability to change genders. Recent ethnographic research done in Mexico documents that, among poor and lower socioeconomic families, husbands help with childcare and chores when women work outside the home for paid wages.

Current Census data support both social and economic fertility models. Comparing immigration status, both native-born women and naturalized citizens have lower fertility than noncitizens. Later generation Hispanic women have birth rates similar to their non-Hispanic White counterparts. As Hispanic women acculturate and attain more formal schooling, fertility decreases (Fig. 1).

Fertility and family planning studies that include measures of religiosity tend to use small samples either from surveys or focus groups. Findings have not been consistent. Abortion is illegal in most Latin American countries (Cuba and Puerto Rico are the exceptions) and, although most of Latin America subscribes to Catholicism, this does not seem to deter abortion rates. Hospital data from across Latin America detail complications of clandestine abortions. However, restricting abortion estimates to hospital data overlooks the women who die before accessing medical care. According to the Alan Guttmacher Institute, an estimated 5,000 women die every year as a result of clandestine abortions in Latin America; an estimated 800,000 are hospitalized due to abortion complications. Approximately 1 out of every 30 (3%) women in Colombia, Brazil, and the Dominican Republic has had an abortion; in Mexico the rate is 2.5%, and in the United States, the abortion rate is 1.9% (reported as 19/1,000). The Centers for Disease Control (CDC) compiles data in the United States but only for legal abortions. The national (reported) abortion rate for

	15 to19	20 to 24	25 to 29	30 to 34	35 to 39	40 to 44	45 to 50
◆ Native born	39.6	115.7	117.4	91.5	47.4	17	5.1
■ Naturalized	46.8	88.5	114.8	111.7	60.4	18.4	4.8
▲ Not a citizen	68.4	161.7	158.2	117.4	68.3	25.6	5.5

Family Planning. Fig. 1 Births in the last 12 months per 1,000 Hispanic women by citizenship and age. Source: US Census Bureau, American Community Survey, 2006. See detailed Table 9 www.census.gov/population/www/socdemo/fertility.html

Hispanic women in the United States is 1.6%. This is probably underestimated given that, during focus groups, women report bringing pregnancy termination methods from their home countries.

A very popular abortifacient in Latin America is a prostaglandin sold as Cyotec, also known as Misoprostol. In most of Latin America, it is available over the counter for the treatment of peptic ulcers. For pregnancy termination, it may either be taken orally or inserted into the vagina. In 2000, researchers at three obstetrics and gynecology clinics in New York noted that low-income immigrant women were already using Misoprostol as an alternative to going to an abortion clinic, because it was easier and less expensive. It was available for approximately $2 a pill compared to hundreds of dollars for a medical abortion. Immigrant women reported getting this pill from doctors, pharmacies, relatives, and from contacts in other countries. In 2009, the *New York Times* reported its use in immigrant Dominican neighborhoods.

Clinic-based studies attempting to obtain information on values affecting family planning beliefs and practices have often been contradictory and ambiguous. Still, some of the qualitative research has captured information not discernible from survey data. For example, the National Council of La Raza recently conducted multiethnic focus groups across several cities and discovered that, among their sample, Hispanic Americans receive their birth control from trusted sources in their home countries, suggesting it is easier to obtain there than in the United States. Moreover, some participants in their Bronx sample reported not only buying birth control at Latino-owned stores known as “bodegas,” but also receiving contraceptive injections at these locations.

The role of Hispanic men in family planning has received less attention but does merit discussion. Hispanic men, in popular culture, have long been portrayed as hypersexual. The myth of the womanizing Don Juan can be traced to the Golden Age of Spain and continues in Latin America as a manifestation of machismo. A great deal has been written about both the positive and negative qualities of machismo. Across research on machismo, a man’s ability to seduce (many) women is a revered trait. In the 1950s, research conducted in Puerto Rico reported that men use condoms to prevent sexually transmitted infections and less so for birth control. They used condoms with women other than their primary partners. Although the NCLR multiethnic sample found men did report condom use, most of which were purchased at gas stations, they felt their primary partners would suspect that they were being unfaithful if they suggested condom use. The NCLR male sample reported not liking the condoms they received for free because these allowed for less pleasure than condoms they bought. Currently, the only other reliable family planning available to men is vasectomy, a surgical procedure which prohibits the sperm from entering the semen and renders the man sterile, and which can only rarely be reversed successfully. According to data from the NSFG, Hispanic men are approximately half as likely to obtain a vasectomy as their non-Hispanic White counterparts.

Finally, very little has been written about barrier methods such as the diaphragm or sponge. The general consensus is that Hispanic women feel uncomfortable touching their genitals. Because much of the qualitative research has been done with lower socioeconomic subjects, it is not clear that more educated, later generation women would have the same perceived discomfort using vaginal barrier methods.

In summary, national data in the United States reveal that the top two family planning methods used by Hispanic women are sterilization and Depo Provera. It is not clear whether they elect these or whether family planning providers feel low-literacy, low-income groups are best managed with these methods. Hispanic women are likely to receive family planning services at clinics as opposed to from private providers. This may be attributable to lower levels of health insurance. They also receive family planning methods from their home countries as well as through community networks that, it may be argued, are not qualified to be dispensing medical contraception. An example of these providers is Hispanic grocery stores, also known as bodegas. More alarming is that these same sources supply immigrant women with pregnancy termination methods that may pose substantial risk to the user.

Family Reunification

Katherine Crow
WebMD Health Foundation, Rancho Santa Fe, CA, USA

Family reunification occurs when families join each other in a new locale after separation. There are different reasons that families become separated, such as forced displacement because of war and a search for employment in another country in order to send money home to family.

Once immigrants are settled in a new country, they often start the process of sponsoring the migration of other family members to join them. Most countries allow their permanent residents or naturalized citizens to sponsor the migration of relatives. Policies and procedures on family migration vary from country to country. For example, in the USA, there are no restrictions on the number of visas provided for the migration of spouses, dependent children, and parents of US citizens. However, permanent residents are limited in number of spouse and children visas issued. In Australia and Canada, there is no difference between citizens and permanent residents in terms of sponsorship of immediate relatives for migration. Also, adult children and siblings must meet English language and skills requirements to relocate to Australia.

Families often experience a great deal of stress as a result of separation, regardless of the reason, and the fact that reunification can take several years. In the case of war, families may have been separated by force and sent to different refugee camps. Family members in such situations will often send letters to villages where they used to live in an attempt to locate each other as well as asking new arrivals to the refugee camp if they can identify the location of others' family members. For example, the Lost Boys of Sudan were often unaware if family members were still alive. This sense of not knowing the fate of family members caused a great deal of stress. In the case of a family member leaving the nuclear family by choice to seek work in another country, the remaining family members left at home also experience stress even if they are monetarily benefitting from the money sent home by the absent parent. Children often feel abandoned by the parent who left and if it is years before family reunification takes place, children and parents frequently report that they feel like strangers to each other when reunified.

Family Violence

Diana Bulgaru Iliescu
Institute of Legal Medicine Iasi, Iasi, Romania

Family violence, also known as domestic violence, includes physical and sexual violence of a family member. That family member may be a parent, a spouse or partner, or child, or other member of the family who is residing in the household. These physical forms of violence may be accompanied by intimidation; verbal and emotional abuse; financial abuse; isolation of the victim from family and friends; and deprivation of or control over essential elements of living, such as transportation, clothing, and access to the telephone.

The actual prevalence and incidence of family violence are generally impossible to determine. Various studies suggest that between 10% and 52% of women are abused by an intimate partner at some time during their lives and between 10% and 27% of women are sexually abused, either as children or as adults. The estimates vary depending upon the design of the study and the way violence is measured and defined. Worldwide, it has been estimated that approximately 40 million children are abused each year and that at least 4% of children in industrialized countries are physically abused each year.

Many cases of family violence remain unreported. Many persons are abused in the course of a longer period of time and at the same time they are trapped in hopeless situations. These cases may include relationships in which the victim is financially dependent; in which the victim fears that he or she may lose their children, discredit their family, or be ostracized by the other members of the family; and those in which the victim sees no alternative.

Women may be vulnerable to victimization because of their physical size. However, men may also be victims of abuse by their female partner. It may be difficult in some circumstances to determine if a partner is inflicting violence in an attempt to defend him- or herself from the abuse, if the individual is instigating the violence, or if it is a case of mutual battering. It is important to remember that domestic violence may also occur in the context of same-sex relationships.

Parents who are violent with their own children may consider this behavior normal and natural in order to impose certain norms of their family. Their aggressive behavior is facilitated by the fact that usually young children cannot defend or seek for medical care by themselves. Besides the physical trauma, the abused children frequently suffer from long-term psychological effects. The abused child lives under the uncertainty and the anxiety of more abuse. They may later abuse their life partners, children, or parents.

There is a growing awareness of the occurrence of violence against elderly family members. Like other forms of family violence, elder violence may be physical or sexual in nature and may be accompanied by emotional and/or financial abuse. Elders are at increased risk of violence from family members in situations in which the elderly person has diminished capacity and needs assistance with the functions of daily living. There is also an increased risk in situations in which the elderly person is residing with an adult child who is abusing substances or is dependent on the elderly parent for housing.

Family violence is not restricted to one social class, but occurs across all social classes and income levels. Sociological studies have identified financial problems as being a primary trigger factor in many cases of family violence. Some studies have suggested that family violence occurs more frequently in urban areas partially due to the particular environmental conditions (noise, increased density of population, and people crowded in small spaces) which increase individuals' levels of aggression. However, other studies suggest that the incidence of family violence may be as high in rural areas, in part because of individuals' relative isolation.

Family violence is now recognized as a public health problem due to its high prevalence and serious health consequences. In addition to the physical injury suffered by victims, victims and witnesses to the violence may suffer severe emotional injury. A major consequence of the family violence is the psychological trauma suffered by the victims which can disturb their mental and relational balance. Victims begin to organize their lives around their trauma, experiencing their trauma and negative emotions repeatedly. Thus the victim progressively sets up an exaggerated type of behavior, dominated by intense negative emotions such as fear of the life partner, anxiety, worry, depression, sleep disturbances, marked irritability, disorder of concentration, etc. The victim may develop posttraumatic stress disorder or depression. In some cases, the family violence may lead the victim to attempt suicide. Children who are abused may run away in an attempt to escape the violence. Data suggest that children who witness violence inflicted by one parent against the other have an increased risk of later perpetrating family violence themselves or becoming a victim of family violence.

Various theories have been developed in an attempt to explain family violence. Explanations include an acceptance of the violence by the larger society; mental illness on the part of the perpetrator, the victim, or both; a desire for greater control and power by the perpetrator, perhaps due to his or her own insecurities; and difficulties coping with stress and frustration that may be caused by finances, conflicts over children, and other issues. The *general systems theory* suggests that family violence occurs as the result of a complex feedback system that exists at the individual, family, and societal levels. Societal level factors include the level of violence in a particular society, the extent to which a family is socialized to violence, the extent to which cultural norms are accepting of violence, and the organization of society. Family-level factors include the extent to which individuals ascribe to physical punishment for wrongdoings, the extent to which sibling violence is tolerated or encouraged, and the extent to which family members are socialized to violence. Individual level factors may include insecurity, jealousy, frustration over any number of issues, mental illness, substance abuse, and feelings of shame, among others.

Immigrant women and children may be at increased risk of family violence. In situations in which it occurs, they may be afraid to seek assistance from law enforcement authorities or other entities because the perpetrator of the violence may have threatened them with further violence or with the possibility of deportation from the country. They may also be afraid that health care personnel or the police will report them to the immigration authorities, particularly in situations in which the victim or a household member is present in the country illegally. There may be additional barriers to seeking assistance, such as isolation as the result of the perpetrator's abuse and inability to speak the language of the host country.

Farmworkers

Thomas A. Arcury
Department of Family and Community Medicine,
Center for Worker Health, Wake Forest University
School of Medicine, Winston-Salem, NC, USA

Migrant and seasonal farmworkers in the USA and in other nations provide the hand labor required for the production of many agricultural products including fruits, vegetables, mushrooms, Christmas trees, flowers, sod, and tobacco. In the USA and Canada, the migrant and seasonal farmworker population has become overwhelmingly Latino and immigrant. Agriculture remains an extremely dangerous industry. While providing an essential service to society, farmworkers are exposed to numerous occupational and environmental health risks that result in high rates of physical injury and illness. Farmworkers are also exposed to significant psychological stressors, including discrimination, separation from family, long work hours, and fear of unemployment and underemployment, which increase their risks for mental illness and substance abuse.

Farmworkers in the USA have few of the protections granted to other workers in modern industrial societies. Since the 1930s, agriculture as an industry and farmworkers as employees have been affected by "agricultural exceptionalism." This exceptionalism exempts the agricultural industry from most labor standards and safety regulations, such as the Fair Labor Standards Act. As employees, farmworkers are excluded from the protections of the National Labor Relations Act, which governs worker organizing and collective bargaining. The only national regulation that requires occupational safety training for farmworkers is the US Environmental Protection Agency's Worker Protection Standard (WPS) which focuses on pesticide safety. Two states, California and Washington, require that farmworkers receive safety training on heat stress. In addition to the limited requirements for farmworker occupational safety training, the Occupational Safety and Health Administration sets standards for field sanitation for all farmworkers and regulations for migrant farmworker housing. Health scientists and advocates have consistently documented the limited regulatory protection for farm labor. The situation of farmworkers was summarized in 1951 by President's Commission on Migratory Labor in stating "[the US] depend[s] on misfortune to build up our force of migratory workers and when the supply is low because there is not enough misfortune at home, we rely on misfortune abroad to replenish the supply." The circumstances for farmworkers have seen only limited improvement since 1951. Therefore, although their work is essential and their exposure to harm is high, farmworkers generally receive low wages, and they are seldom provided health benefits by their employers.

Farmworkers Defined

Who is considered a farmworker varies among analysts and for different programs and regulations. Factors included in defining farmworkers, and their eligibility for health, social, and educational services, include the different agricultural commodities (crops, dairy, poultry, livestock) and sectors (materials processing, fisheries, forestry) in which individuals work, their migration statuses, their ages, their incomes, and eligibility periods (e.g., employed in farm work in the last 24 months, or the last 36 months, or 12 of the last 24 months).

Farmworkers include individuals who work in agricultural production, with agricultural production including planting, cultivating, harvesting and processing crops for sale, and caring for animals. Agricultural crops include food commodities, such as fruits and vegetables, and non-food commodities such as flowers and ornamental plants, sod, Christmas trees, and tobacco. Agricultural production excludes manufacturing activities, such as preserving fruits and vegetables, working in grain storage, slaughtering or butchering of livestock and poultry, or making cheese and cooking food. Seasonal farmworkers are individuals whose principal employment is in agriculture on a seasonal basis rather than year round. Seasonal farmworkers do not change residence in order to work in agriculture. Migrant farmworkers are individuals whose principal employment is in agriculture on a seasonal basis, and who, for purposes of employment, establish a temporary home. The migration may be from place to place within a state, interstate, or international. Many definitions of migrant farmworkers include the family members who accompany them.

The National Agricultural Workers Survey (NAWS) differentiates six types of farmworkers: (1) non-migrant workers are equivalent to seasonal farmworkers (for 2002, the NAWS estimates that 57% of farmworkers were non-migrant), (2) foreign-born newcomer migrants are foreign-born farmworkers who have traveled to the USA for the first time, (3) international shuttle farmworkers travel from permanent homes in a foreign county to the USA for employment but work only within a 75-mile radius of that location, (4) domestic shuttle farmworkers have permanent residences in the USA but travel 75 miles or more to do farm work in a single location and work only within a 75-mile radius of that location, (5) international follow-the-crop farmworkers travel to multiple US farm locations for work from permanent homes in a foreign county, and (6) domestic follow-the-crop farmworkers travel to multiple US farm locations for work from permanent homes in the USA. For 2002, the NAWS estimated that 13% of farmworkers were foreign-born newcomers, 57% were non-migrant or settled, 8% were follow-the-crop migrants, and 18% were shuttle migrants.

Number and Demographic Characteristics of Farmworkers

Farmworkers are employed across the USA. Although the number of farmworkers in the USA is large, an accurate count of their numbers is difficult to establish. Much depends on how “farmworker” is defined. A national census of farmworkers has not been completed since the early 1990s; this census put the number of farmworkers plus family members at over three million. Estimates of farmworkers in the ten states with the largest farmworker populations were prepared for 2000. An analysis of the 2006 Current Population Survey produced an estimate of 1.01 million hired farmworkers in the USA. The 2007 US Census of Agriculture reports 2,636,509 agricultural workers employed on 482,186 farms. These included 911,439 workers who worked 150 days or more, and 1,725,070 workers who worked 150 days or less; 98,135 farms reported having only workers who worked at least 150 days, 280,894 farms reported having only workers who worked less than 150 days, and 103,157 farms reported having workers who worked both 150 or more days and less than 150 days. A total of 38,784 farms reported hiring migrant farm labor.

The farmworker population is ethnically diverse. It includes African Americans, American Indians, Asian immigrants, and Caribbean immigrants. However, since the early 1990s, the majority of migrant and seasonal farmworkers have been from Latin America, particularly from Mexico. The NAWS indicates that 84% of migrant and seasonal farmworkers in the US self-identify as Hispanics, with 75% of all farmworkers having been born in Mexico, 23% in the USA, 2% in Central America, and 1% in other countries. Mexican farmworkers are a diverse group, coming from urban as well as rural Mexico, with at least one-quarter being from native communities and speaking an indigenous language.

Two trends in the ethnic composition of the farmworker population are important to the health of farmworkers and to the provision of health care for farmworkers. The first is the growing number of farmworkers from Mexico and other Central American countries who speak an indigenous language. These farmworkers are from among the poorest communities in their nations, with the greatest health risks and the least health care. Providing health care and occupational safety and health training to these indigenous language speaking farmworkers is especially difficult due to the large number of indigenous languages spoken, the small number of farmworkers who speak each language, and that most of these languages are not written. The second trend in the ethnic composition of the farmworker population that is important to health and health care is the growing number of farmworkers from Southeast Asia and from Eastern Europe. The number of these new immigrant farmworkers remains small and the locations in which they work are limited, but if the numbers of these immigrants grow, training related to their language, health beliefs, and health histories will be required.

Farmworkers tend to be young, with most under age 35 (the NAWS reports that farmworkers have an average age of 33.6 years). The great majority of farmworkers are men. Most farmworkers have little education. The 2002 NAWS found that most farmworkers have less than a high school education. The 2006 Current Population Survey reports that 30.0% of agricultural workers have less than 9 years of education, and 24.5% have from 9 to 12 years of school. Farmworkers are poor; at least 30% of farmworkers have annual incomes below the federal poverty level.

Finally, about half of migrant and seasonal farmworkers in the USA are not documented. This places them at risk for deportation and limits their access to services. A temporary labor program is available to farmworkers through the H2A visa program. Although no annual limitations on the number of H2A visas are enforced, the US Department of Labor certification process requires employers to certify that US workers are not available before they may hire an immigrant worker with an H2A visa. For 2007, 50,791 H2A visas were issued for the entire USA; this was an increase from 37,149 H2A visas issued in 2006. An H2A visa allows an individual to enter the USA to work in agriculture for a specified period of time for a particular farmer, who is obligated to provide an average of 35 h of work per week, a specific hourly wage, inspected housing, and to meet all safety requirements.

Occupational Exposures and Injuries

The number of farmworkers in the USA is large, and their work, living arrangements, and migratory lifestyle expose these workers to numerous hazards. However, few data are available to document the number and types of occupational injuries and illnesses that farmworkers experience. National and state public health systems do not require the specific reporting of agricultural injuries and standard injury reporting systems have difficulty delineating agricultural injuries. With the lack of national, regional, or local surveillance data, information on the prevalence of injuries and illness among farmworkers is based on local observational studies or reports from farmworker health, service, and advocacy organizations. The observational studies generally have small samples, are focused on small areas, and they are limited in the health data they collect; an exception is the state-wide and comprehensive California Agricultural Workers Health Survey. Health data from health and service providers are limited to those farmworkers who present to obtain services. These study designs and data collection procedures limit the generalizability of these health data.

Even with the limited available information, it is still clear that immediate occupational injuries and illnesses common among farmworkers include musculoskeletal injuries, hearing loss, eye injuries and symptoms, skin disease, mental illness, heat stress, pesticide exposure and its sequelae, and green tobacco sickness. Long-term health outcomes from these occupational exposures include neurological disease and cancer. The nature of farm work, with significant distance between work sites, low income, and migratory nature, means injuries and illnesses resulting from lifestyle factors including transportation and housing hazards must also considered. Lifestyle related injuries and illnesses common among farmworkers include infectious diseases such as tuberculosis, HIV/AIDS, and sexually transmitted infections, alcohol abuse, and poor oral health.

Access to Health Care

Providing health services to farmworkers has been a concern for several decades. Farmworkers are overwhelmingly poor, they are seldom provided health insurance by their employers, and they are seldom provided paid sick leave when they need to obtain health care. These characteristics limit farm worker access to health care. Farmworkers experience other barriers to health services, including linguistic and cultural differences from the majority population, low educational attainment, mobility, inadequate transportation, lack of documentation, and a limited number of health care facilities. A final barrier to health services for farmworkers is the limited number of health care facilities provided for this population.

Several programs have been implemented by governmental agencies, as well as by nonprofit organizations, to address the health services needs of farmworkers and their families. Often, local health programs are provided by clinics, organizations, churches, and academic health programs (e.g., medical and nursing schools). The Bureau of Primary Health Care, Health Resources and Services Administration (HRSA), provides funds for migrant health clinics, and many states provide additional funds for these programs; however, the number of facilities, their locations, and their hours of operation cannot respond to the needs of the farmworker population. In addition to funding Migrant Health Centers and Community Health Centers, HRSA helps to address barriers to health services for farmworkers by funding nonprofit organizations that support the efforts of local clinics and service organizations. These "central grantees" each have a different focus. Farmworker Justice, Inc., focuses migrant health legislation and policy. The focus of Farmworker Health Services, Inc., is supporting outreach worker programs for Migrant and Community Health Centers by providing products, services, and activities that enable them to understand and effectively address farmworker health issues. Migrant Clinicians Network, Inc., works to strengthen the infrastructure for health care facilities serving farmworkers and other mobile poor populations. Migrant Health Promotion has developed six model outreach programs and provides training and support to organizations in the use of these programs. The National Center for Farmworker Health, Inc., provides information, services, and products to healthcare centers. National Association of Community Health Centers, Inc., serves as an informational resource for community-based health centers by providing education, training, technical assistance, and leadership development.

Directions

The number of farmworkers in the USA is large and they are employed in all regions of the nation. The occupational and environmental hazards to which farmworkers are exposed are many. The information documenting farmworker health is limited. Health services available for farmworkers are also limited. Accurate and current information on the number and characteristics of farmworkers is needed, as is a better surveillance system documenting the occupational injuries and illnesses experienced by farmworkers. More informed health and safety regulations that reflect the current industrial nature of agriculture are needed for farmworkers and all agricultural workers.

Finally, the system for providing health care to farmworkers needs to be expanded.

Fatalism

Moon Choi
Department of Epidemiology and Community Health,
Virginia Commonwealth University School of
Medicine, Richmond, VA, USA

Fatalism refers to an attitude of perceiving the world in which everything is seen as ordained by fate. Individuals with a fatalistic viewpoint believe that all past, present, and future events (e.g., illness or death) have already been determined. Accordingly, future events are inevitable, and individuals are powerless to change their circumstances. Perceptions of what controls future events vary; it could be luck, destiny, or god. However, fatalism would be most likely to stem from ideas derived from theology or physics.

Fatalism influences health behaviors and outcomes. Fatalism has been reported as a psychological and socio-cultural barrier for the prevention and early detection of cancer among minority immigrants in multicultural societies. For example, an immigrant woman with a belief in fatalism might think that she will get cancer if she is destined to get it – regardless of her efforts to prevent it. In this context, fatalism would influence low cancer screening rates among minority immigrants.

Rainbow Babies and Children's Hospital, Cleveland,
OH, USA
[2]Division of General Pediatrics and Adolescent
Medicine, Rainbow Babies and Children's Hospital,
Cleveland, OH, USA

Sexually Transmitted and Other Genital Infections

Sexually transmitted infections (STIs) are likely to be common among the immigrant population due to lack of access to health care, antibiotics, and condoms. Refugee populations and those fleeing war and abuse may also have been in situations in which sexually transmitted infections would be difficult to avoid. Certain STIs are rare in the United States but are more highly prevalent in developing countries. HIV (not included below) is not a female genital disease, but its presence makes the transmission or acquisition of other infections more likely; the reverse is also true. Two infections described below – bacterial vaginosis and vaginal yeast infections – are not transmitted sexually but are characterized by vaginal discharge and may be associated with HIV infection.

Other genital infections may be associated with poor hygiene or crowded living conditions. Immigrant females may have inadequate facilities for washing or may not have had proper instruction in female hygiene. Refugees may have been living in overcrowded camps, and recent immigrants may continue to live in overcrowded areas where proper hygiene is difficult.

Sexually Transmitted Infections

Chancroid

Chancroid is a painful genital ulcer caused by the bacterium *Haemophilus ducreyi*. This sexually transmitted infection is occasionally found in the United States but is more common in developing countries, including many parts of Africa. Chancroid increases the likelihood of transmitting and acquiring HIV. A health care provider must examine the genital ulcer to diagnose chancroid; cultures may be done. The infection can be treated with antibiotics. Condoms and avoidance of contact with ulcers can help to prevent transmission of chancroid.

Chlamydia

Chlamydia, caused by the bacterium *Chlamydia trachomatis*, is one of the most common sexually transmitted infections in adolescents and young adults. The infection is transmitted through vaginal, anal, or oral sex. Female genital symptoms include vaginal discharge, pelvic or abdominal pain, or pain with urination. The infection is diagnosed in females with either a urine or cervical sample and can be treated with oral antibiotics. Untreated, the infection may spread to the uterus and fallopian tubes and cause pelvic inflammatory disease (PID). PID is a serious infection that can result in chronic pelvic pain and infertility. The risk of transmitting or acquiring chlamydia can be decreased by condom use.

Genital Herpes

Genital herpes is a sexually transmitted infection caused by the herpes simplex virus (HSV); it can be caused by HSV type 1 or HSV type 2. Most people who carry the herpes simplex virus do not have any symptoms. Symptoms that do occur are usually most serious and severe during the first episode or outbreak of herpes; these symptoms include painful blisters, sores or ulcers, and fever. A health care provider may examine the genital sore and take a culture to diagnose genital herpes. Blood tests are available to check for antibodies to the herpes virus; however, these results are often difficult to interpret. Genital herpes cannot be cured. Additional outbreaks can be suppressed or shortened with antiviral medications. Condoms reduce the risk of transmitting or acquiring herpes.

Genital Warts

Genital warts are caused by the human papillomavirus (HPV) which is passed during sexual contact. There are about 40 types of HPV; only some cause genital warts. The warts are usually small bumps in the genital area. A health care provider must examine the genital area to diagnose genital warts. Topical treatments are available but may need to be repeated. For some people, genital warts go away without treatment; others need multiple courses of treatment. A vaccine is available to prevent most genital warts in males and females. The risk of HPV infection may be lowered through the use of condoms.

Gonorrhea

Gonorrhea is a sexually transmitted infection that is caused by the bacterium *Neisseria gonorrhoeae*. Symptoms of a genital infection in females include vaginal discharge, pelvic or abdominal pain, or pain with urination. Like chlamydia, the infection is diagnosed in females with either a urine or cervical sample and can be treated with oral antibiotics. Untreated, the infection may spread to the uterus and fallopian tubes and cause pelvic inflammatory disease (PID). PID is a serious infection that can result in chronic pelvic pain and infertility. Condoms decrease the risk of transmitting or acquiring gonorrhea.

Granuloma Inguinale (Donovanosis)

Granuloma inguinale is a sexually transmitted infection rarely found in the United States. Caused by the bacterium *Klebsiella granulomatis*, granuloma inguinale is characterized by painless, growing ulcers. A health care provider diagnoses the infection by examining a biopsy of the ulcer. Treatment is with antibiotics.

Lymphogranuloma Venereum

Lymphogranuloma venereum (LGV) is caused by a variant of *Chlamydia trachomatis* (serovars L1, L2, or L3). The infection rarely occurs in the United States. Most people with LGV have tender, persistent lymph nodes near their groin; they may have a small, transient ulcer. A health care provider must examine the area to diagnose LGV. Cultures and blood tests may be done. Treatment is with antibiotics.

Molluscum Contagiosum

Molluscum contagiosum presents as flesh-colored bumps on the skin. It is caused by a pox virus. The infection is common in childhood and is spread by skin-to-skin contact. It also can be spread by sexual contact and can be found in the genital area. The infection usually resolves on its own but can be treated with medication or by a health care provider. Treatment of genital lesions is generally recommended to prevent spreading the virus.

Syphilis

Syphilis is a sexually transmitted infection caused by a bacterium called *Treponema pallidum* that may initially present with a painless ulcer (called a chancre) in the vaginal area. After that primary stage, which will resolve without treatment, the secondary stage of syphilis is characterized by rash (particularly on the palms and soles), fever, swollen glands, and fatigue. If untreated, latent and late syphilis may occur, resulting in brain damage and dementia. Syphilis is diagnosed by blood tests and is treated with antibiotics. Condoms and avoidance of contact with ulcers can help to prevent transmission of syphilis.

Trichomoniasis

Trichomoniasis is caused by *Trichomonas vaginalis*, a protozoan parasite. A sexually transmitted infection, trichomoniasis has symptoms in females that include vaginal discharge, odor, pain with urination, and vaginal itching or burning. Trichomoniasis increases the risk of acquiring HIV if exposed during intercourse. A health care provider must examine the vagina and vaginal discharge to diagnose trichomoniasis. Treatment is with oral antibiotics. The chances of transmitting or acquiring trichomoniasis can be decreased by using condoms.

Nonsexually Transmitted Infections

Bacterial Vaginosis

Bacterial vaginosis is caused by an overgrowth of certain bacteria in the vagina; it is not a sexually transmitted infection. Common symptoms of bacterial vaginosis are vaginal discharge, odor, burning, or itching. Bacterial vaginosis increases the risk of acquiring HIV and other sexually transmitted infections. A health care provider must examine the vagina and vaginal discharge to diagnose bacterial vaginosis. Treatment is with oral or topical antibiotics.

Folliculitis

Folliculitis is a bacterial infection of the hair follicle. It is often found in the pubic area. Folliculitis often resolves without treatment, but it may require medication or other medical treatment.

Genital Tuberculosis

Genital tuberculosis is common in women in countries where tuberculosis, caused by *Mycobacterium tuberculosis*, is endemic. The infection spreads to the genital tract from the lungs or other nongenital area. Symptoms include vaginal bleeding and pelvic or abdominal pain. Women may also present with infertility. A health care provider makes the diagnosis with special x-ray and laboratory studies. Treatment is with medication.

Pediculosis Pubis

Pediculosis pubis is also known as pubic lice and is usually transmitted through sexual contact. The main symptom is severe itching around the pubic area; nits and lice may also be seen. Treatment is with topical pediculcides.

Streptococcal Vaginitis

Streptococcal vaginitis, caused by Group A Streptococci bacteria, is found mainly in prepubertal girls. Symptoms include vaginal discharge, redness, soreness, and irritation. A health care provider diagnoses the infection by examining the area and taking a bacterial culture. Treatment is with antibiotics.

Vaginal Yeast Infections

Vaginal yeast infections are typically caused by *Candida albicans*; they are not sexually transmitted. Symptoms include vaginal discharge and vaginal itching or irritation. Women who have recently taken antibiotics or oral steroids, women with elevated blood sugars (as in diabetes), and women with compromised immunity (HIV, chemotherapy) are at greater risk for developing yeast infections. A health care provider must examine the vagina and vaginal discharge to diagnose a vaginal yeast infection. Treatment is with oral or topical antifungal medications.

Genital Cancers

Many female genital cancers are preventable through regular screening which may not be available to the immigrant population. Quick access to treatment may also be unavailable.

Cervical Cancer

Cervical cancer is cancer of the cervix, the lower part of the uterus. The main cause of cervical cancer is human papillomavirus (HPV). A vaccine to prevent HPV is available. Regular PAP tests screen for changes in cervical cells that could progress to cervical cancer. When detected early, cervical cancer is treatable and recovery rates are high.

Ovarian Cancer

Ovarian cancer is most common in women over 40 years of age. It can cause symptoms such as abdominal pain, pelvic pain, or bloating. No simple screening test for ovarian cancer exists. Treatment is with medication and surgery

Uterine Cancer

Uterine cancer is found mainly in women who have gone through menopause. The most common symptom is vaginal bleeding. A health care provider makes the diagnosis by performing an endometrial biopsy – taking a piece of the inner lining of the uterus. Treatment, including medication and surgery, is most effective when the cancer is found early.

Menstrual Disorders

Immigrant adolescents and women may be more susceptible to menstrual disorders because of nutritional issues and lack of health care access. A few common menstrual disorders are described below.

Amenorrhea

Amenorrhea may be primary (no menstrual period) or secondary (no menstrual period within 6 months). Possible causes are numerous and include genetic abnormalities, excessive diet or exercise, chronic disease, thyroid problems, or pregnancy. A health care provider will examine for causes of amenorrhea and possibly do laboratory tests. Treatment is directed at the cause of amenorrhea.

Dysmenorrhea

Dysmenorrhea, or menstrual cramping, is common among women. Caused by a chemical released during menstruation, dysmenorrhea can result in cramping, nausea, vomiting, and diarrhea. Secondary causes of menstrual cramps include genital infections and abnormalities of the genital anatomy. Dysmenorrhea can be managed with nonsteroidal anti-inflammatory medications or other medications.

Endometriosis

Endometriosis is a condition in which uterine lining cells are present outside the uterus and cause pelvic pain and menstrual cramps. The condition tends to run in families. A health care provider makes the diagnosis, which may require surgery. Treatment is with medications.

Other Genital Diseases

Contact Dermatitis

Contact dermatitis is a skin rash caused by contact with an irritating substance. Soaps, cleansers, and chemicals are common irritants. Contact dermatitis can occur in the genital area and appears as a red, often itchy, sometimes painful rash. Treatment involves avoiding the irritant and topical medication.

Fibroids

Fibroids (leiomyomas) occur in up to 50% of women older than 35 years of age; they are a benign tumor of the uterus. Fibroids may be small or large, but are generally slow-growing. They are more common in overweight people and in people with certain ethnic backgrounds. Symptoms include heavy menstrual bleeding and abdominal pain. A health care provider makes the diagnosis by ultrasound or surgery. Treatment is with medication or surgery.

Lichen Sclerosus

Lichen sclerosus occurs on the labia and causes the skin to become thin and white. Other symptoms include itching and pain. The cause of lichen sclerosus is unknown. A health care provider diagnoses lichen sclerosus and treats the disease with medications.

Female Sex Workers

Bettina Rausa
Salk Institute for Biological Studies, La Jolla, CA, USA

Sex workers, more commonly referred to as prostitutes, work in the sex industry and trade in sex commercially. Sex work is legal in approximately 50% of countries around the world. Examples of countries in which sex work is illegal include the United States (except for 11 counties in the state of Nevada), China, India, the Philippines, Romania, Saudi Arabia, and Uganda.

In the case of migrant female sex workers, trafficking is a prevailing issue. Trafficking of humans, in conjunction with arms dealing, is the second largest criminal industry worldwide, followed by drug dealing, and the numbers are rising. In 2000, United Nations estimates were that 4 million women and children had been trafficked into the sex industry. From places such as Southeast Asia, Latin America, and Eastern Europe, up to 50,000 women and girls are trafficked annually – taken from developing and economically unstable countries and trafficked to countries that are more industrialized and economically stable. The United Nations estimates that sex trafficking generates 5–7 billion dollars annually.

Many migrant female sex workers, especially those who are trafficked, are forced to work in prostitution and/or in the sex entertainment industry. Typically they do not know how to get out of this situation or where to turn to for help. Fear of deportation, lack of language skills, and other cultural barriers in the new home country create further obstacles to freedom and alternative employment. Frequently traffickers and pimps use oppressive techniques to maintain the sex workers' dependence. Common techniques include debt bondage, isolation, confiscation of legal documents such as passports and visas, threats of violence, imprisonment and/or deportation, and controlling the sex workers' finances. Shame and fear of stigmatization add to female sex workers remaining hidden victims.

Over the last several years, many governments have engaged in efforts to combat trafficking through prevention, protection, and prosecution. However, because the crime of human trafficking is highly clandestine, most cases continue unreported, and traffickers remain at large. Frequently traffickers are associated with international criminal organizations, which make them highly mobile and difficult to prosecute.

Often traffickers use deception to lure women into believing they will obtain legitimate work or to convince them to become mail order brides. Some women agree to engage in sex work, or are already sex workers in their countries of origin. However, they are not usually aware, nor do they expect that they will be forced into financial bondage to their traffickers, working in squalid, isolated, and confined conditions. Until their debts to the traffickers are paid off, the sex workers will likely have to engage in sex work every day, several hours per day, sometimes for years. In addition, frequently they are moved from one location to another, and with each move they become indebted further to the trafficker, thereby becoming "sex slaves."

Sometimes traffickers use elaborate schemes to convince women to go willingly or even to force them to migrate. Regularly, for example, trafficked female sex workers from the Ukraine are offered work abroad as models. To lure the women, traffickers set up bogus modeling schools, use phony contracts, and employ the use of elaborate, yet fake, photo sessions – being careful to attend to critical details. These elements serve to instill trust among the women themselves. The concept of "trust" is very important in this scenario, and most Ukrainian traffickers are women themselves. Although Ukrainian women are trafficked as sex workers throughout the world, their primary destinations are the former Soviet states, Europe, Canada, and the United States.

Female sex workers from Nigeria have been working along roadsides in Italy for decades. Most are lured with promises of well-paying jobs in factories, offices, and on farms. The majority of these women come from rural areas and have little or no education. Routinely, once they arrive in Italy, they are placed with a Nigerian madam, usually a former prostitute, and are indebted instantly to her. Often those trafficked are made to undergo religious rites that involve swearing never to reveal the identity of their traffickers and madams to the police and to pay off their debts. These rites have significant implications for the trafficked women, because they believe strongly that if they do not do as they are told, they risk harm to themselves and their families. They are required to pay their debts in a few months time, in addition to paying monthly rent for their roadside spot, which is where they solicit sex from paying clients. In order to earn enough money, they must work continuously, servicing a high number of clients every day. This has significant consequences for the health status of these women. In addition to the stress and harsh living conditions, they face social and cultural stigma from their countries of origin where prostitution is looked down upon. However, extreme poverty and the promise of easy earnings outside of their country often create situations for trafficked women in which they are encouraged by their own family members, even husbands, to accept sex work abroad.

Prior to 1949, there were no migratory restrictions to Hong Kong from mainland China. Since Hong Kong's transformation into a fast-growing manufacturing economy, numerous factory workers were needed, and mainland Chinese immigrants provided an abundant workforce. Since the 1980s, however, there has been a gradual tightening of border controls, with immigration laws strictly enforced, and routine repatriation of undocumented Chinese immigrants. The sex industry in Hong Kong is dominated by Chinese migrant female sex workers. Sex work is a tolerated choice for these women for whom it appears to be the best available option to support their families. But, given their immigration status and the general stigma attached to Chinese immigrants by Hong Kong nationals, these sex workers are relegated to the lower end of the local sex market. They work in places such as massage parlors, saunas, motels, and one-woman brothels, which are concentrated in the older, overcrowded, working-class, residential districts that are frequented by local clients. They are highly visible at the street level, as opposed to other sex workers who provide sex labor in night clubs or through escort services. In addition, since the Hong Kong government began tightening border controls, Chinese migrant sex workers have become an easy target for law enforcement officials, and they now account for a significant portion of the female prison population in Hong Kong. They are prosecuted primarily for working without a visa, because sex work itself is not illegal. In fact, sex work in Hong Kong is typically accepted as "immigrant work." However, since mainland Chinese immigrants are considered an "undesirable burden," they are subject to mass arrests and imprisonment. Currently, Hong Kong has the highest proportion of female prisoners in the world: about 22% of the total prison population, compared with the global averages of between 2% and 9%. In 2004, mainland Chinese immigration violators made up approximately 60% of the women in prison.

Primarily, migrant female sex workers in the United States (US) are from Southeast Asia, Latin America, and Eastern Europe. Research on the trafficking of women to the US, however, has been less well documented than in other countries. In 1998, one of the first cases surfaced in the media and illuminated this issue for many Americans. The trafficked women were scattered across 14 states, but Atlanta, Georgia, was discovered to be the base of operations for the network. Incidentally, most were minors. A significant portion of the US sex industry operates behind legitimate businesses that act as fronts for prostitution; examples include: restaurants, night clubs, health clubs, saunas, escort services, strip clubs, pornography emporiums, peep shows, and massage parlors. Although large trafficking rings and criminal organizations are involved in much of the trafficking of women to the US, there are also many smaller operations.

Most of the research available regarding the health status and health issues faced by migrant female sex workers focuses on sexually transmitted diseases (STDs) and HIV/AIDS. Instead of emphasizing the worker's vulnerability to acquiring sexually transmitted diseases from numerous sex clients who often prefer, and, in some cases, demand not to use condoms, often female sex workers are regarded as the vectors of these diseases. Although research of the specific health issues women face as a result of sex work is limited, the repercussions of sex work on women's physical and psychological well being is extensive.

A study of 68 local female sex workers in St. Paul and Minneapolis, Minnesota revealed significant health problems as a result of engaging in sex work. For example, high rates of STDs, such as Chlamydia, gonorrhea, syphilis, genital herpes, and warts; pregnancies with low rates of prenatal care, frequently resulting in low birth weight or premature births (migrant female sex workers report being subjected to forced abortions); and drug use, including crack cocaine and alcohol. Many female sex workers, including migrants, report the use of drugs and/or alcohol as a way to cope with engaging in sex work.

Violence is a constant presence in the lives of most female sex workers. Often reported are rape and assault, which frequently lead to broken bones, head injuries, and many types of internal injuries. Other major health issues include stress-related difficulties such as sleep disorders, flashbacks, and depression – all symptoms of Post Traumatic Stress Disorder (PTSD). High rates of self-destructive behavior, including attempted suicide and cutting are frequently cited. Furthermore, 76% of the women in the Minnesota study reported difficulty establishing intimate relationships outside of prostitution, which they attributed to an inability to separate feelings of fear, disgust, and an emotionally distanced attitude developed in prostitution. Although the Twin Cities women reported having good access to health care, only 35% revealed their experiences as prostitutes to their primary health care providers. Many female sex workers, including migrants, keep this crucial information from their health care providers, listing the primary reasons for their silence as (1) the illegality of their work, (2) the illegality of their immigration status – thus, fear of arrest, prosecution, and deportation, and (3) the social stigma and cultural barriers associated with sex work.

In 2002, a comprehensive study highlighting the health issues faced by migrant female sex workers in Indonesia, the Philippines, Thailand, Venezuela, and the US, shed a rare light on both the physical and psychological health challenges for these women. Although this research revealed similar health problems as those found in the women in the Minnesota study, migrant female sex workers cope with additional issues related to their cultural, ethnic, and religious backgrounds; the physical demands of the migration process; and frequent relocation from one place to another. An inability to speak the native language, discrimination, illegal immigration status, lack of access to health care, and often being confined or limited in their ability to leave their work locations further compound their overall health problems. Furthermore, if they are in a country illegally, health care access can be self-restricted by fear of deportation. Even where sex work is legal, it is still stigmatized, and migrant female sex workers, who face more cultural, racial, and ethnic barriers to care, are hampered further by feelings of shame when discussing their health problems as a consequence of sex work activity.

The five-country study reveals the health problems of migrant female sex workers which most commonly include pulmonary tuberculosis, anemia, hepatitis-B, and STDs – including chronic syphilis, gonorrhea, and herpes. They suffer pelvic inflammatory disease, inflammation of the uterus, vaginal irritation, bleeding caused by multiple and violent sex partners, general pain and soreness of the vaginal area, perforated anal and vaginal walls, peritonitis, mutilation, chronic choking from gonorrheal tonsillitis, and asphyxiation from oral penetration. Often younger girls who become pregnant are unable to sustain the pregnancy. Furthermore, they are more susceptible to STDs and to HIV infections, due to a thinner genital tract mucous membrane that offers a less effective barrier to viruses. Although migrant female sex workers are forced by their pimps or madams to use contraception at times, many do become pregnant, only to be forced to have abortions. This can causes extreme difficulty, especially for those who have strong emotional and/or religious convictions regarding abortion. Migrant female sex workers have reported undergoing self-induced abortions using abortifacients or by physically stomping on or punching their own stomachs. Whether or not a condom is used is ordinarily dictated by the client, and usage rates vary from 30% to 80%.

Physical injuries are a large extent of the health problems suffered by migrant female sex workers. These injuries are sustained primarily as a result of violence, including physical and sexual assault (rape). Injuries include bruises from being hit and beaten; vaginal and rectal bleeding as a result of violent intercourse; head trauma; mouth injuries and broken teeth; broken bones; ruptured blood vessels in the eyes and nose from being choked; bleeding all over the body – including the face and lips from being bitten; broken and bruised ribs; and stomach, head, back, throat, and face pain. All of the women surveyed in the 2002 five-country study reported high rates and frequency of violence, some reporting experiencing violence 100% of the time.

Emotional, behavioral, and psychological effects of sex work, and the violence that accompanies it, significantly impact the health of migrant female sex workers. Women most report feeling depressed, guilty, self-blame, numb, hopeless, anger, and rage, while additional complaints include difficulty sleeping, an exaggerated startle response, feeling on guard, loss of appetite, engaging in self injury, and having suicidal thoughts.

Even when sex work is legalized, as in many parts of Europe, and primarily due to their immigration status, migrant female sex workers remain outside established legal, social, and medical structures – even though on average they outnumber local sex workers. Many involved in the sex industry do not identify themselves as sex workers and consider their work to be temporary. However, the reality is that impoverishment; victimization by traffickers, pimps, and madams; illegal immigration status; and language and cultural barriers often trap them as sex workers. Recommendations for helping migrant sex workers to improve their health status include using direct field work programs to teach sex workers about disease and injury prevention; using cultural mediators of the same nationality and cultural background to communicate directly with or between the sex worker and health care providers and educators; and training former sex workers to be peer educators and supporters. Ideally, migrant female sex workers from different cultural, racial, and religious backgrounds would have access to health services and health information that is culturally relevant and appropriate.

Individuals and organizations who advocate on behalf of sex workers have major philosophical differences concerning the legalization and regulation of the sex industry. On the one hand, legalization and regulation have been promoted as ways to eliminate trafficking, violence and abuse, and to assure that sex workers have access to health care and other essential services. Proponents also argue that it would help stem the tide of sex trafficking of women and girls, even though there is some evidence to contradict this claim. Those who oppose the legalization of sex work argue that all sex work is a form of oppression and violence, rarely do those who engage in sex work do so by choice, and sex workers are victims of poverty and exploitation.

Fertility

Amy N. Sharpton
Department of Veterans Affairs, Louis Stokes DVA
Medical Center Cleveland, Brecksville, OH, USA

Introduction

The forces influencing population growth differ dramatically across the world's major regions. For example, as compared to developed countries, the current annual rate of growth in nondeveloped countries is increasing nearly six times as fast. Certainly, migration is not a new phenomenon; it is responsible for the base population of many current industrialized nations. Experts suggest, however, that the current dynamic of population growth differs from that of earlier periods due to increased pressures to migrate to more developed countries – pressures caused mainly by the comparatively high rate of population growth and widening economic disparities. The manner in which the developed countries respond to the growth of immigration pressures will have a major impact on their demographic and economic futures.

Migration

Migration, either voluntary or forced, is prompted often by social choice or by economic necessity. Current worldwide immigration patterns reflect a flow of people from poor countries to those with more developed economies, especially to those industrialized countries with aging workforces. The swell of immigrants is changing the composition of populations; for example, 7% of Britain and France's populations is now foreign-born, while immigrants comprise nearly 10% of Germany's population and 17% of the Canadian populace.

In comparison to other countries, historically the USA has had a welcoming immigration policy, periods of restriction and bias notwithstanding. Since the mid-1960s, there has been an increase in immigration to the USA, particularly from countries in Latin America and Asia. Over the past decade, the USA has seen unprecedented numbers of immigrants. The 2000 Census reflected the trend, as 10% of America's residents were born in other countries, the highest percentage since 1930, and the largest number in the country's history. Furthermore, never before has there been such a marked shift in the locations from which immigrants originate. Due to quotas favoring northern Europeans, before 1965 more than three-fourths of all immigrants to the USA came from Europe.

Immigration and Fertility

Total fertility is the number of children the average woman in a given population is likely to have throughout her lifetime; the figure is based on current birth rates. The number ranges from more than seven children in developing countries in Africa, to around one child per woman in Eastern European and highly developed Asian countries. Associated with total fertility rate is *replacement rate*. The *replacement rate* is the number of children each woman needs to have to maintain the current population levels of a given population – known as zero population growth.

Replacement occurs when a child matures and has an offspring. In developed countries, the necessary replacement rate is about 2.1. The need for the extra 0.1 child per woman is due to the potential for death and to account for those who choose or are unable to have children. In less developed countries, due to higher childhood and adult death rates, the replacement rate is around 2.3. Used to give a more accurate measure of population trends, *population growth rate* is calculated as birth rate − death rate + net migration rate.

Total Fertility Rates, Immigration, and Strength of the Economy

Many economists contend that total fertility rates are closely tied to growth rates for countries and can be an excellent indicator of future population growth or decline for a country or for a particular population. As modern societies became more productive, fertility rates began declining. Because rising life expectancy kept populations expanding, the trend went unnoticed. By the 1960s and 1970s, however, more countries started seeing their birthrates sink beneath replacement levels. Today, women in more than 60 countries do not bear enough children to keep the population growing. Even in less developed countries, the trend toward a lower birth rate is apparent. Over the last few decades, Mexico's rate went from nearly seven children per woman to 2.3.

Outcomes of a Declining Birth Rate

Across Europe, birth rates are falling; the total fertility rate is less than two children per woman in every member nation of the European Union. As a result, European populations are either growing very slowly or beginning to decrease. At the same time, low fertility is accelerating the aging of the populations. As a region, Europe in 2000 had the highest percentage of people age 65 or older – 15%, a figure that is expected to double by 2050. These trends indicate difficult times ahead for European economies. For example, a shrinking workforce can reduce productivity. At the same time, the growing ratio of elderly individuals threatens the solvency of pension and social insurance systems that would assist in caring for the elderly. As household sizes decrease, the ability to care for the elderly diminishes, even as elderly people face growing health care needs and costs.

Economic growth depends strongly on an expanding population. Until the 1960s, neoclassical economists believed that population growth reduced a society's standard of living by dividing up the same "pie" of available resources into smaller and smaller slices. Economists have come to understand gradually, however, that in industrialized countries, due to economies of scale and specialization of labor, population growth drives productivity growth.

US Fertility

The USA has the highest population growth rate of all industrialized countries. There are approximately four million births and 2.4 million deaths annually in the USA, with growth due to natural increase at 1.6 million per year. However, when factoring in immigration totals, the US population is growing by 3.3 million per year.

US Population Growth: Immigrants and Rate of Fertility

As compared to women in their home countries, analysis of data collected by the Census Bureau in 2002 shows that women from the top 10 immigrant-sending countries living in the USA collectively tend to have higher fertility. As a group, immigrants from these countries have 23% more children than women in their home countries. Among Mexican immigrants in the USA, for example, fertility averages 3.5 children per woman compared to 2.4 children per woman in Mexico, and among Chinese immigrants, fertility is 2.3 in the USA compared to 1.7 in China. Exceptions to this trend include immigrants from three countries: India, Vietnam, and the Philippines – immigrant fertility is lower in the USA than in their home countries. When education level is controlled for, the disparity in fertility rate is even greater between the USA and the home country. Given the education level of immigrants and the fertility of similarly educated women in their home countries, one would expect immigrants from the top sending countries to have 2.15 children on average in the USA, not the 2.9 they actually have.

Filipinos

RUTH MAGTANONG
Department of Anthropology, Case Western Reserve University, Cleveland, OH, USA

Filipinos are individuals with origins from the country of the Philippines, a consortium of islands off the southeastern coast of the main Asian continent. While Pilipino/Tagalog is the national language, often English is widely spoken in addition to other regional languages besides Tagalog and/or the hybrid of Tagalog/English, otherwise known as “Tag-Lish.” A primary motivation for immigration among Filipinos is the pursuit of economic opportunities as a means to financially support immediate family members and/or extended kin who remain in residence in the Philippines. Filipino immigrants reflect ethnolinguistic, demographic, and socioeconomic diversity. In the context of immigrant health, there is limited information concerning the health issues of Filipino immigrants. In health studies, Filipinos are either underrepresented or merged with other Asian groups, e.g., Asian Americans. Also, few studies distinguish between first generation immigrants born in the Philippines and subsequent generations who were born in the host countries. Some reasons for the limited attention to Filipino immigrants in health research may result from a relatively seamless assimilation into the host countries and the challenges associated with finding representative samples of Filipinos. Furthermore, possible factors considered to contribute to the Filipino immigrants’ seemingly rapid integration into host countries like the United States compared to other immigrant populations are that many Filipino immigrants choose to marry non-Filipinos and Filipino immigrants are already familiar with American culture before immigrating to the United States because the Philippines used to be an American territory. Within the Filipino American community, dialogs regarding cultural identity and activism for social change aimed to minimize discrimination, injustice, and economic exploitation shifted self-identification from “Filipino” to “Pilipino” in the 1960s. Currently, both labels are recognized and preference is determined by individual choice.

Immigration Patterns

In the early 1900s, Filipino immigrants were mainly composed of male laborers from rural areas. After World War II (WWII), families immigrated to the United States as military dependents. Post-1960s, many Filipinos immigrating, predominately to the United States, have been well-educated and demonstrate high levels of English proficiency. Also, increasing numbers are migrating to the Middle East, Europe, and Australia for employment. A significant proportion of these immigrants are professionals, mainly physicians, nurses, dentists, teachers, lawyers, and engineers. The majority of Filipino immigrants are college graduates. While the first wave of immigrants resettled in rural communities, the second wave of immigrants chose urban centers and suburban areas reflecting changes in socioeconomic status and demographics. The 1965 Family Reunification Act and the 1990 Amendment to the Immigration and Naturalization Act allowed grandparents and aging WWII veterans to enter the United States. With the 1990 amendment, WWII veterans were granted American citizenship, but were not given service-related compensation such as healthcare benefits.

Labor emigration has a long history in the Philippines and active support from the government. The Philippines Overseas Employment Administration (POEA) regulates the recruitment of laborers for contract work in different countries. Also, the Philippines is one of the largest exporters of physicians and nurses – approximately one third are women and a majority are individuals under 40 years of age. Despite the large numbers of Filipino immigrants with the professional qualifications and technical requirements to be competitive, many individuals have difficulty obtaining jobs that match their education and training experience. Currently, poor treatment and cases of infringement of human rights among overseas Filipino workers (OFWs) have received political attention, resulting in the push for the POEA to take a more active policy in protecting the welfare and ensuring the rights of OFWs in contractual agreements with overseas employers. Temporary OFWs are contract workers intending to return to the Philippines. These individuals are recruited through private organizations to be employed as laborers in factories, domestic homes, retail and construction in the Middle East. Generally, Filipino immigrants moving to North America or Europe have procured permanent employment opportunities and do not intend to return to the Philippines. These individuals are often employed as healthcare professionals.

In 1983, Filipinos in the United States represented the largest population among Asian Americans in the Western region (including Alaska and Hawaii). In 2000, there were over 1.8 million Filipinos living in the United States; Filipinos comprised the second largest Asian group. In addition, there were approximately three million OFWs with official temporary contracts More than eight million Filipinos are estimated to live outside the Philippines. The strength in these numbers generate vast revenue for the Philippines. Remittances recorded between 1990 and 2001 for money Filipino immigrants were sending back to the Philippines through official channels accounted for 5% of the GNP of the Philippines. In 2001, over 6 billion USD were sent home.

The Principle of Balance (Timbang)

Among Filipino immigrants, health and illness result from maintaining or losing balance. One of the underlying beliefs behind this concept is that rapid changes from “hot” to “cold” and vice versa will cause illness, while optimal health is maintained by staying “warm.” Bathing is one of the strategies used to maintain the body’s balance. Beliefs relating to hot and cold also include environmental changes that affect the body. Drastic changes in temperature can upset the balance of the body and cause illness, for example. One woman in Becker’s study of chronic illness among elderly Filipino Americans living in San Francisco claimed that the heart condition she developed in the United States was caused by the cold climate in contrast to the humid climate of the Philippines that allows the body to perspire. Within this hot-cold system, perspiring allows the body to maintain balance. Balance can also be altered by specific food and drinks. Illness can also result from emotional and social stress. This concept of balance is expressed in social interactions through reciprocity. Social and emotional distress, and consequently ill health, can result from difficulty in maintaining family obligations and social responsibility. Furthermore, specific so-called culture-bound syndromes observed among Filipino immigrants such as *amok*, *mali-mali*, and *lanti* are described as “loss of equilibrium.”

Health Issues

Studies on health issues of Filipino immigrants, mostly from Filipino immigrants living in the United States, primarily attribute health problems to life-style and cultural changes. Compared to individuals living in the Philippines, Filipino immigrants are at greater risk for developing chronic conditions. Higher prevalence rates of hypertension are observed in Filipinos living in the US compared to those living in the Philippines among those aged 65 and older. Compared to Filipinos in the Philippines, Filipino immigrants between 55 and 65 years old in Hawaii are at higher risk for coronary heart disease. High prevalence rates of hyperuricemia and gout among Filipino men have been reported in Seattle and Hawaii. These medical conditions may relate to the increased intake of high-protein foods. Anderson suggested that some Filipinos may have difficulty processing foods with higher purine loads resulting from these dietary changes post-immigration. Also, studies show high incidence of tuberculosis among Filipino immigrants. Filipinos are three times more likely to be diagnosed with diabetes compared to Caucasians. While Filipino men are reported to be at greater risk for liver cancer and lymphoma, the cancer rates overall among Filipino immigrants are the lowest compared to other ethnic groups. Filipino children show similar patterns of risk for diabetes, hypertension, and metabolic syndrome.

In terms of mental health, effects of perceived discrimination on health may include symptoms of depression, increased substance abuse, and chronic conditions. The large scale epidemiological survey of mental health among 2,095 Asian American immigrants, the National Latino and Asian American Study (NLAAS), was conducted in 2002–2003 and targeted three nationalities: Chinese, Filipino (n = 508), and Vietnamese. Filipino immigrants reported the highest levels of everyday discrimination, stating physical appearance such as height or weight as reasons for discrimination rather than income or education, compared to other Asian groups. Perceived discrimination was a significant predictor for cardiovascular conditions and associated with increased risk for respiratory and pain conditions such as frequent headaches, ulcers, nausea, and chronic back problems. These chronic somatic problems have been associated with increased use of pain medications. A moderate incidence was found for clinically diagnosed schizophrenia among Filipino immigrants living in Hawaii compared to other immigrant groups. Later age diagnoses and a high mortality ratio for women were reflected. In San Francisco between 1968 and 1972, 57% of female Filipino immigrants were admitted into psychiatric facilities. Most of the cases involved major life events strongly linked to loss of status and feelings of shame. Thus, some doctors questioned whether some of these cases were truly severe mental illnesses or were only temporary disturbances during a readjustment period. Furthermore, compared to other Asian groups, incidence of suicide was low, but diagnoses of clinical depression were often triggered by emotional stress related to family obligations and social responsibility. While the "family" can offer sources of care and support enhancing mental well-being, it can also be a source of stress especially for the children of Filipino immigrants caught between different generations and perspectives. Although often portraying successful assimilation stories, studies of Filipino immigrant youth reflect internal conflicts and emotional struggles potentially placing these individuals at increased risk for attempted suicides and clinical depression.

Finland

Sarah Parsons
Norton Cancer Institute, Louisville, KY, USA

Finland is a nation of approximately 5.2 million people located in the far northern regions of Europe.

Despite a unique language, spoken by only 23 million people worldwide, and a homogenous religious population with 90% Lutheran, the people of Finland represent a diverse group. The majority are Finns who speak Finnish, though 6% of the population are Finland-Swedes who speak Swedish; smaller portions of the population are composed of Gypsies (5,500) and Sami (4,400) who speak Lappish. Over the past 15 years, the population of Finland has changed with a surge of immigrants. Due in part to the fall of the Soviet Union and to Finland joining the European Union in 1995, the number of foreigners permanently living in Finland has dramatically increased from 26,300 in 1990 to 155,660 in 2009. Foreigners residing in Finland in 2009 were from 175 different countries, with 2,435 from the USA. In addition, the number of foreign-born Finnish citizens has doubled over the past 15 years. Immigrants now comprise 6% of Finland's population, representing a much larger portion than prior to 1990. Finland continues to grant citizenship to 2,000–3,000 immigrants annually.

Immigration from Finland to the USA primarily took place from 1864–1924, though there have been smaller trends of migration over the years. The Finns settled across the northern tier of the USA with concentrations in Massachusetts, New York City, Michigan, Wisconsin, Minnesota, Oregon, Washington, and Colorado. The 1990 Census registered 658,870 US residents claiming Finland ancestry with the highest concentration in Michigan, representing 1.2% of the state's population. Historically, assimilation of the Finnish Americans has been difficult due to language barriers and cultural differences. They were quick to adapt to American culture, though privately maintained their own cultural traditions, including cuisine, holidays, religion, and language. The immigrants banded together in small communities to provide support to each other as well as provide support to their country of origin when needed. Finnish Americans are typically politically active and fought for fair wages and working conditions, organizing strikes and protests. This led to the development of a reputation as "troublemakers" in the early twentieth century. The backlash of persecution that followed created tension and caused Finnish Americans to blend more among other European Americans for fear discrimination. They continued to maintain Finnish traditions behind closed doors and passed on their culture to their descendents.

One aspect of Finland's culture is their belief in natural medicine, including massage, cupping (bloodletting), and sauna. Immigrants in the nineteenth and twentieth centuries continued these practices, though today, sauna is the primary retained health practice. Sauna is an historic part of healing rituals; when the Finns get sick, they make a sauna. Sauna can help with respiratory and circulation problems, relax stiff muscles, and relieve aches and pains. There is a Finnish proverb that says if sauna, whiskey, and tar salve don't make you well, death is imminent. Modern immigrants employ sauna, chiropractors, acupuncture, and alternative medicine for relief of ailments.

Despite the emphasis on natural and alternative medicine, Finnish immigrants have a high incidence of heart disease, respiratory illness, high cholesterol, lactose intolerance, stroke, alcoholism, and depression. It is speculated that the increased rate of heart disease is partly due to the traditional Finnish diet, which is high in fat. Respiratory illness is directly related to tobacco smoking, common among native Finns and Finnish immigrants. The use of modern medicine, improved preventive health care, and health education would be helpful in this population to address these common medical problems.

First Generation Immigrants

Amy N. Sharpton
Department of Veterans Affairs, Louis Stokes DVA Medical Center Cleveland, Brecksville, OH, USA

Introduction

Nearly every American can trace his or her family history to one or more ancestors who entered the USA as an immigrant. From 1607 to the present, it is estimated that the total number of immigrants to the USA is between 35 and 50 million. As immigrants adjust to life in a new country, predictably they face a variety of challenges. In recent decades, researchers have sought to define those challenges and to determine their unique affects on each immigrant generation. In this context, first generation immigrant will refer to the first generation to immigrate to the USA, rather than the immigrants' children – the first generation born in the USA. This is an important distinction, as even within various social sciences, often the terms *first*, *second*, and *third generationimmigrants* are defined divergently across studies.

First Generation Immigrants and Health Care

Compared to their US-born counterparts, on average, first generation immigrants disproportionately lack health coverage and receive fewer health services. These findings hold constant even when factors are controlled for, including sociodemographic status, socioeconomic status, and lifestyle. For example, a 2003 Kaiser Foundation study reported that low-income first generation immigrants were nearly two times as likely to be uninsured as low-income native-born persons. Furthermore, first generation immigrants are approximately twice as likely as citizens not to receive health services. Factors that limit their access to quality health care include: a reduction in available programs for noncitizens, confusion over program eligibility, concerns that enrollment will jeopardize one's immigration status, and language barriers.

As compared to US-born citizens, there are significant differences in the physical and mental health status measures among first generation immigrants to the USA. Considering that they lack health coverage disproportionately and receive fewer health services, it is surprising that first generation immigrant adults enjoy some advantages over their US-born counterparts for certain health measures. Researchers have suggested that the length of stay in the USA is a key factor in health status – noting that, in general, the trend is the longer the first generation immigrant stays in the USA, the more likely it is that a decrease will be seen in the aforementioned health measures.

First Generation Immigrants and Religion

Churches and religious organizations help to create for the immigrant a sense of community in the new country, and frequently they are a major source of assistance for those in need – spiritually, socially, economically, etc. Relationships among congregants of ethnic churches are reinforced with traditional foods and other familiar traditions. American places of religious worship have a centuries-long tradition of service to those who are in need most. Spiritual support delivered in a familiar cultural context, combined with material assistance, increases the appeal of church membership and participation for first generation immigrants to the USA. In fact, participation and commitment by the immigrant in the US setting may often be greater than what was exhibited in the country of origin.

Another notable aspect of the social dynamics of immigration is the relationship between immigrant religions and new American-born religious movements. In the 1960s, a trend began to emerge in which native-born spiritual seekers sometimes gravitated toward immigrant religions, centers, and teachers. One example popular in the New York City area is joining a Faulun Gong group that blends traditional Chinese religious and health practices.

Law, Politics, and Policy

Through legal means, thousands of immigrants enter the USA each year. In 2004, almost a million people legally immigrated to the USA under qualifying categories. These categories include: employment-based preference, family preference, immediate relatives of US citizens, diversity, and refugees/asylees. Recent legislation has authorized the category, diversity, which allows a limited number of individuals to immigrate based on past underrepresentation in the immigrant population.

Many in the USA are concerned about illegal immigration, and proposed policies are discussed and drafted frequently as potential solutions. Bills have been introduced to resolve the immigration controversy, such as the one rejected in 2007. The authors of that bill proposed to allow illegal immigrants to obtain a renewable visa if they were present on January 1, 2007. The bill was defeated eventually due largely to growing debate and disagreement over how to handle the massive illegal immigration to the USA over the past 15 years.

Some policies have been aimed at both legal and illegal immigrants. Federal policy and law relative to first generation immigrants has been shaped by numerous key legislative events. Often first generation immigrants are limited in their English proficiency, the three hallmark legislative events that impact upon that particular aspect of their transition into a new culture include: Title VI of The Civil Rights Act (1964), Lau *v.* Nichols (1974), and Executive Order 13166 (2000). The most recent event, EO 13166 in 2000, has resulted in each federal agency being charged with taking reasonable steps to provide meaningful access to its own federally conducted activities. The Order was designed to provide persons who are limited in their English proficiency with greater access to federally conducted and federally assisted programs and activities.

Fitness

Julio Guerrero[1], Ranjita Misra[2]
[1]Department of Health & Kinesiology, Texas A&M University, College Station, TX, USA
[2]Center for the Study of Health Disparities (CSHD), Department of Health & Kinesiology, Texas A&M University, College Station, TX, USA

Introduction

Fitness is the quality of life characterized by how effectively the body can meet ordinary physical demands, as well as those demands that are unexpected and more challenging. Physical fitness is the capacity to perform normal daily activities with little effort, while being able to perform more difficult activities with increased effort and without significant fatigue. On the other hand, low physical fitness leads to significant fatigue even with light activity. Fitness levels differ among individuals and can be improved by engaging in physical activity, but can be worsened through physical inactivity.

Widespread acceptance exists of three physical fitness classifications related to skill, health, and physiology. Skill-related fitness is composed of agility, balance, coordination, speed, power, and reaction time. This class is the most advanced level of fitness and is associated mostly with sport and motor-skills performance; therefore, it is not necessary to master to achieve optimal health. Health-related physical fitness is associated with optimal health and directly impacts the risks associated with the premature development of diseases and adverse health conditions. The components of health-related fitness are cardiorespiratory endurance, muscular strength, muscular endurance, flexibility, and body composition. Since each of these components affects the body's ability to function, regular physical activity is required to achieve optimal health-related fitness. Finally, physiologic fitness relates to the health status of biological systems that have been influenced by regular physical activity. The components of physiologic fitness are metabolism, morphology (or fat content and distribution), and bone integrity. Since improvement of health-related fitness is positively correlated with improvement in physiologic fitness, both categories are closely related to health promotion and disease prevention.

The Components of Physical Fitness

Physical fitness is comprised of five components: cardiorespiratory endurance, muscular strength, muscular endurance, flexibility, and body composition. Each component affects the overall physical capacity and health status of individuals.

Cardiorespiratory endurance is the capacity to perform activities at moderate to high levels of intensity for a prolonged period of time. Though there are several ways to gauge intensity, a basic way to determine intensity level is to monitor an individual's ability to speak while performing physical activity. Moderate intensity physical activity causes the breathing rate to increase but does not restrict the individual's ability to carry conversation. High intensity physical activity, on the other hand, causes such an increase in breathing rate that conversation becomes difficult or impossible. Intensity levels are the same for everyone, but fit individuals have the capacity to perform more movement before reaching high levels of intensity, while unfit individuals experience high levels of intensity with less movement.

Muscular strength is the body's capacity to exert quick episodes of physical force at high intensity levels. Maximum strength is only achieved briefly because fatigue develops quickly, while lack of strength limits the amount of force one can exert.

Muscular endurance is the body's capacity to exert physical force over an extended period of time. Muscular endurance enables the body to delay the onset of fatigue while performing continuous moderate to high physical activity. Fatigue develops more quickly at higher intensity levels.

Flexibility is the body's capacity to perform movements through the full range-of-motion around single or multiple joints by stretching the muscles that stabilize those joints. More flexible individuals are able to perform more movements through the full range-of-motion and are at lower risk of incurring muscle, bone, or joint injuries. On the other hand, lack of flexibility restricts the range-of-motion of movements and may cause injury by stretching the muscles beyond comfort.

Body composition is the total makeup of the body as it pertains to lean body mass (primarily bone and muscle) and body fat. In general, there is a direct relationship between body composition and overall health. Higher body fat percentage increases the risk of developing several diseases and adverse conditions, such as cardiovascular and metabolic diseases. Also, the capacity to perform physical activity lowers with higher body fat percentages. Conversely, lower body fat percentages help to prevent the onset of diseases and conditions and increase the capacity to perform physical activity.

How to Improve Fitness

Regular physical activity is required to improve physical fitness. Exercise programs help, especially if a structured routine is needed, but are not essential. The body responds to any frequent physical activity by adapting at the cellular level, though more specific results are reached by following exercise programs. Physical activity is bodily movement produced by the contraction of skeletal muscles. Exercise, on the other hand, is planned, structured, and repetitive physical activity performed with a specific purpose, usually to improve one or more components of physical fitness. In general, the more physically active individuals are, the more fit they become. However, too much physical activity can lead to overuse injuries and should be avoided. Recommendations vary concerning the minimum amount needed of daily physical activity; however, in general, 60 minutes of moderate to high intensity activity is recommended with 20–30 minute concentration on cardiorespiratory endurance.

Fitness can be improved by following a few simple principles. First, the FITT (Frequency Intensity Type Time) principle allows individuals to track the amount of daily physical activity. Frequency refers to how often physical activity is performed during the course of one week, while intensity refers to the difficulty of the activities. Type refers to the type of the activity performed to improve one of the fitness components. Most activities only improve certain components, so individuals should engage in a variety of activities to maximize their physical fitness. Finally, time refers to the duration the activity is performed during one session or over one day. Physical activity does not have to be performed in one continuous session; intermittent activity also improves physical fitness. In fact, some argue that intermittent activity may be more advantageous than activity confined to one session since engagement in physical activity is spread out throughout the entire day and not confined to only one period of the day.

Other principles that may improve physical fitness are overload, specificity, adaptability, stimulation, and reversibility. Overload refers to exerting enough effort during physical activity to cause at least slight discomfort, but not exhaustion or injury. In other words, in order for fitness to improve, individuals should push themselves to at least a moderate level of intensity. Specificity occurs when the performance of a specific activity is improved by continually engaging in that activity only. According to this principle, frequent jogging will improve a person’s ability to jog, or frequent gardening will improve gardening, and so on. Adaptability refers to the body’s response to frequent physical activity. As one engages in activity, eventually the body becomes more efficient and performance improves. Fit persons must then exert more effort to reach moderate and high levels of intensity because the body has become more able to meet the demands of physical activity. Related to adaptability is the principle of stimulation in which the body must be stimulated continually in order to improve fitness. Otherwise, adaptation can inhibit further improvements if the intensity level is not increased. Finally, when physical activity is discontinued, even for brief periods of time, fitness levels begin to diminish. This is the principle of reversibility. These principles apply to any amount or type of physical activity or exercise program.

Benefits of Physical Fitness

Frequent physical activity is beneficial to overall health as it may serve to delay or prevent the onset of many diseases and adverse health conditions. Most benefits are achieved by engaging in frequent cardiorespiratory activities (e.g., brisk walking, jogging, biking, swimming, household chores, and aerobics classes). The body becomes more efficient at utilizing body fat as an energy source, which leads to body fat reduction and energy increase. Also, cardiorespiratory endurance is associated with a reduction in blood pressure and stress levels, and is associated with an increase in heart function, blood capillary density, work capacity, and blood sugar use for energy. These outcomes decrease the likelihood of developing obesity, diabetes, cancer, and cardiovascular disease. Adaptations occur at various lengths of time, from 6 weeks to 6 months, depending on the time and frequency an individual engages in cardiorespiratory activities. Many experts recommend 20–30 min of cardiorespiratory activity most days of the week, but more activity leads to quicker results, and some activity is better than not engaging in activity at all.

Several health benefits are associated with muscular strength and endurance. Since strength building activities promote increases in bone density, one of the most important benefits is the prevention of osteoporosis. Muscular strength and endurance activities such as lifting or moving heavy objects, walking upstairs, and weight training lead to increases in muscular size, strength, and stamina. Also, by increasing the strength of opposing muscles that work on the joints, these activities lead to improvements in joint stabilization and posture.

Flexibility may be the most neglected component of physical fitness, but can still affect health outcomes. A lack of flexibility is associated with adverse conditions of the muscles, bones, and joints and should be a focus in achieving optimal fitness. Engaging in flexibility activities such as stretching, yoga, and activities involving the full range-of-motion assists with maintaining or improving range-of-motion through physical activity and helps to maintain muscle elasticity. As a result, injuries caused by movements beyond the range-of-motion are not as likely to occur nor tend to be as severe as those occurring in inflexible individuals. Finally, since muscle elasticity decreases with age, flexibility is more crucial for older individuals.

Diseases and conditions associated with body composition have been presented previously. In general, higher body fat percentages increase the risk of developing several chronic diseases. Engaging in cardiorespiratory activities is the most effective way to decrease body fat since the body becomes more effective at fat utilization. However, to decrease body fat percentage, muscular strength and endurance activities should be performed also. Therefore, frequent cardiorespiratory activity coupled with muscular strength and endurance activities influence body composition toward more lean body mass and less fat mass.

Summary

Physical fitness determines how effectively and efficiently the body handles the demands of daily life, both those that are ordinary in nature and the demands that are more challenging. The level of physical fitness is different for all individuals, but optimal physical fitness is achieved only by engaging in frequent and intense physical activity. By focusing on the five components of physical activity, individuals may optimize their health and may delay or prevent the onset of debilitating diseases.

Five-Year Bar

Kathrin Mautino
Mautino & Mautino, San Diego, CA, USA

Individuals who violate certain provisions of the Immigration and Nationality Act may be barred from returning to the United States for a 5-year period. Individuals who violate the terms of an F (student) visa cannot return for 5 years after their last departure after the violation. More generally, however, people speak of the 5-year bar that comes from an order of expedited removal.

Normally, an individual wishing to come to the United States applies for admission at a Port of Entry, which includes international airports. That individual is inspected and, if the Customs and Border Protection (CBP) officer is satisfied, the individual is admitted. If the officer is not satisfied with the documentation, the officer may allow the individual to withdraw his/her application for admission. In that case, there are no legal bars to the person reapplying for admission in the future.

However, a CBP officer can also issue an "expedited removal" order against the individual if fraud or misrepresentation was involved with the attempted entry. Individuals illegally in the United States found within 100 miles of a land border and who cannot establish that they have been in the United States for a 2-year period are also subject to expedited removal, although enforcement of this provision is not consistent. The individual expeditiously removed is then barred for 5 years from returning to the United States. A waiver is available, but only a small percentage of applications are approved.

Many individuals who receive expedited removal orders do not understand what the consequences are. They believe that they have simply been turned away. Unfortunately, many of these individuals then proceed to try again. An individual with a second removal order faces a 20-year bar to returning to the United States, and the chances of getting a waiver are significantly reduced.

Many of the individuals expeditiously removed have used false documents to attempt to enter the United States. If that document is a United States passport or other citizenship document, the individual may be found to have made a false claim to United States citizenship. There is no waiver for a false claim charge, meaning that the person is permanently barred from immigrating to the United States.

Individuals can be held by CBP officers for several hours, while their application for admission is reviewed and validated. CBP guidelines provide that an individual must have access to necessary medicines, food, and water if held for an extensive period of time. However, anecdotal evidence suggests that this does not always occur. Individuals with chronic health conditions such as diabetes report that they have been unable to take insulin shots or other necessary medications.

CBP officers are also responsible for the enforcement of customs laws, including those related to the importation of medicines and other pharmacological substances. Generally, importation of prescription medicines from abroad (including Mexico and Canada) is prohibited. Individuals importing less than a 3-month supply for personal use can, in limited circumstances, and in the discretion of the CBP officer, bring their medicine into the United States. However, the medicine must be declared and other requirements exist, including that the medicine not violate United States drug laws.

Focus Groups

Beverley Russell
Center for Community Health Education Research and Service, Northeastern University, Boston, MA, USA

Focus group is a term used to better understand how a group of people having something in common might feel, perceive, or understand an issue – getting people together to ask questions that hopefully will shed more light on why they feel the way they do. This is essentially what a focus group is.

Focus group as a concept began as a marketing research tool in which a small group of people (about eight to ten individuals) sit at a roundtable discussing a selected topic of interest in an informal setting. As a marketing tool, the discussion could be about a particular product, for example, and the participants are asked their opinion about the product. This information becomes useful to the product managers and market researchers in deciding if their product is appealing to the group, if it needs improvement, and ultimately if it would be purchased by the targeted population group.

Applications

In the example above, the information gathered in the focus group helps to tell the product manager and marketing researcher more about the consumer's habits, who and how they might use the product and what they would expect of the product. For example, if the product is a shaving cream for men or a hair product for women, the focus group participants would reflect the population that the researcher believes might use the product. Feedback from the participants will let the researcher know if the product is appealing to that particular demographic group.

Focus groups can also be used to better understand individuals' perception of health-related issues. For example, if a researcher is interested in what people understand about their illness, the care they receive, or how they feel the care could be improved, using the focus group format may provide the answers.

Characteristics

Focus group participants are usually selected based on a set of predetermined criteria. Depending on the purpose of the focus group, one key factor in the success is selection of the participants based upon specific characteristics or demographics, for example, the participants' age, gender, education, race, or ethnicity. Participants in a focus group are generally selected based on their use of and knowledge, attitudes, or feelings about a product, service, or concept. The participants should be prepared to discuss the topics at hand and provide quality input about that topic.

There is no ideal number of participants for a focus group, although eight to ten participants are the norm. Often, the size of the group is dependent on the comfort level of the moderator/facilitator. The moderator/facilitator has to make sure that one or two participants do not take over the discussion, making it difficult for everyone else to share their thoughts. Groups of more than ten are more difficult for the moderator/facilitator to control.

Moderators

A moderator or facilitator directs or guides the discussion – they are seen as discussion leaders – to make sure the opinions or reactions of all the participants in the group are heard. They try to stimulate the discussion within the group yet saying or adding as little as possible. They usually work from a guide that directs them with a plan about the topics to cover and questions to ask to stimulate the discussions. The moderator tries to include everyone in the discussion and allow time for all the topics to be covered.

Sessions

When planning a focus group session, the physical location of the session is very important. The location should encourage relaxed participation and informal, spontaneous comments. It must be of an adequate size and have comfortable seating and ventilation. Most importantly, the location must be geographically convenient for the participants. Focus group discussions are usually tape-recorded or video-taped to ensure that everything being said is captured. The facility should be relatively soundproof to minimize outside noises and distractions. Depending on the organization requesting the focus group, one-way mirrors may also be used to observe the group without intrusion.

Once the location, moderator, and participants are selected, the moderator begins with an introduction. The introduction includes welcoming the participants, informing them of what will take place during the session, sets up ground rules for how the discussion will follow. The participants are asked to introduce themselves to the group as a way to help them be at ease. Following the outlined plan, the moderator starts with general topic discussions and gradually moves to more specific ones. Once the specific topics are discussed, the moderator will move the discussion into a wrap-up phase.

At the conclusion of the focus group, the moderator may prepare a report for the researcher that includes a written summary of the results of the session as interpreted by the moderator and an analysis of the tape-recorded discussions.

Finally, the use of focus groups is a valuable tool for communities to have their voices heard about issues important to them such as the design of health-related programs that respond to their particular needs and practices.

Food

Patrice J. Tyson
Pediatric Gastroenterology and Nutrition, Rainbow Babies and Children's Hospital, Cleveland, OH, USA

Food is the source of how humans and animals obtain nutrients required to sustain life. It is composed of carbohydrates, proteins, fats, and water. We eat or drink food on a regular basis to maintain health.

Across the world, food intake is a common thread that connects people not only locally but also across nations and continents. It must be consumed on a daily basis but in the right proportions to prevent disease. As man has evolved so has his obtainment, preparation, storage, and sharing of food. In earlier years, our predecessors were hunters and gatherers of food. Farming then became a major source of getting food followed by mass processing of food items. Food that once was cooked over an outdoor flame can now be prepared indoors enclosed in an oven or in a fraction of the time in a microwave oven. Electricity and its various offspring, including refrigerators and freezers, help keep food unspoiled for longer amounts of time. Meats are no longer cured with salt and dried for preservation regularly, but instead can be frozen for consumption in the months ahead. This is important especially in climates that experience harsh winter weather making growing food or food attainment physically difficult. Sharing food has become easier with transport from one corner of the world to another occurring regularly on a daily basis.

Although we all need food, obtaining it, preparation, and presentation vary in many parts of the world. For example, a fish caught in Tokyo, Japan, is more likely to be served raw as sushi versus one caught in Louisiana, United States, where frying in oil is more accepted. Food may also have different meanings to people of different backgrounds. While pork for a person of the Protestant faith may carry no significance, a Muslim follower may see it as unclean and therefore not fit for consumption. We must be cognizant and sensitive to location, culture, and personal background even as they pertain to food. Today's world focuses on how food elements such as agriculture are grown or meat sources such as chickens are raised. According to the United States Department of Agriculture, organic foods, including organic meat, eggs, and dairy products, come from animals that are given no antibiotics or growth hormones and are produced without using most conventional pesticides, bioengineering, or ionizing radiation. They are thought to be more beneficial for our bodies and have become popularly sought out in today's culture.

For some populations, food variety is of lower importance than availability. Worldwide agriculture produces enough food to provide each person with over 2,500 kcal/day. This is more than enough to meet the energy requirements of each of the nearly 7 billion persons on earth assuming equal distribution. Unfortunately, there are still about 854 million people who are classified as food insecure. Food insecurity is when a person does not have enough food to maintain an active and healthy life. Obtaining knowledge regarding household size, food availability is essential to ensure food security. Food security means that the food needs are met all the time in a household. Food insecure households should be referred to the appropriate social programs that can assist where available. There are social programs to help such as 'Women, Infants and Children' in the United States. It focuses on providing support for supplemental foods for low-income pregnant, breastfeeding, and non-breastfeeding postpartum women, and to infants and children up to age five who are at risk nutritionally.

Another recent concern regarding food availability are food deserts. This is defined as large areas such as urban neighborhoods where major grocery stores are not located, leaving the inhabitants with resources limited to fast foods and no access to healthier, affordable options. There is more focus to this problem to improve food access for those affected.

While food items are important, water is also considered food that is paramount to survival. Worldwide access to clean water is a major concern. Water is a clear, tasteless, odorless fluid with natural supplies coming from the oceans. Our bodies require a minimum amount daily. It contributes to health as well as disease if it is not sanitary. Contaminated drinking water is a major cause of disease in developing countries worldwide. Around 1.1 billion people globally do not have access to improved water supply sources, whereas 2.4 billion people do not have access to any type of improved sanitation facility. The World Health Organization has a number of programs and projects focused on improving water sanitation worldwide. Improvement in water quality and access will lead to fewer deaths related to water-borne diseases and relief of dehydration that contributes to malnutrition worldwide.

While it is important to remember the necessity of food, it is also very desirous. Its consumption is also for pleasure, celebration, religious expressions, comfort, and countless other uses. Food stimulates all of our senses: sight – the bright colors of the variety of fruits and vegetables; sound – popping corn; smell – a freshly baked cake; texture – the ridges of a potato chip; and of course, taste – such as contrasting salty and sweet flavors of chocolate covered pretzels. The balance for the need and the love of food keeps our bodies in harmony. In all parts of the world, we must maintain this balance to keep fighting illness, prevent disease, and remain healthy for long and fulfilling lives.

Food Industry

Amy N. Sharpton
Department of Veterans Affairs, Louis Stokes DVA
Medical Center Cleveland, Brecksville, OH, USA

The food industry is a collective of diverse businesses that supply much of the food energy consumed by the world population. The food industry includes a variety of business categories such as regulation (policies and regulations for food production and sale), education (academic, vocational, and consultancy), research and development, financial services (insurance and credit), manufacturing (agrichemicals, seed, farm machinery, agricultural construction, etc.), agriculture, food processing, marketing, and wholesale and distribution.

There has been an increased focus recently on the relationship between the food industry in developed countries and immigrants. Much of the debate centers on the agricultural aspect of the food industry. Immigrants, especially those who are in a country illegally, are among the most vulnerable workers in a society. Most developed countries require workers to have proper documentation. In theory, this functions as a deterrent to the employment of unauthorized immigrants. As in the case of the United States, however, the penalties against employers are relatively small, while the acceptable identification requirements are ill-defined and lack oversight. These factors combine to make it easy for employers to hire unauthorized labor – a marginalized group who likely will not report abuses to authorities. These jobs may be more attractive to immigrants because often the minimum wages in one country can be several times the prevailing wage in the immigrant's country of birth.

There are two chief arguments concerning the relationship between the food industry in developed countries and immigrants. One position holds that the relationship is a win–win – the overall quality of life is improved for the immigrants, while the demand is filled for workers in these hard to fill positions. Furthermore, although foreign-born workers are likely to earn substantially less than native-born workers during their careers, the disparity is much smaller for foreign-born workers' children. The other position holds that the relationship is a win–lose proposition, with immigrants being exploited, while powerful business owners in the food industry gain significantly. The argument has intensified as the economies have flagged in developed countries. As jobs have grown scarce, many citizens have grown to resent immigrants, seeing them as taking up part of the available resources and as a threat to their financial security.

There is disagreement among economists as to whether immigration policy should exclude persons who are less educated in terms of a formal education. One camp of economists contends that there is value to the economy overall as a sector of the job market is not being disrupted owing to labor shortages – as the positions in the food industry are less glamorous and frequently involve long hours in less than ideal conditions. Still, other economists disagree and contend that immigration policy should be shaped by the desire to attract only highly skilled individuals with skill sets more appropriate for employment in sectors of the labor market that will enable a nation to compete better globally. As this debate unfolds and immigration policies are reshaped, persons continue to migrate. Research indicates frequently they will work in some capacity in the food industry.

Calls for Further Research, Policy Reform, and Oversight

Research such as the Southern Policy Law Center's recent report, *Injustice on Our Plates*, details the need for policy reform to protect immigrants working in the food industry. The latest literature outlines frequent abuses to immigrants who are marginalized frequently and who have little power to protect themselves.

Immigration to the United States is at an all-time high. In 1994, one in ten persons in the US labor force was born elsewhere, but in 2009, one in seven was foreign born. Giving consideration to the bills and laws being discussed in Congress regarding immigration reform, researchers in the growing field of agriculture and applied economics have called for research that considers the economic impacts of reducing the availability of immigrant workers in the various sectors of the food industry.

Food Insecurity

Marissa A. Hendrickson
Division of Pediatric Emergency Medicine,
Department of Pediatrics, University of Minnesota
Medical School, Minneapolis, MN, USA

A population is defined as food-secure when all people, at all times, have physical and economic access to sufficient, safe, and nutritious food to meet their dietary needs and food preferences for an active and healthy life. Food insecurity, by contrast, is a state in which individuals or families have limited or uncertain ability to acquire, in a socially acceptable manner, nutritionally adequate and safe foods sufficient for an active and healthy life for all members of the household. Although the subjective experience of hunger and the objective physiologic and anthropometric changes of malnutrition may follow from food insecurity, these findings are not required for an individual or family to be considered food-insecure. Rather, food insecurity can stem from difficulties with any of three general aspects of food security: availability, access, or utilization. For people to be considered food-secure, the quantity of food available to them must be adequate to meet their caloric needs, they must have access to a reasonable range of food choices they can obtain in a socially acceptable manner, and they must be able to utilize the food resources they have in a way that leads to a nutritionally appropriate intake.

A variety of definitions and approaches have been used to measure food insecurity at the individual, family, and national levels. In some assessments of food insecurity in the developing world, an estimate of total calories available per capita, based on local food production and food importation, is used as a proxy for the availability aspect of food insecurity. In this approach, an individual is defined as food-insecure if he or she consumes less than a nutritional target, expressed in calories per day. This method allows for comparisons between countries in terms of the sufficiency of the total amount of food available, but is not as useful for capturing and analyzing variability in access and utilization that may lead to individual or household-level food insecurity.

Much of the research on food insecurity in the medical and social science literature, by contrast, is based on a more detailed, qualitative assessment of food insecurity. There have been a number of questionnaires developed and standardized to allow researchers to determine family or individual food security status based on brief interviews. These include the Radimer/Cornell hunger and food insecurity survey items, the United States Department of Agriculture, Current Population Survey food security questionnaire, and the Household Food Insecurity Access Scale. These scales all include items that assess feelings of uncertainty or anxiety about the subject's ability to obtain food, perceptions of insufficient quantity or quality of food, and reductions in food intake due to economic constraints. They also include questions that directly address limitations in the ability to provide appropriate food for the children in the household. These questionnaires have been widely adapted and validated for use in both developing and developed countries. Scoring of responses allows classification of the individual or household as food-secure or food-insecure. In some cases, food-insecure respondents can be further subdivided into those with low food security, those with very low food security, and those with very low food security among household children.

Research using these and other measurement schemes has found evidence of significant food insecurity even in developed nations. In the United States in 2008, it was estimated that 15% of households were food-insecure at least some time during the year. Although a large proportion of published research on food insecurity in developed nations is focused on the United States, similar studies have been conducted in a variety of settings. Recent large surveys from both Canada and Australia have found 7% of respondents in those nations met criteria for food insecurity. Within developed nations, there are subsets of the population who have much higher rates of food insecurity. In a small sample of inner city London residents in 2003, 20% were found to be food-insecure. In the 2008 US survey, 23% of children were estimated to reside in food-insecure households and 37% of households headed by single women met criteria for food insecurity. In Toronto, one survey focused on high-poverty neighborhoods found that approximately two-thirds of families in those neighborhoods were food-insecure.

Correlations have been found between food insecurity and a number of adverse health effects. Despite the fact that adults have been shown to act to shield children from the worst effects of household food insecurity, children from food-insecure households have been found to have higher rates of undernutrition, poorer physical function, poorer health status, increased rates of acute and chronic illness, more depression and suicidality, more behavior and emotional problems, and higher developmental risk. In adults, food insecurity has been linked to a wide variety of chronic diseases and overall poorer health status. The relationship between food insecurity and obesity has been widely studied, but has yielded conflicting results.

In a number of studies, immigrants have been found to have higher rates of food insecurity and associated health problems. A survey of Mexican immigrants in New York City in 2004, using a single-item measure, found 28% of respondents reported they had felt hungry in the past 6 months but could not afford to obtain food. Report of hunger in this population was higher among men, those who had worked as day laborers, and those who received no public assistance. Hunger was also associated with more reported days of poor physical and mental health. Individuals who reported sending money to friends and family in their home countries were also more likely to report hunger. This is noteworthy because many developing countries, particularly those in Central America and the Caribbean, are highly dependent on such remittances to offset local food insecurity.

Food insecurity among immigrants is also associated with poor dietary habits. A small survey of Colombian immigrants using a food bank in London, Ontario, Canada, was conducted in 2005. This was a highly educated sample, with 64% having completed a college or university degree. Although previous studies have found that not all food bank users meet criteria for food insecurity, in this sample all respondents reported at least household-level food insecurity. Forty-four percent reported food insecurity with individual hunger, and 39% reported the most severe degree of food insecurity, that with hunger among children. High proportions of this sample reported lower than optimal intakes of fruits, vegetables, and dairy products, and significant majorities reported lower intake of fruits, vegetables, meats, and dairy while in Canada than when they were in Colombia. Sixty-five percent said they consumed more grain products since coming to Canada, and 56% were overweight or obese.

Several studies have found increased risk of food insecurity among immigrants and their children, even when compared to comparably low-income native-born families. In an evaluation of about 6,000 low-income families from a nationally representative sample of US families with children, 20% of all foreign-born children as well as 20% of native-born children with two foreign-born parents and noncitizen mothers lived in households that met criteria for food insecurity. This proportion was cut in half, to 10%, if both parents were foreign-born but the mother was a US citizen, and was 8% in families where both parents were US born. In another large US sample focused on mothers with children aged 3 and under, the rate of household food insecurity for immigrant mothers was found to be over twice that of US-born mothers, 35% vs. 16%. In addition, this study found a small but statistically significant difference in report of fair or poor child health, reported by 14% of immigrant mothers and 12% of native-born mothers. These findings were despite significant differences in some factors that should have been protective in the immigrant families, notably a markedly higher rate of breastfeeding (82% vs. 37%) and a lower rate of low birth weight children (10% vs. 15%). Even immigrant families that had been in the United States for 11 or more years continued to have an elevated rate of food insecurity, at 25%.

In the United States, food-insecure immigrants have been found to have relatively low participation in public assistance programs, even when they are apparently eligible. In one study of 630 legal immigrants in California, Texas, and Illinois, only 20% of responding households were found to be fully food-secure. Forty-one percent met criteria for food insecurity with moderate or severe hunger, and 7.5% reported that their children, at times, did not eat for a whole day because there was no money to buy food. Even in this highly food-insecure sample, 40% were not participating in any public assistance programs. Although the study did not systematically investigate the reasons for low participation in public assistance, some immigrants commented in interviews that they were concerned that accepting public assistance would adversely affect their ability to become naturalized citizens or would place them at risk for deportation. An additional finding of that study was that Latino immigrants were at higher risk of food insecurity than Asian immigrants to the same area, indicating that varying cultural practices and attitudes may lead to differing risk levels for food insecurity.

The higher prevalence of food insecurity in immigrant populations as well as the documented associations between household food insecurity and adverse health effects indicate the need for professionals, researchers, and advocates working with immigrant populations to consider the possibility of food insecurity, even in developed nations. Although food insecurity, as defined by qualitative survey methodologies, may not be associated with objective findings of hunger or malnutrition, it remains an important consideration for the medical and psychosocial well-being of families.

Food Stamps

Tambra K. Cain
Barrett, Twomey, Broom, Hughes & Hoke, LLP,
Carbondale, IL, USA

The Food Stamp Program, also known as Supplemental Nutrition Assistance Program (SNAP), is a Federal program administered by the US Department of Agriculture that provides assistance to low-income and no-income people and families living in the USA.

In response to the Great Depression, the first food stamp program was initiated in 1939. Participants in that first FSP program were required to buy coupons to purchase their groceries. For each such coupon purchased, the participant received a different coupon that could be used to purchase surplus foods. That FSP program only lasted until 1943. The next such program, called the Pilot Food Stamp Program, was initiated in 1961 by President John F. Kennedy. The Pilot FSP lasted until 1964, when the Food Stamp Act was passed, and brought about the system of food stamps that prevailed until the SNAP program came into existence in 2008.

In the past, the Food Stamp Program used paper coupons or stamps that were worth various denominations and were color coded. Brown-colored coupons represented $1.00, blue-colored coupons represented $5.00, and green-colored coupons represented $10.00. Today, SNAP benefits are available through an Electronic Benefits Transfer (EBT) card, which operates much like a debit or prepaid credit card. The transition from stamps and coupons to EBT cards was authorized by the Food, Conservation, and Energy Act of 2008 on June 18, 2008, which was enacted over President George W. Bush's veto. Some of the benefits to using the EBT system over paper food stamps are that there are no minimum dollar amounts per transaction, fraud prevention, personal security, and increased privacy.

SNAP benefits can be used to buy breads, cereals, fruits, vegetables, meats, and dairy products. SNAP benefits may be used to purchase seeds and plants which produce food for the household to eat. In certain locations, some restaurants are authorized to accept SNAP benefits from qualified homeless, elderly, or disabled people. SNAP benefits cannot be used to buy alcohol of any kind, nonfood items, or hot foods.

The number of Americans receiving food stamps reached 39.68 million in February 2010, the highest number since the program's inception in 1962. In 2006, an average of 37 million individuals were eligible for food stamp benefits each month, and 25 million received them. From 2005 to 2007, Arkansas, Illinois, Kentucky, Maine, Missouri, Oregon, Tennessee, and West Virginia had significantly higher participation rates than two-thirds of the States; and California, Colorado, Kansas, Nevada, and Wyoming had significantly lower rates than two-thirds of the States in all 3 fiscal years. The rate of SNAP participation appears to correlate to the rate of poverty. Those areas with the highest concentration of persons below the federal poverty guidelines are the areas that have the highest participation.

To receive food stamps, everyone in the household must meet certain income requirements, have or apply for a Social Security number, and be either a US citizen, US national, or have status as a qualified alien. Most able-bodied people between the ages of 18 and 60 must register for work to participate in an employment or training program to qualify for food stamps. Some college students also may be eligible.

To meet the income requirements, the entire household cannot have more than $2,000 in resources. However, if the household includes a person older than 60 years of age or who is disabled, the resource limit is $3,000. Supplemental Security Income (SSI) or benefits under the Temporary Assistance for Needy Families (TANF) program are not counted as income for food stamp purposes. Financial resources include cash, bank accounts, real estate, vehicles, and other property.

Some exceptions to financial limitations exist. For example, an applicant's primary home and the land it sits on are not considered resources when determining food stamp eligibility. Most states now use TANF rules on vehicles. Licensed vehicles are not counted if they are used for income-producing purposes, needed for long distance travel for work (other than daily commute), used as the home, needed to transport a physically disabled household member, needed to carry most of the household's fuel or water, or if the household has little equity in the vehicle (less than $1,500, if sold). If a vehicle has a fair market value or equity value more than $4,650.00, it is counted as a resource. The applicant may qualify for other income exclusions if it includes a person age 60 or older or disabled. The income limits are different for different household sizes and may change each year.

Some non-US citizens are eligible for food stamps without a waiting period. Those "qualified aliens," as they are termed in the legislation, include legal immigrant children under the age of 18; blind or disabled legal immigrants who receive disability benefits; individuals born on or before August 22, 1931, and who legally resided in the USA on August 22, 1996; lawful permanent residents who are active duty members or veterans of the US armed forces or a spouse or a child of a veteran or active duty service member; certain refugees; certain asylees; certain deportees; Cuban or Haitian entrants under §501(e) of the Refugee Education Assistance Act of 1980; and Amerasian immigrants under §584 of the Foreign Operations, Export Financing and Related Programs Appropriations Act of 1988.

The following legal non-US citizens are eligible for SNAP, even though they are not qualified aliens: Hmong or Highland Laotian tribal members and their spouses and children who helped the US military during the Vietnam era; American Indians born in Canada; and members of Indian tribes under §4(e) of the Indian Self-Determination and Education Assistance Act.

Certain qualified aliens are eligible only if they have lived in the USA for 5 years in qualified status. These individuals include lawful permanent residents; parolees who have been paroled for at least 1 year under §212(d)(5) of the Immigration and Nationality Act (INA); conditional entrants under §203(a)(7) of INA in effect prior to April 1, 1980; and battered spouses, children, or the parent or child of battered persons with a petition pending under §204(a)(1)(A) or (B) or §244(a)(3) of INA. (In this context, the term "parolee" refers to a category of individuals under the US immigration law, not someone who has been paroled from prison.)

During the SNAP application process, an applicant should provide identification: proof of income, proof of living expenses (such as child care; rent receipts or mortgage payments, and utility bills), any medical bills for household members who are aged 60 or older, and, if applicable, government payments such as Social Security or SSI for household members who are disabled.

Even though SNAP is a Federal program, SNAP is administered at state and local levels. An applicant can apply at any Social Security office if the applicant is currently receiving SSI benefits and if there is a food stamp representative at that office. Otherwise, an applicant must apply in person at one of the state offices. Currently, there are a few states that allow applicants to apply for SNAP benefits online.

The number of SNAP recipients has increased each year since 2000. The number of children receiving SNAP benefits rose from approximately 8.7 million in

2000 to 12.6 million in 2007. The number of children receiving SNAP benefits rose from approximately 8.7 million in 2000 to 12.6 million in 2007. Congress allocated $54 billion for the SNAP program in 2009, a marked increase from the $39 billion in 2008. Currently, the SNAP program feeds approximately one in eight adults and one in four children. So long as poverty continues to increase in the USA, the need for programs such as SNAP will remain.

Foreign Medical Graduates

Cristina Gavrilovici
Department of Legal Medicine, Medical Deontology and Bioethics, University of Medicine and Pharmacy "Gr. T. Popa", Iasi, Romania

International medical graduates are a growing category of highly educated immigrants spread all over the world. Some of them study abroad and come back to their country of origin; some go to another country, eventually pass the license exam, and try to find a job position in the host country. Both situations are challenging in terms of professional performance, social adjustment, personal fulfillment, and well-being.

It is well acknowledged that there are psychological and emotional problems confronting graduate medical students and doctors in general, whether they are immigrants or not. The prevalence of psychological distress exceeds that of general population. Moreover, the psychological distress of these students in low-income countries appears to be higher than in Western countries. For international medical graduates, these issues are even more sensitive. It is inevitable that becoming an international student is a transition that will challenge an individual and his or her sense of well-being. Some of these students tend to suffer from poor health during their overseas stay.

Many of their concerns are traditionally overlooked. For international students, an unfortunate aspect of living and studying overseas can be the experience of perceived abuse or exclusion from involvement in activity or interaction with others. When abuse occurs, it is most likely to be verbal abuse or feeling excluded. One concern is whether the abuse experienced by international students is culturally motivated. Students who have reported abuse have had significantly stronger perceptions of being treated differently in the host country because of their cultural background than those who did not.

There is some evidence that international students are at high risk of psychological problems. A study of international medical graduates in a large Australian university found that there are some changes in health and risk behavior. About one-third of the students evaluated their health as being only fair, almost one-fifth reported a considerable or strong adverse effect of their health on work, and about 10% had entertained suicidal thoughts. A small but worrying minority had begun using hard drugs, gambling, or smoking, and one quarter had increased their drinking, some to a considerable degree. In a large Finnish study of international medical graduates, one-third of medical students and young doctors reported mental health problems that required treatment.

Loneliness, tiredness, sadness, and worrying are reported as a frequent source of problems. Even more, some of them may develop elevated levels of depression, anxiety, and stress, as well as a rise in the occurrence of syndrome-like tendencies resembling paranoia, anxiety, depression, and somatic complaints. Given the conceptual basis of the anxiety scale – a prolonged period of coping with demands for high achievement that are extremely important for the person to meet if self-esteem is to be maintained – it is not surprising that international students have reported higher than average levels of anxiety. Local students on the whole tend to have better mental health than students from the other countries. Despite an increased need for treatment, there is no corresponding increase in care-seeking, most of the evidence showing an inappropriate health care use among international medical graduates. One reason for this may be the stigma attached to having a mental disorder. Studies have found that the more symptoms of serious personality problems reported by individuals, the less likely they were to seek help. Other reasons for these tendencies were attributed to certain psychosocial factors such as information received regarding study opportunities, social contacts with other tenants, and future job opportunities.

Among the factors that influence well-being in a new culture are similarities between the culture of origin and the host culture (with greater differences suggesting increased difficulty in adjustment), gender, age, and situational variables such as length of stay. Age and gender are two key factors identified in the research literature but have not been consistently found in research studies. In general, female students have shown greater levels of psychological distress than male students and have experienced a higher rate of physical abuse and sexual harassment than male students, thus indicating lower levels of safety, greater experience of bad treatment, and more instances of self-harm or ideation among female students. Female students have reported more diagnoses of sexually transmitted diseases. These changes may be due to some changes in patterns of sexual activity, especially for those whose home country had strict cultural constraints on sexual interaction, especially for young females. There is some evidence for initiation of sexual activity in Australia, with the change more apparent for female than male students.

It is generally thought that the longer international students spend in the host country, the greater their adaptation. On the other side, while sociocultural adjustment relates to length of stay, psychological adjustment does not.

There is a growing recognition that students' academic performance is related to their health and social and psychological well-being. Poor health can make it difficult to maintain the energy and focus on study and work. Occupational status is believed to be particularly important for the psychological well-being of the future immigrant physician, because – more than for other occupational groups – their work role is one that that shapes strongly their self-identity. Immigrant medical students who passed the licensure examination and already obtained a job in their profession have been found to have significantly higher scores on measures of work satisfaction, mood, self-assessed health, self-esteem, and general satisfaction with life than those who did not pass the medical examinations and did not have yet the chance to work as physicians.

For immigrant medical graduate students, obtaining a medical license and finding appropriate professional employment are the first two stages in the process of integration into the medical care system. Success in these two tasks means not only that the immigrants can continue to view themselves as physicians, but also that their self-identity has been socially legitimized by the host society.

Foreign-Born

Beverley Russell
Center for Community Health Education Research and Service, Northeastern University, Boston, MA, USA

The term *foreign-born*, also called non-native, describes persons who are born outside of the country in which they reside currently. Frequently, they are not citizens of their current country of residence. The term *foreign-born* can be used to describe persons who are immigrants or persons who are expatriates. Immigrants are foreign-born people and their families who enter the USA and settle. This is a generic phrase that includes everyone from the US-born children of foreigners, to naturalized citizens, to the undocumented.

Foreign-born residents can, under certain circumstances, change their status and become citizens through naturalization. For example, foreign-born, like immigrants, can make a commitment to live in a country permanently; or, like expatriates, they can live abroad in another country for an extended period of time with a plan to return to their birth country.

In terms of citizenship, the status of those who are foreign-born differs depending on the country to which one emigrated. There are countries, such as Germany and Japan, where it is very difficult, if not impossible, for the foreign-born to become citizens. In countries such as Canada and the USA, foreign-born can become citizens.

The foreign-born living in the USA include immigrants (legal permanent residents), temporary migrants (e.g., students), humanitarian migrants (e.g., refugees), and unauthorized migrants (people illegally residing in the USA). Foreign-born immigrants (legal permanent residents) or nonnatives in the USA cannot vote, although they may work, pay taxes, send their children to school, and serve in the military – much like the citizens of the country in which they reside.

This gap between the voting public and the total population raises important issues about government accountability to residents who cannot vote, and the civic responsibilities newcomers are expected to assume within their communities. In response, several communities across the USA are seeking to grant noncitizen residents the right to vote in municipal and/or school board elections. Today, the practice of noncitizen voting has spread to more than 20 countries around the world, to include communities in New Zealand, Chile, Israel, and all Member States of the European Union. A recent report by the Center for Immigration Studies indicates there are now 35.2 million foreign-born people living in the USA, an estimated 12.1% of the population. With the number of voters potentially hanging in the balance, the result of the proposed legislation to afford the right to vote on local issues will be especially important for many US communities and for those interested in voting as a tool for political incorporation.

Foreign-born immigrants are entitled to the same rights as citizens, although they cannot vote or hold political office. Approximately 40% of immigrants become citizens through the naturalization process. To become naturalized, with some exceptions, foreign-born immigrants must reside in the USA for 5 years and demonstrate a level of English proficiency and knowledge of US history and government.

Location

France, currently the 20th most populous country in the world – population 65.8 million, is a nation located in the western region of the continent of Europe. It is bordered by Belgium and Luxembourg to the northeast, Germany and Switzerland to the east, Italy to the southeast, and Spain to the southwest. It is bordered by or contains also several key bodies of water including the Mediterranean Sea that lies to south of France, where the Principality of Monaco forms a small enclave; the coastline of the Atlantic Ocean that runs along the country's west side; and the English Channel to the north, across which is situated the country's last neighbor, England.

History

Historical records indicate that France has been inhabited since the Neolithic period, while written history begins in France with its invasion by the Romans between 118 and 50 B.C. The Roman legacy is apparent, particularly in the southern part of the country, where Roman circuses are still used for bullfights and music productions. Furthermore, some of the nation's main roads still follow the routes used originally 2,000 years ago. A chief legacy of the Roman Empire is the Catholic Church that still holds great influence in the region.

Charlemagne became emperor of the Roman Empire in 800, and with his rule, society began to shift toward feudalism. The era of the Middle Ages, while characterized frequently as a period of stagnation or decline, can be described also as a complex mix of economic and cultural developments; examples include the music and poems of the Troubadours and the love lyrics of the Trouveres of northern France; the building of Gothic cathedrals; and, economically, recessions owing to pandemic disease and wars.

The start of the sixteenth century marks the end of the feudal system, and France began to emerge as a modern state. Louis XIV, who was king from 1643 to 1715, was a powerful monarch. During his tenure, French influence extended deep into Western Europe. In fact, the French language was used in the European courts and France's culture was exported all over Europe. From Louis XIV's reign through the next century, France expanded to other continents, and a series of French wars developed with England and Spain over control of North America.

The French Revolution began in 1789 and lead to the creation of the Republic. While Napoléon reunited the country and his ambition paved the way for him to rule most of Western Europe, ultimately, that very ambition was his downfall. He was defeated in 1815 by British and Prussian forces; however, he is still revered in some Eastern European countries. Following Napoleon's defeat, France returned to a monarchy and underwent another revolution in 1848, which allowed Napoleon's nephew to be elected president and become emperor. The close of the nineteenth century marked the start of the industrialization of the country, the development of its railways, and the bitter wars with Prussia and Germany.

The separation of the Church from the State, confirmed in France in 1905, was a traumatic process for the nation, particularly in rural areas. Today, the French state is careful to avoid any religious alliance. Under a "don't ask, don't tell" policy, the law forbids French students and civil servants from displaying any sign explicitly revealing their religious allegiance. The mandate applies to such symbols as the Christian cross and the head covering traditionally worn by Muslim women, the hijab. The policy has been copied recently in other countries such as Tunisia and Turkey.

After two world wars in which France lost a large percentage of the male workforce to injury or death, and during which a significant portion of its industry was destroyed, France went through a period of reconstruction, development, and prosperity. France and Germany were at the start of the Treaties that grew eventually into the European Union.

Geography

Metropolitan France is located in Western Europe; in addition to this primary land holding, the country possesses several territories in North America, the Caribbean, South America, the southern Indian Ocean, the Pacific Ocean, and Antarctica. Metropolitan France covers 547,030 km^2, the largest area among European Union (EU) nations; it is approximately 80% the size of the United States' state of Texas. France features a varied terrain, from coastal plains in the north and west to the mountainous Alps in the southeast, the Massif Central in the south-central, and the Pyrenees in the southwest. France also has extensive river systems such as the Seine, the Loire, the Garonne, and the Rhone. Three of the streams flow from east to west, the Seine into the English Channel, the Loire into the Atlantic, and the Garonne into the Bay of Biscay, while the Rhône flows from north to south into the Mediterranean. Excepting the utmost north region, France may be described geographically as four river basins and a plateau.

Including its overseas departments and territories, excluding Adélie Land, France's total land area is 674,843 km^2. France enjoys the second-largest Exclusive Economic Zone (EEZ) in the world; it covers 11,035,000 km^2. An EEZ is a sea zone over which a state has special rights over the exploration and use of marine resources; an EEZ stretches 200 nautical miles from the coast to the seaward edge of the state's territorial sea.

The north and northwest regions of France feature a temperate climate, while the interplay between maritime influences and latitude and altitude produce a varied climate throughout the remainder of the country. A Mediterranean climate prevails in the southeast; in the west, the climate is predominantly oceanic, with a high level of rainfall, mild winters, and cool-to-warm summers; in the Alps and mountainous regions a mainly alpine climate is found, with an average of more than 150 days per year with temperatures below freezing point and snow cover lasting for up to 6 months. At 4,810 m, Western Europe's highest point, Mont Blanc, is located in the Alps, near the Italian and Swiss borders.

Ecology

A study in 2010 by Yale and Columbia Universities ranked France the most environmentally conscious nation of the G-20. By percentage of land area, it is the second most wooded of all EU nations, as forests account for 27–28% of the land. French forests, such as the heavily wooded Vosges Mountains in the northeast and the Pyrenees Mountains in the southwest, are among the most diversified woodlands of Europe, featuring more than 140 varieties of trees. Presently, France has nine national parks, 46 natural parks, and a goal of converting by 2020, 20% of its EEZ into a Marine Protected Area.

An Environmental Charter was included in the French Constitution in 2004. For many decades, France has had as part of the government's cabinet, a member whose function is organized around environmental concerns. Today, the full title of the position is *Minister of Ecology, Sustainable Development, Transport, and Housing*. The current title reflects the influence of the Green party and the pro-environmental movement in French politics over the past decade. The Ministry is responsible for policy on the State Environment, Transportation, Sea, and Housing.

Demographics, People, and Culture

France, the 20th most populous country in the world, has a population estimated in January 2011 at 65.8 million people, of whom 63,136,180 live in metropolitan France, whereas 2,685,705 live in the French overseas departments and territories. In 2003, the nation's natural population growth – the difference of births minus deaths, excluding immigration factors – accounted nearly for all of the natural population growth in the entire EU; the rate rose in 2006 to its highest since the end of the baby boom in 1973.

The French language derives from the Latin dialect spoken by the Romans in Gaul, and includes also many Celtic and Germanic words. Today, French remains one of six official languages at the United Nations and has been a unifying factor in Africa, Asia, the Pacific, and the Caribbean.

A law with origins in France's 1789 Revolution and reaffirmed in the Constitution of 1958 prohibits the French state from collecting data on ethnicity and race. Devoid of official data on the country's ethnic minorities, it has been estimated that 40% of the French population overall is descended at least partially from the waves of immigrants the country has received. Additionally, it is estimated that between three million and six million residents are of North African ancestry, 2.5 million are of Black African ancestry, and five million are of Italian ancestry. Due to more recent immigration, it is estimated that there are presently five million Arab-Berber people and approximately 500,000 Turks living in France.

With a rich culture, diverse geography, and a plentitude of attractions, France has been the world's most popular tourist destination for over 20 years, hosting 81.9 million tourists in 2007. Notable cultural attractions include Paris; the French Riviera; the Atlantic beaches; the resorts of the French Alps; castles of the Loire Valley, Brittany, and Normandy; and world-renowned food and fashion. Just a few of the country's notable landmarks are the Arc de Triomphe, an iconic triumphal arch in Paris; the Calanques, a series of miniature fjords to the south of Marseille; the Chateau de Versailles, France's most exquisite chateau; the Eiffel Tower, a symbol of Paris; and the Notre Dame Cathedral, the landmark cathedral of Gothic architecture.

Education

France has a public education system that is highly centralized, free for children beginning at age 2, and is compulsory between ages 6 and 16. Private education is primarily Roman Catholic. Higher education in France began with the founding of the University of Paris in 1,150 and now consists of 91 public universities and 175 professional schools, including the post-graduate Grandes Ecoles. Private, college-level institutions have been growing in recent years, which feature curriculums structured on the American system of credits and semesters.

Government and Politics

The French Republic is a unitary semi-presidential republic with strong democratic traditions. The constitution of the Fifth Republic was approved by referendum in September 1958, and it strengthened the authority of the executive in relation to the French parliament. France's executive branch has two leaders: the President of the Republic, who is the head of state and is elected directly by universal adult suffrage for a 5-year term; and the Government, led by the president-appointed Prime Minister.

The French parliament has two chambers or houses, a bicameral legislature, comprised of a National Assembly and a Senate. The National Assembly deputies represent local constituencies and are elected directly for 5-year terms. As the Assembly has the capacity to dismiss the cabinet, the majority in the Assembly determines the choice of government. Senators are chosen by an electoral college for 6-year terms; beginning in September 2008, now half of the seats are submitted to election every 3 years. In the event of disagreement between the two chambers, the National Assembly has the final say. The government has a strong influence in shaping the agenda of Parliament.

Economy

Characterized by substantial agricultural resources, a large industrial base, and a highly skilled work force, France has the world's fifth-largest economy. In recent years, the services sector has been increasingly vital to the country's economic activity and has been a critical factor in nearly all job creation. The French government's economic policies are targeted at investment and domestic growth, achieving and maintaining a stable fiscal environment, creating jobs, and reducing the high unemployment rate.

In January 1999, France joined ten other EU countries in adopting as its currency the Euro. Subsequently, monetary policy has been set by the European Central Bank, and on January 1, 2002, France, along with the other EU countries, dropped the national currency in favor of Euro bills and coins. Despite significant reform and privatization over the past 15 years, however, the French government continues to control a large share of economic activity. Government spending, for example, was 55.6% of GDP in 2009, ranking among the highest in the G-7. Furthermore, the government continues to own shares in corporations in a range of sectors, including banking, energy production and distribution, automobiles, transportation, and telecommunications.

France has been highly successful in developing dynamic telecommunications, aerospace, and weapons sectors. It has virtually no domestic oil production and has relied heavily on the development of nuclear power, which now accounts for approximately 80% of the country's electricity production. Agriculture is important also to the French economy. France is the world's second-largest agricultural producer, after the United States. Approximately 17% of all agricultural land within the EU-27 is located in France; France is the EU's leading agricultural exporter. Although the country is expanding its forestry and fishery industries, France remains cautious regarding the cultivation of genetically modified (GM) plants at the domestic and EU levels. The nation is a proponent of the European preference principle and is attentive to protecting its interests in further agricultural trade liberalization at the EU and World Trade Organization (WTO) levels.

Health

France has a universal health care system that is financed largely by the government through a national health insurance system. The World Health Organization noted in its 2000 assessment of world health care systems that France provides the "best overall health care" in the world. In 2005, France spent 11.2% of GDP on health care, a figure much higher than the average spent by countries in Europe. Approximately 77% of health expenditures are covered by the government.

Most general physicians in France are in private practice, although they draw their income from the publicly funded insurance funds. The French government has assumed responsibility for the financial and operational management of health insurance, doing so by setting premium levels relative to income and by setting the prices of goods and services refunded. It generally refunds patients 70% of most health care costs, and 100% in case of costly or long-term ailments. Supplemental coverage may be bought from private insurers, most of them nonprofit, mutual insurers.

Immigration

France has had various waves of immigrants throughout its history. Between 1921 and 1935, for example, an estimated 1.1 million net immigrants settled in France, and an estimated 1.6 million European *pieds-noirs*, French citizens of various origins who lived in French Algeria before independence, returned to France as the country's North African possessions gained independence. During the 1960s, the nation's reconstruction and economic growth led to significant labor-immigration, as employers found workers in villages in Southern Europe and in North Africa. French law facilitated the immigration to mainland France of thousands of ethnic or national French from former colonies of North and West Africa, India, and Indochina.

Since the 1980s, France has continued to be a country of mass immigration. In recent years, immigrants have accounted for one quarter of the country's rebounding population growth. In 2004, a total of 140,033 people immigrated to France. Of them, 90,250 were from Africa and 13,710 from Europe. In 2008, France granted citizenship to 137,000 persons, mostly to people from Morocco, Algeria, and Turkey. According to a 2006 study by the French National Institute for Statistics and Economic Studies, the natural increase is close to 300,000 persons, a level that has not been reached in more than 30 years, while net migration is estimated at 93,600 persons, slightly more than in 2005.

Functional Health

Amy N. Sharpton
Department of Veterans Affairs, Louis Stokes DVA
Medical Center Cleveland, Brecksville, OH, USA

Functional health is science-based health care that treats illness and promotes wellness with a focus on the unique aspects of each patient. Interventions are tailored uniquely for individuals and are aimed at restoring physiological, psychological, and structural balance. Functional health can be thought of in terms of an optimal quality of life, as well as the absence of disease.

Functional health has been shaped by four core concepts: the biochemical individuality of each patient; the interconnectedness of organ function; a patient-centered approach; and the health and disease continuum.

Dr. Roger Williams is credited with coining the term "biochemical individuality." He discovered anatomical and physiological variations among people and how they related to their individual response to the environment. With efforts such as The Human Genome Project, the field of biochemical individuality has revolutionized how medicine views genes and their function. The genetic structure is no longer seen as "rigid" as previously considered. In terms of achieving functional health, due to differences at the biochemical level, what is an appropriate and effective treatment for one patient may not be for another.

A core aspect of functional health is the recognition of the interconnectedness of organ function. Chronic illnesses, for example, often comprise multiple organ systems and are only resolved as a complex system. Working on digestion, for example, without working on detoxification or immunity may be ineffective.

A patient-centered approach involves treating the patient as an individual with a specific history, genetic makeup, hormones, and lifestyle. Furthermore, there is collaboration between the provider and patient. Patient questions are encouraged, and the patient takes an active role in his or her care.

The view that health and disease is a continuum is the recognition that health is a relative state with illness. Disease and death are at one end of the continuum, and health and vitality are at the other. By understanding that most systems operate somewhere between dysfunctional and optimal levels, health is judged as interconnected.

Functional Health Literacy

Functional health literacy refers to individual level skills that move beyond readability and empower an individual to obtain, process, and use health information and services to make decisions and take actions. Functional health literacy includes skills necessary in the navigation of the complex health care system, includes prose, document, and quantitative literacy, and the ability to engage in the exchange of oral communication. The relationship between literacy and health is complex, impacting health knowledge, health status, quality of care, and access to health services.

Physical Activity Guidelines

The US Department of Health and Human Services reports that functional health affects all ages, sexes, and socioeconomic subgroups. Of particular focus is the functional health of older adults – since impairment disproportionately affects this age group. Additionally, it is difficult to define for older adults what is good functional health, because frequently there is an incongruity between what older adults think they can achieve physically and what they actually can achieve. Regarding other age groups, functional health may be an issue at earlier ages because of the overall absolute lack of physical fitness.

G

Gambling

Wooksoo Kim
School of Social Work, University at Buffalo, The State University of New York (SUNY), Buffalo, NY, USA

The last several decades have been marked by the increased availability and accessibility of legalized gambling. The biggest contributor to the increase – the "democratization" of gambling – was the lottery, which has been a successful funding source in many states. Because they require little skill to play, involve a relatively small monetary risk, and offer wider accessibility, lotteries are played by people from every socioeconomic level and every age group. Casinos have also attracted more people to gambling – especially older adults after their retirement – for its purported entertainment value and resort-like environment. More recently, Internet-based gambling has seen rapid growth among younger generations of gamblers. As the availability and accessibility of gambling has increased, the 12-month prevalence rate of gambling behavior in the United States has increased from 61% in 1974 to 82% in 2001. The growth of gambling has been accompanied by a growing number of gambling problems. Current research indicates that nearly 1 in every 20 people in the United States is considered to have a problem or pathological gambling issue.

Immigrants may be most vulnerable to developing gambling-related problems for several reasons. Because of the seemingly large and quick rewards for relatively little effort, gambling is more prevalent among disadvantaged populations, i.e., minorities and people with lower socioeconomic status. With fewer financial resources and the expectation of better living, immigrants may be at a higher risk of gambling than the established population. In addition, cultural attitudes may increase the propensity for gambling and, consequently, a higher incidence of problem gambling. For example, the Chinese culture accepts and encourages gambling among friends and family for entertainment or cultural holidays. *Mah-jong*, a popular Chinese game, is frequently played at family parties or celebratory occasions and children learn to play *Mah-jong* from family members. Because of the cultural attitude toward gambling, they may not consider such social activities gambling. Finally, acculturation may contribute to increased levels of gambling for two reasons. First, immigrants who successfully adapt to the host culture act more like the established residents in the new environment with more gambling activities. On the other hand, as immigrants experience the adverse effects of acculturation, they may engage in gambling as a negative coping strategy, responding to emotional and psychological difficulties. The availability and accessibility of gambling is critical to the growth of gambling among immigrants. Sociocultural environments play such a critical role in immigrants' adaptation in which even members of the same ethnic group could exhibit different patterns of addictive behaviors depending on where they migrate.

Given the limited amount of research on gambling among immigrants, the most critical issue is lack of empirical knowledge. Although many immigrant cultures may have permissive attitudes toward gambling, they also stigmatize problem gambling (i.e., excessive gambling). This paradoxical attitude calls for additional research on the gambling issue. The stigma of problem gambling, along with the cultural definition of gambling as entertainment, may be reflected in the low rate of reported gambling and work as a barrier to treatment for people in need of help.

Gangs

Gary Edmunds
Center for Minority Public Health, Case Western Reserve University, Cleveland, OH, USA

Gang organizations have existed for more than 150 years in the USA. As an example, gangs of Irish and Italian immigrants proliferated in cities on the east coast of the USA during the nineteenth century. Five critical periods have affected the social and organizational development of gangs: the Great Wave of Immigration, the Expansion of Industrial Production (1940s through 1960s), the Deregulation of the Illicit Drug Market (1970s and 1980s), the Escalation of Mass Incarceration (1980s to present), and the Proliferation of Monopolistic Market Activity. Two factors are common to all five periods: poverty or a limited family income and worsened opportunities for socioeconomic mobility. These factors rendered gangs increasingly attractive.

In 2002, the National Youth Gang Survey estimated that there were 21,500 gangs in the USA, comprising approximately 731,500 gang members. Eighty-five percent of these members were believed to reside in large cities. According to the 1999 National Youth Gang Survey, almost one-half of all gang members were Hispanic/Latino, approximately one-third were African American, 13% were non-Hispanic White, 7% were Asian, and 3% were categorized as "other."

There are various forms of collective behavior that may occur; the absence of a standard definition for "gang" makes it difficult to distinguish between these activities. Bands can have a leader but lack a group organizational structure, or they can be a collective of individuals who act without a leader to oppose or attack something ("ganging"). A "crew" consists of three to five individuals who are organized specifically to commit theft. "Posse" refers to Jamaican groups that are organized for the sale of illegal drugs. The term "syndicate" refers to a group that is organized to engage in a wide range of legal and illegal businesses. In lower class communities impacted by poverty, racism, disenfranchisement, and low levels of social control, these forms of collective behavior are often characterized by territoriality, illegality, and self-definition.

Gangs can be thought of as being of first, second, or third generation. First generation gangs are generally localized to their own "turf" or territory and have a loose leadership structure. Their activities tend to be opportunistic. Second generation gangs are organized along the lines of a business with a central leadership and broader reach. They have a market orientation instead of a turf orientation, with much of their activity centered on drug trade. Third generation gangs are highly sophisticated and operate in a global environment, seeking increasing power and financial acquisition.

A gang is considered to be transnational if it has one or more of the following characteristics: (1) the gang is criminally active and operates in more than one country; (2) the criminal activities committed by gang members in one country are planned, directed, and controlled by gang leaders in another country; (3) the gangs are mobile and able to adapt to new areas; and (4) the criminal activities are sophisticated and transcend borders. However, because there is no standard definition for a transnational gang, the lines between transnational gangs and organized criminal enterprises are unclear. Transnational gangs are known to exist in the USA and other countries and have included Asians, Russians, Africans, Serbians, Bosnians, and Jamaicans, as well as individuals of other ethnicities and nationalities.

Two predominantly Latino gangs, Mara Salvatrucha (MS-13) and the Calle 18 (18th Street Gang or MS-18), have spread from the Los Angeles, California, area to other areas across the USA and elsewhere, becoming, in effect, transnational. MS-13's members include former Salvadoran guerillas and government soldiers with extensive combat experience; the gang has become notorious for its use of violence and brutality. MS-18, originally formed by Mexican migrants who were excluded from other Latino gangs in Los Angeles, became one of the first multiracial, multiethnic gangs in Los Angeles. MS-18 members in the USA now distribute drugs for Mexican and Colombian drug traffickers. MS-13 and MS-18 gang members may be involved in smuggling operations and could potentially use their skills and resources to smuggle terrorists into the USA; however, there is no indication that this has yet occurred. Because Central American immigrants live in some of the toughest areas of Los Angeles, they are frequent targets for existing gangs and gang recruitment.

MS-13 is now active in 33 states in the USA and various Central American countries. Most of its members are originally from El Salvador, Honduras, and Guatemala but have lived most of their lives in the USA. In some Central American countries, MS-13 has achieved the status of a third generation gang. The deportation of gang members to their countries of origin has facilitated the establishment of these gangs in Central America and the transport of new and longer-term gang members to the USA through illegal channels. The incarceration and deportation of the gang members from the USA has not been a successful law enforcement strategy but has resulted, instead, in the export of violent individuals to vulnerable Central American communities and the establishment, reinforcement, and expansion of these gangs throughout the USA and Central America.

Gatekeeper

Anahí Viladrich
Department of Sociology, Queens College, City University of New York (CUNY), Flushing, NY, USA

The term gatekeeper has been customarily used to refer to the role of primary health specialists (usually a general practitioner or family doctor) that serve as main points of entry into the health system. The positive nuances of this term call attention to physicians' role in providing first-hand responses to their patients' needs. In this model, the doctor gatekeeper resembles the traditional family doctor who works holistically with patients and families within their communities at large.

Gatekeepers serving at community health centers, such as those treating minorities and immigrant populations, can play a pivotal role in health promotion and disease prevention particularly among disadvantaged communities. On the basis of knowing immigrants' needs well, they are in an optimal position to respond to their most pressing medical issues while coordinating needed referrals in an efficacious way – thus saving key resources, mostly money and time. Culturally versed gatekeepers also play important roles as "health brokers," particularly by understanding their immigrant patients' cultural beliefs (including being fluent in other languages), so they may be in a unique place to help them navigate the health system. Recent research has shown the "brokering" role that foreign doctors play in facilitating access and utilization of health care services to members of their same ethnic aggregate or national group.

Gatekeepers are often familiar with, and sensitive to, immigrants' explanatory models of disease; therefore, they may be able to help build bridges between traditional health systems and biomedicine. In addition, given their expertise with foreign patients' cultural and social milieus, gatekeepers may gain their trust and respect, aspects that are key when seeking adherence regarding time-sensitive health issues, such as scheduling children's vaccination and drug therapies for infectious diseases (i.e., tuberculosis and HIV) particularly among vulnerable populations, such as unauthorized immigrants.

Lately, the term gatekeeper has been utilized to designate the functions of primary care physicians in most managed care plans, which are mostly aimed at rationing and limiting the use of health care services. Gatekeepers within managed health care plans may be practitioners of general internal medicine, family medicine, pediatrics or obstetrics–gynecology, who are chosen by their patients from a fixed list of physicians. Whichever doctors play the role as gatekeepers, they are selected according to the needs of a relatively healthy "commercial" (i.e., non-Medicare) population of plan members. Within the managed care system in the USA, not only are gatekeepers the first providers with whom eligible immigrant patients get in contact with, but they are also the ones in charge of prescribing most medical procedures. Therefore, gatekeepers are key in managing the total cost of health care by limiting immigrants' access to specialized treatments. In recent years, the managed care system has spurred controversy regarding gatekeepers' role in severely curving the access and use of health services, including restricting admissions into hospitals and lengths of stay. Compared to other developed countries, US doctors are most likely to report their patients' difficulties in affording the rising costs of health care amid the increasing barriers they face in obtaining needed health services.

Critics argue that while doctors' gatekeeping role in the USA has led to lowering both health standards and the overall quality of health care, it has not been successful in controlling rising medical costs. For some authors, the very foundations on which health maintenance organizations' decisions are made are culturally biased, as they represent a population of largely middle-White healthy males that does not reflect the rich ethnic and immigrant diversity in the USA. In addition, although most health maintenance plans are required to have a formal grievance system in place, many patients (particular immigrants and ethnic minorities) are unfamiliar with these regulations. They often have limited knowledge about the required administrative procedures to follow which, together with their limited language skills, may severely restrict their ability to successfully advocate for their health rights. Without policy safeguards, the current physicians' gatekeeping role of most health maintenance organizations could actually contribute to worsen health care disparities, particularly in detriment to vulnerable immigrant populations.

Changes in the role of doctors are seen in other recipient societies as well, including those who still enjoy the benefits of universal health care and national health insurance plans. For instance, despite the fact that all nations within the European Union have ratified the human right to health care, rising national deficits and policy concerns about growing immigration streams have led to tightening the gatekeeping role of primary health doctors in those countries. Doctors' new roles tend to limit the access to specialized care available to documented immigrants and to discourage the use of primary health care services among unauthorized individuals. In England, for instance, efforts to reduce costs have led to proposals aimed at ending the figure of the family doctor as the main first point of contact for patients within the National Health Service. Nurses will be playing that role now, thus creating an additional barrier between immigrant patients and their doctors.

Gender

Cristina Cazacu Chinole
Center for Ethics and Public Policies, Bucharest and Iasi, Romania

The term "gender" has been used in social sciences for decades, yet it has entered only recently in general usage. The terms "gender" and "sex" are sometimes incorrectly used interchangeably but they have distinct meanings. While "sex" refers to the biological and physiological characteristics that define men and women, "gender" refers to the socially constructed roles, behaviors, activities, and attributes that a particular society considers appropriate for men and women.

Other definitions emphasize that "sex" refers to being male or female according to reproductive organs and functions assigned by chromosomal complement, and "gender" refers to socially defined and derived expectations and roles rooted in biology and shaped by environment and experience. In other words, while aspects of sex are more or less the same between different human societies, aspects of gender often vary greatly. People are born female or male and then learn to be girls and boys and later, to be women and men. It is the learned behavior that makes up gender identity and determines gender roles.

According to World Health Organization definition, the different roles of men and women are prescribed by society. Men and women have different opportunities; often women have fewer opportunities and limited access to resources that may be available for men. In most societies, women have less power to make decisions, exercise their human rights, including those related to protecting health and seeking care in cases of ill health. But men and women as such are not a homogenous group, as what it means to be a man or a woman varies across cultures, races, and classes. Gender differences vary in intensity, as a result of the interplay of these factors.

Yet, what is common throughout all cultures is the historically configured relationship of subordination of women to men. This imbalance of power has a pervasive influence in many aspects of women's and men's lives, rendering them differentially vulnerable.

As men and women assume different roles and responsibilities, this sexual division of labor involves differential health risks. The female immigrants' experiences and needs are qualitatively different from those of men; this in turn has a different effect on their health.

It is important to take into account gender differences in the migratory process. Gender roles have a direct effect on who migrates, why and where, and how the decision is made and have an impact on the migrants themselves and on their health. Existing research demonstrates that migration may offer new opportunities for women to improve their lives and escape oppression, but sometimes it exposes women to new forms of vulnerability and oppression, exclusion or isolation as it entrenches traditional roles.

There is a need for further studies about the health and well-being of migrant populations, which include a gender perspective. There are many unanswered questions about the way in which gender interacts with other social health determinants and affects the health of migrant populations.

Gender Role

Andrea M. Przybysz
Case Western Reserve University School of Law,
Cleveland, OH, USA

As gender dynamics and the model for the traditional family have changed, immigrant concepts of gender roles and the traditional family have also changed. Historically, in the United States, new immigrant families tended to look like the television American families of the 1940s and 1950s, a time before women had careers, biracial marriages were considered normal, and children were purposefully born outside marriage. Today new immigrant families are experiencing a paradigm shift based on trends that American society has seen generally. So, where women are succeeding in the workplace and have a greater chance at upward mobility, this trend extends to immigrant women, and is important to immigrant health for several reasons.

First, where immigrant women have a greater chance of success than their husbands, husbands face an increased risk of depression and feelings of inferiority. Some immigrant women may be uncomfortable with the role due to an ingrained belief and greater satisfaction in being good wives and tending to family concerns. It is worthwhile to note that not all immigrants arrive to their host nation uneducated and underfunded. Malaysian women, for example, hold 50–60% of their nation's technology jobs such that if and when they immigrate, they typically are relocating to advance already strong careers.

But, in the alternative case of Malaysian women immigrating for other reasons, women accustomed to being the family's breadwinner may face misery if forced to quit work or unable to find a job. These feelings may parallel the feelings Latino men (in the machismo model) endure when struggling to find work in their host countries. This phenomenon suggests that it may not be necessary, at least initially, for immigrants to acculturate or incorporate the host culture's gender dynamics into their own cultural repertoire. Consequently, what is important to one's well-being, at least initially, is the opportunity to adhere to the individual's known and core set of beliefs regarding gender identity and conformity whether or not those beliefs are consistent with what Western society accords as progressive and in line with cultural mores. As time goes on, however, the need to acculturate and subscribe to the host culture's notion of gender roles increases (the acculturation hypothesis). According to the acculturation hypothesis, individuals, particularly women, who do not successfully incorporate new gender ideals into their ideology risk higher rates of mental illness.

Instead, women who immigrate with their partners do best by initially preserving their gender perspectives and ideas of proper gender roles. Unfortunately, little research has been devoted to the ways in which women who remain in their country of origin cope when their husbands emigrate. When husbands emigrate in hopes of finding a job that pays wages sufficient to send to their families back home, women necessarily expand their household roles, and subsequently, their gender roles. As a result of new gender roles and responsibilities, many women experience increased anxiety and depression. Preliminary evidence suggests that women who marry and conform to traditional female roles more readily oppose alternative egalitarian ideologies of gender.

The androgynous model coincides with the prevailing belief that gender roles are not intrinsic or biologic forces, but rather forces affected by environmental factors. Environmental factors that influence changing gender roles include gains in education, religion, the workplace, and historically masculine activities. The androgynous model also espouses the notion that how well a woman who remains behind adapts to environmental changes bears directly on her partner's success abroad. Regrettably, where successful adaptation aids a man's well-being abroad, statistically, successful adaptation adversely affects the woman's psychological well-being. It appears that the women who weather their partner's absence best, tend to do so by relying on the culture's traditional gender roles. This suggests that when women immigrate, it is best, at least for a time, to maintain one's core notions of gender. This is not, however, to say that gender ideals are stagnant. Attitudes on gender roles vary with time and between generations.

It is possible that the longer one is in a country (once she or he begins to acculturate by choice), or the longer one is in a situation involving increased obligations, the nervousness associated with stepping out of one's traditional role reasonably dissipates. But, changing ideology is a difficult process that takes much time and introspection; gender roles – perhaps some of the most ingrained roles in society – will not go lightly. It is worthwhile, particularly given today's constraints of dispersed and temporarily dispersed families, to determine whether education on gender roles where gender is introduced as a topic which is broad and androgynous, opposed to hyper-feminine or hyper-masculine, would help alleviate some of the initial tensions individuals face during the process of immigrating.

Based on the idea that gender roles and attitudes are difficult to alter, it seems that the best approach for low-income immigrants is to facilitate a gradual adjustment. While this may not be the most economically successful scenario in today's world, a world opening to women more quickly than to men, and while this scenario may not be feasible in terms of practicality in moving entire families, it is likely the easiest way to preserve the typical family model and permit immigrant families to adjust slowly to new gender roles.

It is also important to recognize that females and males, beyond gender conformity issues, are faced with very different problem sets when they immigrate. Researchers should encourage health care intervention efforts that consider not only a cultural perspective, but also consider a gendered perspective and analyze results accordingly. A case study of Carribean immigrants best illustrates this point. Research has found that female Caribbean immigrants tend to identify personal problems and an inability to adjust as their most significant stressors. When these problems are significant, female Caribbean immigrants tend to experience higher levels of negative physical health and depression. Male Caribbean immigrants, on the other hand, report loneliness. While an inability to adjust and loneliness are arguably related issues, male Caribbeans fair better with increased social networking. Female Caribbeans responded well to community and ethnic-related social events, and benefit from counseling and health and benefit from education.

Gender-Based Violence

SUSAN HATTERS FRIEDMAN
Departments of Psychiatry and Pediatrics,
Case Western Reserve University School of Medicine,
Cleveland, OH, USA

Gender-based violence (GBV) is a term which encompasses a harmful act against someone's will, which occurs based on gender or sex. It can occur within the family or within the community. Most acts are not perpetrated by strangers, but rather by the very people upon whom the victims depend. GBV violates universal human rights in addition to usually being unlawful. Typically a female victim is more vulnerable to violence and has a lower status in society. Often the term is used interchangeably with Violence Against Women; however, men may also be victims of sexual violence based on gender – for example, when they are detained.

GBV can occur at any time in life. Cross-culturally different types of GBV occur. GBV includes not only domestic violence but also a range of offenses including sexual violence, trafficking, forced prostitution, rape by armed combatants in wartime, sexual slavery, harmful traditional practices (forced marriages, sex-selective abortions, honor killings, genital mutilation, and denial of education), sexual harassment, and confinement.

Research shows that certain groups are more vulnerable to GBV victimization than others. Those who are more dependent on others and who lack power in a society are more at risk. These groups include: single women (who may be heads of household), orphans and unaccompanied children, working children, child soldiers, the disabled, and the elderly. Refugees, internally displaced persons, and those in war-torn nations are at elevated risk as well.

Often victims do not report the crime because of fear of reprisal, self-blame, and stigma. GBV may ultimately end in homicide or suicide. Physical injuries, pregnancy, and sexually transmitted disease may also occur. Psychological consequences include post-traumatic stress disorder, depression, or anxiety.

The UN estimates that across the world, one-third of women have been victimized by a beating, forced sex, or other abuse. Further, statistics indicate that approximately two million women are trafficked each year, 90 million African women have experienced genital mutilation, more than 20,000 women were raped during the Bosnian war, and over 250,000 women were raped in the Rwandan genocide.

Prevention of GBV entails changing sociocultural norms which tacitly support GBV, rebuilding family connections and support systems, and empowering women and girls of all ages. A recent study found that immigrant status and its social context may have some protection against dating violence, a type of GBV.

Another recent study discussed targeting not only the micro level for prevention, but also the meso level (social organizations) and the macro level (beliefs about corporal punishment common in the immigrant group, for example).

Before any treatment of victims can proceed, it is important that members of the group be aware of the problem, and how and where to report GBV. Actions suggested by the UN include community awareness activities, training about response (including medical, psychological, and psychosocial needs as well as the justice system response), planning of reporting/monitoring/evaluation, empowerment of the immigrant community's response, and a plan to work with the abusers.

In treatment, ensuring confidentiality and physical safety are paramount. Maintaining compassionate non-judgment and respectfulness is important. Documentation of GBV is vital for the purposes of later proof. Support groups may be very helpful for immigrant women involved in GBV situations. Women may be provided a safe place to talk, taught about management of situations, and are encouraged to become less dependent on their abusers, moving toward self-sufficiency. Developing a common understanding of GBV and their situation is critical.

Genocide

Archana Brojmohun[1], Domenic Craner[2]
[1]Department of Psychiatry, University Hospitals Case Medical Center, Cleveland, OH, USA
[2]Cleveland State University, Cleveland, OH, USA

The term genocide was coined in 1944 by the Polish Lawyer Raphael Lemkin and is defined as the deliberate and systematic destruction of a racial, political, or cultural group. In 1944, the General Assembly of the United Nations adopted the Convention on the Prevention and Punishment of the Crime of Genocide (CPPCG), which was eventually ratified by 140 nations, including the United States in 1986. The CPPCG characterizes genocide as follows: Genocide means any of the following acts committed with intent to destroy, in whole or in part, a national, ethnical, racial, or religious group, such as killing members of the group, causing serious bodily or mental harm to members of the group, deliberately inflicting on the group conditions of life calculated to bring about its physical destruction in whole or in part, imposing measures intended to prevent births within the group, or forcibly transferring children of the group to another group.

Genocide is not a "new world" novelty. In fact, there is archeological evidence suggesting that genocide might have taken place as early as the Stone Age. However, the twentieth century has been described as being "a century of genocides" with the worst massacres taking place, the most significant being the Holocaust. Other notable and more recent genocides took place in China (1959, 65,000 victims), Indonesia (1965–1966; 0.5–1 million victims), Guatemala (1978–1986; 60,000–2,00,000 victims), Uganda (1972–1979 and 1980–1986; up to a million victims), Burma, now known as Myanmar, (1978; 5,000 victims), Bosnia (1992–1995; 2,25,000 victims), Burundi (1993–1994; 50,000 victims), and Rwanda (1994; 0.5–1 million victims).

When discussing genocide and its effect on the world especially through immigration, it is important to understand the effects that genocide has on a population as a whole, as well as understanding the reasoning behind the acts being committed.

The genocide of a population stems from numerous issues. Looking back in time at one of the most infamous genocides of a population, the Holocaust, which occurred before and during World War II, the root issue is seen as Hitler's attempt to create the "perfect" Aryan race of people, referred to as eugenics. During this time Hitler also targeted those of Jewish heritage and attempted to use them as a scapegoat to explain Germany's economic woes.

One of the major genocides of the twentieth century happened in Rwanda, where up to one million people are believed to have perished. The strife was mainly between two groups of people, the Hutus and the Tutsis. In 1998, the International Criminal Tribunal for Rwanda made the landmark decision that war rape in Rwanda was an element of the crime of genocide. The Trial Chamber held that "sexual assault formed an integral part of the process of destroying the Tutsi ethnic group and that the rape was systematic and had been perpetrated against Tutsi women only, manifesting the specific intent required for those acts to constitute genocide." There was evidence to suggest that military leaders encouraged or even ordered their men to rape Tutsi women as well as condoned the acts taking place. The sexual violence in Rwanda stands out in terms of the organized nature of the propaganda that contributed significantly to fueling sexual violence against Tutsi women, the very public nature of the rapes, and the level of brutality toward the women. Therefore it is important not to underestimate the psychological trauma cause by sexual violence toward women from areas of genocides since the sexual violence impacts them in many ways, not only physically, but also psychologically to a much deeper level since the goal was to eradicate the Tutsi race.

In countries and regions experiencing the genocide of a people, individuals may be forced to migrate from their native land. These forced migrants, or refugees, are leaving their homelands usually against their will. In many cases, these individuals are unable to return due to persecution. Immigrants from the areas plagued by genocide have multiple health problems, ranging from the most common ones to illnesses specifically occurring in their country of origin. Moreover, psychiatric issues are more predominant in immigrants who come from those areas.

There are numerous barriers to accessing proper healthcare. First and foremost, immigrant healthcare is affected by the socio-political status of the countries of origin, and very often this is unstable, especially politically. Moreover, those people have taken refuge in camps in neighboring countries, resulting sometimes in massive exoduses. Morbidity and mortality rates in refugee camps tend to be extremely high. It is also important to remember that those "transients" have limited access to food and water let alone proper healthcare. They rarely have the basic concept of prompt medical visits as well as the importance of follow up appointments. Language and communication skills are also important barriers. When proper translation and paraphrasing are not available, this can cause a sense of alienation to this already very vulnerable population.

There are many different medical diseases and conditions that the immigrant populations from areas where genocides have taken place are predisposed to. The Immigration and Naturalization Service (INS) recommends screening for tuberculosis, HIV, syphilis, as well as other sexually transmitted diseases, hepatitis B, and parasitic infections, especially if refugees have lived in refugee camps for a significant amount of time. It is important to consider: (1) nutritional status, including growth and development, especially in children; (2) mental health, including screening for anxiety, depression, posttraumatic stress disorder, physical abuse, and substance abuse; (3) infectious diseases, including screening for diseases common to the refugee's country of origin, and (4) preventive screening, including cancer screening often not available in Third World countries (e.g., Papanicolaou [Pap] smears for the detection of cervical cancer). For example, a recent immigrant presenting with fever may have hepatitis, typhus, Q fever, encephalitis, dengue fever, typhoid, viral hemorrhagic fevers, helminthes (worms), malaria, or other infectious diseases that are endemic to the countries where they come from. Diarrhea may be caused by viral infections, Shigella (intestinal bacteria), amebiasis (parasites), cholera, or other unusual causes.

Physical examination frequently reveals dental problems. Common problems in children include anemia, asthma, hypertension, inherited diseases, and orthopedic problems. Refugees may have physical signs related to traditional health practices, such as coining (rubbing of coins over the skin) or cupping (application of heated cups to the skin) that can be mistaken for signs of abuse. Physical signs of trauma and torture, including scars from beatings, whippings, burns, and electric shocks, as well as lacerations may be present. Presentations of unusual diseases are common, including congestive heart failure from cardiomyopathy (enlarged and malfunctioning heart) in Chagas' disease (parasitic infection). A physical deformity or radiograph may reveal old fractures, including those resulting from falanga (beating of the soles of the feet). Female genital mutilation (formerly referred to as female circumcision) is practiced in some societies but can also be a result of sexual violence such as in female survivors of the Rwandan genocide.

This particular patient population has often been through numerous atrocities prior to immigration and thus the impact on mental health is very significant. Women, children, the elderly, and disabled are the most vulnerable. Very often, these patients come from areas of the world where torture and other forms of sexual, physical, and emotional abuse are still prevalent. Some of them have been victims of torture while others have witnessed the torture of loved ones. The World Health Organization (WHO) estimated that, in the situations of armed conflicts throughout the world, "10% of the people who experience traumatic events will have serious mental health problems and another 10% will develop behavior that will hinder their ability to function effectively. The most common conditions are depression, anxiety and psychosomatic (psychologically induced physical complaints) problems such as insomnia or back and stomach aches." In the instance of mental health, forced migration of a population due to genocide can cause many different challenges for a person to face.

In this entry, we will address the most important mental health issues that immigrants from countries plagued by genocides have to face. We will discuss the following:

1. Posttraumatic stress disorder (PTSD)
2. Depression and anxiety
3. Bereavement
4. Cultural assimilation and developmental effects

PTSD is an anxiety disorder that develops after a person sees or is involved in an extreme traumatic event. The person reacts to this experience with fear and helplessness, persistently relives the event, and tries to avoid being reminded of it. Immigrants from countries where genocides have taken place are at high risk of developing PTSD since these people may have experienced and been subject to torture, rapes, mass murders, massive displacements among the many atrocities. Survivors suffer from confusion, anxiety, depression, flashbacks, difficulty concentrating, sleep disturbances, anti-social behavior and acting out.

The physical and mental health problems of the survivors of the genocide in Rwanda have been well documented. In a community based study examining 2,091 subjects, 25% met symptom criteria for PTSD. Respondents who met PTSD criteria were less likely to have positive attitudes towards the Rwandan national trials, suggesting that the effects of trauma need to be considered if reconciliation has to be successful. In another study conducted in two communes close to Kigali, the capital of Rwanda, subjects were asked to freely list problems that occurred after the genocide in 1994. They were also asked to sort pile the problems that occur together as "syndromes." The results suggest that this population experiences depression, referred to as *agahinda* or deep sadness or grief, as a result of the events. They may also experience PTSD which is referred to as *guhahamuka*, or mental trauma. Local people do not classify the effects of trauma into the same depression and PTSD syndromes as in the US. However, these disorders are often comorbid, making distinction between the two syndromes difficult.

Another significant place where genocide happened was in the Balkans. A survey among Kosovar Albanians found that 17% reported symptoms of PTSD. There was a significant decrease in mental health status and social functioning with increasing amount of traumatic events in the elderly and those with psychiatric illnesses or chronic health conditions. In another study conducted on Bosnian survivors of genocide, they were reported of having been severely traumatized as a result of the Serbian nationalists' genocide. Results indicated that individuals were exposed to an average of 16 types of traumatic experiences; 42% met criteria for PTSD.

Depression and anxiety are also very common among immigrants who come from areas where genocides have taken place. Being victims or witnesses of torture, displacement, and losing loved ones may similarly predispose people to anxiety and depression. Depression usually manifests as a low mood most of time, difficulty falling asleep or frequently waking up at night, low energy and poor motivation, hopelessness and helplessness, as well as ruminatory thoughts. In severe cases, depressed patients attempt suicide. Anxiety can manifest as hypervigilance, that is an increased awareness of danger and the surroundings; constant worry about everything in general or as panic attacks which are characterized by the sudden onset of difficulty breathing, nervousness and a sense that something bad is about to happen. In a study that was done in Afghanistan, 39% described symptoms of anxiety. In the study above that was carried out in Kosovo, there were also reports of severe depression.

Immigrants from areas where genocides took place may have interruptions in their ability to adequately cope with the grief and loss they have experienced. Research on traumatic loss, such as someone would face after surviving the genocide of their people, has shown to have stronger, more long lasting effects on an individual which can prolong a survivor's grief symptoms. It has been said that loss through genocide can complicate the grieving process through a variety of ways. For one, according to a research on the Rwanda genocide in 1994, due to the violent nature of the loss in genocide, survivors may be forced to deal with many other stressors brought on by the loss and may be lacking in social support when an individual's whole community is affected. Suffering from PTSD symptoms might also inhibit one's ability to properly grieve for their loved ones. Survivors of genocide might have their grieving process inhibited due to the inability to participate in certain cultural funeral rituals such as viewing the body that promote closure in the loss of a loved one, due to threats or anxiety caused by threats and violence.

In 1995, there were 165,839 widows in Rwanda following the genocide. Research was done on many of these widows to follow their grieving patterns and the widows' ability to properly grieve after the traumatic loss of their husbands. Three years after the loss of their husbands at least 20% of the women who were interviewed by the researchers were considered to be prolonged grievers (or having prolonged symptoms of grief). This complication in the grieving process was attributed to the traumatic nature of the loss these women had faced. The most prominent feeling reported by women who had lost their husbands in the genocide was separation anxiety. Other symptoms reported were mistrust of others, and the feeling that life was meaningless or empty now that their husbands were gone. The study of individuals who have survived genocides such as the one in Rwanda have sparked the debate to include more specific criteria for diagnoses related to grief and loss in mental health.

Genocide carries with it negative psychological effects on a group of people being forced to leave their country. These forced migrants must often discontinue their cultural practices out of fear that those exact practices are what caused the acts of genocide to occur in the first place. Immigrants who have relocated due to these acts may also worry that their cultural practices will not be accepted by those surrounding them in their new land. These fears might create a feeling of forced assimilation into a new culture for those who have been forced to migrate to a new land. Issues such as how a society accepts others from outside can affect an immigrant's ability to continue their rituals and practices that they have held dear up until their forced migration to a new country. Researchers have shown patterns of emotional climates of fear in countries that have experienced genocide or other acts against humanity. This inability to continue with past rituals and cultural practices creates an inability for immigrants escaping genocide to move beyond the experience.

Immigrants from countries where genocides have taken place are vulnerable and at a high risk for the development of certain condition as compared to other immigrants. Most important of all, this patient population deserves a lot of empathy, care, and understanding as they have already been through the worst imaginable atrocities.

Introduction

Germany, officially the Federal Republic of Germany, is a country located in the western and central regions of the continent of Europe. The nation covers an area of 357,021 km^2, and is bordered to the north by the North Sea, Denmark, and the Baltic Sea; to the east by Poland and the Czech Republic; to the south by Austria and Switzerland; and to the west by France, Luxembourg, Belgium, and the Netherlands. With 81.8 million inhabitants, Germany is the most populous member state of the European Union (EU). The country is home to the third greatest number of international migrants worldwide; in 2009, immigrants in Germany comprised 12.3% of the country's total population and 5.4% of the world's population.

History

Beginning in the tenth century, German territories formed a central part of the Holy Roman Empire. During the sixteenth century, northern German regions became the center of the Protestant Reformation; however, the southern and western regions remained influenced by Roman Catholicism. The country was first unified in 1871, with the inception of the German Empire. The German Revolution, from November 1918 until August 1919, followed World War I, and at the formal establishment of the Weimar Republic, it resulted in the replacement of Germany's imperial government with a republic government.

Germany's liberal democracy lapsed in the early 1930s, leading to the ascent of the National Socialist German Workers' Party (NSDAP) and Adolf Hitler in 1933; this year is recognized generally as the end of the Weimar Republic and the beginning of Hitler's Third Reich. The period was marked by a dictatorship and the initiation of World War II. At the conclusion of World War II, during 1945–1949, Germany was divided into four occupation zones – with the United States, Great Britain, France, and the Soviet Union each controlling a zone. Subsequently, Germany was divided into two states, the socialist German Democratic Republic (GDR), informally called East Germany; and the Federal Republic of Germany, informally called West Germany. Germany was reunified on October 3, 1990. The Bonn-Berlin Act was adopted by the parliament in March of 1994, identifying Berlin as the capital of the reunified Germany once again. The act enabled Bonn to hold status as a federal city, thereby, retaining some federal ministries. The relocation of the government was completed in 1999.

Since reunification, Germany has taken a more active role in the European Union (EU) and in the North Atlantic Treaty Organization (NATO). For example, Germany sent troops to Afghanistan as part of a NATO effort to provide security in that country after the Taliban were expelled. Notably, this deployment was controversial. After the war, Germany was bound by domestic law only to deploy troops for defense roles. Although deployments to foreign territories were understood not to be covered by the defense provision, a parliamentary vote on the issue effectively legalized the participation in a peacekeeping context.

The first female Chancellor of Germany, Angela Merkel, was elected in 2005. Supported by her own parliamentary group, she led a grand coalition from 2005 to 2009. Following the general elections in September of 2009, Merkel built the current coalition government that replaced the Social Democratic Party with the Free Democratic Party (FDP).

Geography

Germany is located in the western and central regions of the continent of Europe. The nation covers 357,000 km^2, comprised of 349,000 km^2 of land and 8,000 km^2 of water. In terms of area, it is the seventh largest country in Europe and the 63rd largest in the world. Germany shares borders with more European countries than any other country on the continent: Denmark in the north; Poland and the Czech Republic in the east; Austria and Switzerland in the south; France and Luxembourg in the southwest; and Belgium and the Netherlands in the northwest.

The nation's elevation ranges from 2,962 m in the south in the mountains of the Alps, to the shores of the North Sea in the northwest, and to the Baltic Sea in the northeast. Between these extremes lie the uplands of central Germany and the low-lying lands of northern Germany, traversed by some of Europe's major rivers such as the Rhine, Danube, and Elbe. The most significant natural resources are iron ore, coal, potash, timber, lignite, uranium, copper, natural gas, salt, nickel, arable land, and water.

Climate

Most of Germany has a temperate seasonal climate, with a relatively moderate temperature variation between summer and winter, though temperatures can exceed 30°C for prolonged periods. The climate is moderated by the North Atlantic Drift, the northern extension of the Gulf Stream. This warmer water affects the areas bordering the North Sea, including the area along the Rhine, as it is a contributory to North Sea. Consequently, in the northwest and the north, the climate is oceanic, typified by cool summers, warm winters, and a narrow annual temperature range. As precipitation is dispersed more evenly through the year, ordinarily, it lacks a dry season. Rainfall occurs year round, peaking during the summer. In the east, the climate is more continental; winters can be harsh and cold, while summers can be very warm, with a long dry period. Central and Southern Germany are transition regions that vary from moderately oceanic to continental.

Although the maritime and continental climates prevail over most of the country, the Alpine regions in the extreme south and, to a lesser degree, areas of the Central German Uplands have a so-called mountain climate. This climate is characterized by lower temperatures because of higher altitudes and greater precipitation caused by air becoming moisture laden as it lifts over higher terrain.

Biodiversity

Germany is known for its many zoological gardens, wildlife parks, aquaria, and bird parks. More than 400 registered zoos and animal parks operate in Germany; it is believed to be the largest number in any single country of the world. The Zoologischer Garten Berlin is the oldest zoo in Germany and presents the most comprehensive collection of species in the world.

Culture

Germany is referred to by many as *the land of poets and thinkers*; German culture has a rich and lengthy history, with significant contributions to world literature, philosophy, science, technology, art, music, cinema, religious tradition, and more. German cultural contributions have been influenced by European high culture, Western pop culture, and the globally connected subculture.

In Germany, the 16 federated states manage the cultural institutions. There are 240 subsidized theaters, hundreds of symphonic orchestras, thousands of museums, and over 25,000 libraries spread over 16 states. These cultural opportunities are enjoyed by many millions: there are over 91 million German museum visits every year; annually, 20 million go to theaters and operas; while 3.6 million attend performances by symphonic orchestras. The United Nations Educational, Scientific, and Cultural Organization (UNESCO) has inscribed 33 properties in Germany on the World Heritage List.

Government

Germany is a federal, parliamentary, representative democratic republic that is governed under a framework laid out in the 1949 *Grundgesetz* – translated as *Basic Law* – a constitutional-type document. In the articles of the document are expressed the fundamental principles guaranteeing human dignity, the separation of powers, the federal structure, and that the rule of law is valid in perpetuity. Generally, amendments to the *Grundgesetz* require a two-thirds majority of both chambers of the parliament.

The President is the head of state and is invested primarily with representative responsibilities and powers. He or she is elected by the federal convention, an institution consisting of the members of parliament and an equal number of state delegates. The second highest German official is the President of the Parliament, who is elected by the parliament, and is responsible for overseeing the daily sessions of the body. The third highest official and the head of government is the Chancellor, who is appointed by the President of the Parliament, and who exercises executive power, similar to the role of a Prime Minister in other parliamentary democracies.

Economy

Germany has a social market economy, a mixed economy that seeks to strike a balance between capitalism and the market economic system of socialism, combining private enterprise with government regulation. In 2009, Germany had the largest national economy in Europe and the fourth largest worldwide by nominal GDP. Contributions to the economy by sector are service (70%), industry (29.1%), and agriculture (0.9%). In July 2010, the average national unemployment rate was 7.5%, ranging from 4.1% in Bavaria to 13.6% in Berlin. Germany was the world's largest exporter from 2003 to 2008. Most of the country's export products are in engineering, especially in machinery, automobiles, chemical goods, and metals. Germany is the leading producer of wind turbines and solar power technology in the world.

Notably, more than 2 decades after German reunification, standards of living and per capita incomes remain significantly higher in the states of the former West Germany as compared to states of the former East Germany. The modernization and integration of the eastern German economy is scheduled to last until the year 2019, with annual transfers from west to east amounting to roughly $80 billion.

Demographics

Germany is the most populous country in the European Union; in terms of population, it ranks as the 15th largest country in the world. In January 2010, the nation had an estimated 81.8 million inhabitants and a population density of 229.4 inhabitants per square kilometer. Germany has one of the lowest fertility rates in the world, at 1.4 children per mother, or 7.9 births per 1,000 inhabitants in 2009. Depending on the level of net migration, it is forecast that the population will shrink to between 65 and 70 million by 2060.

Germans comprise 91% of the population of Germany. As of 2004, about seven million foreign citizens were registered in Germany, and 19% of the country's residents were of foreign or partially foreign descent, including persons descending or partially descending from ethnic German repatriates, 96% of whom lived in Western Germany or Berlin. It is estimated by the Federal Statistical Office of Germany that nearly 30% of Germans aged 5 years and younger have at least one parent who was born abroad.

Education

In Germany, the federated states are responsible individually for educational oversight, and the federal government has only a minor role. Kindergarten education is optional and is provided for all children between 3 and 6 years old, after which school attendance is compulsory for a minimum of 9 years. Usually, primary education lasts for 4 years; public schools are not stratified at this stage. Secondary education, however, includes three traditional types of schools: the *Gymnasium* enrolls the most academically gifted children, prepares students for university studies, and attendance lasts 8 or 9 years; the *Realschule* lasts 6 years and has a broader range of emphasis for intermediate students; and the *Hauptschule* prepares students for vocational education. Admission into a school is based on academic ability as determined by teacher recommendations.

Health Care

Germany's health care system has the distinction of being the world's oldest universal health care system, with origins dating back to social legislation in 1883. Currently, the population is covered by a basic health insurance plan provided by statute that provides a standard level of coverage. Private health insurance is available, making available additional benefits. According to the World Health Organization (WHO), Germany's health care system was 77% government funded and 23% privately funded as of 2004. In 2005, Germany spent 10.7% of GDP on health care; ranked 20th in the world in life expectancy with 76.5 years for men and 82.1 years for women; and it had a very low infant mortality rate of 4.3 per 1,000 live births.

Migration

While in the nineteenth and first half of the twentieth century Germany was noted as a country of emigration, since the mid-1950s, the nation has become one of the most important European destinations for migrants. The recruitment of guest workers, the influx of ethnic Germans from Eastern Europe and the former Soviet states, and the reception of asylum-seekers have led to the growth of the immigrant population in the country. On January 1, 2005, Germany adopted a new immigration law that altered the legal method of immigration to Germany, adding new immigration categories to attract professionals for the German labor market. The new law eased immigration for skilled employees and academics; however, for unskilled workers the labor market remains relatively closed.

The United Nations Population Fund lists Germany as host to the third highest number of international migrants worldwide, hosting approximately ten million of all 191 million migrants. Since 2000, as a result of restrictions to Germany's laws on asylum and immigration, the number of immigrants seeking asylum or claiming German ethnicity has been declining steadily. In 2009, 20% of the population had immigrant roots, the highest recorded since 1945. As of 2008, the largest national group of people with a migrant background was from Turkey (2.5 million), followed by Italy (776,000), and Poland (687,000). Large numbers of people with full or significant German ancestry are found in the United States (50 million), Brazil (5 million), and Canada (3 million).

As Germany continues to experience a considerable rate of immigration, the integration of migrants has become a main focus of federal policy – a policy with both economic and social import. Historically, Germany has had an immigration policy by which citizenship was rarely granted, regardless of how long the immigrant had legally resided in the country. Over the past decade, however, there have been several key policy developments. In 2000, for example, a new citizenship law was enacted. For the first time in Germany's history, children born to foreigners automatically receive German citizenship, provided one parent has been a legal resident for at least 8 years. However, if children choose to hold dual citizenship, German and the citizenship of their birth parents' country of origin, they must choose to retain one or the other by the age of 23. In August 2000, Germany introduced a "green card" system to help address that demand for highly qualified information technology experts. However, in contrast with the American green card, which allows for permanent residency, Germany limits its green card holders' residency to a maximum of 5 years.

Although the shift in immigration policy allows some immigrants easier entrance into the country and navigation through the process of citizenship acquisition, frequently still, new immigrants face prejudices and challenges integrating into the native population. Some migrant groups experience higher rates of delinquency and more general integration problems. In spite of police operations and legal measures meant to arrest such behavior, migrants may still be subject to racist assaults. The rate of occurrence is even greater in rural areas or small towns in the former East Germany.

Ghetto

Domnița Oana Bădărău
Department of Bioethics, Case Western Reserve University School of Medicine, Cleveland, OH, USA

When first used in the sixteenth century, the word "ghetto" had a different significance than it has today. Originally, "ghetto" was an area in Venice to which Jews were constrained to live. The Venetian ghetto was meant to diminish the influence of Jews in affairs of the state because this population was often very rich and dominated the commercial activity of Venice. With time, the word came to have a broader significance and to not reflect only areas where Jews live. The ghetto was a form of an ethnic enclave, gathering together people belonging to the same ethnicity. Later it came to mean a population that did not necessarily share the same ethnicity, but belonged to the same social class. Such neighborhoods were the result of social discrimination and racism, as it was impossible for minorities, religious or otherwise, to settle where they chose.

In the nineteenth century such enclaves were formed on ethnic basis as in the USA, due to racial segregation of housing. The mass of migrants in several of the biggest American cities, such as New York, Chicago, and Boston, made it possible for new ethnic enclaves with Italian, Chinese, Spanish, and Jewish populations to rise. This was an effect of the industrialization process which was reinforced by rapid urbanization. In a similar time frame, African American neighborhoods began to form in American cities as a result of the migration of African Americans from the rural South. In order to escape Southern racism, many African Americans moved toward Northern cities seeking employment in the new industrial economy of the north. During the nineteenth century and the beginning of the twentieth century, technological progress led to major changes in demography and urbanization. A new labor force moved from the rural areas to the more developed and industrializing cities. The labor competition was fierce partly because of the large migration of African Americans in a short period of time and partly because of the waves of European immigrants also in search of jobs. As a result, shortages in housing occurred and the new population had no choice but to accept any kind of housing they could afford. Ethnic identity strengthened as they found a common goal in protecting their neighborhoods. The white collar workers moved to suburban residential areas to get away from the pressure created by the new residents and used restrictive covenant clauses to ensure that their neighborhoods would maintain their type of population.

As industrialization created new job opportunities and labor was needed in order to extract natural resources or perform other type of manual labor, more African Americans moved toward the cities. The population of these cities, mostly White, resorted to discriminating actions directed at keeping the newcomers away from their neighborhoods. This practice was called redlining and it denied or made it impossible for African Americans to have access to various facilities such as food stores, health insurance and care, and housing. This contributed to the formation of ethnic districts, preponderantly formed in the USA by African Americans in conditions of segregation, and which came to be called "Ghettos."

Technological and industrial progress brought significant changes in the geography of urban communities, resulting in fragmentation of the urban form. Associated with the economic and social background, this fragmentation translated into the end of a coherent, uniform city and, instead, emerged as an independent city, a melting pot, divided into different social groups. In other words, through time, the formation of ghettos changed in correlation with the economic, social, and political factors. Discrimination and racism in the USA then led to urban decay, which was deepened by the restrictions that the African American population faced. The newly formed ethic enclave was marginalized and denied basic rights.

White flight was a new sociologic and demographic change that put a mark on the evolution of the ghetto. As the minority population was increasing in the cities, the White population was moving to new areas, the suburbs, where it was possible to maintain a restrictive housing policy. Once World War II came to an end, a new wave of African Americans, immigrants from Mexico, and even European immigrants established themselves in large American cities. As a result, social inequalities grew and much of the middle class White population decided to move to more private and quiet areas. This led to a decline in the infrastructure of the cities as the neighborhoods inhabited by African Americans or immigrants were left behind. While the transportation infrastructure to connect the cities with the suburban areas was developing, the city infrastructure was declining, because White flight significantly reduced the city's budget. At the same time, federal guaranteed mortgages were exclusively favoring the White population and minorities were left only one choice, renting. Even though some African Americans could afford to buy a property, they could not move into a suburban White area as the redlining policy was still in place.

Following the White flight and the hurdles in economy, the ghettos suffered severe changes that had an impact on the city as a whole. By mid-1970s urban decay was visible in the poor transportation, the high unemployment, and the many abandoned buildings. Many parts of New York City were offering an unhealthy landscape, with empty lots, a weak infrastructure, and a high unemployment rate. The birth of the suburban areas diverted taxes from the cities and as the infrastructure of highways and railroads needed to connect the suburbs with the city grew, the cities' infrastructure was neglected. The abandoned city areas attracted criminals and soon street gangs formed. Left abandoned and in a precarious socioeconomical state, the ghetto became a place for illegal activities, such as drug trafficking. Facing racial discrimination, the population of the ghetto was vulnerable and was left with no choice other than to live in such areas. Clearly, suburban sprawl combined with the development and growth of industrial capitalism had changed the geography of the city.

The ghetto came to be associated with a confined urban area, marked by invisible borders, where a specific ethnic or racial population, mainly African American, lived and struggled in poverty. Nonetheless, the term ghetto means much more than that and it has to do with a certain style of life and is the starting point for an authentic culture that reflects the social disparities, the racism, the roots, and the soul of the urban African American population. A home not only for the African Americans, but for many immigrants and other minorities, the ghetto is not solely related to violence and poverty. The ghetto is in fact a cultural and ethnic experience, influenced by socioeconomic factors that have influenced the lives of the ghetto population. Harlem is one of the most famous neighborhoods of this kind and was a center for the artistic work of the African American community. The old architecture of the city was preserved in Harlem and the old buildings are now a symbol of the old New York.

Although one of the most emblematic ethnic enclaves, the African American ghetto is not the only type of ghetto. The Brazilians have the so-called favelas, the Spanish have *el barrio*, now also common in the western USA along the border with Mexico, while in Europe, most ghettos were the homes of the Jewish population, confined in certain areas of European cities. Either formed voluntarily, by a population that due to the economic and social conditions settles in a city's neighborhood, or formed involuntarily, when minorities are forced into particular areas, the ghetto's substance has varied with time. The ghetto, a place of segregation, of alienation for minorities, the poor and underdeveloped, which suffers the violence of gangs and illicit businesses, is also the place where the African American culture grew and expressed itself. Many singers and writers came from the ghetto and used this experience in their work, bringing originality and passion in their art.

Global Health

AMY N. SHARPTON
Department of Veterans Affairs, Louis Stokes DVA Medical Center Cleveland, Brecksville, OH, USA

Global Health: Definition

Recently, several prominent organizations have called for a common definition for global health. As of yet, however, a consensus has not been reached. As organizations grapple with a definition of global health that captures its essence adequately, common themes have emerged. In general, organizations have defined global health in three different ways: (a) as a state or condition; (b) as a goal; and (c) as a field of study, research, and practice. Global health has been framed by leading organizations as health concerns that transcend national boundaries, have the potential to influence or be influenced by circumstances in other countries, and are best addressed cooperatively. Themes that underpin global health literature include an equal concern for the health of all people worldwide, the recognition of a shared responsibility for improving health status, and achieving equity in access to and quality of care.

Significance of Global Health

The general public of developed countries frequently associates global health with concerns exclusive to developing countries. But recent research underscores that importance of global health to citizens of all countries – from the least to the most developed. Researchers have outlined four broad reasons why citizens of all nations should share in the responsibility of global health. Their rationales are concerned with the following categories: humanitarian, equity, direct impact, and indirect impact.

The three diseases impacting most upon developing nations are AIDS, tuberculosis, and malaria. In 2005, an estimated 2.8 million people died from AIDS, while more than 15 million children have been orphaned as a result of the virus. More than three million people die annually from tuberculosis (TB) or malaria. Advocates for a global health perspective contend that such suffering is needless and that humankind can work together to save millions of adults and children from such pain.

Concerning equity, it is particularly notable that approximately 90% of the world's health care resources are spent on diseases that affect 10% of the global population. Working to solve global health problems will help ensure that financial resources are distributed equitably across all countries.

The interconnectedness of populations continues to increase with globalization. As such, diseases can move as freely as people and products. Infectious diseases can cross national borders easily and pose immediate threats to developed countries. Working to solve global health problems includes addressing diseases that are not usually thought of as threats to developed nations.

Global health matters to all citizens for indirect reasons as well. For example, rising incidences of diseases like HIV/AIDS, malaria, and tuberculosis are increasing poverty, political instability, and strife in many countries. Due to globalization, these outcomes in less developed countries carry the potential for negative political and economic consequences worldwide. Working to address global health problems can help prevent civil strife in other countries, can support economic stability, and may lead to an increased quality of life worldwide.

Global Health Trends

Infectious and Communicable Diseases

The emergence and reemergence of infectious and communicable diseases is a highly concerning trend. An infectious disease is any disease caused by pathogen invasion, including bacterial, viral, fungal, or protozoan infection. Frequently, infectious diseases are contagious, although some are not but can be transmitted from animal to person or from person to person. A communicable disease is carried by microorganisms and can be transmitted through people, animals, surfaces, foods, or air. Of particular concern to global health are those diseases that are becoming drug resistant, examples include malaria, tuberculosis, viruses such as severe acute respiratory syndrome (SARS), avian influenza, and other pandemics.

The World Health Organization reports that human mobility largely is responsible for the reemergence of infectious diseases. In addition to human transport, ecologies are taxed with accommodating a revolving door of new insects, livestock, and food products that carry infectious agents from country to country and from continent to continent. The spread of poliomyelitis from Nigeria between August 2003 and July 2005 is an example of the reintroduction of an infectious disease to an area where interventions had achieved the goal of elimination. Wild poliovirus, genetically linked to endemic poliovirus in northern Nigeria, was reintroduced into polio-free countries in

Africa, the Middle East, and Asia. In many countries, routine polio vaccination programs had been neglected by governments after a polio-free status was reached, and campaigns to deliver vaccines to children had been stopped due to a lack of resources. When wild poliovirus was reintroduced, there was no protective barrier to transmission; as a consequence, polio reemerged in 18 polio-free countries.

Health Inequities

Health inequity is defined as disparities in health resulting from systemic, avoidable, and unjust social and economic policies and practices that create barriers to opportunity. Within and across countries and cultures, there are persistent health inequities in access to health information and in access to care. The inequities manifest in measures such as life expectancy and under-five mortality, among others. For example, the range in average life expectancy worldwide is from 34 years in Sierra Leone to 81.9 years in Japan. Furthermore, in Indonesia the under-five mortality is nearly four times higher in the poorest fifth of the population than in the richest fifth; and in England and Wales the latest data reflect a 7.4 year gap in life expectancy between men in professional occupations and men in manual labor occupations. The World Health Organization has reported that a combination of bad policies, economics, and politics is mostly to blame.

Fragile Health Systems

The fragile health systems in developing countries pose an added threat, as the basic health care needs are greater frequently than the available human resources. In those cases, the capacity of the health system cannot meet the demands of basic health care for the vast majority of the population. Through medical assistance programs, organizations such as Direct Relief seek to equip health professionals who are working in resource-poor communities to better meet the challenges of diagnosing, treating, and caring for people – without regard to politics, religion, gender, race, or ability to pay.

Direct Relief has worked for several years with the Dean of the Medical College in Malawi, who has trained the small team of Malawian doctors running the health system. Currently there are approximately 250 physicians working to care for the health needs of a country of 13 million. The work of this and similar organizations serves to strengthen clinics in poor areas – around the world and in the United States. In so doing, in addition to the individual health needs that are met, a network is created for responding to disasters.

Global Health Initiatives

An emerging trend in health is a focus on partnerships, including those between the public and private sectors, as well as global health initiatives. Global health initiatives typically are programs targeted at specific diseases. Usually, the endeavors channel additional resources to specific health efforts. The major global health initiatives launched between 1998 and 2000 were: (a) Roll Back Malaria, (b) Stop TB, and (c) the Global Alliance for Vaccines and Immunizations.

Roll Back Malaria is a global strategy to reduce deaths from malaria. Specific strategies outlined in the initiative are: increasing access to prompt and effective treatment; increasing protective intermittent therapy for pregnant women; providing prevention tools such as insecticide-treated bed nets; facilitating rapid response to malaria outbreaks; and developing new products for the prevention and treatment of malaria.

The chief goal of Stop TB is to stop around the world the spread of TB. One of its objectives is to promote implementation of the directly observed therapy short-course strategy (DOTS). The DOTS strategy combines diagnosis of TB and registration of each patient, followed by a standardized multi-drug treatment and a secure supply of anti-TB drugs for all patients in treatment. Individual patient outcome evaluation is done to ensure cure, while cohort evaluations are done to monitor the overall performance of the program.

The Global Alliance for Vaccines and Immunization is a global effort to strengthen childhood immunization programs and to bring new vaccines into use in developing countries. The initiative includes vaccines against hepatitis B, childhood meningitis, yellow fever, and respiratory infections – the leading cause of death in children under 5.

The United Nation's Summit on the Millennium Development Goals was held September 20–22, 2010. The Summit concluded with the adoption of a global action plan to achieve eight anti-poverty goals by 2015, as well as new commitments for women's and children's health and other initiatives against poverty, hunger, and disease. The eight Millennium Development Goals are ending poverty and hunger, providing universal education, establishing gender equality, increasing child health, increasing maternal health, combating HIV/AIDS, establishing environmental sustainability, and entering into global partnership.

Grief and Grieving

Moon Choi
Department of Epidemiology and Community Health,
Virginia Commonwealth University School of
Medicine, Richmond, VA, USA

Grief is a complex emotional response to loss. A wide range of feelings can arise from a loss, such as shock, sadness, anger, guilt, anxiety, fear, psychological numbness, disbelief, loneliness, or depression. Grief often involves physical symptoms such as fatigue, lowered immunity, loss of appetite, or sleeplessness. Various types of losses can cause intense grief, including death of a loved one, loss of health, losing a job, a relationship breakup, loss of a friendship, loss of safety after a traumatic event, or immigration. Subtle or less obvious losses can also lead to grief. Some examples include graduation from school, retirement, moving to a new home, or changing jobs.

There are two classic grief theories: stage-oriented grief theory and task-based grief theory. Psychiatrist Elizabeth Kübler-Ross developed a grief model of five stages, based on her research on patients suffering from terminal illness. But later this model has been applied to other types of losses such as death of a loved one. The five stages of grief consist of denial, anger, bargaining, depression, and acceptance. Kübler-Ross and Kessler noted that the five stages are not stops on a linear timeline in grief. Bereaved individuals can engage in several phases simultaneously or skip some stages. However, this stage-oriented grief theory has been criticized because it limits the mourner to a passive role.

Task-based grief theory emphasizes an active role of the mourner – they need to take action and can do something with their grief and grieving. This approach also allows interventions from the outside. William Worden suggested a task-based grief model. Worden's model includes four tasks: to accept the reality of the loss, to work through the pain of grief, to adjust to an environment in which the deceased is missing, and to emotionally relocate the deceased and move on with life. The task-based approach to grief contributes to explicate what tasks grieving individuals need to accomplish to heal.

Grief theories are helpful in framing and identifying the feelings, symptoms, and tasks that individuals with loss may be experiencing. Thus, these theories help people prepare to cope with loss and grief, which are inevitable across the life course. Nonetheless, grief is a personal and highly individual experience. Therefore, grief theories should be used only as a guideline.

The grief process depends on an individual's personality, coping style, life experience, faith, and the nature of the loss. Grieving signifies culturally patterned expectations about the expression of grief. For example, Buddhist worship at shrines of deceased loved ones shows the importance of continuing bonds with the deceased, which are not recognized in most US cultures. Therefore, professionals working with immigrants need to be knowledgeable about the influence of cultures and religions on coping with loss and expression of grief.

Guest Worker

Domniţa Oana Bădărău
Department of Bioethics, Case Western Reserve University School of Medicine, Cleveland, OH, USA

According to the United Nations Expert Group Meeting on International Migration and Development on June 2005, there are 90 million migrant workers worldwide. Economic development and the demand for high-tech skills created the opportunities for skilled and unskilled workers to find employment outside their country. As a result, employment market disparities between countries grew deeper and affected vital sectors of the origin countries. This negative effect can be avoided if the developed countries that receive professionals on the labor market would provide the necessary human capital for the countries of origin. Furthermore, developing public policies and guest worker programs that would reduce the dependence of the migrant could counteract the negative effects of labor migration. Cooperation between sending and receiving countries will make recruitment more efficacious and would improve the distribution of human resources.

The significant migration process that started decades ago is only increasing nowadays and migrants go through some terrible experience in order to arrive in developed countries. Reports about people dying in the Arizona desert or in the Mediterranean Sea evidence the decision that these people made: to search a better life outside their country.

Nevertheless, the foreign workers must not be confused with refugees, as the migrant workers are motivated to enter the employment market of another country and not by an external factor that practically forces them to leave the origin country. In fact, migrant workers are drawn to settle in developed countries by an increase in the demand for human capital. Migration is a phenomenon that extends over centuries and the intensity and flow increased along with the technological development and the industrialization. However, international migration is a rather new development and long distance migration worldwide is rare. One of the influencing factors is the emotional context and its impact on an individual's life, as it means separating themselves from family. In addition to this, governments regulate the immigration process and control the influx of migrants within the national borders.

Migration is a phenomenon caused by economic or noneconomic factors. Individuals that are economically driven to leave their origin countries are usually entering the labor market of the receiving country as they identify a demand that they think they can satisfy. Even so, within migrant workers we can establish categories, depending on their education and skills, and their regular (documented) or irregular status (nondocumented). A special category is represented by *guest workers*, who are usually highly skilled individuals that come to meet the demand in the labor market of the receiving state. Their status is somehow special because their migration is either encouraged by a public policy that facilitates the access of highly skilled workers in the economy sectors that need an outside input, or by a stable agreement that offers an income and documented access to a developed country. The latter situation refers to students that have been awarded fellowships and who will be paid for their research projects. However, they are most likely facing significant wage differences in part as a direct result of their status.

Guest Worker Programs in Western Europe

Western European countries promoted worker recruitment programs until the mid-1970s, as the economical development required additional work force, mostly unskilled workers. Countries like France, the United Kingdom, and the Netherlands recruited the workers from their former colonies territories, who had a right to citizenship. However, in the USA, during the Cold War period, another type of labor migration was being encouraged, the migration of scientists from the Soviet area.

Germany was one of the countries that developed a rotation system in order to ensure that the guest workers were in the country only for a limited period. The state involvement was significant and the guest workers had limited rights. These guest workers were being discriminated and poorly paid and their stay in the receiving country was designed only to serve the labor market demand. Their social interaction was minimal and their necessities reduce to basic accommodation. Though these systems existed, they finally lead to irregular flows of migrants, mainly as a result of family reunions.

Europe's economic boom was sustained by the labor force of the guest workers who were employed in the low paid jobs and did not have high expectations or a significant power to negotiate. Sectors of the economy became highly dependent on the guest workers' labor and it soon became clear that the *rotation principle* had fallen into nonuse. By the time the oil crisis came, the guest workers had settled in the receiving countries and managed to bring their family with them. The socioeconomical consequences arose, especially as a result of the crisis and the work force recruitment ceased. Even so, the hoped-for result did not come, as the guest workers did not leave the receiving country; by that time they were settled and had formed ethnic enclaves.

From Guest Worker to Permanent Resident

The large number of guest workers that came to Western European countries and the family reunions clearly point out that many of them would not leave the receiving countries. Many of these guest workers have lived in the receiving countries for many years and they have formed a family or managed to bring their closest family members to them. Guest workers are usually expected to leave the receiving country after a time, because even if the earnings are higher than in the origin country, the living expenses are also higher; it was assumed that this would have a discouraging effect, which will make guest workers want to return to their countries. Many of them did so and left the receiving country with the savings resulted from the higher income. The origin country's living cost is lower and the savings could ensure a good living.

Nevertheless, if a crisis emerges and the economy is severely affected, the migrants will find it wiser to remain in the developed countries rather than return to the origin ones. The sending countries, usually developing countries, would feel the consequences of a crisis more acutely. Following this reasoning, it is more profitable for guest workers to remain in the receiving countries during economical crisis.

Another aspect that cannot be neglected is that the guest workers gradually become integrated into society, participating in the welfare system, social manifestations, and education. As a result, they become entitled to receive the state's protection in case of unemployment, disease and should be granted access to such benefits. Moreover, there are legal aspects that proibit a State from expelling documented migrants without clear and convincing evidence that there is a legal basis for doing so.

The guest worker system in Western Europe promoted a labor market model in which the migrant was rendered inferior. The receiving society was not willing to integrate them and guest workers were victims of economical disparities and racial discrimination. This aspect pushed the guest workers to live in specific areas, where the infrastructure was poor. Ethnic enclaves were thus formed and the guest workers developed a cultural and social model of inclusion. In these neighborhoods, they could freely express their culture and beliefs and raise a family.

Today's Europe is the result of this socioeconomical policy and the effects that it produced on migration, foreign workers, and ethnical identity. The trends of migrant workers flow in Europe raised concerns about the factors that produce negative effects toward migrants. This refers to the social exclusion, restricted access to all the labor market's segments, and poor housing. Concerns were raised regarding whether the temporary labor recruitment is not entirely beneficial and could bring about increasing difficulties.

A 2001 Report, the Sussmuth Commission Report, argued that Germany was already an immigration country that could satisfy the labor shortage only by employing both skilled and unskilled foreign workers. Moreover, in Britain, a released Home Office report from 2001 emphasizes the positive effects of foreign workers. The debate over the costs and benefits of labor migration was present also in Canada, USA, Australia, and Japan. All these countries have a high immigration rate.

Changing the approach to labor migration was based on economical reasons. It is a fact that the labor force in the developed countries is not willing to accept some of the low skilled jobs and the countries are unable to export all these jobs in the developing countries. There are sectors of the economy that cannot be moved over the borders, require few skills, and are poorly paid. The construction industry, services industry, and the health care system have to be based in the same country with the beneficiaries of the services. A reasonable solution appears to be allowing the migrants, the guest workers to be employed in filling the labor market gap.

Another factor to be taken into consideration is the aging population opposed to the decreasing birthrates. As a direct effect, the working population will decrease and will put pressure on the social welfare system, at the same time that the older population will almost double its size.

Models of Guest Worker Programs

State policies regarding migrant admission programs can be classified into two categories: relatively open and closed government policies. The first schema allows the foreign worker the possibility of settling in the receiving country, upon completing some requirements. A certain period has to have passed between the time the migrant entered the labor market as a guest worker and the time when he applies for a more permanent status.

Closed temporary labor migration programs follow the rule that the guest worker has to return to his origin country after an agreed period. Seasonal workers fit into this category, as their services are required only at specific moments of time and for a limited period.

Temporary migration schemes bear benefits for the countries involved and for the individual as well. A shortage in labor is met in the receiving country, while the origin country will benefit from the knowledge and skills that the guest workers accumulate in the developed country. Once the labor shortage is resolved, the country will compete more successfully on the global markets. Besides the skills and knowledge of the guest workers that return, the origin country will be sensitive to the effect of the remittances. The money sent back home can be reinvested or can help improve the standard of life of the family left behind by the guest worker.

Documented migration, such as guest worker schemes, represents an opportunity both for the receiving country and the origin one, rather than a threat. The demand of one State can be met by interaction with another State, in order to maximize mutual benefits.

Gujaratis

Jaina Amin
Department of Psychiatry, University Hospitals Case Medical Center, Cleveland, OH, USA

Gujarat is one of the states in India, located in the northwest. The languages spoken there are Gujarati, Hindi, and English. The major religions practiced there are Hinduism, Islam, Jainism, Sikhism, and Christianity. The population of Gujarat is around 5.06 crore (1 crore = 10 million). Ancestrally, Gujaratis are similar to most other North Indians, who for the most part seem to share background with the central Eurasians. (Eurasian was first coined in 1844, to refer to individuals of European (i.e., British) and Asian (i.e., Indian) descent.)

Many people in India migrate within Gujarat looking for work. However, there have been trends in immigration out of India by those seeking a better life. Initially, the Gujarati people moved to East Africa and worked themselves up to own businesses and work in management between the British and Africans. Many subsequently immigrated to England or Canada as these two countries had less restrictive immigration laws. And then in 1972, when Idi Amin expelled all South Asians from Uganda, approximately 7,000 persons went to Canada as refugees. Prior to the 1940s, the USA had very restrictive immigration laws and restricted Asian women from entering the USA. Thus, many of the Asian men married Mexican women. After World War II, the US immigration laws became less restrictive and more Indians in addition to the professionals and students already present started entering the USA.

Gujarati people have also immigrated to Australia, Canada, England, and the USA. Despite emigrating from their native land, Gujarati people maintain strong cultural ties and traditional norms. Traditionally a family dwelling would contain three generations of a family. However, in Western society this is more difficult to maintain but families will often continue to maintain strong ties, with cousins, aunts, and grandparents, when they cannot live in the same house. It is traditional for the oldest male child to take in the parents and care for them, and this tradition is maintained still. Thus, the use of nursing homes or assisted living facilities is relatively rare.

Gujarati people will tend to gravitate toward each other and buy homes in similar areas. This allows them to have a sense of community even if their biological family may be far away. In a traditional home, Gujarati will be spoken in the home, and English at work or school. Cultural programs are a large part of socializing not only for the adults, but for their children. Girls can learn the traditional classical dances of Bharatanatyam, which is a classical Tamil dance; Kathak, which is a classical Hindi dance; and/or Raas Garba, which are traditional Gujarati dances. Raas and Garba are two separate dances where Raas is danced with sticks, dandiya, and a partner, while Garba is danced in a circle not requiring a partner.

In India, children grow up learning both Gujarati and Hindi, as Hindi is a more "universal" language across India. In order to not lose their traditions, parents will have their children take classes, and speak these languages at home. Growing up in an Indian home can create ethnic identity crises for the younger generations, especially if the older generations are in disharmony with the dominant culture.

H

H1N1 Virus

Lisa M. Yee
San Diego, CA, USA

Each year, approximately three to five million illnesses and 250,000 to 500,000 deaths worldwide are attributed to influenza. As the 2008–2009 influenza season waned in April 2009, a novel strain of influenza A virus was identified by the US Centers for Disease Control and Prevention (CDC). The first cases were detected in California; subsequently, several deaths of young adults and children in Mexico from a severe respiratory illness were identified to have the same novel influenza A strain. Cases were soon reported from countries outside North America, including the UK, Australia, Chile, and Japan. Based on sustained person-to-person transmission in community outbreaks in at least one country in two or more World Health Organization (WHO) regions, the pandemic alert level was raised from phase 5 to phase 6, thus an indication that containment of the virus to a particular geographic region was not possible. The 2009 H1N1 influenza virus had been detected by laboratories in 74 countries and territories when WHO declared a global pandemic of H1N1 influenza A on June 11, 2009, the first influenza pandemic in 41 years.

The 2009 H1N1 influenza virus was determined to be have been globally distributed in less than 6 weeks, compared to the pattern typically seen of 6 months or more from past influenza pandemics. Modern air, sea, and land transportation was one factor in the rapid spread of the 2009 H1N1 influenza virus.

Another contributing factor was the lack of immunity of the general population worldwide against the virus. The 2009 H1N1 influenza strain was ultimately determined to exhibit "antigenic shift" or novel reassortment of previously seen individual gene segments that originated from humans, birds, and pigs from North America and Eurasia. The 2009 H1N1 influenza virus was transmitted easily from person-to-person. Pregnant women and persons aged 24 years or younger were at higher risk for severe complications from infection with 2009 H1N1 influenza. American Indian and Alaska Natives in the USA were observed to have disproportionally higher case fatality rates from 2009 H1N1 influenza than the general population. This trend was also seen in indigenous populations from Canada, Australia, and New Zealand.

Traditional (e.g., television, radio, newspapers, Internet) and social (e.g., Twitter, Facebook, YouTube) media were utilized to disseminate public health recommendations and information about the 2009 H1N1 influenza. WHO frequently updated its website to include press briefing transcripts, situation updates, fact sheets, and guidance documents. In the USA, the CDC maintained a Spanish language HINI "mirror" website which reflected information published on the English language site. Key resources were also developed in multiple languages including Chinese, Vietnamese, Korean, French, German, Arabic, Russian, Amharic, Farsi, Somali, Karen, Cambodian, and Kirundi. These materials were easily accessible on the website by the public, as well as professionals in medicine, public health, immigrant health, and social services.

Vaccine development and distribution activities were initiated as one aspect of the public health response to the pandemic, in addition to evolving infection control, prevention, and treatment guidance. In October 2009, the 2009 H1N1 influenza vaccine supply became available in the USA. The initial vaccination strategy targeted high-priority populations including health care workers and first responders (e.g., paramedics, emergency medical technicians), infants 6 months through young adults 24 years of

Sana Loue & Martha Sajatovic (eds.), *Encyclopedia of Immigrant Health*, DOI 10.1007/978-1-4419-5659-0,

age, and adults 25 through 64 years of age with chronic health disorders. As production increased, 2009 H1N1 influenza vaccination eventually became available for the general population. Large scale immunization efforts were organized and public health entities offered free vaccination through public health or community clinics, and single-day vaccination sites in public venues (e.g., stadium parking lots, high school auditoriums, large church buildings) to provide additional vaccination locations for the public. Despite the availability of free vaccine, immigrant and migrant populations were more at risk for not receiving 2009 H1N1 influenza information and vaccination recommendations, thought to be due to language barriers, transportation or work issues, or concern about legal status.

One year after the declaration of the pandemic, laboratory-confirmed cases of 2009 H1N1 virus have been reported in more than 214 countries and overseas territories or communities, including over 18,156 deaths.

Hague Convention on Child Abduction

Domniţa Oana Bădărău
Department of Bioethics, Case Western Reserve University School of Medicine, Cleveland, OH, USA

With increasing globalization, violent acts toward children are no longer seen in a national context, as offenders can easily cross borders and avoid punishment or take the victim to another country. The Declaration of the Rights of the Child in 1959 stated that special protection and care is to be given to children and their safety and health, whether it is mental, physical, spiritual, or moral. The basic principle to follow is to always have in mind the best interests of the child.

The need to regulate and to establish a framework for nations when confronted with child abuse is an obvious and necessary concern. When talking about children's rights, the main focus should be on the child's best interest, regardless of who the offender may be. The regulator must consider the protection of children not only against external threats from outside of the family, but also parental abuse and neglect.

One of the most significant international agreements that governs the procedure in case of kidnapping of children or taking a child across the national border without consent is the Hague Convention on the Civil Aspects of International Child Abduction, established in 1980. With more than 50 signatories, the Convention is a multilateral treaty establishing a procedure that ensures that any child that is a victim of kidnapping or retention will be taken back to his or her national or resident country as soon as possible. The abduction is considered an international matter and the priority is to return the child to his previous residence, under the same legal conditions as it was before the kidnapping occurred. Most important, the Convention is a step forward in cooperation between States all around the world and recognizes that parental kidnapping is as serious a problem as any other type of abduction. Regarding the removal of the child from his previous environment, this must be made by a person that seeks to obtain legal custody in another country than the one where the child lives. Indeed, in most of the cases, this person is one of the child's parents or a third party that acted upon a parent's instructions.

The Hague Convention on the Civil Aspects of International Child Abduction entered into force by the end of 1983 and it sets a specific *modus operandi* in case there is any unlawful change in the actual domicile or residence of a child, even though this change was made by one of the child's parents. Transport of a child across international borders without having permission of doing so it is subject to international jurisdiction; the Convention ensures that the parent that acts in this manner will not benefit from a different law than the one existing in the State of domicile/residence of the child at the moment of the abduction. Each party that has become a member of the Convention has the obligation to ensure that the custody rights and the access rights given by one of the contracting States will be respected in the same manner in any other contracting State. This way, the international agreement ensures that kidnappers will not be able to benefit from a more indulgent law, one that will provide them more rights.

Stated purposes of the Convention are the *rights of custody* and the *rights of access* that are defined within the Convention's text. For example, the *rights of custody* will include all the rights that are relevant to the care of the child and in establishing a residence. On the other hand, the *rights of access* are considered to be any lawful act to take a child away from his continuous and steady residence, but only for a determined period of time.

In understanding the role and the functions of the Hague Convention, a fundamental fact is that the treaty itself does not give any particular rights or create a new legal status. Rather, it seeks to protect the best interest of a child by facilitating respect for the national law that established certain rights for one of the two parents. Moreover, this relates to the legal custody of the child and the problems that might derive from it; it does not address legal custody battles, but establishes ways that the custody rights given by one member State will be respected in all the other member States. The Convention merely ensures that a child will be returned safely to the country where he had his legal domicile/residence before the disruptive act had taken place. The purpose is not to bring the child under the guardianship of the parent who is entitled by law, but just to return him to the country from which he was kidnapped. For a better understanding of this principle, the Convention defines the wrongful removal or retention of a child. In doing so, the agreement emphasizes the situations when the Convention is to be applied and states that when the child attains the age of 16, the articles of the Convention will no longer be applicable.

According to Article 3 of the Convention, there are two conditions when the removal or the retention of a child is subject to this international agreement. The first is when removal/retention interferes with the custody rights given to a person, institution or any other type of tutelage, and violate them. Of course, these rights should have been previously given by the legal authority of one of the Convention's member States and the child should have had a continued residence in that State previous to his removal. Another condition is that the rights that are severely affected by the removal of the child are fully exercised before the disruptive act or should have been exercised if not for the removal.

The Hague Convention on Child Abduction rests on three pillars that ensure the international cooperation and an effective and quick approach to the matter: *Central Authority*, *implementation of measures*, and *preventive measure*s. Designating a Central Authority is compulsory at the time of ratification or the time when the Convention enters into force. In fact an office or a position, the Central Authority is an agency that has the duty to see that the obligations and functions of the Convention are applied and respected. Another prerequisite is that it has strong and operative connections with the justice and social systems in that country. The implementation of measures comprises all the resources, the cooperation, communication, consistency, transparency, all the procedures, and the progressive implementation that help clarify the structure of the Convention and carry out the obligations of the Convention.

In order to ensure that the purpose of the Convention is met, the member States should also adopt *preventive measures* that will help to reduce the risk of abductions. These include enforcement of the domestic law, establishment of bilateral agreements, and the creation of specialized organisms that provide counseling and facilitate mediation to those involved in custody battles.

Haiti

Guitele Jeudy Rahill
Department of Social Work, College of Nursing and Health Professions, Arkansas State University, State University (Jonesboro), Jonesboro, AR, USA

Introduction

This document presents an argument for the need to clarify culturally bound mental health symptoms for Haitians in Haiti, in the USA and abroad. It begins with a brief introduction to Haitian geography and history. It continues with the impact of centuries of violent and oppressive rule and of inequity and stigma that often characterize Haitian life in the USA. Next, it presents a discussion of the January 12, 2010, earthquake and its expected psychological impact on Haitians at home and abroad. Following, three examples of mental health symptoms that were directly observed by the writer during a visit to Port-au-Prince in May, 2010 are offered as support for the need to clarify culturally bound mental health symptoms for Haitians in Haiti, in the USA and abroad. Finally, a call is made for purposeful focus on the mental health symptoms of Haitian survivors of the Haitian earthquake of 2010, with emphasis on identifying and treating those symptoms in a biopsychosocial context that is familiar and meaningful for individuals of Haitian descent.

Haiti: Beauty in the Midst of Conflict

Haiti occupies the western third of Hispaniola, an island it shares with the Dominican Republic. The Atlantic Ocean borders Haiti on the north and the Caribbean Sea forms the southern boundary. Haiti is the first Black republic in the western hemisphere. It gained independence from France in 1804. General Jean Jacques Dessalines, who featured prominently in the war for independence, was assassinated in 1806.

Before and during French rule, Haiti was known as the Pearl of the Antilles and was one of the richest colonies in the world due to its abundant natural resources and slave labor. Despite freeing itself from French rule, Haiti remains the poorest nation in the western hemisphere. Internal division between the light-skinned Haitian elite and the dark-skinned peasants at the time of the country's independence from France led to centuries of conflict that persists today. As an example, a civil war between the Black northern kingdom of Henri Christophe and the southern republic of the light-skinned Alexandre Pétion divided the country between 1807 and 1820. For over two centuries now, the elite have maintained control of the government and have occupied the most desirable sections of Haiti. The peasants have traditionally lived in the rural areas and in condensed regions of the capital.

Past US Involvement in Haiti

The USA invaded and occupied Haiti for 19 years, beginning in 1915. The main legacy of that period of occupation was a trained military. Sadly, American Marines forced peasants to build roads and perhaps violated other civil rights, fostering organized resistance to their presence under the leadership of Charlemagne Péralte. Péralte would subsequently be assassinated by US Marines in 1919. Following the US occupation, Haiti has been embroiled in persistent and recurrent political turmoil, with a series of leaders who did not always seem concerned with the plight of the masses.

The Age of Duvalierism

Among the most notorious of Haiti's past leaders was the dictator, Francois "Papa Doc" Duvalier. He was a self-proclaimed "President a vie," or "President for life." He died in 1971, ending a regime of terror that was supported by his *tonton makouts*, a military group that insured compliance with Papa Doc's demands. His only known son, Jean Claude Duvalier, assumed power upon his father's death and became known as "Baby Doc." The latter left Haiti in 1986 after widespread protests influenced the USA to arrange for political asylum for him and his family in France. At the time that this manuscript is being composed, Jean Claude Duvalier had recently returned to Haiti a year after the 2011 earthquake and weeks after a failed election that was fraught with accusations of fraud and misconduct.

Despite the cruelty associated with the Duvaliers, it was not until 1990 that a friend of the masses, Jean Bertrand Aristide, was elected as president. A coup d'état facilitated by the army, and encouraged by those who did not appreciate Aristide's loyalty to the masses and the fact that some questionable elements from the underclass seemed so supportive of him, led to the overthrow of Aristide's government in 1991. He was placed back in power in 1994 after 3 years of violence in the nation illustrated that the masses were dissatisfied with the subsequent rulers and with him being deposed. Shortly afterward, the USA withdrew its support of Aristide, perhaps because he demonstrated friendships with Cuba's dictator Fidel Castro and with other enemies of the USA. President Rene Preval is the leader of the nation at the time that this article is written.

Haitian Immigration to the USA

Although many Haitians left Haiti following Aristide's exile, it was not the first emigration of Haitians from Haiti. The first groups of Haitian immigrants traveled to the USA during the American occupation of Haiti, fleeing the harshness of the American invasion and occupation. It is believed that many of these early Haitian immigrants assimilated into African-American society, identifying themselves as West Indians. The early years of Papa Doc Duvalier's regime also influenced the emigration of many educated upper class Haitians to the USA. Most of these immigrants were anti-Duvalierists, and were from the educated upper class. Their primary language was French, although many spoke English and all of them also knew how to speak *Kreyòl*. However, many identified as "French" since that language was associated with being higher class. Many of these educated Haitians also traveled and remained in France, in Canada (especially Quebec and Montreal), in Guadeloupe, and in the French Congo, where their high education level and their ability to speak French made them natural leaders in education and medicine. Their emigration led to a decrease in the number of educated persons in Haiti. Many middle and lower class Haitians soon followed, seizing the opportunity to flee the violence in Haiti, while grasping at the available economic opportunities.

Possibly the most well-known and greatest influx of Haitians to the USA is that of the "boat people." The first boat people landed in Florida in 1972 following Papa Doc's 1971 death. They were largely uneducated Haitians from both rural and urban regions of Haiti who had made tremendous personal and financial sacrifices to flee the violence and inequity that characterized Baby Doc's regime. They were also fleeing the political upheaval that was anticipated following the death of Papa Doc. Their primary language was Haitian *Kreyòl*. Their treacherous journeys to Miami in overloaded boats were often fruitless, as the USA developed policies that classified them as economic rather than political refugees. Consequently, their boats were either intercepted at sea and they were returned to Haiti, or they were imprisoned in Miami-Dade's Krome Detention Center. As prisoners, they were subject to deportation. Many actually requested deportation rather than languishing in Krome. In 1993, the US Supreme

Court supported the deportation of Haitian immigrants on the grounds that they had entered the USA illegally. Although the flow of Haitian boat people stemmed only with the election of Aristide in 1990, many continue to attempt the life-threatening journey to the USA.

Haitian Enclaves in the USA and the World

There has been an estimated 87% growth in the number of Haitians in the USA over the past 2 decades. Between 400,000 and 750,000 persons of Haitian origin currently reside in the USA. These figures are probably lower than the actual numbers since many who fear deportation do not participate in the United States census. Also, stigma associated with being erroneously associated as carriers of the human immunodeficiency virus (HIV) causes many to keep a low profile or to self-identify as being from the "West Indies," or from other Caribbean groups.

Miami-Dade-Dade County has the largest population of Haitians in Florida, in excess of 109,000, roughly 4.7% of the total population. North Miami-Dade is known for its large Haitian-American population, and Miami-Dade-Dade's Little Haiti has the largest concentration of Haitians in the state. Miami is currently the number one place of Haitian settlement in the USA, followed by Boston, New York, and Chicago. Baltimore, Washington DC, New Orleans, Houston, and Los Angeles also have a substantial number of Haitian residents.

The USA is not the only place where Haitians have set up residence. There are Haitians in Canada, particularly in Montreal and Quebec. Many have left Haiti to work as school teachers and college professors in the French Congo, in Guadeloupe, in Martinique, and in other French-speaking enclaves. Some with less education have flocked to the Dominican Republic, Cuba, and the Bahamas, in search of employment or of opportunities for commerce. Among those who have remained in Haiti, many have remained by choice because they have the financial means to enjoy both Haiti and the other countries to which they travel for work and, or, vacation. Other less fortunate Haitians, if they desire to travel, may have remained because they lack the opportunity to travel to other countries. Still others remain because they possess strong love and respect for their country and out of a sense of respect for their ancestors' struggles and achievements. Those who have remained in Haiti are the ones who may be most affected by the confluence of structural and natural violence which have characterized the experience of Haitians at home and abroad. They are among those who were additionally traumatized by the devastating events which impacted the small island nation on January 12, 2010.

Need for Clarification of Haitian Expression of Mental Health Symptoms

In spite of the large presence of Haitians in the USA and in other nations around the world, there is a dearth of literature on how to provide mental health services to Haitians. There are several factors that call for culturally based clinical approaches with Haitians in the USA and around the globe. First, their health beliefs and practices often clash with Western conventional health care. Second, there was a documented 60–75% of US Haitians who were erroneously diagnosed as paranoid schizophrenics, and the error was discovered only after treatment with neuroleptics and related psychotropic medications proved ineffective. Third, there is a dearth of culturally bound syndromes for Haiti in the current Diagnositc and Statistical Manual of Mental Disorders (DSM IV-TR). Fourth, the January 12, 2010, earthquake that occurred in Haiti will have mental health consequences for Haitians at home and in the diaspora. These could range from mild stress to acute stress disorder to posttraumatic stress disorder, depending on whether survivors had a direct experience of trauma and loss or indirectly witnessed the devastating impact of the earthquake.

Grief Interrupted: Psychosocial Symptoms Among Haitians in the Aftermath of the January 12, 2010, Earthquake – Where Do We Go from Here?

On January 12, 2010, a 7.0 earthquake hit the tiny island nation of Haiti at about 4:53 PM (Haiti local time). The epicenter of the earthquake was approximately 10 miles from the nation's capital, Port-au-Prince. An estimated 230,000 people of the three million who were affected by the earthquake lost their lives. Some estimate this figure to be an underestimation since many of the deceased are still unaccounted for at the time of the writing of this article.

In the aftermath of the earthquake, many international aid organizations, representatives from diverse nations, and foreign journalists flocked to Haiti to provide humanitarian and medical aid and to document the physical impact of the earthquake on those who survived. Little is known about the psychosocial impact of the earthquake on the survivors and on those in the Haitian diaspora who are part of their social network.

What is clear is that Port-au-Prince, the nation's capital, is still under debris at the time that this article is being written. The government gives the appearance of making furtive efforts to rebuild, involving engineers, architects, and other professionals from around the world. Many of those who died when buildings collapsed on them are still under the rubble. Seldom are those who are directly impacted by personal, social, economic, and psychological loss involved in discussions about how to obtain shelter, or how to manage the recurrent psychological aftershocks of the earthquake. In the meantime, what is known about grief, loss, trauma, and the traditional Haitian grieving process suggests a dangerous omission to the Haiti Reconstruction plans: consideration of what may be grievous disruption to the traditional Haitian grieving process. This omission may bring serious mental health consequences for the survivors of the January 12, 2010, earthquake.

Haitian Death Rituals Before the Earthquake

Before the January 12, 2010, earthquake, the immediate family, close and distant relatives, friends, and friends of friends gathered together to cry and pray with the family of the deceased. It would appear as if the entire community was affected by one individual's death and by one family's grief. It was always expected that the oldest surviving family member would make the funeral arrangements and notify friends and family living away. The bodies of Haitians who die in Haiti or in the USA have been known to be kept for days and sometimes over a week, awaiting family members and friends to gather from all over the world. Specific protocols were in place to signify to others who may not have known the deceased that there has been a loss in the family. These include the "deuil," a tradition of wearing black, navy blue, dark brown, dark purple, or some other dark color to indicate mourning. The depth of darkness of the mourning dress indicated the survivor's familial proximity to the deceased, i.e., black for parent, children, etc. . . . The taking on of "deuil" signified that mourning had officially begun, and occurred at least by the 7th day after the death of a loved one.

Impact of the January 12, 2010, Earthquake on the Grieving Process of Port-Au-Prince Residents and Haitians in the Diaspora

Recent travel to Port-au-Prince indicates that there has been an egregious disruption in the grieving process. Two examples will serve as corroboration. In May of 2010, the writer was returning from a visit to a tent city in Cite Soleil, one of the worst slums in Port-au-Prince. On the road lay a man covered in blood, and his helmet lay about 12 feet from him. Men, women, and children walked past him, glancing casually and returning to their tasks. Surprised, the writer addressed this with members of a community focus group the following day. The response was that Haitians have become *dekonsantre* (desensitized) to death. The explanation was that in the immediate aftermath of the earthquake, impacted persons sought friends, family members or neighbors to comfort them in their grief. However, many who had lost five family members only found others who may have lost eight family members or more when they reached out for comfort. What had been a beautiful ritual of communal grieving and support had become a lonely experience of isolation and detachment.

A second example of grief interrupted in Haiti was the writer's observation of a beautiful woman walking down a congested street of Pétion Ville in the same week that the above situation occurred. The woman was slim and tall, with long slender arms on which she wore a dusty bracelet. She wore rags that remained from what appeared to have been a beautiful dress. The dress was so covered with dust and dirt that it was hard to determine what the original color had been. As she walked down the angled sidewalk, she gesticulated wildly, her mouth forming silent words that could not be heard above the din of afternoon traffic in Pétion Ville. She pointed erratically to debris on her left, then to the sky, and then to debris ahead and on her right. Behind her trailed a boy who was small in stature and in posture. His face was dusted with the same gray matter that colored his mother's dress. He wore a look of consternation mixed with fear and awe on his face. His eyes never left the back of her head, as if he strained to hear her words. He looked tired and thirsty. Yet, he followed her. No one intervened, although many noticed. It was hard to tell how long both had been walking, where they were from, or where they were going. They simply walked on. No one seemed to have time to comment or comfort.

A final example of grief interrupted involves Haitians in the diaspora; specifically, this writer's own experiences in the aftermath of the January 12, 2010, earthquake. Personal loss had to be managed and grieving postponed as she prepared for the tragic loss of a dear aunt at the same time that she prepared for a service trip to a rural Haitian orphanage and a subsequent research trip among earthquake survivors. Following, she had an even more personal tragic experience as she was the victim of a home invasion and assault in faculty housing on her university campus. For her and for other Haitians in the diaspora who experience compounded trauma, culturally specific mental health intervention is a must.

Conclusion

Despite the large presence of Haitians in the USA and around the world, and in spite of a history marked by structural and political violence, there has been a serious lack of focus on their mental health. The January 12, 2010, earthquake has compounded centuries of violence, oppression, and deprivation. Haitians are a resilient people. However, loss from an earthquake is new to them. Purposeful attention to their psychological health and survival is needed, if they are to continue as a resilient people. Mental health must be an integral part of Haitian reconstruction, not only for Haitians in Port-au-Prince, but for those who reside in the diaspora.

Health Barriers

Steven P. Wallace, E. Richard Brown
Center for Health Policy Research, School of Public Health, University of California Los Angeles (UCLA), Los Angeles, CA, USA

Most voluntary immigrants have better health than their native-born peers. This good health status means that immigrants in the USA arrive with more "health capital" than natives, although that advantage declines over time. The decline in health advantage is largely due to health barriers that immigrants face, including health risks and significant health care barriers. This entry will briefly describe some of the disproportionate health risks that immigrants face and provide more extensive information about the barriers they experience in obtaining health care that might buffer some of those risks. Because of the heterogeneity of immigrant populations and the circumstances where they live, the examples and data will largely focus on the largest immigrant group in the USA (Mexican immigrants) and the state with the most immigrants (California). The pattern of health risks and barriers that immigrants in the USA face is similar to those that immigrants in other countries face, although the types and magnitude of risks and barriers vary considerably by both receiving and sending countries.

The Immigrant Health Advantage

Most immigrant populations in the USA – as in other wealthy countries – have better mortality patterns than their native-born peers, regardless of race/ethnicity. Immigrant Latino males, for example, had a 3.8 year life expectancy advantage over US-born Latino men in 1999–2001, while Latino immigrant women enjoyed a 2.1 year advantage over their native-born counterparts. This advantage in mortality is also seen in disease prevalence rates among adults. Among the most common chronic conditions, native-born Latino adults had higher rates of most diseases than immigrant Latinos in the 2007 California Health Interview Survey, even after adjusting for age, education, gender, and poverty. For example, native Latinos were 1.3 times more likely to have diabetes than similar immigrant Latinos, 1.4 times more likely to have any diagnosed heart disease, and three times more likely to report asthma.

This health advantage could be used as an excuse to pay less attention to health barriers experienced by immigrants. The longer immigrants stay in the USA, however, the more their health status becomes similar to that of the US born. Diabetes rates, for example, are 50% higher among Latino immigrants in California who have been in the USA 15 or more years compared to those in the country for a shorter time, after adjusting for age, education, gender, and poverty levels. If we can identify the risks and health barriers that immigrants experience, we might be able to reduce the barriers and thereby extend the health advantage immigrants bring, saving both money and lives in the process.

Work-Related Barriers

Most immigrants who come to the USA are part of working families. In California, for example, 91.8% of recent Mexican immigrant men ages 18–64 are in the labor force, compared to 84.5% of US-born non-Hispanic Whites. Yet the segment of the labor market that employs Mexican immigrants is the lowest paid and includes some of the most dangerous of occupations. While almost 20% of employed men in California are Mexican immigrants, they are disproportionately concentrated in low-skill occupations such as agricultural workers, gardeners, certain construction jobs (such as cement workers, roofers, and laborers), some manufacturing jobs (such as packaging machine operators and metal/plastic workers), and various service occupations (such as dishwashers and cooks). This pattern is similar throughout the world where international labor migration is often concentrated in "3-D" jobs: dirty, difficult, and dangerous.

The risk of accidental death or suffering a fatal injury on the job in the USA is highest in the occupations that employ large numbers of Mexican immigrants. Heavily Mexican immigrant occupations that pose a particularly high risk for occupational injury and illness in the USA include agriculture, sweatshop textile work, day labor, and construction. Farm work alone employs less than 3% of the work force nationally, but accounts for 13% of all workplace fatalities. Mexican immigrants account for at least 40% of the agricultural labor force nationally, and 85% in California. In addition to deaths from equipment accidents and other causes, farmworker health is compromised by exposure to pesticides and other chemicals; their families are likewise at risk for both primary and secondhand pesticide exposure. Other occupational injuries include back injuries that are common among immigrant nursing home aides and construction workers, lacerations and broken bones from falls, and burns. Immigrant workers are more likely than others to not report these injuries for fear of losing their jobs, as well as due to not wanting to lose wages from taking unpaid time off, even when their injury would be covered by workers compensation insurance (which does not verify immigration status). Some immigrant workers are not aware of their rights under workers compensation, which also serves as a barrier to obtaining care for their work-related injuries and illnesses.

While farming has the highest fatality *rate*, transportation and material moving have the highest *number* of occupational fatalities, followed by construction/extraction, service, mechanics, farming/fishing/forestry, and manufacturing. These occupations that have the most occupational deaths also disproportionately employ immigrant workers.

In 2006, Mexican immigrants in heavily immigrant occupations in California earned $20,200 per year for men and $13,300 for women, approximately one-third less than Mexican immigrants who worked in occupations that were not reliant on Mexican immigrant labor. The jobs that rely on Mexican immigrant labor also are less likely to offer health insurance, leaving 60% of working Mexican immigrant men and 46% of similar women uninsured in California.

The segmented labor market that relies on large numbers of immigrant workers serves to concentrate immigrants into an employment sector that creates both an above average need for health services, while at the same time creating multiple barriers to the workers seeking needed care.

Access to Health Care Barriers

Barriers to health care for immigrants make it more difficult for immigrants to maintain their initially good health status. The timely and appropriate use of health services promotes cost-effective care, particularly preventive services and care for ambulatory-sensitive conditions like diabetes and hypertension. From this perspective, policies and financing for immigrant health are not a burden, but an investment. Most immigrants, however, face a number of barriers to obtaining needed health care, including a lack of available services, accessibility barriers, and problems with the acceptability of the care provided.

Problems with the *availability* of services include both the shortage of primary care providers in the low-income neighborhoods most often inhabited by recent immigrants, as well as the distance to specialists and acute care facilities. Immigrants are more likely to live in health professional shortage areas (HPSA), which means that they are more likely to have difficulty finding an available physician within their community. Even for those living in HPSAs that are served by a community health center (about half of HPSAs in the USA have a federally funded community health center) or public clinics, specialty care and specialized testing can still be difficult to obtain.

Hospitals in low-income immigrant communities have difficulty surviving because of the high rates of uncompensated care that the communities require (due to the low rates of health insurance, see below). As a result, a number of well-known safety-net hospitals have closed in recent years, such as M.L. King Hospital in South Los Angeles, leaving the immediately surrounding community with few acute care beds. South Los Angeles (Service Planning Area 6) includes over one million residents; half of nonelderly adults in the area were born abroad, most commonly in Mexico. In 2006, South Los Angeles had 1.14 hospital beds per 1,000 residents compared to 2.21/1,000 county wide and 3.22/1,000 in the wealthiest part of town ("Westside"). Those hospitals contained about five emergency room treatment stations per 100,000 residents in South Los Angeles, compared to 15 countywide and 23 in the Westside. Outside of hospitals, South Los Angeles had 7.7 pharmacies per 100,000 population versus 15.1 countywide and 21.8 in the Westside. Some public hospitals that survive, such as Grady in Atlanta, are cutting back on critical services like dialysis units in an attempt to reduce budget deficits. The October 2009 closure of Grady's dialysis unit left their mostly uninsured and immigrant patients without an affordable source for that life-sustaining treatment. These data indicate that there is a shortage of available health services in low-income immigrant communities, which is a significant barrier to obtaining needed care.

Accessibility can also be impaired when immigrants seek to use the few providers that exist in communities where immigrants settle. Common barriers to access include lack of knowledge of available care, high out-of-pocket costs, inconvenient service hours, and fear of the authorities.

Any newcomer takes a while to learn about health care and other services that are available in a new neighborhood. International immigrants have the additional disadvantage of having come from countries where the health care system is organized very differently (regardless of their country of origin). Without prior knowledge of the intricacies of public program eligibility and benefits in the USA, often combined with limited English proficiency and low levels of education, finding appropriate services and programs can be daunting. Community services that are free or low cost, such as community health centers, often run at capacity, constraining their ability to conduct outreach and publicity for to immigrants.

The barrier of cost is significant because immigrant workers have low rates of health insurance as well as low rates of coverage for sick leave from their employer. Noncitizen immigrant Latinos have low rates of health insurance coverage due to the fact that their employers have the lowest rate of offering insurance. In California, for example, only 49% of undocumented Latino workers (i.e., those without a work permit, or "green card") were offered insurance by their employer, compared with 82% of citizen Latinos. The proportion of workers who were offered insurance who enrolled in the health insurance plan offered was somewhat higher among the undocumented (84% vs. 72%), indicating that there is a clear desire for health insurance when it is available and affordable. In addition, documented immigrants are ineligible for federally supported Medicaid for their first 5 years in the country, even if they would otherwise qualify. And undocumented immigrants are not eligible for any public assistance for health care through Medicaid except in life-threatening emergencies. It is worth noting that California provides Medicaid coverage to all documented low-income immigrants in families with children, supporting those in their first 5 years in the country with entirely state funds. Several California counties also have programs that provide health insurance to low-income children who are not otherwise eligible for insurance, who are primarily undocumented children. Despite these additional programs, according to the 2003 California Health Interview Survey only 47% of undocumented Mexican immigrants had health insurance, compared to 67% of legal permanent residents, 80% of Mexican immigrants with U.S. citizenship, and 85% of U.S.-born Mexican-Americans.

While California and the USA are unique in the developed world in not providing universal health insurance, they are not unique in creating financial and other barriers to some classes of immigrants, especially undocumented or irregular immigrants. According to the United Nation's 2009 Human Development Report, 60% of developed nations restrict preventive care benefits to irregular immigrants and almost 30% restrict emergency care benefits to them. Restrictions on temporary legal immigrants are less common, and for permanent immigrants the least common.

As a result of the lack of benefits in the occupations that employ large numbers of immigrant workers in the USA, they often have to pay twice when they seek medical care – once to pay for the doctor visit and a second time in lost wages when they take unpaid time off work to seek care. One study found that half of undocumented workers in California worked at firms that did not offer sick leave. Partly as a result of these trends, immigrants also have low rates of preventive service use, including cancer screenings (e.g., mammography, colonoscopy), adult immunizations, and well-checks. For example, according to the 2007 California Health Interview Survey, 50% of noncitizen immigrants age 50 and over had never had colon cancer screening compared to 22% of US-born persons age 50 and over. The exception is Pap tests for cervical cancer, where noncitizen women ages 18–64 have had a recent test (within the past 3 years) at about the same rate (83%) as US-born women (87%). The difference with Pap tests is that both the federal government and the state of California have special programs to pay for Pap tests and cervical cancer treatment that is available to all women, regardless of their immigration status. Pap tests are also performed in community clinics and other outpatient sites that immigrants commonly use. Colonoscopy does not receive this level of government support, which results in reduced access for persons without insurance and a regular source of medical care.

Another barrier to access to existing services is fear about immigration status. Policy initiatives at the local, state, and federal level continually target undocumented immigrants in attempt to limit their use of public services, even when there is no evidence that they are commonly using the services. Other policies are designed to frighten or make life more difficult for undocumented immigrants by preventing them from obtaining driver's licenses, ordering landlords not to rent to them (which the courts routinely overturn), or requiring the police to check the immigration status of everyone arrested. While these latter laws are not directly related to health care, they create a hostile climate that extends to the use of health services. In 2009, the National Conference of State Legislatures identified 353 new laws and resolutions that were passed related to immigrants. Some helped immigrants, such as laws allowing undocumented immigrants who attended high school in the state to pay in-state tuition in public colleges. The majority involved restrictions on the undocumented.

The continual media coverage of the deportations of undocumented immigrants further creates fear in immigrant communities that leads many to avoid contact with any public authority to the extent possible. Even if a person is a legal permanent resident, some fear that their ability to gain citizenship or sponsor other family member to immigrate the USA could be compromised by using publicly funded services. There are also "mixed status" families where one or both parents are undocumented but their children were born in the USA and are therefore automatically citizens. While the children qualify for public health care programs, the parents often hesitate to enroll their children in the programs because of the fear that the use of those programs will make it difficult for the parents to regularize their status in the future. A published government directive states that the use of government-supported health care cannot be used as evidence that an applicant for legal immigration could be a "public charge," but the same directive allows the use of cash assistance to be evidence of a public charge. The resulting confusion and mistrust in many immigrant communities creates barriers to seeking low-cost and free health services for which they may be eligible. While some politicians claim that most immigrants are motivated to come to the USA to obtain social welfare benefits, such as free health care, the evidence is that this is rarely a consideration.

Discrimination against immigrants in policy and actions is common throughout the world during periods of high unemployment and economic crisis. Western Europe experienced growing anti-immigrant sentiment and policies during the economic crisis that peaked in 2009, such as France deporting many Roma immigrants and anti-immigrant political parties gaining influence in the UK, Italy, the Netherlands, and Sweden. Heavily publicized deportations, police harassment, and heightened surveillance of immigrant populations will have a similar chilling effect on the use of government-sponsored health services and programs in all these countries, as it has in the USA.

Even when immigrants use the services available in their communities, the care provided may not be *acceptable* and discourage further timely use or compliance with recommended courses of treatment. Language barriers between providers and patients are a significant problem in both building trust and communicating information. In the 2005 California Health Interview Survey, 13% of adults with limited English proficiency (LEP) who had a doctor visit reported that they had difficulty understanding their doctor. The US Office for Civil Rights published a guidance in 2001 stating that the Civil Rights Act requires all federal programs provide "meaningful access" to those programs to persons who have LEP by providing translation services (www.lep.gov). In practice, this requirement applies only to institutional providers and public health programs that serve a significant number of persons with LEP. This leaves out all private providers as well as those institutional providers with smaller LEP caseloads. There are also National Standards on Culturally and Linguistically Appropriate Services (CLAS) that are also oriented primarily to institutions and not individual providers. There are frameworks, therefore, to guide health care providers, but they are unevenly and incompletely implemented.

Other acceptability barriers result when workers move locations frequently, such as those following crop harvests. Continuity of care is lost when migrant laborers use multiple clinics in different states or even countries. This is particularly important for migrants with chronic conditions that benefit from careful monitoring such as diabetes, diseases that have long courses of treatment such as tuberculosis, and for maintaining health records that are needed for later medical encounters such as information about previous caesarean section births. The fragmented nature of the US health care system and the low level of exchangeable electronic medical records work against an adequate continuity of care for migrant families with these types of health needs.

Perceived discrimination is a further barrier to acceptable care. Some studies suggest that immigrant Latinos are more likely to report racial discrimination in health care more than US-born Latinos, independently of language ability, income, and health insurance status. They also commonly report discrimination based on their health insurance (if on public insurance), or lack of insurance. When combined with other barriers, the perception of poor treatment due to their race/ethnicity will discourage Latino immigrants from seeking timely health care and is likely to reduce their willingness to follow medical advice.

Barriers Leading to Lower Health Care Use and Spending

The multiple barriers to health care use are reflected in the consistent findings that immigrants use fewer health care resources, even after adjusting for need and other standard predictors of use. In California, only one-third of noncitizen Mexican immigrants have a usual source of care; they are 30% less likely than US-born Mexican-Americans to have a usual source of care even after controlling for other determinants including insurance, age, poverty, and health status. Noncitizen Mexican immigrants report 2.4 doctor visits per year, 1.5 fewer than US-born Mexican-Americans after sociodemographics and need are considered. And 14% of noncitizen Mexican immigrants had an emergency room visit in the past year, *half* the adjusted rate of their native peers. Recent Mexican immigrants are also less likely to have received preventive services such as a mammogram, colonoscopy, or influenza immunization.

It is important to distinguish between rates and numbers in this context. Some hospitals complain that uninsured immigrants are overflowing their emergency rooms and creating a financial burden. This can happen, even though the rate of emergency room use is exceptionally low among immigrants, if the hospital is one of the few facilities in an area with a large number of immigrants. The undersupply of health care noted earlier is the cause of the problem, not immigrants since the emergency rooms would be even more overcrowded if the same neighborhood housed low-income native-born persons who are more likely to use emergency rooms. Another result of having an undersupply of facilities in dense communities are long waits that further discourage use even when needed. In September 2010, it was reported that the largest public hospital in Los Angeles, with a high immigrant census, had an average wait of 12½ hours in the emergency room from the time the patients are triaged until they are seen and then admitted or discharged.

It is logical that barriers to health care that result in lower levels of use also result in lower spending for immigrant health. An analysis of US health care spending in 2003 found that immigrants who had been in the USA under 10 years were 39% less likely than US-born persons to have any medical expenditures after controlling for sociodemographic differences, health status, and health insurance. Immigrants with longer stays were 25% less likely than the native-born to have any health care expenses. For those who did have health care costs, immigrants had substantially lower expenditures (14–20% after adjustments for population differences) than US-born persons. Even immigrants with full-year health insurance had lower spending than natives, both for total spending as well as out of pocket expenses. It is possible that immigrants obtain lower-cost insurance that exposes them to more restricted provider networks and/or higher copayments that act as barriers to care. Other availability, accessibility, and acceptability barriers discussed above may continue to serve as barriers to immigrants even when they have health insurance. Since the study controlled for self-assessed health, chronic conditions, and functional limitations, most of the health advantage enjoyed by immigrants was taken into account. The low medical expenditures for immigrants suggests that they account for a disproportionately small share of the US health care budget and create no significant financial burden on the country's health care system.

Health Care Reform Limitations

The central goal of the 2010 US health care reform, the Patient Protection and Affordable Care Act (ACA), was to expand health insurance coverage and reduce the number or persons without insurance by over half. It is estimated that under the ACA about one-third of all those in the country who will remain without health insurance will be undocumented immigrants since under half of undocumented immigrants nationally have any form of health insurance. The undocumented are explicitly excluded from public health insurance (Medicaid), new federal subsidies to purchase private insurance, and from participation in the new purchasing exchanges that should provide more affordable insurance. Low-income persons without immigration documents will continue to be eligible only for federal government payment for emergency services in life-threatening situations and for the delivery of babies (who are US citizens as a result of being born on US soil and therefore eligible for public insurance).

In addition to insurance, the USA has a network of primary care clinics (community health centers, or CHCs) that offer services based on the patients' ability to pay. Immigrants, both undocumented and documented, can access those clinics and the federal funding for the clinics increased under health care reform. It is possible that access to health care for all immigrants might increase with the expanded CHC presence since 57% of all recent immigrants to California use CHCs as their usual source of care, if they have one.

The lack of insurance is a key, but not the only, barrier to health and health care for immigrants. In addition to reducing health risks that immigrants face because of the type of jobs that they are recruited for, barriers to equitable health care put the long-term health of immigrants at risk. Equitable health and health care for immigrants require new efforts to assure that the full range of medical care facilities and providers are available in immigrant communities, that those resources are accessible to community members, and that the services provided are acceptable. While these types of barriers exist for many different groups in the USA, immigrants face a unique set of barriers that will require targeted interventions to address.

Conclusion

The concentration of immigrants in low-paid jobs with above average occupational health risks is not unique to the USA, as noted by the World Health Organization's 2010 consultation on immigrant health. The organization and financing of the medical care system in the USA are unusual, but the underlying issues of barriers for immigrants to the availability, accessibility, and acceptability of services can be found in health care systems throughout the world. These issues are fundamental to the WHO immigrant health consultation that identifies "avoid disparities in health status and access" as one of the four pillars of a public health approach to migrant health. The other pillars include ensuring migrants' health rights, which are integral to accessibility; minimizing the negative impact of the migration process, which is related to the vulnerability of immigrants in the labor market as well as social exclusion that serves as a barrier to health care; and reducing excess mortality and morbidity, where health barriers are implicated.

In taking a public health approach to immigrant health internationally, there is a tendency to emphasize linguistic and cultural barriers to care as particularly important for immigrant populations. While improving the ability of health care systems to communicate with diverse populations important, making that the lead immigrant health issue diverts attention from the even harder task of improving the availability of services in immigrant communities and making those services accessible. A clinic with providers who speak the same language as the immigrant community where it is located will not be accessible if the community is afraid that showing up at the clinic could lead to deportation. In all nations, therefore, reducing health barriers that immigrants face requires a multisectoral effort to change policies and systems to decrease occupational and other barriers to health, while improving the availability of health care, assuring that the available care is accessible, and enhancing the acceptability of the care that is accessed. Human mobility will continue to increase worldwide as a result of globalization, making these issues relevant across nations for many years to come.

Health Beliefs

Ranjita Misra[1], Elizabeth C. Kaster[2]
[1]Center for the Study of Health Disparities (CSHD), Department of Health & Kinesiology, Texas A&M University, College Station, TX, USA
[2]Department of Health & Kinesiology, Texas A&M University, College Station, TX, USA

Health beliefs are what people believe about their health, what they think constitutes their health, what they consider the cause of their illness, and ways to overcome an illness it. These beliefs are, of course, culturally determined, and all come together to form larger health belief systems. Different cultures have different definitions of what constitutes health and what causes illness. Culture itself can be defined many ways, but it is basically the characteristics that comprise a group of people's way of life, such as attitudes, beliefs, practices, etc.

Our thoughts and emotions follow our beliefs and create the attitudes, assumptions, expectations, and behaviors that determine how we react to life events and what we think is possible. These underlying belief systems drive our behavior. Similarly, health beliefs influence health behaviors and health outcomes. Results of clinical trials show that participants who received placebos have favorable responses to alleviating many health conditions and symptoms (30–90% of the time) based on their beliefs in the effectiveness of medical treatment. Several other examples include success in the use of hypnosis to control or eliminate a wide variety of unpleasant symptoms based on the power of expectation and attitude toward health. Cancer patients also show spontaneous remissions when their beliefs change or when patients reinterpret their symptoms and alter their attitudes about their lives.

Health beliefs also have a profound effect on the health of the community since beliefs and traditions of community members influence behavior changes targeted through community awareness and intervention programs. The beliefs of those in a community regarding specific health behaviors such as smoking or exercise can influence policy, for example, on whether or not funds will be spent on antismoking legislation, no-smoking ordinances, bike trails, or highway infrastructure. These beliefs also influence the types of food, recreational activities, restaurants, and health services available in a community.

Health-related beliefs and practices among different ethnic groups can produce positive health and well-being and beneficial health outcomes, have serious and harmful health outcomes, or result in no harmful health effects and hence are harmless. Examples of each are provided below.

The popular Western belief, "an ounce of prevention is worth a pound of cure," aptly illustrates the value of prevention – the planning for and taking action to prevent or forestall the occurrence of an undesirable event. Prevention is more desirable than intervention, which is the taking of action during an event or after the event has already occurred. Preventive activities include immunization for childhood diseases, the use of protective clothing or sunscreen to prevent skin cancer, health education and health promotion programs, the use of automotive passenger restraints and bicycle helmets, chlorination of a community's water supply, and safe housing projects.

Cigarette smoking, the largest preventable cause of death and disability in developed countries (and a rapidly growing health problem in developing countries), is a classic example of a behavior for which an ounce of prevention is truly worth a pound of cure. Despite thousands of conclusive studies establishing cigarette smoking as a cause of cancer, and despite the resulting coughing, odor, facial wrinkles, skin discoloration, ostracism, and increasingly socially unacceptable nature of this behavior, smoking rates remain high in certain population groups. Among US youths, in the late 1990s, more than one third of high school seniors reported having smoked during the preceding 2 weeks. Unfortunately, because the debilitating effects of smoking are not visibly present for many years following initiation of the behavior, most individuals are not willing to do the "ounce of prevention" part of the adage.

A different story emerges for those who do quit smoking. Smokers who have quit for up to 5 years soon regain positive health benefits, such as less coughing, better breathing, and life expectancies equivalent to individuals of the same age who have never smoked. An additional benefit to society is purely economic: for every dollar invested in a smoking cessation program, society gets back $10 in terms of decreased rates of tobacco-related morbidity and mortality (or a cost savings of over $50 billion per year at current rates of investment).

Some health beliefs do not themselves lead to negative or positive health outcomes. For example, many cultures equate balance with health and imbalance with illness. Cambodians and Asian Indians, two of the Asian Americans subgroups in the United States, believe that imbalance caused by natural forces or changes in the environment is the basis of illness. They also believe that illness can have spiritual causes. Bangladeshis in London believed the absence of sweating (due to the cold British climate and lack of physical labor) was the cause of diabetes among immigrant Bangladeshis and a reason why the condition improved or disappeared upon return to hot countries. In the same study, 14 out of 18 immigrants agreed that if they returned to Bangladesh, their diabetes might be cured. Such beliefs do not by themselves affect the course of the illness. Rather, their impact depends on whether the individual refuses recommended medical treatment in favor of using only an unproven remedy, such as sweating.

Similarly, some Hispanics or Latinos believe that physical or mental illness may be attributed to an imbalance between the person and their environment. Influences include emotional, spiritual, and social states, as well as physical factors such as humoral imbalances expressed as too much "hot" or "cold." "Cold" conditions are treated with "hot" medications and "hot" with "cold" medications, thus bringing the individual back into balance. Problems that are primarily spiritual in nature are treated with prayer and ritual. Some Hispanics who follow these beliefs may not express them to health professionals. However, Hispanics who use traditional or an ethnomedical approach of treating illness may be troubled by simultaneously using cosmopolitan treatments such as antibiotics, antihypertensive, etc.

Societies and cultures throughout the world are replete with traditional health beliefs and practices surrounding fertility. For example, pregnant women in many Asian cultures are advised that if they eat blackberries their baby will have black spots, or that if they eat a twin banana they will give birth to twins. Such beliefs have their foundation in folklore and traditional practices. Some Vietnamese traditionally believe that disease is caused by an imbalance of the humoral forces of yin and yang. When ill, many Vietnamese may use herbal medicines and a set of indigenous folk practices referred to as "southern medicine" in an effort to restore the yin/yang balance. These practices, from the Western viewpoint, were once thought to pose barriers to health. Recent investigations, however, revealed that certain beliefs and practices predicted neither lack of access to, nor underutilization of health services. In fact, individuals should not be discouraged from placing faith in such beliefs as they may result in positive health outcomes.

Individuals from different religions also hold beliefs that relate to the cause and treatment of illness. For example, some Hindus have a strong belief in astrology and believe that the movement of the planets has a major influence on human life. Many Hindus are strict vegetarians and connect this dietary choice to spirituality. Eating beef is prohibited since cows are considered sacred as they are believed to symbolize fertility and represent life and the sustenance of life. Other meat is not eaten because it involves harming a living creature. In the case of pork, the pig is seen as a scavenger and, therefore, the meat is considered unclean. Chicken and fish may be acceptable to some Hindus. However, food prepared in a medical facility may not be accepted because it may have come in contact with a forbidden food. Similarly, many refuse medication by capsule as cows and pigs are a source for the manufacturing of some capsules. In fact, past research has demonstrated that individuals who maintain vegetarian diets may experience lower rates of heart disease, obesity, and other unwanted health conditions.

However, certain health beliefs and practices result in physical harm or negative health outcomes. Female circumcision, or female genital mutilation as it is known in many industrialized countries (FMG), is a graphic illustration of a health belief and practice with a negative health outcome. Mostly practiced in Africa, the belief is that the practice of FMG ensures virginity and family honor, secures fertility, and promotes the economic and social future of daughters. FMG is also believed to preserve group identity, help maintain cleanliness and health, and further marriage goals, including enhancement of sexual pleasure for men. Some proponents of FGM justify the practice by asserting it “attenuates sexual desires in girls and protects their morals,” while others maintain that it is a “religious tradition.” In fact, it is not a requirement of any religion. The practice of FGM may lead to a range of complications that may occur immediately after the practice or in ensuing years; these complications range from disability to premature death. The practice is also believed to play a significant role in facilitating the transmission of human immunodeficiency virus (HIV) infection through numerous mechanisms. Hence, it is shunned by many international health organizations including the World Health Organization (WHO), and the practice of FGM is currently outlawed in the United Kingdom, Sweden, Belgium, the United States, Canada, Switzerland, France, Denmark, and in some African nations, such as Egypt, Kenya, and Senegal.

Conclusion

Health professionals often experience difficulties in providing care to ethnic minorities because of the disparity between minority and immigrant health beliefs and Western medical systems. The distance between the immigrant and minority health beliefs and Western health belief system appears to magnify the difficulties encountered in any cross-cultural health service delivery setting. It is important that doctors know about the traditional or ethno-medical treatments in order to compensate for affects of these treatments and to foster trust between them and their patients. The belief of many of the Asian and Hispanic subgroups regarding the causation of illness emphasizes social and spiritual dysfunction as causal factors. Management strategies such as preventive care, traditional and ethnomedicine, and the role of traditional healers should be considered for positive health outcomes.

of Family Medicine, University of Virginia School of
Medicine, Charlottesville, VA, USA

Background

There are over 185 million persons worldwide who live outside their countries of birth. In the USA, immigrants number 33 million or 11.5% of the total population. This level of immigration is unprecedented; even at the highest peak of immigration in the early twentieth century, the number of immigrants was only 40% of what it is today. International migration has also had a major impact on other developed countries. While the USA has the largest number of immigrants, as a percentage of the total population, Australia has the highest foreign-born population, followed by

Canada, Sweden, USA, the Netherlands, Norway, United Kingdom, and Russian Federation. Thus, caring for immigrants has become a near-universal experience for health care professionals in developed countries around the world. To competently and compassionately care for foreign-born individuals, physicians and other health care providers need to develop and apply a specific set of skills. This entry provides an introduction to these skills and additional resources.

It is first important to distinguish between different categories of immigrants, as this affects their legal status and rights and responsibilities. Immigrants are individuals who migrate from their home country because of perceived economic advantages, professional advancement, a desire to join family members, or other reasons that generally do not involve extreme threats to safety or survival. However, many immigrants (especially from Mexico, Central and South America) have experienced war and political violence. The Immigration and Nationality Act (INA), created in 1952, is the basic body of immigration law in the USA. Immigrants are permitted entry through one of many different types of visas. Far larger numbers of immigrants enter without documents, and primarily emigrate for work opportunities. Immigrants, whether documented or undocumented, are not guaranteed the same benefits and services as are refugees.

Refugees are a unique subset of immigrants. A refugee is defined as any person who is outside any country of such person's nationality or, in the case of a person having no nationality, is outside any country in which such person last habitually resided, and who is unable or unwilling to return to that country because of persecution or a well-founded fear of persecution on account of race, religion, nationality, membership in a particular social group, or political opinion. The 1951 Geneva Convention, written in the aftermath of World War II focusing mainly on Europe's displaced population, is the main international instrument of refugee law. The Convention defines who a refugee is and the kind of legal protection, other assistance and social rights he or she should receive from the countries who have signed the document. The Convention also defines a refugee's obligations to host governments. The 1967 Protocol expanded the scope of the Convention as the problem of displacement spread around the world. In the USA, this commitment was codified and expanded with the passing of the *Refugee Act of 1980* by Congress. It also provided for the establishment of an Office of Refugee Resettlement (ORR) within the US Department of Health and Human Services (HSS) to help refugees begin their lives in the USA. The structure and procedures evolved and by 2004, federal handling of refugee affairs was led by the Bureau of Population, Refugees and Migration (PRM) of the US Department of State, working with the ORR at HHS. Each year, the President of the USA sends a proposal to the Congress for the maximum number of refugees to be admitted into the country for the upcoming fiscal year, as specified under section 207(e) (1)–(7) of the Immigration and Nationality Act. In recent years, the number of refugees admitted to the USA has ranged between 40,000 and 80,000 individuals. Worldwide, the number of refugees is estimated to be 16 million, in addition to 26 million internally displaced persons.

There are clear differences in the services provided to refugees and immigrants in the USA. Other countries will vary in the services provided. In the USA, refugees are provided relocation services, including but not limited to housing, job placement and skills training, cash and medical assistance with school enrollment for children, English language training, and aid for victims of torture. Refugees are entitled to free health screening and immunization services that are usually provided at a local health department, English as a Second Language (ESL) classes, and Medicaid (for 8 months). Immigrants who are not refugees are not guaranteed any of these services but may be eligible for some services, primarily related to public health protection, such as screening and treatment for tuberculosis at local health departments. In countries with universal, government-sponsored health insurance, access of immigrants to health care is more favorable.

Health Needs of Immigrants

The health needs of immigrants – both medical and psychological – will vary depending on where the immigrant was born and where he was living before arrival in the "third country," that is, the country of resettlement: the conditions under which he was living, and his access to health care, clean water, shelter, food, and other support at that location. Refugees, because they do not make a voluntary choice to leave their country, generally have been living under more extreme physical and emotional conditions and thus require more intensive screening and health care services upon arrival and for months or years to follow. Immigrants from developing countries will also need screening for certain diseases, such as tuberculosis and HIV.

Clinical Evaluation

A complete history and physical exam should be conducted for every refugee. Patients should be reassured that all information is confidential and is being asked in order to better understand their health status to provide appropriate care. In addition to the usual elements of a history and physical, the history and physical examination should include:

1. Immigration history: country of origin, country of departure, and dates for each move; reasons for leaving the country of origin; history of torture or physical or emotional violence
2. Nutritional status, including growth and development, especially in children
3. Infectious diseases, including screening for diseases common to the refugee's country of origin or transit
4. Mental health, including screening for depression, anxiety, posttraumatic stress disorder, somatization disorder, and substance abuse
5. Health promotion and screening, including cancer screening (Pap smears, mammograms, colonoscopies, etc.)

Physical examination should include height and weight of both children and adults to assess nutritional status. Refugees should be assessed for physical signs related to traditional health practices, such as coining (rubbing coins over the skin), or to trauma and torture. Documentation of all findings is very important, as such documentation may be needed for asylum or legal proceedings. Identification of such findings may also facilitate discussion of this sensitive subject with the patient who otherwise may have denied prior abuse. Examination of the teeth is also important, as dental care among refugees is usually absent and referral to a dentist is a common need.

Laboratory and screening tests should include screening for common infectious diseases including tuberculosis, hepatitis B, intestinal parasites and HIV (adults and children of infected parents). Previous immunization with bacilli Calmette-Guérin (BCG) vaccine should not be considered when interpreting tuberculin skin test (PPD) results. Refugees are required by the Department of Homeland Security to be tested for tuberculosis and syphilis. HIV testing was required until recently. Other useful tests are complete blood count, comprehensive metabolic panel, thyroid-stimulating hormone, and urinalysis. Most refugees have had limited prior access to screening tests. Routine age-appropriate screening should be offered, including Pap smears, mammograms, and colonoscopy. Challenges to providing screening tests will be described in a later section.

Children and adults should be provided with age-appropriate vaccinations. Some refugees may come with vaccination records, but that is the exception rather than the rule.

Children should have additional evaluation for growth and development. Nutritional deficiencies are particularly common among children, including stunted growth and anemia. Additionally, children may have had limited exposure to formal education, and children with developmental delays would likely not have been identified and treated, or may have even been dismissed from school. This evaluation is particularly challenging, especially on initial assessment, and may require discussion with teachers and refugee agency staff over time after resettlement to determine if the child is delayed. Referral to a developmental pediatrician should be made early if there are any concerns.

Many refugees have been traumatized psychologically by their experiences at home and through dislocation and relocation. Common situations include loss of spouses, parents, or other family members to violence or illness; experience personally or through a close relative of torture or physical abuse; loss of home and possessions; and separation from family members and friends. Once resettled in the USA or other final destination, they are faced with a whole set of other stressors, including learning a new language and culture, obtaining a job, earning enough income to provide for their family, and for children, going to school in a new environment. Refugees often come from countries where discussion of emotional distress is considered taboo, and thus identification and treatment of refugee patients with any of these conditions pose considerable challenges. Patients will often present with multiple physical complaints, and once "medical" etiologies are investigated and ruled out, it is necessary to address the psychological basis for the symptoms with the patients, in a culturally sensitive way. It may take several visits to gain the trust of patients with psychological distress and emotional disorders and to negotiate acceptable treatment regimens. Consultation with and referrals to mental health specialists, including psychologists and psychiatrists, should be done when the primary care physician feels such expertise is required. Specialized clinics are available in some cities with large refugee populations, including centers for victims of torture. Often, patients are less interested in "psychological" treatment than in assistance with meeting socioeconomic needs, such as obtaining better employment, and thus the assistance of social workers is essential.

Initial screening of refugees is generally done by health departments, and treatment of some diseases, such as active or latent tuberculosis, may be done by them also. It is important for physicians to learn what services are provided to refugees and immigrants in their communities by the health department and other agencies. Collaboration and sharing of information is the most beneficial approach to providing high quality as well as cost-effective care.

Barriers to Health Care Access: The Patient's Perspective

There are many potential barriers to accessing health care services from the immigrant's perspective. In the USA, refugees receive Medicaid (publicly funded insurance) for 8 months, which is generally extended for children to the age of 18. Unfortunately, some clinicians do not accept Medicaid, and dental care is excluded for adults with Medicaid. In most other developed countries, health care is provided universally, so this should not be a barrier per se. However, barriers to accessing health care extend beyond health coverage, including lack of language fluency and access to trained interpreters, limited education and literacy in their own language, lack of knowledge as to where to go for health care, lack of knowledge about what conditions require medical attention, when to use the emergency room versus going to a primary care physician, lack of transportation, and fear of losing employment to take time off from work to see the doctor. Seeking help for emotional problems is taboo for many cultures and thus presents unique barriers.

Barriers to Health Care Access: The Clinician's Perspective

Physicians and other health care providers often find caring for immigrants challenging. Much of the challenge is related to the more obvious communication barriers. Working with trained interpreters requires training and experience on the part of the clinician. In addition, interpreters are very costly. Larger hospitals and health systems are more likely to have access to interpreters, either in person, or through language lines, than smaller hospitals and practices due to the cost. All communication with limited English (or other dominant language of the respective location) proficient (LEP) patients requires more time, and more complicated exchanges, such as informed consent for procedures, will require even more time and patience. Follow-up communication (e.g., conveying lab results and instructions) is more difficult, and patient education materials in multiple languages may not be easily available for all conditions for which they are needed. Add to that the challenges of learning about different cultures, tropical diseases that the clinician hasn't thought about since medical school, and psychological and physical traumas that are painful to address. Physicians often identify caring for chronic diseases and health screening as particularly frustrating areas, as refugee and immigrant patients often have not had experience with chronic disease management or preventive screening and thus do not always accept these services or return for follow-up appointments. Finally, physicians do not always understand the legal rights and responsibilities of immigrants and refugees, or the services available to them in the community.

Cultural and Linguistic Standards and Laws

In the USA, title VI of the Civil Right Act (1964) states that "No person in the United States shall on the ground of race, color or national origin, be excluded from participation in, be denied benefits of, or be subjected to discrimination under any program or activity receiving Federal financial assistance." In 2000, President Clinton signed into law an executive order "ensuring that LEP persons who are eligible for Federal programs and services have meaningful access to the health and social service benefits that they provide and that this access must be at no additional cost to the LEP person."

In 2001, National Standards on Cultural and Linguistically Appropriate Services (CLAS) were developed by the Office of Minority Health, US Department of Health and Human Services. The CLAS standards are primarily directed at health care organizations; however, individual providers are also encouraged to use the standards to make their practices more culturally and linguistically accessible. The principles and activities of culturally and linguistically appropriate services should be integrated throughout an organization and undertaken in partnership with the communities being served. The 14 standards are organized by themes: Culturally Competent Care (Standards 1–3), Language Access Services (Standards 4–7), and Organizational Supports for Cultural Competence (Standards 8–14).

Within this framework, there are three types of standards of varying stringency: mandates, guidelines, and recommendations. CLAS mandates are current Federal requirements for all recipients of Federal funds (Standards 4, 5, 6, and 7). These standards are:

Standard 4: Health care organizations must offer and provide language assistance services, including bilingual staff and interpreter services, at no cost to each patient/consumer with limited English proficiency at all points of contact, in a timely manner during all hours of operation.

Standard 5: Health care organizations must provide to patients/consumers in their preferred language both verbal offers and written notices informing them of their right to receive language assistance services.

Standard 6: Health care organizations must assure the competence of language assistance provided to limited English proficient patients/consumers by interpreters and bilingual staff. Family and friends should not be used to provide interpretation services (except on request by the patient/consumer).

Standard 7: Health care organizations must make available easily understood patient-related materials and post signage in the languages of the commonly encountered groups and/or groups represented in the service area.

Thus, interpreter and translation services must be provided, by law, at any health care organization receiving federal funding, without cost to the patient. Federal funding includes Medicare and Medicaid. Agencies in the community assisting LEP clients are generally aware of these requirements and will advocate locally for these services to be provided to patients receiving care.

Training and Licensure Requirements

The Liaison Committee on Medical Education (LCME) sets the standards for medical education in the USA; two standards are specific to working with patients from diverse cultures:

ED-21: The faculty and students must demonstrate an understanding of the manner in which people of diverse cultures and belief systems perceive health and illness and respond to various symptoms, diseases, and treatments.

ED-22: Medical students must learn to recognize and appropriately address gender and cultural biases in themselves and others, and in the process of health care delivery.

The Accreditation Council for Graduate Medical Education (ACGME) and Institute of Medicine have recommended that cultural competency education be part of residency training. A recent survey of over 8000 residency programs in the USA demonstrated that just over 50% of programs are now providing this education. A number of residency programs also offer specialized tracks in health disparities, global health, and care of immigrants, and new fellowship programs in immigrant and global health are emerging. In 2008, the State of New Jersey enacted legislation requiring all colleges of medicine in the state to provide cultural competency training as a condition of receiving a diploma. All license renewals will require continuing medical education training (6 hours) in cultural competency. Other states are following suit. This new emphasis on cultural and linguistic competency in medical education will assist new and practicing physicians in acquiring the skills they need to provide care to the growing number of immigrants they will serve.

Core Values in Immigrant Medicine

Patricia Walker and Elizabeth Barnett, in their introduction to *Immigrant Medicine* (2007), identify a set of core values that should be practiced by providers working with refugees and immigrants: global health equity, respect, trust, cultural humility, and compassion. Physicians can learn a lot from listening to their patients' stories, and develop mutual respect and trust that is essential for an effective therapeutic alliance. When the challenges of caring for immigrant patients seem overwhelming, stepping back, reflecting on their patients' traumatic experiences and enormous strengths in surviving adversity most Western physicians have never seen, will help the clinician in overcoming these hurdles and lead to a more fulfilling and successful partnership.

In addition to these core values, an important role for physicians and other health providers is that of advocate. For example, advocating for health insurance reimbursement for interpreter services leading to legislative changes can help cover the expense of interpreter services and contribute to better communication. Eleven states in the USA (as of 2005) allow reimbursement for interpreter services provided for Medicaid and State Children's Health Insurance Program (SCHIP) enrollees. These include Hawaii, Idaho, Kansas, Maine, Massachusetts, Minnesota, Montana, New Hampshire, Utah, Vermont, and Washington. Physicians can also advocate within hospitals for better interpreter services, cultural competency training, and translated education materials. There is no limit to what is possible with perseverance and imagination.

Collaboration is Essential in Immigrant Health Care

Finally, two desirable, if not essential, components to providing effective and compassionate care for immigrants are collaboration and teamwork. Ideally, the physician will be a member of a team of health care providers consisting of other physicians (e.g., psychiatrists, developmental specialists, infectious disease specialists), nurses, social workers, psychologists, community agencies and volunteers, public health department personnel, interpreters, health educators, and teachers. An example of this model is the International Family Medicine Clinic (IFMC), founded at the University of Virginia (UVA) in 2002. In partnership with the International Rescue Committee (IRC, refugee resettlement agency) and the Charlottesville-Albemarle Health Department, the IFMC provides primary health care services for all refugees resettled in Central Virginia by the IRC. The IRC, with informed consent by the patient, provides the overseas medical examination to the IFMC. The Health Department, which conducts the initial screening of refugees, sends all results of testing to the IFMC, where identified illnesses are treated (except for active and latent tuberculosis, which are managed by the Health Department). Quarterly meetings are held with these partners, plus the IFMC social worker, the UVA language office director, and other health and nutrition agencies that work with refugees in the community, to share information and optimize care. Resident trainees provide care to the refugees. An entire curriculum in refugee and immigrant health and cultural competence has evolved from this. Further, a new Global Health Leadership Track provides additional refugee and global health training for residents in Family Medicine and Internal Medicine. Physicians in smaller practices without access to a university can develop immigrant health collaborative teams using available resources in their communities.

Health Care Utilization

Cătălin Jan Iov
University of Medicine & Pharmacy “Gr. T. Popa”, Iasi, Romania

Health status is a critical issue in defining the state of a society's welfare. Health status is dependent on numerous factors, including the availability and utilization of health services. In an ideal world, everyone would be able to access any kind of medical service, any type of medical procedure, treatment, or drug. However, in the real world in which we live, access to health care is mediated by factors such as the individual's or family's income, the availability of medical insurance, the patient's preferences and beliefs, culture, doctor–patient relations, patient education, institutional practices and policies, discrimination, and other factors. These factors, as well as others, may constitute barriers to accessing health care producing disparities across groups.

Immigrants often decide to leave their countries of origin due to the poor quality of living, reflected in their income, food availability and quality, health care availability and quality, life security, etc. They want a better life, better material conditions, and a safer and healthier life. Accordingly, immigrant utilization of health care services has become the focus of much discussion in recent years, particularly in those countries in which immigrants constitute a large proportion of the population or in which there is a large and growing influx of immigrants. For example, researchers reported that there were about five million immigrants to Canada during 2000–2001 representing approximately 18.4% of the population at that time.

Health status is strongly dependent on the utilization of medical services, of health care. Health care utilization can be primarily defined as the rate of accessing medical services by individuals. Health care utilization is often measured by the number of physician visits, hospital nights, and bed disability days, the use of home health services, and the use of other health professionals.

Several models have been proposed for use in examining health care utilization. A frequently utilized behavioral model developed by Andersen and colleagues explains health care utilization in terms of the propensity to use services. This model specifies that health care utilization depends on three sets of factors: predisposing factors, enabling factors, and need factors. Predisposing factors include sex, age, and social status. Enabling factors consist of the conditions facilitating or inhibiting the use of medical services, such as the distance to the health center, the type of municipality, the hours during which the health facility is open, and the family size. Need variables include the presence of disease or illness and psychological status.

Sociodemographic characteristics such as sex, race, residential area, geographical area, parental status, marital status, work status, income, education, insurance, and age may constitute barriers to health care utilization. Particular attention has been paid to the effects of race and ethnicity on health care utilization. It has been reported, for example, that Mexican Americans use medical services less often than White and Black non-Hispanics and other Hispanics.

Language is also a very important factor in accessing and utilizing health care after migration to a new country. As the welfare of the immigrant in the new country is often strongly dependent on the immigrant's ability to integrate into the new society, poor language skills in the language of the new host country is a barrier to the receipt of health care services.

The extent of similarities and differences between the immigrant's home culture and that of the receiving country is also an important factor in the extent of health care utilization. The extent to which the immigrant retains his or her own culture and adopts the culture of the new country, known as the process of acculturation, has been found to be associated with various health behaviors and with health care utilization. Past research has demonstrated a strong effect of acculturation on weight and diet, smoking, substance use, cancer screening, hypertension, AIDS risk, compliance with treatment, and alcohol use.

Women, in particular, may confront difficulties in accessing health care services. In some cultures, women are considered inferior and/or are expected to place the health concerns of their family members before their own. As a consequence, they may not seek out and utilize the health care services that they need, such as screening for particular diseases.

Health care service utilization requires a certain level of knowledge. That is, an individual may not utilize a service unless he or she is aware of its existence, its purpose, and its importance. As an example, researchers have found that immigrants may often rely on hospital emergency departments for their medical care in order to see a specialist, not understanding that, at least in the USA, access to specialist care often requires a referral from a primary care physician. As yet another example, immigrants may be less likely than native-born individuals to utilize preventive care services, such as disease screening, because they are not suffering from pain and do not have any symptoms.

An individual's income is an important determinant of health care utilization. Studies have shown that individuals' access to health care dramatically decreases with a decrease in income. The availability of health insurance is also critical, particularly in those countries in which access to government-funded health care is limited, restricted, or nonexistent. Immigrants may encounter greater difficulties in attempts to utilize health care services because of restrictions on noncitizens' access to governmentally funded health care and the unavailability of employment-based health care insurance.

Individuals may be reluctant to utilize health care services because of their immigration status. If they are present in a country illegally, they may fear that utilization of health care services will result in greater visibility and ultimately lead to their removal back to their country of origin. In some cases, immigrants may rely on more traditional healing remedies, such as plants, teas, and faith in lieu of Western medicine, specifically in order to avoid coming to the attention of immigration authorities. This fear may be exacerbated in smaller towns in which immigrants are more visible as a function of the lesser populace. Governmental legislation may also result in heightened fear of discovery among immigrants needing medical care. As an example, California's (U.S.) Proposition 187 had mandated that health care providers report to immigration authorities any patients who appeared to be present in the country illegally and also limited immigrants' access to health care. The passage of this law heightened immigrants' fears of deportation as a result of seeking health care and, as a result, potentially presented a threat to the public health because of the nontreatment of infectious disease. That legislation was later held to be invalid when it was challenged in court.

Health Disparities

Brittany Daugherty
Department of Psychology, John Carroll University,
Cleveland, OH, USA

Researchers and practitioners have differing opinions on what constitutes health disparities and consequently a consensus definition has not been achieved. In the USA, the common terminology is health disparity while the terms "health equality" and "health equity" are used more frequently in other nations. Common characteristics of health disparities include a chain of events that signify a difference in (1) environment, (2) access to, utilization of, and quality of health care, (3) health status, or (4) a particular health outcome. Assessing the lack of quality of health care and the inability to access adequate care are the prominent measurements of health disparities. Disparity, inequality, and inequity often used interchangeably; however, keen differences exist between these important health terms. Health inequity refers to health differences that are unnecessary, unavoidable, unfair, and unjust. Disagreements concerning the definition of health disparity and the usage of other public health terms can hinder the development of health interventions.

Health disparities are usually determined by either structural biases or uncontrollable circumstances which inhibit vulnerable populations from receiving the care they need. These biases and circumstances can be noted in the seven determinants of health disparities; (1) natural or biological; (2) voluntary health-damaging behavior; (3) the health advantage of one group over another when a health-promoting behavior is adopted; (4) a health-damaging behavior that is chosen due to limited lifestyle choices; (5) exposure to unhealthy and dangerous living and working conditions; (6) inadequate access to health care and basic services; and (7) health-related social mobility. In order to eliminate health disparities, health care quality must be effective, safe, timely, equitable, and efficient. The health of a population can be measured by indicators that exhibit mortality, well-being, lifestyle behaviors, and health-related risk factors. These indicators are useful criteria for identifying health disparities among groups. Groups who suffer from health disparities include racial/ethnic minorities, uninsured individuals, and residents of rural areas.

Race and Ethnicity

Race and ethnicity have emerged as factors in identifying and remediating health disparities. Minorities when compared to their nonminority counterparts are at increased risk for mortality and morbidity. In 2005, African Americans had a higher rate of infant mortality than any other racial group at 13.63 infant deaths per 1,000 live deaths. They also undergo twice the number of outpatient department visits and emergency department visits (63.5 visits per 100; 79.9 visits per 100 persons) than Whites (31.3 visits per 100 persons; 36.3 per 100 persons). In 2007, 6.8% of African Americans were significantly less likely than Whites (14.7%) to receive mental health treatment or counseling.

African American patients also visited the emergency room within 7 days of discharge from the hospital more often than Whites. This could demonstrate distinct differences during inpatient care and/or follow-up care based on race. Hispanics, the largest immigrant group in the USA and one-third the population are the most likely of any racial minority group to be uninsured and low income, being 30% more likely to lack health insurance than Blacks or Whites. Sixty percent of Hispanics are known to be uninsured for a significant amount of time. In 2007, the overall mortality of African Americans was 25% higher than that of Whites, due to health concerns such as diabetes, heart disease, stroke, HIV, and cancer.

Minorities have long suffered from psychosocial stressors associated with racial and ethnic discrimination. Bias and discrimination occurs in any social system and the health system is not exempt. The Tuskegee Syphilis Study initiated in 1932 by the U.S. Public Health Service studied the progression of syphilis in African American men in Macon County, Alabama among 600 poor African American sharecroppers suffering from the sexually transmitted infections. This study, historically designated as unethical, serves as a case for examination of the detrimental effects of discrimination. This incident has influenced many minorities to have negative views toward public health services and preventative programs. Racial/ethnic health disparities continue to persist. Minority health disparities not only disclose the association between vulnerable populations and health care but also the link between racial discrimination and health status.

Reducing racial health disparities is a priority for The American Medical Association (AMA) and the National Medical Association (NMA). Despite their conflicting histories, they are committed to collaborating on eliminating racial injustice in health disparities. Many other organizations including the AMA have put forth great effort to recruit minority physicians by implementing math and science programs in certain communities and funding minority medical programs.

Gender

Health differences as they pertain to gender affect our perception of gender stereotypes and gender equality. Mental health is one area in which there is a major gender gap. Mental health disorders have affected women disproportionately. Depression and posttraumatic stress disorder (PTSD) have been known to affect women in larger numbers than men. Women are also predominately affected by a comorbidity of mental disorders. According to the World Health Organization, depressive disorders account for almost 41.9% of the disability from neuropsychiatric disorders among women compared to 29.3% of men. These disabilities can possibly result in physical ailments as well as a longer and stronger dependency on psychotherapy and medications. In 2007, it was reported that 53.3% of women were more likely to use prescription drugs than 43.2% of men. Men on the other hand are most likely to be diagnosed with antisocial behavior disorder and alcoholism than women. In addition to mental health, other health status indicators may show gender variations as well.

Health Insurance

The lack of insurance benefits is a major problem for majority of children, women, and elderly population. In 2006, there were 43.6% of Americans were uninsured, many of whom lived within an urban area, had lower incomes and were of minority status, or immigrants. The growth of the uninsured population consists mostly of individuals between the ages 18 and 64 who are employed. In 2007, one-third of people under 65 years of age, with a family income 200% below the poverty line, were uninsured for at least 12 months compared to higher income families, prior to being interviewed. Being uninsured compromises the health of millions and can lead to serious illness that could have been treated by early diagnosis and treatment. Those who are uninsured are more likely than insured individuals to be disproportionately affected by health disparities. Uninsured individuals are six times more likely to lack a usual source of care and four times more likely to be without a usual source of care due to financial reasons. Individuals with no insurance are twice as likely to visit the emergency room as insured individuals. Without a continuous source of care, uninsured individuals are the most likely to receive lower quality care and have illnesses difficult to manage. The lack of health insurance affects the delivery of emergency care, prenatal care, and childhood illnesses. Uninsured women and children may be at particular risk that causes many preventable and treatable illnesses to become chronic illnesses and even become fatal. Not only do those who are uninsured spend a higher amount out of pocket to cover health expenses, they are often charged full price for health care services. While other countries may have different mechanisms other than the US model of insurance to protect the population, not all groups can be assured of adequate and appropriate medical care and this variability may create disparities in access to care.

Geography and Residency

Residency is of great importance to public health and to the study of health disparities. Where vulnerable populations reside affects their access to health services, employment, and educational opportunities. Research of health disparities in urban, rural, and other subareas is an evolving area of study. Neighborhood studies have shown that those who reside in urban areas, for example, tend to reveal health disparities. Today the majority of the world's population lives in urban areas, in both high- and low-income countries. Most commonly seen in urban areas are issues of: air pollution, mental health disorders, communicable diseases such as tuberculosis, malaria, and whooping cough, and non-communicable diseases such as heart disease, diabetes, and obesity. Urban areas are most often associated with future technology, employment, and favorable lifestyle, thus are often chosen over rural communities as places to live. These benefits of urban living come with the cost of higher rates of mental illness, homicide, and physical health problems.

As urban areas continue to grow, so does the presence of urban dwellers. Urban dwellers are individuals who live in slum areas and are affected by the inadequate infrastructure and health issues of urban areas. There are more than a billion urban dwellers living in overcrowded areas heavily impacted by urban health issues such as traffic, violence, and crime. Ethnoburbs are suburban areas that emerge around large cities where there are significant growth of immigrants or ethnic group. The increase in migration toward ethnoburbs are concentrated mostly in the South, Midwest, and the Plains states. They are a newly acquired settlement recognized in racial/ethnic urban studies. Suburban and rural communities are also seeing an increase in immigrants. Suburbs are seen as urban areas as well, however, they are comprised of two elements: rurban and exurban areas. Rurban areas are most often low class and near poverty areas while exurban areas are clusters of developments right outside of the city limits. Suburbs are highly variable due to its increase in ethnic diversity. Rural areas are most affected by geographical isolation and limited job opportunities. Rural areas make up 20% of the American population, have fewer practicing physicians, and are less likely to be insured. Rural areas are more likely to have higher mortality rates, higher rates of chronic health conditions and suicide. With their limited resources and declining population, rural areas are in need of more efficient strategies, such as lowering health care costs, improving access to health services, and the implementing advanced technology.

Immigrants

Immigration reveals a complex relationship to health disparities. Immigrants are often healthier than their counterparts in their country of origin; referred to as the "healthy immigrant concept." However, the length of immigrant residency has been shown to have a major impact on the health of immigrants. When immigrants arrive, their health is most likely to be equivalent those of their home country. As time of residency increases in a new country, health outcomes tend to shift toward those of the host country. Immigrants have a rather unique experience regarding health care. As immigrants arrive in new countries, they are presented with drastic lifestyle changes. They often face opposition in new countries, where they may be perceived responsible for straining the infrastructure of the host country and inappropriately using health resources. The vulnerability of immigrants is influenced by residential location, proficiency in the English language, and immigration status. According to a 2007 study, immigrants overall have lower rates of health insurance, use less health care, and receive lower quality care.

Health disparities related to immigrant status are much more distinct in the USA, as Latinos make up the largest immigrant population. Prior to 1996 immigrants were able to receive Medicaid health care benefits; however, since then the Personal Responsibility and Work Opportunity Reconciliation Act (PRWORA) has restricted immigrants from applying. The law requires immigrants to wait 5 years after being granted permanent residence to apply for federal health benefits. As a result, this federal law exacerbates rates of the uninsured. The primary sources of care for immigrants are community health centers and public clinics. Even so, these particular clinics are sparse in suburban and rural areas which have an influx of immigrant populations. For the estimated 12 million immigrants who reside in the USA illegally, fear of deportation prohibits them from seeking appropriate health treatment. The lack of health services available to uninsured immigrants' increases overall health care costs for everyone as well as puts individuals at risk for diseases and infections. With a majority of immigrants being of Hispanic descent, race plays a major role in health disparities. Hispanic immigrants make up one-third of the US population, making them the largest growing immigrant group in the nation. However, this growing group of immigrants faces a problem in obtaining quality health care. Their immigrant status, especially when undocumented, has a detrimental effect on their ability to access health care and insurance.

Initiatives

Eliminating health disparities has become a great challenge to researchers, practitioners, and policy makers. Health policy, health literacy, and research are three main areas in which reforms are being sought to address nationwide health concerns. Health literacy is the capacity to obtain process and understand basic health information needed to make health decisions. It is not only the ability to read, but the ability to interpret and understand health issues. Health literacy allows the ability to accurately read prescriptions and calculate the dosage. Low health literacy has been linked to higher rates of hospitalization and emergency services. The American Medical Association, one of the many organizations addressing health literacy, has specific tools and techniques to improve health literacy and patient–provider communication. Further, the AMA is using its partnerships with other organizations to reach out to patients and provide health literacy resources.

Government initiated health policies are also working to impact health disparities. Healthy People 2010 initiated by the Department of Human and Health Services in 2000 profiles the health concerns of the nation. This report contains over 450 objectives to improve the health of people throughout the nation. Two of their overarching goals are to increase quality and years of healthy life and eliminate health disparities. This initiative has been successful in highlighting health disparities among groups across the nation and establishing goals for the nation's health. The World Health Organization adopted Health for All by 2000 in 1981, an initiative to address health disparities and improve the health of the most vulnerable groups through policy, economics, and direct services across the world.

Insurance retention policy is one factor in closing the gap to health disparities. Insurance retention requires the insured to pay a small portion of an insurance claim, which reduces insurance premiums. This established policy designs programs for vulnerable populations improving the quality and access to health care as well as ensure family care. Insurance retention reaches those in need and helps lower rates of mortality and chronic and acute illnesses. It allows those who are insured to stay insured and reaches out to those who are uninsured as well. With many of the uninsured being noncitizens, racial or ethnic minorities, or of low income, language, discrimination, and health expenses and are becoming significant barriers. It is important that health care providers provide translational services to help non-English speakers, racial and ethnic minorities, and low-income populations to receive the best care possible.

These initiatives are providing a foundation for stronger implementation of further policies and practices to eliminate health disparities. However, there is still more work to be done in order to achieve success in elimination of health disparities.

Conclusion

Health disparities affect millions of people worldwide. Health disparities are manifest in race, ethnicity, gender, insurance status, geographical location, and immigrant status. Public health practitioners, policy makers, and researchers working together to reduce the risks of health disparities in all populations demonstrate that multifaceted approaches are indicated to eliminate health disparities. These efforts command long-term and sustaining interventions. Immigrants worldwide experience multiple conditions that predispose them to health disparities and their circumstances deserves special attention. Elimination of health disparities requires long-term approaches that sustain local efforts in specific populations such as immigrants, countries, and social context.

Health Education

Michael Kelly[1], Susan Wooley[2]
[1]Paso del Norte Health Foundation, El Paso, TX, USA
[2]American School Health Association, Kent, OH, USA

Formal health education is any combination of planned learning experiences that help individuals, groups, or communities gain the information and skills they need to make informed decisions about their health, safety, or well-being and act on those decisions. It is an educational process with approaches that individuals, families, and communities can use in making voluntary and free choices regarding health-related behaviors or lifestyle matters. The decisions might involve individual lifestyle choices such as what to eat or they might involve ways to create changes that will make communities healthier and safer. Such changes might include policies such as tobacco-free public areas or community activism such as creating safe places for being physically active, ridding neighborhoods of illegal drug pushers, or improving the quality of foods served in schools.

Typical settings for the delivery of health education are schools, colleges and universities, community agencies, health care settings, workplace settings, and governmental and nongovernmental agencies/organizations at the local, state, regional, federal, and international levels. Regardless of setting, quality health education consists of the development, delivery, and evaluation of planned, sequential, and developmentally appropriate instruction, learning experiences, and other activities. The purpose of health education is to influence in a positive direction the health behavior of individuals and communities as well as the living and working conditions that influence their health.

Many people and systems provide health education. Families are one's first health educators. In schools, teachers, school nurses, and peers often provide health education. Sources of health education in the community include neighbors and friends, grocers, the media, and health care providers in addition to formal programs that might be conducted in community centers, places of worship, and worksites.

Professionally prepared and trained health educators draw from the biological, environmental, psychological, physical and medical sciences to promote health and prevent disease, disability and premature death through education-driven behavior change activities and policy interventions. Several organizations support the health education professional, including: the American Association for Health Education (AAHE), the American School Health Association (ASHA), Eta Sigma Gamma (ESG), the Society for Public Health Education (SOPHE), the International Union of Health Educators and others. The International Union for Health Promotion and Education, with regional offices across the globe, promotes global health and contributes to the achievement of equity in health between and within countries of the world.

The National Commission of Health Education Credentialing, formed in 1988, drew upon competencies identified through a role delineation project to create and implement a credentialing system for the profession. The competencies serve as the basis for the examination the Commission uses to determine who is eligible to be a Certified Health Education Specialist (CHES). The Commission introduced in 2011 a Master Certified Health Education Specialist (MCHES) designation that reflects advanced competencies in health education. The competencies expected of professional health educators are arranged into the following seven areas of responsibility: Area I: Assess Individual and Community Needs for Health Education; Area II: Plan Health Education Strategies, Interventions, and Programs; Area III: Implement Health Education Strategies, Interventions, and Programs; Area IV: Conduct Evaluation and Research Related to Health Education; Area V: Administer Health Education Strategies, Interventions, and Programs; Area VI: Serve as a Health Education Resource Person; Area VII: Communicate and Advocate for Health and Health Education.

Professional Preparation Programs

Professional health educators have a minimum of a bachelor's degree. An estimated 250 institutions of higher education in the USA offer professional preparation programs in health education. The names of the academic departments housing the discipline and the degrees they confer vary – health education, health communication, health science, public health education, and health promotion. Many larger universities offer masters or doctoral degrees in Health Education.

A typical course of study in Health Education includes content courses, such as: adolescent health, aging, consumer health, death and dying, fitness, human diseases, drugs and society, human sexuality, nutrition, and safety. In addition, Health Education majors take process courses such as: teaching health in secondary schools, community health methods, theory of behavior change, public policy, program planning, program evaluation, and research methods. Together, with a core of science and humanities, the required content and process courses provide graduates with both knowledge about health issues and skills for effectively facilitating learning.

The Promotora is a valuable collaborator with the professional health educator. Frequently found within Hispanic populations, the promotora shares a cultural bond and common language with a community. Thus, some immigrants are more receptive to and less skeptical of a promotora than the classic health educator. In some instances the promotora has training in specific health content or community education. A few community colleges in the USA offer an Associate's Degree for promotoras and states, such as Texas, license these paraprofessionals.

School Health Education

School health education addresses the physical, emotional, and social dimensions of health tailored to students' age and developmental levels. The ultimate goal is to motivate and assist students in maintaining and improving their health, preventing disease, reducing health-related risk behaviors, and being informed consumers of health services and products both now and when they become adults. Intermediate goals include developing students' health literacy and facilitating their acquisition of the knowledge and skills they need to make health-enhancing decisions. Health literacy involves being critical thinkers and problem solvers, responsible and productive citizens, self-directed learners, and effective communicators. School health education is one aspect of a school's health program that includes curricular, environmental, and support systems, programs, and policies that contribute to the health and safety of students and school employees.

Within elementary schools, classroom teachers, school nurses, and physical education teachers frequently provide instruction about health. At the secondary level, many schools offer separate health classes taught by professionally prepared health educators; other schools integrate health education into other subject matter; and some do both. Students receive more content and quality when a separate health course is taught by trained health education teachers than when health education is integrated into other subjects.

National standards exist for school health education; many states also have guidelines for what schools should teach about health. The US Centers for Disease Control and Prevention (CDC) reviewed school health education programs and identified characteristics of those that were effective in addressing behaviors that promote or compromise health, many of which would apply to health education provided in any setting. Those characteristics, among others, include being research-based and theory driven as well as incorporating learning strategies, teaching methods, and materials that are culturally inclusive.

Culturally inclusive curricular materials are free of culturally biased information, but also include information, activities, and examples that are inclusive of diverse cultures and lifestyles (such as gender, race, ethnicity, religion, age, physical/mental ability, and appearance). Strategies promote values, attitudes, and behaviors that acknowledge the cultural diversity of students, optimize relevance to students from multiple cultures in the school community, strengthen students' skills necessary to engage in intercultural interactions, and build on the cultural resources of families and communities.

Among immigrant families coming from non-Western cultures, school health education often introduces both the student and the students' family to Western concepts of disease and health promotion. Within immigrant communities, a disconnect sometimes occurs between the health understandings and messages of the originating community and those of the destination community, reflecting different understandings of disease causation, ways to protect oneself, and sources of healing. Culturally competent health education starts with the assumptions people have regarding health and healing and builds from there in helping them gain the knowledge and skills they need to make health-enhancing decisions and act on those decisions.

School Health Education Project – Bienestar – is an example of a school-based intervention found effective in reducing risks for developing diabetes that is tailored to low-income 4th grade Mexican American students is the *Bienestar* curriculum, consisting of a bilingual parent education and involvement program, a classroom health and physical education curriculum, a student after-school health club, and a school cafeteria program. The Health and Physical Education Program consists of 16 lessons with sections on physical activity, nutrition, wellness, and diabetes. The purpose of the curriculum is to develop knowledge and skills necessary to engage in moderate and vigorous physical activities and adopt healthy dietary behavior. The *Bienestar Health Club* involves after-school learning activities for students aimed at rehearsing and reinforcing the knowledge and skills learned through *Bienestar* classroom-based instruction and promoting leisure time moderate to vigorous physical activity. The parent involvement program reduces the disconnect between health education in the school curriculum and family messages and practices.

Community Health Education

Health educators assist communities in identifying needs, drawing upon problem-solving abilities, and mobilizing resources to develop, promote, implement, and evaluate strategies to improve health. Such strategies include, but are not limited to: community organizing, grant seeking, coalition building, advocacy, and health communication. In a clinic setting, health educators provide patient education, counseling individual patients and helping them understand their health conditions and what they need to do to improve their health and care for themselves and their families linguistically as well as culturally and within their social/familial context. They also provide group educational programs and materials that patients can access while waiting for appointments.

Community Health Project: A Smoke Free Paso del Norte Initiative

The Smoke Free Paso del Norte Initiative is one example of an initiative with multiple programs designed to complement one another for a common health benefit and that is relevant to Mexican American Immigrants. Established by the Paso del Norte Health Foundation 1999, the initiative triangulates health education programs that provide smoking cessation, ones that address prevention of tobacco use among youth, and advocacy for clean indoor air policies. Central to the initiative is a coalition of tobacco control advocates.

The following illustrates how this successful initiative used the seven responsibilities of health educators:

Area I: Assess Individual and Community Needs for Health Education

To determine what exists and what is desired, the project started with a needs assessment that included a survey using a modified version of the Adult Tobacco Survey (ATS) and a review of data from the state's Behavior Risk Factor Surveillance System (BRFSS). By comparing these data (what exists) to *Healthy People 2010* goals (the desired), the coalition determined a need for both prevention and cessation services. The data also provided reference points for evaluation. An assessment of the policy landscape indicated the need and potential opportunity for a clean indoor air ordinance.

Area II: Plan Health Education Strategies, Interventions, and Programs

Over a period of 6 months, the Paso del Norte Health Foundation planned an overall health education strategy and placed it within an initiative strategic plan. The overall approach chosen for tobacco control was the social–ecological model. Planning involved setting region-wide tobacco control goals, and recommending an optimal mix of programs to achieve results.

Each partner agency planned a program to advance the initiative's goals related to the reduction of tobacco use among the primarily Mexican American population in the Paso del Norte region. Some partners custom-designed health education programs such as health communication campaigns for both prevention of initiation and cessation. Other partners adopted an evidence-based program such as the American Lung Association's NOT Program or modified evidence-based programs to fit the needs of Mexican American immigrants within the region.

Area III: Implement Health Education Strategies, Interventions, and Programs

Implementation required financial resources, collaboration, and culturally competent health educators. Skilled educators delivered smoking cessation programs for both adults and youth, produced advocacy materials about a clean indoor air ordinance for use with policy makers, and lead a coalition of partner agencies to leverage resources. An external advertising company implemented the media campaigns.

Area IV: Conduct Evaluation and Research Related to Health Education

The Foundation contracted with external health education experts who had experience in both tobacco control and evaluation. The external evaluators monitored ATS and BRFSS data; observed implementation of health education programs; conducted cost-analysis for cessation media and focus groups for prevention media; and evaluated the coalition's activities, including advocacy activity. The Paso del Norte Health Foundation and the partner agencies used the formative, process, impact, and outcome level data to improve programs, document success, and, when necessary, close ineffective programs.

Area V: Administer Health Education Strategies, Interventions, and Programs

Each program had budgets, timelines, and personnel. A health educator was responsible for the overall administration of a program including preparing periodic reports to funding agencies, adjusting program delivery, making human resource decisions, and overseeing the work of contractors. The health educator shared program administration with an accountant who tracked the finances.

Area VI: Serve as a Health Education Resource Person

The coalition for A Smoke Free Paso del Norte served as a resource for professional health educators to access the latest information about tobacco control. In turn, these health education partners served as resource people within their own agencies and with the public. Each health education partner knew where to refer smokers for cessation services and could provide information about other health education tobacco control programs.

Area VII: Communicate and Advocate for Health and Health Education

Health educators involved in the initiative shared the model used for and the results from A Smoke Free Paso del Norte with professional audiences at conferences and in publications. Partner agencies communicated with one another and received evaluation results, thus promoting continued dedication. The public received various messages in the newspaper and on websites about the initiative structure, results, and plans for the future. The Foundation and the partners designed special communications for key stakeholders, including policy makers and funders.

Culturally competent, professionally trained health educators impart knowledge, develop skills, and empower individuals and communities to take actions that will improve health and safety for individuals, families, and communities. For immigrant populations, cultural competence requires that the health educator identify the populations and subpopulations to include and key opinion leaders in those populations. Those opinion leaders can help the health educator understand the cultural beliefs about disease causation and find or create culturally appropriate interventions. The health educator, in turn, can help immigrants navigate the US health care system, understand how to care for their health conditions in a new environment, and interpret health messages so they are comprehensible.

Health education helps individuals, groups, or communities gain the information and skills they need to make informed decisions about their health, safety, or well-being and to act on those decisions. In addition to professionally prepared health educators, those who contribute to those planned experiences can include the media, promotoras, health care providers, public health practitioners, teachers and counselors, youth leaders, and key community opinion leaders such as clergy. Health education provides a mechanism for immigrant families to engage in healthy behaviors and healthy communities in their new country.

Health Insurance

Beth E. Quill
Childrens' Defense Fund - Texas, Bellaire, TX, USA

Health insurance is the primary payment for health services in the USA and is generally noted as private insurance or government insurance. The purpose of insurance is to provide protection against risk. Risk refers to the possibility of substantial financial loss from event of which the probability of occurrence is low. As a financing mechanism, health insurance helps protect individuals from devastating financial loss when expensive care is required. Health insurance also decreases the risks of costly delay in seeking treatment for conditions that might advance to a more severe, complicated, and expensive condition. Health insurance simply provides some level of payment for medical care. The systematic process of selecting, evaluating, predicting, and rating the risk for determining what will be covered and the extent to which it will be covered is referred to as *underwriting*. The individual protected is the *insured*; the insuring agency is the *insurer*. The historical understanding of insurance is that the *insured* pays the *insurer* a sum of money in advance to a pool of payments from others who are also insured. This pool of funds offsets the costs of the risk for a rare event which can be determined based on the group. This pooling of risk helps determine the rates of payments and also keeps the individual costs reasonable.

Initially, this concept was used to insure workers against wage loss resulting from injuries. In the 1930s, health insurance emerged in its current form. Throughout the 1930s and 1940s, hospital group prepayment plans were common and hospitals became highly dependent upon these plans with 70% of hospital income from individuals.

During this time, Blue Cross-Blue Shield, a private, not-for-profit insurance model was established and dominated the health care industry for decades. This plan reimbursed providers for the costs of the medical care and provided coverage to individuals, including care for routine events. Early financing from the American Medical Association supported the proliferation of Blue Cross-Blue Shield across the country. By 1940, the Blue Cross movement represented a major financing alternative to the arguments for national health insurance. Prior to World War II, commercial insurance companies showed little interest in adding health insurance to their portfolios, but following WW II, labor contracts added benefits and financial incentives encouraged commercial companies to enter the health insurance arena. This growth is evident today with many companies competing for health insurance contracts.

Private insurance, also referred to as "voluntary health insurance," is a plan provided through an employer, union, or purchased by an individual through a private company. *Group insurance* (insurance through an employer, union, or association) comprises approximately 66% of those with health insurance. Although early private policies were often inadequate, major medical coverage to cover catastrophic events was added in the 1950s and since the 1970s, most private policies included major medical and comprehensive coverage. *Self-insurance,* another form of private insurance, is made available by employers who determine they are large enough with sufficient risk diversification to fund their own health insurance for employees. Federal tax policies provided incentives to make this an attractive and economical option for some companies. As managed care plans (plans by providers) appeared, self-insurance became less economical and many companies adopted managed care plans. *Individual private insurance* is an important source of coverage for many Americans. While most Americans obtain coverage through their employer, early retirees, employees of businesses that do not provide insurance, and self-employed individuals rely on individual insurance. In this case, the risk is determined as individual risk rather than group risk and may be more expensive.

Government insurance accounts for approximately 30% of those with insurance and refers to the federal programs such as Medicaid, Medicare, Children's Health Insurance Program (CHIP), military care, and individual state programs. These programs provide specified health benefits for eligible populations. Medicare provides benefits for elderly and disabled; CHIP benefits low-income children; Medicaid provides care for low-income, elderly, disabled, women, and children. Increasing reliance on these programs has occurred as the number of uninsured has increased. The uninsured population has become a major national priority that stimulated the recent Patient Protection and Affordable Care Act (March 21, 2010). This Act is designed to expand health benefits to those without health insurance either through government or private plans.

Health insurance is a major component of health financing in the USA. Internationally, individual countries vary substantially in their governmental and private finding of health care. Immigrants in most circumstances will not have access to necessary care designated for citizens. Legal immigrants who are employed, however, may have access to health coverage in different countries. The risk remains that the health insurance model may preclude care for immigrants who experience delayed treatment and often increased disease burden due to lack of necessary care.

Health Literacy

Susan Koch-Weser
Department of Public Health and Community Medicine, Tufts University School of Medicine, Boston, MA, USA

Introduction

Health literacy, together with language and culture, is fundamental to the success of health communication. In the United States, health literacy began to emerge as a field in the early 1990s when the US Department of Education released the National Adult Literacy Survey (NALS) showing that over 50% of US adults were not able to use everyday prose and documents to find answers to questions. Results indicated that 23% of US adults had very limited, and 25% had limited functional literacy skills. Although researchers and practitioners in the developing world had long been aware of the challenges illiteracy and limited literacy presented to health communications, in the developed world, where illiteracy is rare, scant attention had been paid to the role of literacy in health. The startling results of the NALS had a powerful effect, especially on clinicians who became concerned about the effect of limited literacy on care. At the same time, Adult Basic Education Programs were including health in their community empowerment efforts. It is from these two fields, health care and adult education, that much of the early work in health literacy developed, with public health sometimes serving as a bridge between disciplines.

In the years since the NALS galvanized the field, research has shown limited literacy, and when measured, health literacy, to be associated with a variety of health outcomes. In patient populations limited health literacy has been associated with later stage diagnosis of cancers, poor glycemic control in diabetes, improper use of asthma medications, and poor knowledge of disease and self-management skills for hypertension and diabetes. Research has also explored how health literacy impacts adherence to treatments, the informed consent process, health care costs, and access to entitlements.

Definitions and Models

The most commonly cited definition of health literacy is the one used by the US Department of Health and

Human Services in *Healthy People 2010* and the Institute of Medicine (IOM) report *Health Literacy: A Prescription to End Confusion – the degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions.* The definition is broad and does not specify the form the health information takes (written, verbal, numbers, pictures), nor does it define the skills and capacities. Generally, reading, writing, listening, speaking, and numeracy are considered basic literacy skills, and become health literacy when applied in a health context. With this definition health literacy is determined by the skills possessed by the individual and measured against a clinical standard expressed in the term *appropriate decisions.* A variety of developments in health literacy have pushed thinking beyond this narrow individual skills-based focus.

Despite accepting this definition focusing on individual skills, the IOM report includes discussion of the emerging conceptualization of health literacy as arising from the intersection of demands of a situation and an individual's skills. In addition, the IOM report asserts that culture and language are central to health literacy. Thus health literacy is a complex social determinant of health. Efforts to address health literacy must take culture and language into account and focus not only on improving the skills of individuals, but also on developing the skills of providers and the simplification of procedures, forms, and even signage used by organizations and institutions, such as hospitals, social service agencies, and insurance companies.

The public health field has recognized that health literacy serves not only the individual, but also public health. Donald Nutbeam has proposed three levels of health literacy: functional health literacy, interactive health literacy, and critical health literacy. Functional health literacy is the basic skills. Interactive health literacy is participatory and involves the provision of appropriate and usable information, individuals' ability to assess and carry out the recommendations in the information, and their participation in mutual decision making. Critical health literacy is the ability to analyze information from a variety of sources in order to act. Attention to aspects of health literacy beyond basic skills is necessary, both because it allows individuals to participate more effectively in their care and develop skills necessary to take collective action to address community health. Another valuable expansion of health literacy is the multidimensional model developed by Christina Zarcadoolas, Andrew F. Pleasant, and David S. Greer in which there are four central domains: fundamental literacy, scientific literacy, civic literacy, and cultural literacy. In this model literacy skill in one domain can aid in the development of skills in another, and competencies in one area may help compensate for weaknesses in other areas. The hope is that by explicating the domains of health literacy they can be taken into account to provide guidelines for better health communication.

Measurement

Measuring health literacy is a complex undertaking and at this time there are no comprehensive measures of health literacy. This is partly due to multiple models of health literacy, as well as the myriad skills that make up even basic literacy. Research has been based on a variety of measures, although these measures do not capture all of the skills (reading, writing, speaking, listening, and numeracy) inherent in the most basic definitions of health literacy nor do they delve into broader domains of health literacy.

Much of the research linking health outcomes to health literacy has relied on the Rapid Estimate of Adult Literacy in Medicine (REALM), a word recognition test, or the Test of Functional Health Literacy in Adults (TOFHLA), a cloze test which includes tasks to assess reading and numeracy skills. A Spanish language version of the TOFHLA has also been developed. The REALM and the TOFHLA are general measures of health literacy most appropriate for clinical settings. There are also several disease-specific measures that have been developed for clinical settings. Health contexts vary across diseases, cultures, life course, and settings, making the development of measures for specific purposes appealing. At the same time, many researchers are calling for agreement on definitions and theory to facilitate the development of comprehensive measures that will apply across clinical and public health settings, as well as take a broader skill set into account.

Prevalence

In 2003 the US Department of Education commissioned the National Assessment of Adult Literacy (NAAL) and included health items to assess health literacy. The measures used are not publicly available. Respondents in this nationally representative sample were asked to demonstrate that they could use materials culled from health-related settings. The survey indicated that in terms of health literacy skills 12% of adults were proficient, the majority (53%) had intermediate skills, 22% had basic skills, and 14% had below basic skills. Someone with basic skills would be able to read a pamphlet and find two facts, while someone with intermediate skills could read a prescription label and determine what time to take a dose. Although limited health literacy skills affect adults across all age, racial, ethnic, and educational groups, the NAAL identified vulnerable populations: elderly (65+), ethnic and racial minorities, immigrants, those with low income or limited education, and people with chronic mental or physical health conditions. Reasons for limited health literacy skills include lack of educational opportunity, learning disabilities, cognitive declines in older adults, and lack of practice (literacy skills of any kind tend to erode if they are not practiced).

Future Directions

The development of health literacy as a field has had a profound effect on our understanding of the literacy demands of printed health education materials. Many of the new developments are directed toward seeking to extend the insights to other communications and the delivery of services. Practitioners have been extending best practices developed in health literacy, as well as plain language and communications into new areas. However, to fully understand the processes by which changes to practice will affect health literacy and health outcomes measures that assess health literacy skills beyond reading. In addition, as measures to assess health literacy practices of providers and the health literacy demands of organizations and institutions must be developed. Such measures will likely result from efforts to develop health literacy theory.

Some in the field are working to develop health literacy into a complete theory of health behavior. The theory would provide a framework to examine how people move from finding information to understanding it, evaluating it and communicating about it, to finally using the information to make health behavior changes. There is also interest in exploring how social networks relate to health literacy, as people rarely pursue health information in a vacuum.

Health Outcomes

Jennifer Meigs, Camille D. Miller
Texas Health Institute, Austin, TX, USA

For any sample population, health outcomes are measured by tracking morbidity and mortality. Morbidity represents disease or ill health within a given population, and mortality measures deaths and causes of death within that population. Morbidity and mortality measures give an overarching view of a population's health, but offer limited insight into the root causes of health outcomes. For this reason, researchers track additional health indicators to gain insight into likely causes associated with illness and death in a given population.

Beginning in 1996 the Healthy People project, led by an interagency group within the US Department of Health and Human Services, developed a standard list of leading health indicators to help focus national health outcome research. The project's leading indicators for 2010 include physical activity, overweight and obesity, tobacco and drug use, sexual behavior and sexually transmitted infections, mental health, history of violence, environmental quality, and access to health care, among others. The project database, available publicly online and updated with the latest available data, provides tables that track leading health indicators and outcomes using a variety of national and state population survey data. Policy makers at all levels of government and community service rely on such data to guide health service program assessments and highlight areas for program improvement.

The health outcome data available through the Healthy People 2010 project serve as a rich information source intended to guide policy development. Federal and state policy makers use health outcome data to develop policies and programs focused on large scale service areas and initiatives. At the local level, policy makers use health outcome data to build on federal and state programs, filling gaps and tailoring services to the needs of communities. For example, the US Congress currently uses the Healthy People 2010 project objectives and leading health indicators to assess the progress of certain federal block grants. Likewise, the indicators have been used at a local level by cities, counties, school districts, foundations, and nonprofits to track and assess local health outcomes, and inform program development.

Immigrant Health Outcomes

More than 37 million immigrants currently live in the USA, with the majority born in Latin America, Asia, or the Pacific Islands. A legal immigrant to the USA might be a student with a visa, a permanent resident with documentation, a naturalized citizen, a refugee, or a person seeking political asylum. An undocumented immigrant may have originally immigrated legally, but overstayed the expiration date of his or her documents, or may have avoided inspection when crossing the border. Due to the innate diversity of this group researchers must account for vast differences in baseline health, education, socioeconomic and family status at every stage of information gathering and analysis.

Historical research on immigrant health outcomes has yielded paradoxical results. The health outcomes of recent immigrants are better than those of native-born US citizens when results are controlled for socioeconomic factors. However, as immigrants live and work in the USA, their health outcomes deteriorate and begin to mimic the less-healthy outcomes of native-born citizens. Recent studies also highlight the fact that patients with limited English proficiency, regardless of citizenship, tend not to seek or receive preventive medical care, and are more likely to experience serious medical errors and drug complications when seeking treatment.

Current research indicates that immigrant health outcomes vary both across and within ethnic groups. For instance, Latino and Black male immigrants have shown reduced morbidity risks associated with chronic heart and lung conditions compared to other immigrant and native-born populations, but the same groups show increased risk for stomach or brain cancer and infectious diseases. Conversely, male and female Latino populations have proven more susceptible to diabetes than other populations, regardless of citizenship status. Health outcomes also vary within broadly defined racial and ethnic categories. Pacific Islanders and people born on the Asian continent differ significantly from each other not only in their health outcomes but also their socioeconomic and demographic characteristics. Broad racial or ethnic definitions captured in survey data tend to minimize evidence of significant disparities in health outcomes of certain subgroups.

According to the Pew Research Center, between the years 2005 and 2050, an estimated 117 million people will be added to the US population as a direct result of new immigration. This rapidly growing population and its US citizen descendents represent 82% of projected population growth during that time period. In light of the size and diversity of this population, research into immigrant health outcomes must span multiple language barriers and cultural differences to effectively inform policy development.

Policy Implications

Understanding the paradoxes of immigrant health outcomes can help researchers and policy makers better understand overall health outcomes, refine disease prevention strategies, and assess health care programs. Accurate data allow for the development of targeted programs and policies that improve health care access, quality, and outcomes. The Patient Protection and Affordable Care Act of 2010, also known as the US health care reform bill, improves health data tracking for racial and ethnic subpopulations. The Act authorizes oversampling of historically underrepresented groups, including immigrants, to increase the accuracy of data collected.

In seeking to improve the accuracy and application of health outcomes data, health practitioners and researchers promote community-based participatory research. Characteristics of successful community-based participatory research include the following:

1. The research is designed to increase community resources and supports long-term improvements.
2. It uses a range of methods, both quantitative and qualitative, from multiple disciplines, including culturally distinct models.
3. Its findings are relevant to the needs of both policy makers and advocates, using standard metrics that allow for comparison across studies.

Conclusions

Health outcomes are measured by tracking morbidity and mortality along with certain lifestyle indicators intended to highlight root causes of disease and death within a population. However, many factors other than the current leading health indicators influence health outcomes, including country of origin and native language proficiency. Any successful policy or program aimed at improving health outcomes relies on standardized, current data to establish a baseline, track changes over time, and demonstrate results. With a growing immigrant population in the USA, current health reference points and regular information updates accurately reflecting target populations are key elements to successfully gauging the progress of programs and policies at every level.

Health Perception

Katherine Crow
WebMD Health Foundation, Rancho Santa Fe,
CA, USA

Health perception encompasses both physical and mental well-being, and for some, even spiritual fulfillment. For the newly arrived immigrant, health perceptions may focus on immediate survival rather than long-term health status. Health perception is influenced by the health care system in the country of origin. For example, a study of women who immigrated to the USA after the fall of the former Soviet Union found that when the women received health care services in their homeland, they had relied on their physicians to refer them for health screenings and to provide health education, as this was customary. When the women immigrated, they expected physicians to again take the primary role in directing their care; they were not accustomed to being proactive and requesting health information or tests.

Generally, countries accepting immigrants require medical examinations to be performed prior to entry. Immigrants told at the time of screening that they are in good health may continue to believe that their health status has not changed until a problem is diagnosed. Length of time in the host country can also influence health perception, as immigrants may have a difficult time transitioning to their new home and may face numerous stressors not previously experienced, including finding employment and earning enough income to support their families, feelings of loss and social status, and loneliness and social isolation.

Immigrants may face several barriers to receiving health care services including language differences, lack of translation services, and lack of culturally appropriate health services. Cultural competence and educational programs for health professionals can orient the professionals to the potential importance of cultural rituals, use of traditional remedies (e.g., teas and herbs) and cultural norms. Understanding the multiple meanings and perceptions of health and their influence on interactions with health care professionals can lead to improving immigrants' access to health care, compliance, and satisfaction.

Health Policy

M. Barton Laws
Department of Health Services Policy and Practice,
Brown University, Providence, RI, USA

While there is controversy over the relative contribution of health care to population health and longevity, it is clearly not the most important factor. In every society, social and economic status are strongly associated with life expectancy, health status, and the prevalence of disability, even where there is universal and equal access to health care. In addition to these disparities within societies, it is now generally held that societies with more inequality tend to have worse population health than societies of comparable aggregate wealth but less inequality. Population health is also strongly affected by environmental conditions such as water and air quality; culturally and economically influenced behaviors such as tobacco and other substance abuse, diet, and physical activity patterns; and social conditions associated with psychological stress and violence.

So the subject of health policy is impossibly broad. All public policy is relevant to health, even if it is not explicitly justified or discussed in those terms. This entry will therefore focus primarily on health care policy, but readers should keep in mind that health care is only a small corner of the broad field of human health. Additionally, a component of public policy is explicitly labeled as "public health" – in the United States, representing about 5% of the spending on health care – and we will touch on these policies as well.

Among the wealthy countries other than the United States, there is little relationship between aggregate spending on health care and population health. But the United States is an outlier. Despite not having universal coverage, the United States spends far more per capita on health care than any other wealthy country. Nevertheless, life expectancy and health status indicators in the United States are the worst among the wealthy countries, although the poorest countries are far worse off.

To understand this seeming paradox, and health care policy more generally, we must begin by reviewing some of the basic economics of health care, which in many ways do not resemble the idealized portrait of the market as presented in standard introductory texts.

First, health care is characterized by unusually large externalities, meaning that large costs or benefits to society are not captured in the transaction between consumer and provider. This is actually true of essentially all economic transactions; it is a difference of degree. There are some negative externalities to health care, such as the carbon and other emissions associated with manufacturing of medical devices, or contamination of water by excretion of pharmaceuticals and their metabolites, but at least from a human point of view there are much larger positive externalities. An obvious example is communicable disease control. Successfully treating people with infectious diseases prevents transmission to others. Vaccination that produces herd immunity is even more cost-effective. To the extent that health care can prevent or reverse disease and disability, it keeps more people economically productive, and also more capable of non-monetized contributions to society such as dependent care and volunteer work.

Less tangibly, people care about each other and are gratified when loved ones enjoy better health or have their suffering relieved. More diffusely, many people feel distress knowing that people they do not know are suffering, or abandoned in need. An affluent society simply will not tolerate allowing people to die at the door of the hospital when a modestly expensive intervention would save them. (Note that we nevertheless do tolerate a great deal of avoidable suffering and death, a matter I will discuss under the heading of the Rule of Rescue.)

In summary, health care is a mixed good. If we depended on people to pay for it out of pocket, it would be underproduced from the standpoint of society. Or more precisely, it would at least be misallocated.

A second way in which markets for health care violate standard assumptions is the extreme informational asymmetry between consumer and provider. When we shop for ordinary goods, we generally have a pretty good idea of what we are buying, its quality, and how it compares to competitors' offers; our information can be improved by labeling requirements, warranties, and simply by experience. If we spend a few dollars on a product we find we do not like, we will not do it again. With health care, however, we may not get a second chance. The product consists largely of expertise. People consult physicians because they expect the physician to know much more than they do about their health condition and how to improve it. Most of us, most of the time, cannot assess whether the physician's judgment is correct.

One consequence is that the government must provide quality assurance in the form of a licensing regime. Physicians and other health care professionals must meet requirements of training and demonstrated competence, maintain up-do-date knowledge, and continually satisfy standards. The medical schools and training programs which produce physicians must in turn meet standards of accreditation. This has the effect of restricting the supply and raising the price of physician services, and placing the supply under control of public policy.

Another profound consequence is that demand for medical services is not fundamentally controlled by consumers. While conventional views of the market hold that consumers are "sovereign" in that they choose how to allocate their spending, this is not true for health care. We depend on providers to tell us what we need. This combines with another feature of markets for health care, which is the extreme diversity of need. Most people, most of the time, have roughly comparable basic needs for nutrition, shelter, and other necessities. Beyond that of course we may have discretionary income that we allocate as we please, but to the extent that health care addresses necessities – which it surely would seem to do if life or functional status are at stake – our needs are not at all comparable. They may change dramatically over time as well as differing among individuals.

This means that a hypothetical "free market" in which people spend out of pocket for all of their health care cannot possibly produce socially optimal allocation of resources by any standard, including not only justice but also the material well-being of all. Clearly misfortune can strike anyone – be it a natural disaster, an infectious or congenital disease, an act of violence – leaving someone with a need for health care that he or she may be entirely unable to pay for. To the extent this reduces labor force participation or has other negative externalities we have discussed, it is costly to everyone.

Not only can ill health or physical trauma befall anyone, they likely will befall *everyone*, increasingly with age. They are *unpredictable* and only moderately *controllable*. Hence, the purpose of health insurance is to even out the financial risk of ill health and assure access to those who face high costs – in other words, to make the world more predictable and more just, as well as more prosperous.

This is why, with the exception of the United States, all of the wealthy countries, in one way or another, provide what is called "universal health care" to all of their citizens, and in some cases to other eligible residents or visitors. This means that everyone has access to basic, if not comprehensive medical care, and often dental and mental health care as well, regardless of their financial resources. Many of the less wealthy countries also provide some degree of universal access although limited resources mean people may not receive services which are considered standard in wealthier countries. Such policies are redistributive in that they require subsidies for people who could not otherwise afford comprehensive health care insurance, but the progressivity of financing varies considerably.

There are innumerable variations on how countries achieve this. I will describe only a few paradigmatic examples. In the United Kingdom, health care is largely socialized. Physicians are paid by the state, and hospitals are publicly owned. The constituent countries of the United Kingdom have separate organizations and control through their national governments. In each country, administration is decentralized to regional "Strategic Health Authorities" and local primary care and hospital "Trusts." The system is entirely tax financed. People can purchase additional private insurance for specialist services beyond what the NHS covers, but only about 4% of health care spending is private.

Canada has what is called a "single payer system," which is publicly funded, but has most services provided by private entities. The system is administered at the provincial level, and supported largely by income taxes. Every citizen is insured by the provincial fund, which physicians bill for services. Provinces vary somewhat in the services they cover. While pharmaceutical costs are for the most part covered only for the elderly or poor, the government negotiates with suppliers to keep costs low.

Many European countries have mixed systems in which private insurers are allowed to compete with a publicly sponsored program; or private insurance plans are very tightly regulated and funded through arrangements that make them affordable for lower income people.

Middle income countries such as Mexico, Brazil, and India generally have mixed systems in which a publicly run or subsidized system is available to poor people, at least in principle, but more affluent people generally have private insurance. The quality, accessibility, and true universality of health care in these countries vary. There may in effect be rationing by inconvenience in the form of long waiting times, difficult travel for rural people, and poor amenities in public clinics, and services may simply be overburdened. In India, for example, it has been reported that 700 million people lack access to specialty care because specialist providers are concentrated in the cities.

In the poorest countries, including much of sub-Saharan Africa and some Latin American and Asian countries, the resources to provide any form of universal health care are lacking. Specific health care services may be extended to poor people through internationally sponsored programs focused on particular diseases, such as HIV, tuberculosis, or malaria, and immunization campaigns. There is often controversy as to whether these resources would be better spent building a permanent, comprehensive health care infrastructure, or may even have some counterproductive effects of draining personnel from the general health care system.

The situation in the United States is complicated and requires more extensive discussion. The United States provides a national publicly sponsored insurance plan, called Medicare, to people aged 65 years and older and to people with qualifying disabilities. Medicare pays physicians for outpatient services on a fee-for-service basis, using funds from a payroll tax on workers with a small contribution from premiums paid by participants. Prescription drugs for outpatients are now partially paid for, with substantial cost sharing by consumers above an annual threshold. This cost sharing will be greatly reduced by recent legislation. Hospitals are reimbursed for episodes of care based on patients' diagnoses, funded out of general tax revenues.

Poor people, up to income thresholds that vary by state, may be covered by state-sponsored plans called Medicaid, supported partly by state tax revenues and partly by federal payments to the states. Generally, recipients must either be Medicare eligible, in which case Medicaid pays for services not covered by Medicare and for cost sharing; or be minor children, custodial parents of minor children, or pregnant women. Some states have extended eligibility to others, and the recent reform legislation will eliminate these "categorical eligibility" requirements nationwide for people making up to 133% of the federal poverty level. Children may also be covered at somewhat higher income levels with partial contributions from the federal government to the states through a program called the State Children's Health Insurance Program (SCHIP). Medicaid programs usually contract with private insurance plans to provide coverage.

The rest of Americans are covered by private insurance companies, most of them profit making corporations; or they are not covered at all. An odd feature of the US system, essentially a historical accident arising out of the emergency economic policies imposed during World War II, is that most Americans who have private insurance receive it from their employers who purchase coverage on their behalf. The benefit is a cost to employers, and hence deductible from their taxable income; but is not taxable income for employees. The value of this subsidy is greater for higher income workers, and hence largely regressive.

Some of these health insurance corporations are huge. The largest health insurance company in the United States, WellPoint, owns the Blue Cross/Blue Shield brand in 16 states. The mission of these companies is to make money for their owners and executives, just like any other corporation. Their premium revenues, in addition to paying for beneficiaries' health care, which they call "medical losses," go to profit, administration, marketing, and the cost of strategies to avoid medical losses, which are called "medical underwriting." These include refusing to sell to people with expensive health care needs, or charging them higher premiums; and canceling policies when people develop costly medical problems. As a result, people who do not have access to insurance through their employment may be completely unable to purchase insurance if they are not in good health.

The new legislation, if it ultimately takes full effect in 2014, will restrict these practices. It will also require all people who do not otherwise have insurance to purchase it, with subsidies offered to moderate-income people, or pay a tax penalty. Purchase of insurance will be facilitated through state-run "exchanges." However, the legislation does little to constrain growth in health care costs and it remains to be seen whether insurance will be affordable for many people even with the subsidies, and whether insurance companies will be able to evade the restrictions on medical underwriting, among other questions.

For international migrants, the most obvious issue is whether they can benefit from whatever system of health care organization and financing there may be in their host country. Not surprisingly, illegal migrants cannot normally obtain publicly provided or subsidized benefits legally, although wealthy countries generally have mechanisms for providing emergency critical care and labor and delivery services out of compassionate motives. In the United States, where sentiment against illegal presence in the country is currently very high, fear of deportation causes many to avoid presenting even for urgent problems, although Medicaid will pay for emergency care for otherwise eligible people and hospitals are required to provide it in any case.

For legal migrants, participation in host country health care schemes is normally possible, if not required. In the United States, however, there are limitations on eligibility for publicly subsidized programs even for legally present aliens. Legal permanent residents are ineligible for Medicaid or SCHIP during their first 5 years in the United States, with the exception of refugees and members of the armed services and their families. People with temporary work visas or student visas are generally not eligible for Medicaid or SCHIP. Immigrants who are legally able to work in the United States are at disproportionate risk of not being insured, because they are disproportionately likely to be in low-wage, temporary, or seasonal jobs that do not provide health insurance benefits, or in families supported by low-wage workers.

Resource Allocation

When the current systems of health care financing first developed in the twentieth century, health care constituted a relatively small proportion of national economies. Universal coverage was not very difficult for the wealthy countries to afford, and most Americans could afford their private premiums. On the other hand, the benefits of health care were fairly limited, and the most beneficial services – immunization, antibiotics, trauma care – were not very expensive.

By the late twentieth century, however, technological advances had simultaneously broadened the scope of medicine, produced effective new treatments for more and more disorders, and greatly increased the expense of providing the available medical services. The affordability and cost-effectiveness of medicine became a major concern. It may seem paradoxical, but the United States, the only wealthy country without universal coverage, has had the greatest problem with affordability. Whether through socialized medicine, socialized health insurance, or tight regulation of private insurance, universal systems impose a global budget cap on health care spending, whereas in the United States providers can for the most part simply bill for whatever services they provide, whether the payer is government or a private company. That outcomes are no worse, in fact somewhat better, in systems with capped spending demonstrates that more is not necessarily better when it comes to health care.

All wealthy countries nowadays require that pharmaceuticals, and usually medical devices, must go through a process to determine safety and effectiveness in order to obtain a license to be legally prescribed. However, these requirements do not ensure that a drug or device is safe and effective for all the situations in which it might be used, or that it is more effective or less expensive than existing alternatives. Furthermore, longer term experience with medical interventions often leads to discovery of problems such as adverse effects not found during the initial testing period. Finally, a small benefit bought at a very large cost may simply not be worth it compared to other possible uses for the money, given that our resources are finite.

In order to live within their budgets rationally, therefore, most countries have established agencies that make choices about how limited resources are to be allocated. New drugs that are not superior to less expensive alternatives may be licensed, but not paid for. Treatments that provide insufficient benefit in relation to cost may not be approved for payment, although wealthy people could buy them with their own funds. The United States has no such authority.

As the goal of medicine is not merely to extend life, but to improve its quality, evaluating the cost-effectiveness of medical interventions requires creating some common metric, which incorporates both. The most commonly used measure is called a Quality Adjusted Life Year, abbreviated QALY. One way to compute QALYs is called the Standard Gamble. What if there were a treatment that might cure your osteoarthritis, but it involved some risk of death? (Indeed there is such a treatment – joint replacement surgery, like any surgery, involves a small but nonzero probability of killing you.) The Standard Gamble asks at what probability of death versus certain cure you would be indifferent to the surgery. Often, these questions are not asked about specific conditions such as osteoarthritis of the knee, but refer to vague, general states such as pain, mobility, mental acuity, etc. You can ask these questions of people who actually have a disease or symptoms of interest, or you can ask them of the general public in an even more hypothetical way.

Once we have this information from a sufficient number of people – and how you define sufficient is an interesting question in itself – it is used to calculate QALYs for various states. Let us say that cancer Treatment A on average gains people ten extra years of life, but at 70% value based on the side effects of chemotherapy and the lack of a left lung. This can then be compared with another treatment – say you skip the chemotherapy in which case you can expect to live 8 years but at 90% value, which is worth 7.2 QALYs. And it can also be compared with its cost. For example, if surgery plus chemotherapy costs $250,000, the expenditure represents about $35,700 per QALY. National health care systems either implicitly or explicitly set approximate limits for the spending they are willing to make to purchase one QALY.

For several reasons, much of medical spending in the absence of such analyses and limitations is likely to produce little benefit for the cost, and often no benefit at all. We often do not have very good information about whether a treatment is beneficial, but we nevertheless have a bias to do something if we think it might help. Drug and device companies aggressively market their products and often promote overuse or use in inappropriate circumstances. And providers who are paid by the services they perform have an unconscious bias toward doing more. Limiting access to potentially beneficial treatments on the basis of cost is bound to be controversial, and public disputes do arise over these issues. In the United States, however, it has so far proved politically toxic even to propose undertaking such evaluations.

International migrants who do have insurance coverage may have some special interests in how available resources are allocated. One is whether services can be reimbursed to overcome language or cultural barriers that may hamper communication with providers, obtaining important health information, or accessing services. These include interpretation at the site of care, translation of written materials, patient "navigators" or benefits managers to assist people who are unfamiliar with the systems and procedures of the host country, and promotion of multilingualism and multiculturalism in the health care work force.

Another is whether resource allocation takes into account possibly differential health care needs of ethnic minority populations, who may have elevated risks for certain diseases. The United States sets decennial public health goals, and the goals for 2010 included eliminating racial and ethnic health disparities. Actually achieving this would require differentially allocating resources to disadvantaged populations, or to problems which disproportionately affect some groups, but this did not happen. Although progress toward the nation's public health goals was made in some areas from 2000 to 2010, disparities persisted.

Public Health Policy

Public health means the study and the promotion of health from the perspective of populations rather than individuals, which is largely the domain of medicine. While essentially all public policy has implications for population health, some publicly funded programs and regulations are explicitly labeled as having a public health justification or pertain to a public health department or authority. This line is somewhat arbitrary and changes over time. Delivery of potable water to cities, and the safe removal, treatment, and ultimate disposal of sewage, was labeled as a public health measure when it first became a standard government responsibility in the late nineteenth and early twentieth centuries. Nowadays, however, we generally take it for granted as part of the essential infrastructure of modern life, and do not commonly think of our water and sewer bills, or tax subsidies for these services, as public health expenditures.

The domain of "public health" as usually conceived of today includes sanitary regulation and inspection of food processors, restaurants, and grocery stores; public campaigns to encourage healthful behaviors; regulation of industry and motor vehicles to limit environmental contamination and promote safety for workers and the general population, although these activities are also justified using other labels such as environmental protection and occupational safety and health; and consumer product safety regulation.

Substance abuse prevention is usually thought of as a public health service, as are programs to reduce harm of drug abuse such as needle exchange. Substance abuse treatment is logically a form of individual clinical service but it is nevertheless usually part of a separate system from the medical institution and may be within the institutional domain of an agency otherwise charged with public health responsibilities. Enforcement of prohibition laws is not generally thought of as a public health service, and indeed may be contrary to the interests of public health in reality, although it is usually explicitly justified as a form of protection of public safety. Police protection and firefighting are not usually labeled public health services, although fire prevention and harm reduction such as sprinkler systems, and crime and violence prevention are certainly strong interests of public health researchers and advocates.

Quite evidently, war and peace, the distribution of income, education and the preparation of young people for the job market, criminal justice, land use planning, transportation infrastructure, energy policy – almost everything that government does or fails to do – has public health implications, but much of it is seldom discussed in those terms. On the other hand, while most of medicine is usually distinguished from public health, some kinds of medical services are often labeled as "public health," including immunization campaigns, screening for transmissible diseases, and outreach to the medically underserved, even when these are done by regular clinical providers. Regulation and inspection of hospitals and nursing homes is also usually the domain of public health agencies. So the term can be confusing.

For international migrants, there are often differential impacts of public policies, whether labeled as public health policies or not, and of public policy omissions. For example, economically disadvantaged people are more likely to live near localized sources of air pollution, notably major highways and industrial emitters. The most dangerous components of near highway pollution, ultrafine particles, are found at high levels within only a half kilometer or less of the highway, whereas air quality is usually regulated only at a regional level and so largely ignores such highly localized effects.

Immigrants and members of ethnic minority groups may face discriminatory treatment by the criminal justice system. In the United States, while they are no more likely to use illicit drugs than members of the dominant European settler culture, they are far more likely to be incarcerated for drug offenses, rather than be diverted to treatment programs. Some ethnic minorities have low average educational attainment and hence limited life opportunities, which directly affects lifelong health. Members of ethnic minorities may disproportionately work in dangerous jobs, live in unsafe housing – lead contamination is far more prevalent in the United States in the homes of African American and immigrant families – or lack access to healthy foods.

The Rule of Rescue

Public health is underfunded compared to medical services, on the basis of cost-effectiveness at the population level, for many reasons. One of the most powerful is called the Rule of Rescue – a moral intuition that many people have which demands that everything possible be done to succor an identifiable person in need. In contrast, public health measures that prevent injury and disease, while they may benefit far more people for the same or even less cost, do not benefit specifically identifiable individuals. We will never know who did not get cancer or heart disease because we limited motor vehicle pollution; who was not injured in an unsafe workplace; what child had a chance in life because we sent him to an early intervention program instead of a juvenile penal facility; what child did not start smoking because of a tobacco control program. The beneficiaries of these interventions can only be represented by statistics, not identifiable people.

The Rule of Rescue also operates most powerfully when the individual is in the most desperate straits. Hence the mass media of the entire nation may focus relentlessly on the plight of a single child who has fallen down a well, while hundreds of thousands of children may be suffering from poor nutrition, social deprivation, toxic air, substandard housing, or family violence. Health care is equivalent to pulling the child out of the well, and public health to putting a cap over it so children will not fall down it in the first place. But we feel far more urgency to do the former than the latter.

In summary, to the extent that international migrants may be socially and economically disadvantaged, their health will tend to suffer. A health care system that allocates resources equitably and is adaptive to the special needs of distinct populations can help ameliorate the consequences, but cannot make up for the damage done. Health policy, ultimately, is all of social policy.

Health Promotion

Emily Whitney[1], Uchenna Ndulue[2]

[1]Department of Health Education and Health Promotion, University of Wisconsin-La Crosse, La Crosse, WI, USA

[2]Nuestro Futuro Saludable, Community Health Program, Tufts University, Medford, MA, USA

Health promotion, defined by the Joint Committee on Health Education and Promotion Terminology as "any planned combination of educational, political, environmental, regulatory, or organizational mechanisms that support actions and conditions of living conducive to the health of individuals, groups, and communities," is central to the practice of public health. Health promotion is an all-encompassing, ecological concept that attempts to account for how individual behavioral factors, sociocultural characteristics, and environmental resources shape health in order to develop, implement, and evaluate strategies that support positive health behaviors. Though health promotion has been conceptualized in various ways, common among most understandings is the objective of health promotion to engage individuals, groups, and communities in planned efforts to improve health status and quality of life.

Health promotion activities generally rest on the following assumptions:

- The health status of individuals, groups, and communities can be changed.
- The complex interactions between social, behavioral, biological, and psychological factors help shape health and disease status.
- The principles and theories that underlie the occurrence of disease can be understood.
- Individuals, groups, and communities must be motivated and ready to change in order to make a behavior modification permanent.
- Starting and maintaining a health behavior change can be complicated.
- Various prevention strategies that are culturally appropriate can be developed and implemented to address an identified health issue.
- A behavior modification can be made and that modification may influence an individual's, a group's, or a community's health status.
- There is an understanding of the level of individual responsibility regarding a person's health; however, it should not be viewed as victim-blaming.
- There are a variety of factors such as policies, resources, family, and community relationships that shape and influence health behavior modifications.

These assumptions undergird the goals and objectives of health promotion interventions. Central to these assumptions is the ecological premise that health status is informed by individual health behavior that is changeable and voluntary, but strongly influenced by interpersonal, organizational, and sociocultural forces. Thus, the purpose of a health promotion program is to help individuals, groups, and communities engage in health-promoting behaviors voluntarily.

Health Promotion Programs

Health promotion programs may be comprised of a number of interventions that aim to address intrapersonal, interpersonal, and sociocultural influences on individual health behavior. Health promotion programs can be implemented over several years, such as a tobacco control campaign that includes smoking cessation classes and smoke-free worksite policies, or can be one-time interventions such as a health fair that includes diabetes screening. The intent for health promotion programs is to impact individual behavior within a group or community context, thus the duration, format, and content of a health promotion program depend upon the population and health outcome targeted.

Ideally, the development of health promotion programs should be customized to the population they aim to impact, a process that requires a preparatory assessment of the needs of the target population. This initial needs assessment serves to inform health promotion programs by providing an initial inventory of the health status, concerns, and self-identified priorities of the target population. After this initial assessment, behavioral science theories and planning models are often used to design program interventions, materials, and activities. Through the development of a health promotion intervention, an intentional effort is made to ensure that all components of the program's interventions are culturally accessible, appropriate, and accurate for the target population. In keeping with the above principles, health promotion interventions have been designed for many different populations, including immigrant and voluntary migrant communities.

Health Promotion and Migrant or Immigrant Populations

Immigration to a new region is typically associated with a variety of behavioral, environmental, and lifestyle changes that may expose immigrants and voluntary migrants to a multitude of health related issues due to language, cultural, and social barriers. For example, dietary acculturation, or the adoption of the dietary patterns of the host country in which immigrants reside, may lead to differences in health outcomes (known as "health disparities") among immigrant populations. Food availability, affordability, preparation, and processing may be significantly different and less healthy in the host country than the immigrant's country of origin. Many developed countries, such as the USA, consume diets that are generally high in fat and low in fruits and vegetables. This has implications for immigrants adopting such dietary practices as a diet higher in fat typically leads to increased risk for the development of several diseases, including some cancers and diabetes.

Culturally appropriate health promotion programs have been developed to help reduce health disparities in immigrant and voluntary migrant communities. Health promotion interventions have been created to address health issues including: (1) diabetes, (2) obesity, (3) nutrition, (4) cardiovascular disease, (5) sexually transmitted infections, (6) HIV/AIDS, (7) tuberculosis, and (8) women's health (e.g., breast cancer screening, cervical cancer screenings, prenatal health).

Challenges of Health Promotion

There are many challenges and barriers when it comes to creating and implementing effective health promotion programs for immigrant populations. The variety and diversity of immigrant communities require tailored, specific programs that are culturally accessible; thus, health promotion interventions must be unique to the priority population. Despite this, some common considerations must be made for health promotion interventions targeting immigrant communities. In particular, the successful implementation of a health promotion program in migrant and immigrant populations requires attention to the language, culture, and social norms of the target population.

Language Barriers

The number and diversity of languages spoken by immigrants may serve as a barrier to health promotion. Health promotion interventions are maximally effective when they are culturally relevant, up-to-date, and specific to the target population. Ideally, health promotion interventions are delivered in the language spoken by the target population. However the large level of language diversity that can exist in even relatively small regions make this challenging. For example, in the USA an estimated 47 million people speak a language other than the national language of English. In the state of California, over 43% of the state's population speaks their native languages at home and even a single borough in New York City has approximately 138 different languages spoken.

Cultural and Social Barriers

Culture can be said to be made up of a collective of perspective attitudes, beliefs, and behaviors, essentially the normative values of a particular group. Immigrant and migrant populations' perspectives on health issues may promote or complicate the provision of health promotion interventions. Cultural stigmas in particular can pose unique challenges to health promotion interventions. For example, in some cultures mental illness is often considered to be shameful or humiliating disease that may reflect poorly on the individual and the individual's family. In such cultures, mental illness is not discussed outside of the family even during mental health crises. Understanding this cultural stigma is imperative when creating a mental health promotion campaign for this population as much of the intervention may need to focus on de-stigmatizing mental illness, or may have to center on the family unit as the focus for health promotion activities.

Health promotion interventions must take into account that cultural norms may also work to enhance health disparities precipitated by the immigration event. For example, cultural perceptions that being overweight indicates health may encourage individuals to adopt more high-calorie diets that are prevalent in the host country. Cultural perceptions that it is inappropriate for women to discuss health issues with men may lead to less help-seeking behavior and increased health disparities in host countries where health care providers are predominantly male. Thus, health promotion interventions must be tailored to identify and reinforce health-positive cultural beliefs and behaviors while working to manage cultural norms that encourage or amplify health disparities.

Conclusion

Immigrant populations are generally at greater risk of adverse health events and health promotion efforts can work to prevent health disparities between different groups. However, health promotion interventions must be tailored to the unique need and priorities of specific immigrant communities, with a special eye toward understanding and addressing the specific language, cultural or social norms that may create barriers to health promotion efforts. When this is undertaken intentionally, health promotion interventions can be an effective means for promoting health in migrant and immigrant populations.

Health Services Research

Laura Janine Mintz
Department of Epidemiology and Biostatistics, Case Western Reserve University School of Medicine, Cleveland, OH, USA

Health Services Research was defined by the Board of Directors of the Association for Health Services Research (AHSR), a US-based research institution, as: “the multidisciplinary field of scientific investigation that studies how social factors, financing systems, organizational structures and processes, health technologies, and personal behaviors affect access to health care, the quality and cost of health care, and ultimately our health and well-being. Its research domains are individuals, families, organizations, institutions, communities, and populations.” Investigators who conduct health services research are interested in how health systems do or do not work, and the factors that change the effectiveness of health care.

Health services research in immigrant communities has focused on the topics of health services research in general.

Social factors impacting the health care of immigrants are wide-ranging. Frequently, immigrant communities have different values, attitudes, and beliefs about health care, and about what it means to access health care. Health services research attempts to look at why people do or do not access health care, and what forms of inequality can result from the social interaction of immigrants and the health care system. Additionally, social pressure may lead to immigrants being less likely to seek health care. Alternatively, immigrants may not wish to seek health care that they are entitled to, for fear of persecution or prejudice from health and state authorities. Much of the work of health services research is concerned with health disparities and access to care, both of which are topics that greatly impact immigrant health, usually poorly. Health disparities are the result of language, access, legal status, bias, race, economic status, sexual orientation, and many other factors affecting immigrants – understanding health disparities is a major component of health services research.

Financing systems impact immigrant health for multiple reasons. If the immigrant populations come from a country with a different health care system – less or more government coverage of health care – this may lead to confusion about payment or procurement of health care. In addition, immigrants may be reluctant to seek health care, and thus may only access health care when their health problems have evolved to very costly problems. The impact of immigrant health care on the financing of health care can be a controversial topic. In addition, different health care systems have different ways of financing the health of the population in general, and immigrant populations specifically; much contradictory research exists about how much exactly immigrant health care costs different health systems, and what the best methods would be to reduce this cost. There is much debate about how health systems should be doing preventive health care in immigrant communities, and what strategies work best.

Organizational structures and processes, that is, how an organization is organized, has a large impact on the ability of immigrants to access the system. Additionally, immigrants may not access institutions if they are not designed in such a way that will make institutions sensible to them. Additionally, there are documented health disparities in immigrant populations due to processes in hospitals. For example, "pain disparities" exist where hospitals are not staffed with translators, or when no staff members are fluent in the language of the immigrants. Additionally, when translators are not available, family members are often recruited to translate for each other, which may lead to poorer health outcomes.

Health technologies are an emerging field in health services research about immigrants. The major field of study about health technologies is about the electronic medical record, and how it can increase communication among health care providers and ultimately provide better care for patients. It is not certain if electronic medical records will eventually allow for international communication between the health systems of many countries. People are also using technology to help to reach out to immigrant populations in their own languages and customs, especially when fluent and otherwise culturally competent workers may be in short supply.

Health Services Utilization

Karen Jaynes Williams, Lauren McGirt
Department of Obstetrics and Gynecology,
University of Texas Medical Branch, Galveston,
TX, USA

Health services utilization can be defined as the consumption of health services or the extent to which health services are used. Common crude measures of health services utilization include *utilization of primary care services* (number of primary care visits by persons in a given population in a given year/size of the population) and *utilization of inpatient services* (number of inpatient days/size of the population). The immigration histories and immigration communities among countries differ greatly. To add to this, country-level health care delivery systems (including the financing, insurance, and delivery components) vary substantially. These differences make comparing health services utilization between the immigrant and nonimmigrant groups among different countries difficult. Few studies agree on the nature, direction, or extent of the differences in health services utilization between immigrant and nonimmigrant populations. Much evidence supports the idea of the “healthy immigrant” effect, that healthier people within a country tend to migrate while the less healthy remain in their native country. Additional evidence supports the idea that the longer an immigrant remains in a country, the more his or her disease risks and health services utilization approach resembles those who are native to the country.

The Organization for Economic Co-Operation and Development (OECD) represents governments of democratic countries with market economies working together to develop comparative statistics in order to evaluate and coordinate policy. The health section of the OECD provides comparable statistics in health. A systematic overview of existing research on differences in primary care utilization between immigrant groups and the majority population of seven OECD countries found that the United States more often reported a significantly lower use of primary care among immigrant groups as compared to the majority populations in other industrialized countries. In addition, a study of the strength of the primary care component of the health care systems among OECD member states describes a weak primary care system in the USA and relatively strong primary care systems in other OECD countries.

The USA and EU have the largest number of immigrants in the world, yet immigrants to those two locales face two fundamentally different types of health care systems. Immigrants to the United States encounter a largely market-driven system while immigrants to industrialized EU countries encounter universal, government-sponsored health care access programs. The following discussion addresses these two scenarios, borrowing from Aday’s *Framework for Studying Vulnerable Populations* to structure the utilization discussion. For each health services utilization scenario, (1) general characteristics and health care needs, (2) programs to meet needs (including financing and access), and (3) utilization trends are discussed.

Immigrants and Health Services Utilization in the United States

General Description and Health Care Needs

Although immigration is a global issue, the United States has the largest immigrant population at approximately 39,000,000, with approximately 12% of the population born outside the US. The immigration status of immigrants impacts their utilization of health services. Immigrants admitted for legal permanent residence in the United States are considered documented or legal immigrants and form approximately two-thirds of the foreign-born population. Persons who immigrate without applying for legal residence are considered undocumented or illegal immigrants and are an estimated one-third of the foreign-born population. About 80% of undocumented immigrants are from Latin American countries. Some evidence supports the “Hispanic Paradox” or the idea that, despite lower socioeconomic status, these immigrants have lower mortality rates.

The nature of the individual’s immigration experience contributes to his or her health care needs. For some immigrants, especially undocumented immigrants, the immigration context may increase the prevalence of posttraumatic stress disorder, depression, social isolation, lack of preventive care, and serious health problems. Once in the United States, undocumented workers are likely to find employment in lower paying and less desirable jobs that lack health benefits. Children from immigrant families are generally in worse physical health than children from nonimmigrant families and use health care services at a significant lower frequency.

Programs to Meet Needs

Access to medical care in the USA is affected by a combination of factors, including acceptability and adequacy of services to those in need of care, availability, and affordability of services. Acceptability and adequacy of health services can be affected by complex cultural and social beliefs, miscommunication, misinformation, misunderstanding, and mistrust between medical service provider and patient. Health care providers must be located in areas where immigrants are welcomed; facilities requiring proof of citizenship or residence status for eligibility discourage undocumented immigrants from seeking care. Facilities that fail to provide bilingual staff or translators may also decrease the availability of health care services.

US immigration policies contribute to affordability and utilization of health services. Payment for immigrant health care services comes from Federal programs, including Medicare and Medicaid. However, undocumented immigrants have the less access to these payment sources. Undocumented immigrants are not eligible for Medicare, Medicaid, or CHIP (Children's Health Insurance Program). Immigrants may therefore join the working poor who earn too much through employment to qualify for Medicaid, yet earn too little to afford private health insurance. Since the 1996 welfare reform, most newly arrived older immigrants with less than five years of residence are barred from using Medicaid benefits and are also ineligible for Medicare due to lack of work history. Uninsured and undocumented immigrants may seek care in free neighborhood clinics, clinics accepting cash payment, and emergency rooms. In 2004, the proportional distribution of private and public spending on national health expenditures was about 45% versus 55%.

Utilization Trends

Among populations with continuous private coverage and without coverage (uninsured), immigrants, especially noncitizens, are less likely to use preventive services than natives. The longer immigrants stay in USA, the closer their health care utilization approximates native-born persons. Among the publicly insured, immigrants' utilization is similar to natives, although noncitizen immigrants are significantly less likely to use preventive services. US-born adults have significantly more non-preventive visits than immigrants. The effects of education, having usual source of care, and having other public insurance were stronger among immigrants than natives. Lower utilization of both preventive and non-preventive services may result from a combination of better health and more limited resources. Among Latinos, patterns of access and use of health care services tend to improve with changing legal status. Immigrants with limited resources often seek care in emergency rooms rather than primary care clinics. Restricting immigrants' access to health care services costs the health care system more overall. Providing preventive and primary care is more cost effective than paying for emergency situations or problems resulting from lack of adequate health care services. A 2005 analysis of the 1998 Medical Expenditure Panel Survey shows that immigrants accounted for $39.5 billion in health care expenditures and per capita expenditures were 55% lower than those of US-born individuals. Expenditures for uninsured and publicly insured immigrants were half those of their US born counterparts. Immigrant children had 74% lower per capita health care expenditures than US born children. Emergency room expenditures were more than three times higher for immigrant children than for US born children.

Immigrants and Health Services Utilization in Other Industrialized Countries

General Description and Health Care Needs

As of 2007, 27 European countries form the EU, an economic and political partnership that seeks to harmonize social and economic policies. In 2008, the total number of non-nationals (persons not citizens of the country in which they reside) living in European Union member States was 30.8 million or 6.2% of the total European Union population. Approximately 40% of these come from countries outside of Europe. The EU emphasizes the need to integrate third country nationals into the EU system, giving them equal access to the rights of citizenship and social services including health services. As with US immigrants, the context of immigration contributes to the ease or difficulty in adjusting to the new society and these contexts may contribute to the prevalence of serious health problems. However, once in the EU, immigrants are offered social inclusion and the effective access to social protection. The EU recognizes that immigrants face a higher risk of poverty than the rest of the population and specific obstacles in accessing health care which may hamper their full participation in society. Specific initiatives seek to achieve full participation.

Programs to Meet Needs

Residence in an EU country is commonly the basis for entitlement to use of the health care system, resulting in near universal population coverage. Most of the EU countries have national health care programs, whether national health insurance systems, nationally owned health systems, or social insurance programs. The health systems provide comprehensive benefits, including preventive, public, primary, ambulatory, inpatient, prescription, mental health, and dental health services. Among countries, of course, there is variation in extent of cost sharing and range of benefits covered. The EU member States use a range of mechanisms, including public funds (tax and social insurance) for statutorily mandated benefits and private health insurance and out-of-pocket payments for services not covered in statutory benefits package. Public expenditures generally exceed private expenditures, although the proportion is falling and generally accounts for more than two-thirds of the health care expenditures.

The Council of European Union asserts the four core values of the EU member States' health care system: universal coverage, solidarity in financing, equity of access, and provision of high-quality health care. EU member States seek to provide universal coverage to all residents, including immigrants. Attempts to provide universal coverage may, in some cases, limit the breadth of coverage and therefore undermine financial protection of the insured. Increasingly, the fiscal sustainability of EU systems has been questioned. Response strategies have included increasing public revenues, lessening benefit obligations so that they can be met from existing revenue, and improving the capacity of the health systems.

Utilization Trends

European studies comparing migrants' access to health services are made difficult by incomparability of data (diverging measures of ethnic origin/migration status), incomparability of outcomes, and varying adjustment across studies for socio-economic and health status. The Migrant and Ethnic Minority Health Observatory Project (MEHO), funded by the EU, maps migrant health services to assist researchers and administrators to coordinate data collection and make more valid comparisons. Initial studies show that migrants tend to have lower attendance and referral rates to mammography and cervical cancer screening, more personal contacts per patient with general practitioners, and the same level of use for specialist care compared to nonmigrants in the EU. Emergency room utilization varied (lower, equal and higher across countries) and hospitalization rates were higher than or equal to nonimmigrants. This underscores the importance of understanding utilization of services among immigrant populations and the accompanying health outcomes.

Health Status

William Spears
Center for Global Health Systems, Management, Policy, and Prevention, Community Health, Wright State University, Boonshoft School of Medicine, Kettering, OH, USA

The World Health Organization (WHO) defines health as a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity. The WHO definition, introduced in 1947 is broad, leaving much room for discussion and interpretation. Some believe that health should be more narrowly defined providing more specific guidelines to help identify who is healthy and who is not. Others believe that the definition inspires users to explore possibilities and challenge conventional notions about health. In practice, there has been little effort to develop ways to measure health using this WHO model. On the other hand, the definition is responsible for efforts to develop better conceptualizations of health. It emphasizes that in addition to the physical dimension, there are mental and social aspects of health. This model promotes progress toward higher functioning in several domains: energy, comfort, and integration of mind, body, spirit and social interactions. Social well-being, social health, and mental health appear to be linked.

There are many different ways to measure the status of health populations. Internationally life expectancy, overall mortality rate, healthy life expectancy, and the prevalence of HIV are used to measure health status across counties. In industrialized countries, more specific measures such as disease-specific mortality, low birth-weight births, and self-rated health status are available for analyzing differences in health status. The relationship between health status measures and income and education has been documented and studied for decades. In the last 15–20 years, conceptions of health and the factors that affect health status have become more nuanced. Reports from the Whitehall study in England have led the quest to understand contributions of social determinants to health. These studies are helping to develop a better understanding of health and the factors that influence how it is maintained.

Models of Health

In addition to the WHO definition of health, there are other models used to guide thinking about health. The *medical model of health,* promoted by scientific medicine, focuses on the presence or absence of disease or disability. This emphasis works well for clinicians and those who focus on symptoms. This view restricts health to the sphere of professional knowledge and experience in an illness treatment system. This results in most health resources being used to treat the signs and symptoms of disease. Often, treatment is centered on the individual and devoid of social or cultural context. While the medical model is prominent in industrialized societies, many health professionals are beginning to incorporate social and cultural context into their practices.

The *wellness model of health* has foundations in health promotion. Primary prevention plays an important role in developing efforts to promote wellness. While the wellness model has an individual focus, it can easily provide a context for community wellness. There is increasing interest in assessing lifestyle and personal health behaviors in a community context. Critics of the wellness model point out that many of the components of the model are difficult to measure. The *environmental model of health* adapts health to include the influence of physical and social surroundings. The built environment, air and water quality, damage to the environment as a result of the actions of man are all factors that can influence health of individuals that can be measured only at geographic level (e.g., neighborhood, county, state). Individuals who are well adapted to their environment are less likely to experience stress and disease. How individuals and communities adapt to their social and physical environments is the essence of the environmental model. Proponents of this model are interested in how well individuals and communities harmonize with their ecology. In this model, the healthy individual who is comparatively free from undue pain, discomfort, or disability is in balance with his environment.

Social and Environmental Health

The social aspect of health has started to receive attention in research studies conducted in the last 10–15 years. Studies have associated health status with the social and physical environment in which people work, live, and age. People's health is impacted by the amount of social support and how socially connected they are. Social capital, a concept popularized by Robert Putman, is based in mutual trust, reciprocity among member of the group, and patterns of social engagement. Collective efficacy measures how well members of a community work together for common good. Social capital and collective efficacy have been demonstrated to be supportive of health after controlling for the effects of socioeconomic status in advantaged neighborhoods. Research conducted across a broader range of neighborhood environments has been less conclusive. It is important to continue efforts to understand how connections with our social environments affect health.

Health is determined in large part by individual health behaviors. Many health behaviors are established early in life in the context of family and cultural values. Some behaviors are influenced by knowledge learned in formal education settings and informal circumstances. Individual behaviors also may be influenced by the physical and built environments in which people live. Neighborhoods that contain or have access to parks and sidewalks may be more physically active. Community access to fresh foods may help maintain healthier eating behaviors. Understanding how to support people in modifying unhealthy behaviors is an important focus of health promotion efforts. Stress is another noteworthy influence on health. The way people live and work produce stress that can have a negative impact on health and well-being. Differences in socioeconomic status, race, and ethnic groups can expose individuals to varying levels of stress. Racial discrimination is another stressor that may have a negative impact on health.

Measures of Health Status

There is a wide array of measures of health status. Mortality data are the most universally available health statistics and a consistent resource to monitor changes in leading causes of death. Worldwide, the most common health status measures are life expectancy, all-cause adult mortality, and mortality under 5 years of age. Mortality data are not necessarily the best measure of health; many conditions that result in illness or disability do not result in death. There are many web-based resources that identify and monitor health status measures; the Community Health Status Indicators (CHSI) report is one such tool. This resource allows community advocates access to statistics that can assist in creating a healthy community. The CHSI Project is a partnership between several United States government, nonprofit, and academic agencies. The web-based reports supplied by CHSI give information about how to measure health status and statistics for recommended measures for all counties in the United States. Ten broad categories of health statistics are provided: demographics, summary measures of health, national leading causes of death, measures of birth and death, relative health importance, vulnerable populations, environmental health, preventive services use, risk factors for premature death, and access to care. The variety of the health measures provided by the report helps to understand the breadth of indicators that have been developed to measure health status. Summary measures for health status in the United States supported by CHSI are: life expectancy, all-cause mortality rates, self-rated health status, and average number of unhealthy days in the last month.

Healthy People 2010 is a national health promotion and disease prevention initiative that challenges individuals, communities, and professionals to ensure good health and long life for all. The leading *Healthy People 2010* health indicators are: physical activity, overweight and obesity, tobacco use, substance abuse, responsible sexual behavior, mental health, injury and violence, environmental quality, immunization, and access to health care. It is interesting to note that most of the recommended summary measures are measures of physical health. The information technology that supports measurement has not caught up with the science that acknowledges the significance of the role of the social and physical environmental in health.

Health Status and Socioeconomic Status

For almost every measure of health the more advantaged individuals are, the better their health. Socioeconomic status is a measure of an individual's social standing in the community. The core concepts of socioeconomic status are captured by combining measures of educational attainment, income, and occupational standing. Because these three measures are highly correlated, many studies use only income or education to measure socioeconomic status. Similar associations with health status have been found no matter which socioeconomic status indicator is used. The evidence shows that as rates of osteoarthritis, hypertension, cervical cancer, and all chronic diseases decrease, socioeconomic status increases This is true, too, for rates of unhealthy behaviors such as smoking, sedentary lifestyles, and exercise.

Prior to the mid-1980s, researchers considered only the relationship between poverty and health. It was believed that incomes above the poverty line would not have a significant contribution to improved health. Research published between 1985 and 1995 shows a changing comprehension of health being affected along the continuum of socioeconomic status. Reports by Michael Marmot and colleagues from the Whitehall study in England presented strong evidence showing that among British civil servants, 10-year mortality rates decrease as occupational grades increased. Many studies conducted in this period showed similar results, although they used different measures of mortality and different measures of socioeconomic status; findings clearly showed a gradient between levels of socioeconomic status and mortality.

A direct relationship between socioeconomic status has been identified in most industrialized nations. The strength of this relationship is not uniform; the strength of the association between socioeconomic status and health is weaker in more egalitarian countries such as the Scandinavian countries. Studies of income inequality report that states in the United States with more unequal distribution of income are more likely to have adverse health outcomes.

Social Determinants

As evidence is developed that confirms understanding about relationships between health and socioeconomic status, interest moves to improving knowledge about other factors figuring in the relationship between health and socioeconomic status. There are multiple pathways by which socioeconomic status determines health; a comprehensive analysis must include macroeconomic contexts and social factors as well as more immediate social environments, individual psychological and behavioral factors, and biological predispositions and processes.

A variety of conceptual models have been designed to explain the relationships between various ways that biology, genetics, and social and environmental factors contribute to health. Race, ethnicity, socioeconomic status, and other demographic measures have an impact on health; the impacts are direct, indirect, and interactive. The Institute of Medicine emphasizes that health is a concept for which there are linkages and relationships among the multiple determinants of health. This ecological model assumes that health and well-being are influenced by the interactions that occur among the determinants. The interactions occur in community and are supported by social activities that create community cohesion. Community cohesion is built through social interaction with neighbors that builds trust, such as reciprocal actions of providing support for others and accepting assistance from others. Using an ecological model requires knowledge of the determinants that influence health under the circumstances (e.g., childhood obesity, exercise and nutritional habits at home, access to safe outdoor environments in which to play, schools with physical education class and programs that provide healthy meals). In *Social Determinants of Health Second Edition: The Solid Facts*, Michael Marmot and Richard Wilkinson discuss how social determinants impact health status in populations across the world. This report building on evidence from the Whitehall Study and other research about the social determinants of health provides ten messages about social determinants based on: the social gradient, stress, early life, social exclusion, work, unemployment, social support, addiction, food, and transport.

Health Disparities

Reduction of health disparities is one of the goals *Healthy People 2020*. In the United States, there are documented disparities in income and education between race/ethnic groups. It is critical to the understanding of the role of race/ethnicity in health to examine the extent to which differences in health status may be attributed to socioeconomic differences. Studies that analyze race/ethnicity make it clear that not all differences in health among race/ethnic groups are due to socioeconomic differences. The influence of race and ethnicity on health is not yet understood.

Immigrant Health Status

Immigration plays a significant role in the health status of racial and ethnic minorities. Studies of immigrant health status document differences in health status of immigrants and their native-born American counterparts with the same racial and ethnic origins. Immigrants arrive in the United States healthier than their native-born counterparts, but over time this advantage disintegrates. The "healthy immigrant effect" explanation posits that people who are healthy choose to immigrate, then over a period of years assimilate into the dominant culture, adapting eating habits and other behaviors that impact weight gain and other aspects of health. Research evidence based on self-reported health status, health conditions, activity limitations, and mass body index (BMI) measured over time substantiates this explanation.

Future Directions

Health is more than the absence of disease or infirmity. Research over the past several decades suggests that health is a complex concept. While much of health status research focuses on mortality-related indicators, increasing emphasis is being given to issues related to health and wellness, oral health, and mental health. Current thought is that health is influenced by environmental and social determinants, behavior, genetics, and biology, in addition to the health care system and social policy. Increasingly, measures of lifestyle and behavior are being used to monitor changes in health status. Researchers continue to extend the understanding of how individual and community health interact with the social and physical environment. Differences within and across race and ethnic groups are influenced by differences in genetic makeup and biology and complicated by diverse social and environmental circumstances. Health disparities research strives to understand the influences of individual mechanisms that contribute to illness and disabilities and how those mechanisms are influenced by membership in different subpopulations in society. To understand the causes of disparities in health status will require revised and new research approaches that include basic, clinical, behavioral, epidemiological, translational, and health services research. Determining health status of immigrants will require that in addition to considering the topics addressed above, researchers will need to take into consideration the origins of the immigrants and their circumstances and health prior to immigration.

Healthy Immigrant

Angela C. Lee
Cambridge, MA, USA

On average, newly arriving immigrants are healthier than natives of similar ethnic backgrounds. This is known as the "healthy immigrant effect." It is also referred to as the "healthy immigrant paradox" because immigrants often have high risk factors, such as higher rates of poverty, lower education, and poorer work and housing conditions than native-born residents, and because many immigrants arrive from countries that have lower standards of living, yet still have better health outcomes and lower mortality from the same causes of death. This effect has been widely studied for immigrants to Canada, Australia, Western European countries, and the United States.

Canada and the United States serve as valuable settings for healthy immigrant studies as both countries passed immigration acts – the Immigration Act of 1976 in Canada, and the Hart-Celler Act of 1965 in the United States – that affected the nature and volume of immigration. Prior to the immigration Acts, immigrants mostly arrived to these two countries from European nations such as the United Kingdom, France, Spain, Sweden, Denmark, Italy, and Greece. Subsequent to the passage of the immigration Acts, immigrants began arriving from Asian, Latin American, and Caribbean countries. Immigrants now originate from numerous countries around the world. This expanded pool provides researchers diverse immigrant populations for healthy immigrant studies.

Immigrants are found to be healthier than native populations across a variety of health conditions and indicators. Some studies show that immigrants have significantly lower incidences and risks of mortality from chronic diseases such as cardiovascular disease, hypertension, lung and prostate cancer, chronic obstructive pulmonary diseases, liver cirrhosis, and asthma. Immigrants tend to have lower rates of infectious diseases such as pneumonia and influenza, as well as unintentional injuries and suicide, and higher life expectancies. Pregnancy outcomes such as preterm births, low birth weights, and infant deaths also tend to be better for immigrants as compared to native-born populations. In self-reported surveys of health, immigrants report higher levels of satisfaction with their health status than their native-born counterparts. These trends persist when ethnicity, sex, and age at immigration are controlled variables.

Researchers offer several explanations for the phenomenon. Some posit that the requisite health screenings immigrants must undergo allow only the most physically able and fit for entry into a country. For example, Canada's Immigrant Act of 1976 broadened the criteria for "prohibited classes" of people that were denied entry into the country. People are denied entry if they suffer from an existing disease, disorder, disability, or other health impairment that is likely to be a danger to public health or safety, or will result in excessive demand on the Canadian health care and social services system, as deemed by a medical officer. That is, there is a selection bias in the system and immigrants to Canada and the United States are a healthier group than those who remain in their country of origin. Similarly, there is a self-selection bias as immigrants who are healthier and wealthier tend to be those who are migrants. Third, the healthy immigrant effect is believed to be a consequence of health and social factors. Many immigrants originate from regions of the world where lifestyle-associated behaviors that contribute to chronic diseases, such as inactivity, smoking, alcohol consumption, poor diet, and obesity, are less prevalent than in the developed world. Some posit that high human capital and strong social networks among immigrant families and communities provide a protective effect against ill health. Finally, though less-well studied, the "hygiene" hypothesis and vitamin D hypothesis are possible explanations of the healthy immigrant effect.

Healthy immigrant studies are usually conducted in several ways. Some studies compare health characteristics or outcomes in a cohort of immigrants with those in a demographically similar component of the host populations. A few longitudinal health studies were undertaken where researchers followed immigrant populations through time to ascertain changes in health outcomes. Researchers may also observe the effects of migration by comparing a group of immigrants with nonimmigrant counterparts who remain in their country of origin, although this is less common.

It is unclear for how long the healthy immigrant effect lasts. There is consensus that the health advantage diminishes, and the gap between native health and immigrant health closes the longer an immigrant lives in his/her adopted country. A longer length of residence is associated with health status, mortality patterns, and health behaviors that are convergent toward that of native-born populations. Little is understood of the behavioral and sociocultural factors that may be protective of good health in immigrants. Researchers are still attempting to determine the contribution of acculturation and assimilation on the healthy immigrant effect. Furthermore, questions remain as to whether, or to what extent, the healthy immigrant effect persists for children of immigrants, and how ethnic origin, country of birth, and environmental exposures predict or explain the health and mortality differentials between native and foreign-born populations. In order to fully understand immigrant health, it is also important to disaggregate studies of "immigrants" as this is a heterogeneous group with distinct differences in characteristics among subgroups of foreign-born peoples.

Heat Stroke

Lawrence A. DeLuca, Jr.
Department of Emergency Medicine,
University of Arizona, Tucson, AZ, USA

Heat stroke is the most severe manifestation of a spectrum of illness, and as such represents an immediate threat to life. Even if not immediately fatal, the complications of heat stroke can include renal (kidney) failure, rhabdomyolysis (muscle breakdown), and severe metabolic derangements. Heat stroke is better prevented than treated, and is of particular concern for undocumented immigrants attempting to enter the United States along its southern borders. In Pima County, Arizona, alone there are over 100 heat-related deaths per year, and the risk of death has been demonstrated to increase predictably with rises in the ambient temperature.

Particular Risks for Undocumented Immigrants

Undocumented immigrants are at a particularly high risk for heat-related illness. Increased efforts at securing the United States' southern borders have led to undocumented immigrants seeking out increasingly remote areas to cross. Individuals crossing the border may have a limited ability to carry water or other liquids, and may not have access to shelter from the sun. Some individuals use stimulants such as caffeine in order to stay awake in an attempt to speed their journey. However, these substances may aggravate dehydration by increasing water loss. Individuals may not accurately assess their risk of crossing, or may be abandoned by their *coyotes* (guides/smugglers), leaving them vulnerable in the desert.

The Spectrum of Heat Illness

Heat stroke is generally the last stage of progressive heat illness brought on by progressive exposure to a hot environment, and is preceded by heat cramps, which progress to heat exhaustion. Heat cramps are generally the initial presentation of heat illness. Brought on by continued activity in a hot environment, mild dehydration, and inadequate electrolyte replacement, victims may complain of muscle cramping and aches, and feeling mildly unwell. Left untreated, heat cramps will progress to heat exhaustion. Heat exhaustion is a more severe stage of illness, generally accompanied by an increasing feeling of illness. Individuals with heat exhaustion are frequently nauseated and may vomit and are generally still sweating profusely. While the body is under tremendous physiologic stress, these individuals are still compensating for that stress, and generally still have a normal or mildly elevated body temperature and a normal mental status.

Heat stroke is the terminal event in the progression of untreated heat-related illness. The body's compensatory mechanisms have failed. The victim is sufficiently dehydrated that sweating has slowed or ceased (leading to the classic characterization of hot, dry, red skin), and the body temperature is no longer controlled, and can be as high as 108°F. Unless treated immediately and aggressively, heat stroke will be fatal in a short time.

Treatment of Heat Illness

The progression of heat illness can easily be reversed early in its course with relatively straightforward interventions. Removal of the patient from the hot environment is crucial. The provision of water and food will suffice for relatively mild cases. It is important first and foremost to replace lost body water, but with progressively severe dehydration the use of electrolyte replacement drinks can be considered, so long as they are not sufficiently concentrated to make the victim more nauseated or induce vomiting. Individuals with more severe heat-related illness who cannot tolerate oral fluids may require intravenous (IV) fluids. Again, replacement of body water and electrolytes (essential elements found in the blood) is important for resolution of the illness.

The treatment of heat stroke requires immediate and aggressive therapy. Not only must fluids be replaced and electrolyte derangements corrected, but the body must be rapidly cooled to avoid progressive organ damage. Removal of the patient's garments and the use of evaporative cooling (fans and water sprayed upon the patient) or immersion in ice or ice water have been documented. Patients may develop hemodynamic instability (dangerous fluctuations in heart rate and/or blood pressure), rhabdomyolysis, or progress to multi-organ failure, and are generally best treated in an intensive care setting.

Prevention of Heat Illness

Common-sense measures can help prevent heat-related illness. Adequate hydration is important, especially when exercising or working in a hot environment. Individuals should drink water before, during, and after activity, as the thirst reflex lags behind water loss. Light-colored clothing that reflects heat will reduce the absorption of radiant energy, as will a shaded area. "Sweat suits" or rubberized exercise or work gear should be avoided. Humid environments pose a particular risk, as the body depends on the evaporation of sweat for effective cooling.

Conclusion

Heat illness ranges from relatively mild heat cramps to life-threatening heat stroke, in which the body's cooling mechanisms completely fail. Undocumented immigrants are particularly at risk, as they may face harsh environments and lack of access to shade and water. Treatment may range from simple oral rehydration for heat cramps to intensive care unit admission for severe heat stroke. Prevention requires simple, straightforward measures, such as attention to hydration and the avoidance of prolonged activity in a hot and humid environment.

Helicobacter pylori

Trevor A. Crowell
Department of Internal Medicine, University Hospitals
Case Medical Center, Cleveland, OH, USA

Background

Helicobacter pylori (*H. pylori*) is a bacterium that infects approximately half of the world's population. Infection is acquired typically during childhood and is much more common in the developing world where poverty, crowded living conditions, and poor sanitation increase the risk of infection. Within developed countries, these same risk factors make infection more common among immigrants. Without treatment, infection is lifelong. In most cases the infection causes no symptoms, but it is associated with chronic irritation and inflammation of the stomach (gastritis) and can have serious consequences. Infection with *H. pylori* is associated with the development of anemia, peptic ulcer disease, and two types of cancer – gastric adenocarcinoma and gastric mucosa-associated lymphoid tissue (MALT) lymphoma. The prevalence of infection with *H. pylori* and serious consequences associated with the infection make it an important topic for persons immigrating from resource-limited to resource-rich settings.

Geographic Rates of Occurrence

The incidence of *H. pylori* infection and gastric cancer varies tremendously by geographic region. While the occurrence of gastric cancer is declining in developed countries, it is increasing globally. *H. pylori* infection is thought to be responsible for more than 5% of the current global burden of cancer. *H. pylori* infection and gastric cancer are most common in East Asia, Eastern Europe, and South America, while they are less common in North America and Western Europe. In countries where infection is less common, tremendous ethnic disparities can still exist. In the United States, for example, 26% of non-Hispanic Whites are infected, whereas 62% of Hispanic-Americans are infected. For reasons that remain poorly understood, *H. pylori* infection is exceedingly common in sub-Saharan Africa, but the incidence of gastric cancer remains relatively low.

Clinical Manifestations

H. pylori is adapted uniquely to thrive in the human stomach. It is a curvilinear Gram-negative rod with a flagellum that allows it to swim through the viscous mucus that coats the inside of the stomach. It creates chemicals that alter the composition of the stomach contents, creating an environment that is more favorable to bacterial survival. The bacteria do not invade any tissues, but produce toxins that cause an inflammatory response that leads to tissue damage and release of nutrients for the bacteria to consume. This inflammation can lead to ulceration and, in a smaller proportion of cases, gastric cancer. These clinical manifestations develop typically decades after acquisition of the infection. Earlier in infection, children are at risk for the development of iron-deficiency anemia that is refractory to iron supplementation; this may be associated with malnutrition and growth retardation.

Screening and Treatment

The potential for serious complications of this extremely common infection raises questions about screening and treatment; however, this topic remains controversial because of the limited data on cost-effectiveness. Several methods of screening exist, but the definitive method for diagnosing active infection remains upper gastrointestinal endoscopy with gastric biopsy. This procedure involves sedating a patient, passing a camera through the mouth and into the stomach, removing a small piece of the stomach, and evaluating it under a microscope for evidence of infection. While definitive, this method is costly and exposes the patient to risks associated with anesthesia and instrumentation. It is usually reserved for patients with symptomatic disease. In Japan, all individuals over the age of 40 are offered radiologic screening for gastric cancer. This is costly, exposes the patient to risks associated with radiation, and identifies malignancy only after it has developed. Blood tests can detect antibodies to *H. pylori* and can be a useful screening test for adults without a history of infection. These tests are not approved for use in children and can remain positive even after treatment for the infection; therefore, they are not useful if a patient has been diagnosed and treated previously. The urea breath test is a noninvasive test utilizing a radioactive isotope to detect *H. pylori* metabolism in the gut; this can be used to monitor response to therapy in adults. Since infection with *H. pylori* is very common, but the most serious complications of the infection remain relatively rare, screening is reserved generally for patients in countries with a high incidence of gastric cancer and is begun in adulthood. Screening is not performed on children because of the increased risk for reinfection and the lower likelihood of clinically relevant disease. Children presenting with symptomatic disease such as peptic ulcer disease or unexplained refractory iron-deficiency anemia should undergo upper gastrointestinal endoscopy with gastric biopsy.

Eradication of *H. pylori*

Eradication of *H. pylori* is accomplished usually via a combination of antibiotics and proton-pump inhibitor medications that decrease the acidity of the stomach contents. Often the regimen includes three drugs that must be taken two times daily for 10–14 days. This regimen is very effective, but increased use of these medications and poor adherence to prescribed regimens have contributed to a rise in drug resistance that eventually may make treating *H. pylori* more difficult. Treatment is indicated in children with symptomatic gastritis, peptic ulcer disease, unexplained iron-deficiency anemia, or a first-degree relative diagnosed with gastric cancer. Any adult found to be infected should receive treatment. Eradication of *H. pylori* can correct associated iron-deficiency anemia in children, prevent recurrence of peptic ulcer disease, and lead to clinical regression of gastric lymphoma in up to three-fourths of patients. Additionally, eradication decreases lifetime risk for the development of gastric adenocarcinoma. Transmission among adults is rare, making reinfection in adulthood unlikely.

H. pylori is an extremely common infection of the stomach that can cause a broad spectrum of pathology, from asymptomatic colonization to peptic ulcer disease and malignancy. Immigrants from resource-limited settings are at an increased risk for having this infection and remain at increased risk for developing complications of infection even after settlement in low-risk countries. The role of screening for infection remains a topic of debate, but once detected *H. pylori* often can be eradicated with a 2-week course of medication. Eradication is associated with improvement of symptomatic disease and decreased risk of gastric adenocarcinoma and MALT lymphoma. While worldwide eradication of the organism is unlikely, implementation of appropriate screening and treatment strategies are likely to decrease the burden of infection among those currently at highest risk, including residents and immigrants from the developing world.

Helsinki Declarations

Cristina Cazacu Chinole
Center for Ethics and Public Policies, Bucharest and Iasi, Romania

The Declaration of Helsinki (DoH) is a document issued by the World Medical Association (WMA) that provides ethical guidance for research involving human beings. The Declaration was developed almost 20 years after World War II, as a response to the abuses by Nazi physicians and to complete the Nuremberg Code. This document was developed to offer protection from harm and exploitation of the most vulnerable categories of research subjects. While the Nuremberg Code emphasized the need for voluntary consent, the Helsinki Declaration started from the premise that the very mission of the physician is to safeguard the health of the people. The Declaration aimed to add further provisions to Nuremberg Code, especially aimed at safeguarding population lacking legal capacity for consent, such as children, mentally ill, temporarily incapacitated, when participating in research. Furthermore, it introduced the concept of therapeutic versus nontherapeutic research.

The Declaration was first adopted in 1964 and, since then, it has been revised several times in order to reflect current practices. Significant additions to the initial version were made in 1975, followed by minor additions in 1983 and 1989. One notable change appeared in the 1996 version, when a paragraph from the previous version saying that: “In any medical study, every patient including those of a control group, if any should be assured of the best proven diagnostic and therapeutic method," was followed by a paragraph stating that: "This does not exclude the use of placebo, or no treatment, in studies where no proven. . .method exists." This paragraph was to create controversy and debates the following years due to placebo-controlled, mother-to-child HIV transmission trials carried out in developing countries when concerns were raised by some who publicly criticized such research, since the Declaration of Helsinki prohibited the use of placebos when a proven "prophylactic, diagnostic or therapeutic" method exists somewhere in the world. As these HIV trials have been also strongly defended, pressures for another revision of the Declaration of Helsinki were made.

It took WMA several years to produce a significantly revised version of the Declaration, in 2000. This version was not spared for its share of controversy, mostly because of the new Paragraph 29, which reiterated the same statement from the 1996 version: "The benefits, risks, burdens, and effectiveness of a new method should be tested against those of the best current prophylactic, diagnostic, and therapeutic methods. This does not exclude the use of placebo, or no treatment, in studies where no proven prophylactic, diagnostic or therapeutic method exists."

The following years, as the controversy over this paragraph arose, WMA published "notes of clarification": in 2002, on placebo studies, yet no change to the requirements have been made and in 2004, when it stated that patients are entitled to be informed of the outcomes of the research and to share any benefits that come from the study and that arrangements for patients to benefit from the research after the end of the study should be made. Even if the Declaration did not provide information about who should fund these arrangements, it stated that these are to be included in the protocol and reviewed by an ethics committee. In case such post-study arrangements are judged as inappropriate by the ethics committee, then the study should not be approved.

There have been many calls for a new revision, and 3 years later another revision process was initiated that ended in the latest version which was issued in 2008. According to many, the latest version strengthens previous versions in some areas but it weakens some of the initial provisions in other areas.

The 2000 version was strongly opposed by the US Food and Drug Administration (FDA) that supports the use of placebo controls in the studies which are submitted to the agency for drug approvals. As a result of the changes made, FDA abandoned its previous rule that foreign studies must comply with the provisions of the Declaration of Helsinki. In 2008, the American regulatory agency issued new regulations that basically replaced the Declaration with the International Conference on Harmonization (ICH) Good Clinical Practice Guidance (GCP), as these documents contain weaker provision regarding the use of placebo controls in clinical studies.

While the first version of the Declaration was intended to guide physicians who were engaged in research involving human participants, its latest version urges other categories and organizations which are involved in research with human participants to adopt its principles. Nowadays, the Declaration is considered a fundamental document in the ethics of health care research and its principles have been embodied in national and international guides and regulations. In order to conform to the standards included in the Declaration, researchers that are involved in studies with human subjects need to respect the autonomy of each individual, promote and safeguard his/her health, provide informed consent without coercion, take special measures with vulnerable populations, compare new therapies against best available ones, have a sound scientific knowledge of the subject, assess risks against benefits, engage in studies that would provide a benefit to the population involved, disclose the results of their studies accurately, and fully disclose any ethical concerns in their study protocols.

The relevance of DoH in relation to vulnerable population, such as immigrants, relies on the introduction of principle of distributive justice. Therefore, the Declaration requires that researchers make sure that the risks and benefits of their inquiry are evenly distributed to participants in research, as well as to the communities to which the study participants belong. Furthermore, it calls for the minimization of the use of placebo controls, insists that populations to which the study participants belong benefit from the research, and requires that therapeutic agents be made available to all trial participants, even after the trial has been completed.

Hepatitis

Hannah M. Lee
Division of Gastroenterology/Hepatology, Department of Internal Medicine, Tufts Medical Center, Tufts University School of Medicine, Boston, MA, USA

Introduction: The Impact of Global Migration

The impact of worldwide immigration has implications at many levels. This includes those at the public health level which has resulted in a shift in infectious disease epidemiology. In developed regions of the world, many infectious diseases have fallen to historical low levels of prevalence or have overall eliminated endemic transmission. However, as a consequence of migration patterns, immigration of individuals from areas of high incidence of infectious diseases such as tuberculosis, hepatitis, and HIV have brought a resurgence of these diseases into areas of low prevalence and incidence. Thus, infections that have been well controlled in immigration-receiving nations are now increasingly observed in the foreign-born population. With this growing public health challenge facing these host nations, it will be critical for health care providers, both at the primary care level as well as specialty care, to be able to recognize, diagnose, and manage such diseases. This entry will focus specifically on the viral hepatitis (A, B, C, D) which remains a global public health challenge facing immigrant-receiving nations today.

Viral Hepatitis

The term "hepatitis" is a non-specific one, and is simply defined as inflammation of the liver. Hepatitis can be acute and self-limiting, or chronic and progressive, leading to cirrhosis and end-stage liver disease. Hepatitis results from a wide range of causes, not only from infectious diseases, such as from viruses, but also from drugs and toxins as well as metabolic and autoimmune causes. Viral hepatitis can be caused by infection from any of the six viral agents: hepatitis A (HAV), hepatitis B (HBV), hepatitis C (HCV), hepatitis D (HDV), and hepatitis E (HEV). All of these human hepatitis viruses are RNA-based with the exception of hepatitis B, which is a double-stranded DNA virus. Although each virus has its distinct molecular and antigenic properties, the clinical manifestations after infection of any of these viruses are similar. However, route of transmission may vary. Individuals infected can be asymptomatic or present with fulminant liver failure. Typical symptoms include jaundice, right upper quadrant abdominal pain, fever, nausea, vomiting, and poor appetite. Some of these viruses can lead to chronic infection.

Hepatitis A

HAV is transmitted through the fecal–oral route, through person-to-person spread and in the setting of poor personal hygiene and overcrowding. Infections typically occur during childhood in areas of poor sanitation and crowded living conditions. However, with improvement in sanitation and hygiene, this has resulted in delay of infection. Therefore, the number of persons susceptible to the infection increases. The infection typically occurs in large outbreaks as well as sporadic cases with the source traced to contaminated food, water, milk, various fruits and vegetables imported from endemic countries. HAV is self-limiting and does not progress to chronic infection.

The prevalence of HAV infection varies worldwide, and correlates with socioeconomic conditions, particularly hygienic and sanitary conditions. Developing countries with poor sanitary and hygienic condition that are considered areas of high endemicity include parts of Africa, Asia, and Central and South America. In these geographic areas, infection is acquired often during childhood. Developed countries of low endemicity include Northern and Western Europe, Japan, Australia, New Zealand, USA, and Canada due to good sanitary and hygienic conditions. Although infection rates are very low in these countries, disease may occur among specific risk groups such as travelers to HAV endemic areas, migrant workers, and migrants from developing countries where HAV is endemic.

In the USA, the number of foreign-born persons began to steadily rise in the 1980s, increasing the number of foreign-born US citizens from approximately 9–32.5 million. The largest number within this group originated in Mexico, at 9.8 million (approximately 30% of the population), followed by Asia at 8.5 million (26%), and 7.3 million (23%) from other parts of Latin America. Based on these data, the majority of the foreign-born populations in the USA originate in countries considered highly endemic for hepatitis A. In one study by Weinberg et al., among Hispanic children who lived along the US–Mexico border in San Diego County from 1998 to 2000, hepatitis A cases were seen in 132 cases. The children were matched by age group and exposure period to 354 control subjects of Hispanic children who tested negative for anti-HAV. Of the exposed patients, 67% of them had traveled outside the USA during the incubation period compared to only 25% of children who did not have HAV infection. All but one of the children with infection had traveled to Mexico. It was during the summer months and Christmas holidays that travel had occurred the most frequently with the number of cases peaking 1–2 months after peaks in travel, reflecting the incubation period for hepatitis A. It was found that children with travel-acquired HAV infections were much more likely to have eaten food from street vendors and were more likely to have eaten salad or lettuce during travel compared to control subjects. Other studies have also described the association between pediatric travelers, hepatitis A infection, and the role of travel back to the country of origin.

Because hepatitis A is a potentially serious but vaccine-preventable disease, in 2006, the Advisory Committee on Immunization Practices of the US Public Health Service recommended routine hepatitis A vaccination of all children. In other countries, hepatitis A vaccination may not be included in their national childhood immunization schedule, and may only be recommended in children living in regions or communities with high rates of HAV infections. In the USA, with the implementation of a national hepatitis A immunization recommendation for all children, the goal is to prevent future community-based outbreaks in higher risk areas of the country, particularly in new immigrant growth centers.

Hepatitis B

The World Health Organization has called HBV a major global public health problem. It is estimated that two billion people worldwide have been infected with HBV with more than 350 million with chronic infection. It is estimated that 620,000 persons die annually from HBV-related liver disease. Approximately 25% of adults who become chronically infected during childhood later die from liver cancer or cirrhosis. HBV is 50–100 times more infectious than HIV. Despite causing significant morbidity and mortality, HBV infection is preventable with a vaccination that is safe and effective.

HBV is transmitted by percutaneous or mucosal exposure to infectious blood or body fluids. This most often occurs through injection drug use (IDU), sexual contact with an infected person, or from an infected mother to her infant during delivery. Primary acute HBV infection can be self-limited with subsequent lifelong immunity against reinfection. However, this can progress to chronic infection with continuing viral replication. The risk of developing chronic infection is inversely proportional to the age of exposure. Among those exposed to hepatitis B during birth, 90–95% will go on to develop chronic infection, and those exposed during childhood, 20–40% will develop chronic infection. In contrast, only 5% infected in adulthood will develop chronic infection. The progression from acute to chronic infection occurs when the immune system is not able to effectively destroy and clear virus-infected cells. Immunosuppressed persons, such as hemodialysis patients or persons infected with HIV, are at increased risk for chronic infection. Those chronically infected can remain asymptomatic for years until the development of cirrhosis and end-stage liver disease or advanced cancer. Moreover, those chronically infected often are unaware of their infection and their risks for transmitting the virus.

Worldwide, the transmission patterns of HBV and the seroprevalence of chronic infection vary significantly, although there are limited seroprevalence studies in many countries. Approximately 45% of persons worldwide live in regions where HBV is highly endemic (i.e., HBSAg prevalence is $\geq$8%). Historically, >90% of new infections occurred among infants and young children as the result of perinatal or household transmission during early childhood. Infant immunization programs in many countries have led to marked decreases in incidence and prevalence among younger, vaccinated members of these populations. Countries of intermediate HBV endemicity (i.e., HBSAg prevalence of 2–7%) account for approximately 43% of the world's population. Regions of the world with high or intermediate prevalence of HBSAg include much of Eastern Europe, Asia, Africa, the Middle East, and the Pacific Islands. In countries of low endemicity (i.e., HBSAg prevalence of <2%), such as the United States, and Northern and Western Europe, the majority of new infections occur among adolescents and adults and are attributable to high-risk sexual activity and injection drug use exposures. However, in these areas of low endemicity, prevalence of HBV infection is high among certain foreign-born groups.

In the United States, after the stepwise implementation of the national vaccination strategy to eliminate HBV transmission, the incidence of hepatitis B infection began decreasing in the mid-1980s. In 2007, the rate of infection was the lowest recorded at 1.5 cases/100,000 population since surveillance began in 1966. This represents an estimated decline of greater than 80% from rates reported in 1990, which was the year before the national strategy was implemented. Although the United States is considered a region of low endemicity, the prevalence of chronic HBV infection is high in various parts of the country. In 2006, approximately 800,000–1.4 million US residents were living with chronic infection, with 47–70% of these persons foreign-born. Chronic infection is more likely to occur in high-risk groups such as Asian Americans and emigrants from areas of the world where HBV is prevalent. This includes China, Korea, Southeast Asia, the Indian Subcontinent, Africa and Micronesia. In 2005, a seroprevalence study was conducted in New York City in order to assess the prevalence of chronic HBV infection among the Asian/Pacific Islanders. Among the 925 participants, 137 (14.8%) were found to be HBSAg-positive. The prevalence of chronic infection was highest in those less than 30 years of age. The majority of participants were immigrants, with 46% having lived in the US for less than 10 years. Other screening programs have also been conducted in other cities in the US, including Chicago, Philadelphia, and California, with results showing that 10–15% of Asian/Pacific Islander immigrants to the US have HBV infection.

Similarly, in other areas of the world with low HBV endemicity, immigration of groups from high risk areas has also resulted in increasing prevalence of chronic HBV infection. Various studies from Europe have reported a high prevalence of chronic HBV infection among various immigrant groups. The United Kingdom, in recent years, has experienced a massive influx of migration of groups from areas of intermediate to high endemicity. It is estimated that 325,000 in the UK have chronic HBV infection, and is nearly double the Department of Health's 2002 estimate of 180,000. Moreover, these estimates may be higher due to underreporting.

Spain is currently the main recipient country of immigrants in Europe with an increase from 0.5 million immigrants in 1995 to 5.2 million in 2008. This represents 11.3% of the country's total population. One Spanish study by Monge-Maillo et al. evaluated health characteristics of the two most common immigrant groups, sub-Saharan Africans and Latin Americans. Out of the 2,198 immigrants referred to their clinic over a 20-year period, the prevalence of chronic infection with hepatitis virus was higher among Sub-Saharan Africans with prevalence of HBSAg positivity in 9.8% of the patients.

Hepatitis C

HCV was initially referred to as hepatitis non-A, non-B, and was later identified in 1989. Prior to the introduction of anti-HCV screening tests for blood donors in 1992, HCV represented a major cause of transfusion-dependent hepatitis. The virus is primarily transmitted through blood exposure. The most frequent modes of transmission in the US, Europe, and Australia are from previous or current use of illegal drugs, predominantly injected drugs, and to a lesser extent, intranasal cocaine. On a global scale, cases of infection are often related to unsterile practices in medical procedure, such as in blood transfusions, the use of contaminated vaccination needles, and in hemodialysis. Egypt, for example, is among the countries with highest reported HCV prevalence of at least 15% due to reuse of needles during a national program of schistosomiasis vaccination from the 1950s to the early 1980s. Practices relating to folk remedies and other community-based needle practices, including acupuncture, have also been linked to transmission.

In acute HCV infection, only 25–35% of individuals are symptomatic, thereby making detection and diagnosis of acute infection difficult. Approximately 85% of those infected will go on to develop chronic infection. Among those chronically infected, approximately 20% will progress to cirrhosis over a 20-year period. Similar to chronic HBV infection, the majority of those with chronic HCV infection are asymptomatic until progression to advanced disease has occurred. Annually, 3–6% of patients with cirrhosis will progress to end-stage liver disease, and therefore, may be potential liver transplant candidates. Chronic HCV infection is associated with the development of hepatocellular carcinoma in 1–5% of infected persons, predominantly in those with cirrhosis. In the US, Europe, Australia, and Japan, HCV infection is the leading cause of chronic hepatitis and death from liver disease. It is also the leading indication for liver transplantation.

Worldwide, HCV is the second most common cause of chronic liver disease and hepatocellular carcinoma behind hepatitis B. HCV is a global public health problem with approximately 3% (170 million) of the world's population infected. The prevalence of HCV is relatively low in the US, northern Europe, and Australia, ranging from 0.3% to 1.8% of the population. An increased prevalence of HCV ranging from 1.5% to 9% has been reported in Southeast Asian and the Indian subcontinents, with the highest rates (2–14%) present in northern and central Africa, the eastern Mediterranean, and the Ukraine. There are up to 5–10 million in Europe who are infected, approximately 12 million infected in India, and an estimated 38 million infected in China. The majority who are infected do not know they are. Furthermore, the true prevalence of HCV worldwide is likely underestimated given the lack of appropriate screening and case identification.

HCV infection among the Asian population has often been underappreciated, particularly as HBV infection has long been recognized as a major cause of morbidity and mortality in this population group. However, the prevalence of HCV infection in China alone at approximately 3% and likely higher is greater than the overall US prevalence of 1.8%. Moreover, Southeast Asia is an area with higher hepatitis disease burden than the rest of Asia, with disease prevalence of 5.6% and 6.1% in Thailand and Vietnam, respectively.

HCV is a highly heterogenous virus. Six major genotypes of HCV have been identified worldwide with more than 50 subtypes described. A distinct geographic distribution of these genotypes can be seen: Genotype 1 is the most common type worldwide, and particularly dominate the US, Europe, Australia, and Japan. Genotypes 2 and 3 are less common in these areas. Genotype 3 is most common in India, the Far East, and Australia. Genotype 4 is most common in Africa and the Middle East. This genotype, however, is being identified more frequently in Europe and North America among native injection drug users and immigrants from endemic areas. Genotype 5 is most common in South Africa, while Genotype 6 predominates in Southeast Asia (Vietnam, Thailand, Burma, Malaysia, and Singapore), south China, and Hong Kong. Genotype 6 has also been identified in both the US and Australia among the Southeast Asian immigrant population who are infected. HCV genotypes have not been clearly associated with virulence or pathogenicity of the disease; however, they are an important predictor in treatment outcome.

Hepatitis D

Hepatitis D is largely acquired through parenteral exposure. Because it is a defective RNA viroid, it requires HBSAg for transmission, and therefore, occurs only in individuals who are positive for HBV surface antigen (HBSAg). HDV and HBV coinfection is associated with accelerated progression to cirrhosis, early liver decompensation, and an increased risk for the development of hepatocellular carcinoma. Therefore, those with coinfection are at higher risk for severe liver disease compared to individuals infected with HBV only. The Mediterranean countries, the Middle East, Central Africa, and northern parts of South America are considered areas of high endemicity for HDV. In Western countries, there is a high prevalence of HDV infection in intravenous drug addicts with HBV infection. More than 350 million people worldwide have chronic HBV infection. Of these, 15–20 million individuals are thought to be co-infected or superinfected with HDV. In southern Europe, HDV infection has been highly endemic. However, with the implementation of HBV vaccination programs in the 1980s, the incidence of infection decreased significantly to 5–10%. In Turkey, a wide range in prevalence of HDV infection has been observed. In western Turkey, the prevalence is <5% in contrast to southeast Turkey with prevalence of 27%. In southeast Turkey, almost half of all cases of cirrhosis and hepatocellular carcinoma are due to HDV infection. Mongolia is also a country considered to have high prevalence of HDV infection where up to 1/3 of chronic hepatitis infections are caused by HDV.

Although the prevalence of HDV infection has declined in southern Europe, the infection still remains a significant health problem in Central Europe. Prevalence in this area has been attributed to immigrants from highly endemic areas. At a referral center for liver diseases in Hanover, Germany, approximately 8–10% of HBSAg-positive patients test positive for anti-HDV antibodies. In this patient population, more than three quarters of those infected were foreign-born. Up until the mid-1990s, the majority were from Turkey. Since that time, a significant increase in HDV infection is being seen in patients originating from Eastern Europe and the former states of the Soviet Union. An increasing prevalence of HDV infection is also being observed in England. At King's College Hospital in London, 82 (8.5%) of almost 1,000 consecutive patients with chronic hepatitis B were tested positive for anti-HDV antibodies between 2000 and 2006. Many of these infected patients were born in Africa or Eastern Europe. Similar to Germany and England, a high prevalence of HBSAg-positive individuals with anti-HDV antibodies has been observed in immigrant populations in France, particularly in the African community.

Conclusion

The impact of global migration has affected immigration-receiving nations at many levels. This includes a significant impact at a public health level with a global shift in infectious disease epidemiology. Infections, including viral hepatitis, are increasingly observed in the foreign-born population who come from nations of high prevalence for these infections. With importation of these infections to low prevalence host nations, clinicians in these host nations will be confronted with the challenge of diagnosing and managing these diseases. Both commitment to education and training relating to such diseases pertaining to foreign-born groups and the use of tools and resources relating to international public health will be essential in order to provide appropriate and adequate medical management of these population groups.

Herbal Medicines

Kristin L. Hicks
Department of Psychiatry, Mount Carmel Health Providers, Columbus, OH, USA

Herbal medicines, also called botanical medicines or phytomedicines, are preparations of herbs used for healing. An herb is any form of plant or plant product, such as leaves, seeds, roots, bark, and flowers. The World Health Organization (WHO) recognizes four categories of herbal medicines: raw herbs, herbal materials, herbal preparations, and finished herbal products. Herbal materials include a plant's juices, gums, oils, resins, and dry powders. Herbal preparations include extracts and tinctures of herbal materials produced by biological and chemical methods such as extraction, fractionation, purification, and concentration. For example, a tincture is made by soaking an herb in a solution of water and alcohol, producing a concentrated, preserved liquid product. Herbal preparations are the basis for finished herbal products, which may contain inactive compounds that facilitate dilution or delivery of the active ingredient. Finished herbal products may contain a single or multiple herbal ingredients. Some, including many Traditional Chinese Medicine (TCM) formulations, may include natural ingredients not of plant origin, such as animal products or minerals. Based on this definition, herbal medicines may not contain chemically defined substances, including synthetic compounds and chemicals isolated from herbs.

Herbal medicines often contain complicated mixtures of organic chemicals that work together to produce an effect on the body. In many cases, it is unknown what specific ingredient in a particular herb works to treat an illness. Herbal medicines are drugs in the sense that they clinically modify bodily processes and can have therapeutic or harmful effects, depending on their use. However, there are a few general differences between herbs and conventional drugs. While conventional drugs often consist of a single purified active chemical, herbal medicines may have multiple active chemicals. For example, the opium poppy contains over 30 active chemicals, or constituents, called alkaloids. Morphine is one alkaloid that can be isolated and administered as a conventional drug, while opium is an herbal preparation made from the sap of dried opium seeds. Opium contains up to 12% morphine along with codeine and other non-narcotic alkaloids. Another difference between herbal medicines and conventional drugs is dilution. Herbal medicines tend to be more dilute than pharmaceutical drugs. For example, aspirin is derived from the bark of the willow tree. In order to get the same effects of the average dose of aspirin in pill form, one would need to consume up to

20 cups of willow bark tea. Nearly one-third of conventional drugs, including morphine and aspirin, are derived from plant sources. Morphine and codeine are still extracted from the opium poppy because it is more difficult and costly to synthesize them chemically. Digoxin, a drug used to treat congestive heart failure and abnormal heart rhythms which is derived from the foxglove plant, is another example of a commonly used conventional drug derived from a plant source.

Plants have been used for medicinal purposes since before recorded history and still account for over 75% of medical treatments in nonindustrialized countries. Ancient Egyptian writings indicate the Egyptians used garlic (*Allium sativum*), juniper (*Juniperus communis*), and myrrh (Commiphora molmol) for their healing properties. Over the centuries, diverse cultural groups developed traditional medical systems, such as Ayurveda and TCM, which included the use of herbal medicines. Dandelion (*Taraxacum officinale*) and goldenseal (*Hydrastis canadensis*) have been used in Native American healing traditions for their antimicrobial and other properties. Hoodia (*Hoodia gordonii*), a plant native to the Kalahari Desert in southern Africa, has been used by the Kalahari bushmen to reduce hunger and thirst during long hunts. With the invention of the printing press in 1440 AD, herbalists began to spread the word about effective herbal medicines. Researchers began to discover that people in different parts of the world tended to use the same or similar plants for like purposes. In the early nineteenth century, scientists began to use chemical analysis to extract and modify the active ingredients from plants. Later, chemists began making synthetic versions of plant compounds, and over time the use of herbal medicines declined in favor of conventional drugs in most industrialized countries. In contrast, many nonindustrialized countries never abandoned medical herbalism and continued to develop their existing traditional medical systems. In some countries, such as France and Germany, herbal medicine continued to coexist with modern pharmacology, though at a lower level. Today, herbal medicines fall under the umbrella of complementary/alternative medicine (CAM) in most industrialized countries. CAM refers to a collection of diverse approaches to healing other than those intrinsic to the politically dominant health system of a particular society or culture.

In the past several decades, public dissatisfaction with the cost of prescription drugs, combined with an interest in returning to natural or organic remedies, has led to an increase in herbal medicine use in the industrialized world. However, there is very limited scientific evidence from randomized, controlled trials to support the safety and efficacy of the vast majority of herbal products. Although herbal medicines are commonly perceived as safe because they are natural, many side effects, some potentially lethal, have been reported. For example, the herb *Aristolochia fangchi*, marketed for weight loss, was found to damage the kidney. Herbal medicines may also contain contaminants which cause side effects. A study examining the contents of 260 Asian patent medications found that 25% contained high levels of heavy metals, including lead and mercury, and another 7% contained undeclared pharmaceuticals, added to produce a desired effect. In countries where herbs are not subject to regulation as drugs, it is difficult to determine the true nature and frequency of side effects because herbal manufacturers are not required to record, investigate, or forward information to regulatory bodies of reports or inquiries of adverse events associated with the use of their products.

Quality control has also become an important concern for both health authorities and the public as many studies have shown that existing herbal products vary widely in the amounts of active markers in the product. Variability in the content and concentrations of constituents of plant material, together with the range of extraction techniques and processing steps used by different manufacturers, results in marked variability in the content and quality of commercially available herbal products. While some countries such as Germany and China regulate herbal medicines as pharmaceuticals, herbs are unregulated in most places around the world. In the United States, herbal medicines are sold over-the-counter as dietary supplements, and thus subject to a very limited form of regulation and oversight. Some preparations claim to be standardized, meaning the preparation is guaranteed to contain a specific amount of the active ingredients of the herb; however, there is often no regulatory body enforcing this standardization.

There is good evidence from systematic reviews, including Cochrane reviews, of randomized, controlled trials for the efficacy of certain standardized herbal medicines in particular clinical conditions. Examples include standardized St. Johns wort in relieving symptoms of mild to moderate depression, saw palmetto extract in treating benign prostatic hyperplasia, and standardized ginkgo leaf extract in symptomatic relief of dementia. There are many herbal medicines with reputed therapeutic value that have not gained acceptance in mainstream medicine due to a lack of research. However, some of these are currently undergoing scientific study, specifically to identify their active chemical components, physiological effects, pharmacologic properties, and clinical efficacy.

Herbal medicine is used to prevent and treat many medical conditions. Among the most commonly used herbs are echinacea, ginkgo, garlic, valerian, and ginger. Echinacea may improve the body's immune system while ginkgo has traditionally been used to enhance memory and treat circulatory disorders. Herbs are sold in many forms: as fresh or dried products; liquid or solid extracts; and tablets, capsules, powders, and tea bags. They also come in the form of topicals, including salves, balms, oils, poultices, and compresses. Herbal medicines are best taken under the guidance of a trained healthcare provider as they may cause allergic reactions, interact with conventional drugs, or affect existing health conditions in addition to producing side effects. Some are toxic if used improperly or at high doses. For example, evening primrose may increase the risk of seizures in people with epilepsy, while garlic, ginkgo, and feverfew may increase the risk of bleeding. St. John's wort should not be taken with prescribed antidepressant medication as this could cause serotonin syndrome, a potentially life-threatening condition. In general, individuals aged 65 or older and those with liver or kidney problems are more likely to experience interactions between conventional drugs and herbal medicines. Herbal medicines may be prescribed by traditional herbalists, chiropractors, naturopathic physicians, pharmacists, medical doctors, practitioners of TCM, and others. Typically, naturopathic physicians receive four postgraduate years of training in both conventional and herbal medicine and are recognized as licensed providers in several countries.

The WHO estimates that 80% of people worldwide rely on herbal medicines for some part of their primary health care. On the basis of current trends in market research data, it is likely that the sales of herbal medicines will continue to increase. Evidence-based research can help to validate traditional uses of herbs and to facilitate new drug development. Despite the complexity of herbal products, investigations of efficacy and safety are feasible. The WHO recognizes herbal medicines as valuable and readily available resources and states it is necessary to develop a systematic inventory of medicinal plants, to introduce regulatory measures, apply good manufacturing practices, and include herbal medicines in the conventional pharmacopeia of each nation.

Heroin

Mihaela-Catalina Vicol
Department of Bioethics, University of Medicine and Pharmacy "Gr. T. Popa", Iasi, Romania

Heroin (diacetylmorphine) is a semisynthetic opioid drug synthesized from morphine, which was discovered in the laboratories of the Bayer Company, initially as a remedy against cough. Street language for heroin includes the terms H, white stuff, powder, Hairy, smack, horse, white lady, joy, and boy. Currently, heroin is on the banned substances lists in almost all countries. It is a legally prescribed drug in the United Kingdom and it is also available by prescription for long-term users in the Netherlands, Switzerland, and Germany, as part of the harm reduction programs.

Heroin can be taken by injection (intravenous, intramuscular, subcutaneous), inhalation, smoking, or snorting. The most frequent administration pathway is via intravenous injection, because in this way the "flash," "high," or "rush" as it is variously known, i.e., an intense, sudden orgasmic pleasure, can be reached. In his book "Les toxicomanies," Porot shows that in order to obtain an even more intense or a repeated high, a special method called "tirette," also known as backloading, can be performed. This involves pulling the blood into the syringe and then the mixture of blood and drug is rapidly injected intravenously. There are several methods for smoking heroin, such as: "the dragon pipe," used mostly in Hong-Kong, whereby a mixture of heroin and phenobarbital is boiled and the vapors are collected; or the "Ack-ack," referring to smoking a mixture of heroin and tobacco mixture.

Short-term effects resulting from heroin consumption are related to the high experience, followed by a relaxation period that is often referred to as "the planet," characterized by psychomotor relaxation and "search of the self." Although heroin's effects are extremely powerful, they last for only about 2–3 hours; this is the reason why it has to be frequently administrated to achieve the desired high. Long-term effects include physical and psychological dependence, which occur in 97% of individuals within the first 21 days following the first administration of heroin. Long-term heroin consumption also induces tolerance, i.e., the consumer needs higher doses of drug in order to feel its effects. Heroin use produces symptoms like: disorientation, drowsiness, delirium, slow heart rate, decrease of blood pressure, shallow breathing, and respiratory failure. The chronic use of heroin over a period of 6–7 years may lead to malnutrition or various complications such as HIV/AIDS, hepatitis, cachexia, or severe psychiatric disorders (paranoia, dementia, etc.). The most risks to the heroin addict include overdose, HIV infection, hepatitis, and other chronic complications.

Despite the serious adverse physical and psychological consequences produced by heroin, it continues to be consumed because of the "high" that might help a person to forget about troubles and problems, offering her/him pleasure and euphoria. It has been suggested that immigrants who use heroin may do so in order to deal with the discrepancies that exist between their expectations and the realities they have to face in the host country such as low income, social stigma, and language and cultural differences.

Detection and quantification of heroin use among immigrants are difficult due to their low rates of seeking treatment, their lack of access to treatment, and their unwillingness to participate in research studies related to substance use. Immigrants may refrain from seeking treatment or participating in research for fear of possible legal consequences, including deportation.

A survey on heroin use among Russian immigrants in Israel (2002–2006) found a higher rate of hepatitis C and more heroin use via injection among immigrants as compared with native-born Israelis. In historical context, before 1989, in Israel, approximately 95% of the heroin addicts had come from the Middle East, mostly from Morocco and Tunisia. The profile of that heroin addict was: male, age 18–30, poorly educated, and of low socioeconomic status. After 1990, heroin use was attributed primarily to Russian immigrants, who currently represent 25% of individuals known to be addicted to illicit substances in this country.

A study that aimed at determining the drug use profile of immigrants in Spain between 2004 and 2008 found that 72.3% of drug users came from Latin

America, Portugal, and Eastern Europe. Most were men (80.8%) and the most commonly used drug was heroin (43.8%).

The key factors that may negatively impact on health of the immigrant drug users are: vulnerability to using drugs, low income, low educational level, a low rate of access for treatment due to the lack of health care insurance and/or illegal immigrant status, and cultural differences in perception of diseases. Immigrants who use heroin are doubly vulnerable, first because of their addiction and second because of the legal, political, and economic barriers to accessing treatment for their addiction.

The legal barriers include the possibility of deportation and/or imprisonment due to heroin use, illegal immigration status, or both. Legal provisions may also deny immigrants' access to treatment. Some of the health programs, e.g., Medicaid in the United States, may be accessed only by legal immigrants and only under certain conditions.

The economic status of immigrants is closely related to their health insurance status. Lack of health insurance and low income may limit immigrants' access to health care. Many immigrants are paid less than the native-born citizens and they are either uninsured or have a basic insurance (a mandatory one) that does not cover treatment for addiction.

Hijos de Crianza

Alan J. Dettlaff
Jane Addams College of Social Work, University of Illinois at Chicago, Chicago, IL, USA

Although Latinos are a diverse population representing many different backgrounds and countries of origin, *familismo* is considered to be one of the most important cultural values across Latino populations. This value involves a strong identification and attachment with nuclear and extended family, along with a deep sense of family commitment, involvement, and responsibility. The family offers emotional security and a sense of belonging to its members and is the unit to which individuals turn for help in stressful or difficult situations. The expectation is that when a family member is in need, others will help, particularly those in stable situations. Similarly, when parents of young or minor children are experiencing challenges that affect their ability to adequately parent their children, it is expected that extended family will provide assistance. *Hijos de crianza* refers to children who are raised in the home of a relative within their extended family system in times of need. This practice is common among many Latino families, with relatives assuming full responsibility for the children as if they were their own.

Historically, many situations could result in children being raised by extended family, from a desire to improve the economic situation of the child to the need for additional care following the death of a parent. However, due to recent increases in immigration enforcement across the United States, *hijos de crianza* may be raised by relatives out of necessity following the apprehension and deportation of a noncitizen parent. For example, in 2006, more than 3,600 immigrants were apprehended by US Immigration and Customs Enforcement officials as a result of worksite enforcement operations, an increase of 700% since 2002. In many of these cases, parents were separated from their children for extended periods with no way of contacting them or deported to their country of origin while their children remained in the United States.

Although caring for these children is congruent with Latino cultural values, children who are informally raised by relatives in the United States may experience many barriers to adequately meeting their needs. For example, many public services are restricted to biological or formally adopted children and most eligibility determinations are based on the needs of biological or formally adopted children within a family unit. Even necessities such as obtaining appropriate medical care and enrolling children in school may be difficult due to the lack of a formal legal relationship. Thus, it may be beneficial for relatives to pursue some form of legal guardianship to facilitate access to necessary services for *hijos de crianza*, particularly when it is unlikely that children will be returned to their biological parents.

The need for extended family to be available to raise children is particularly important in times of increased immigration enforcement, as children who do not have available relatives to care for them following the apprehension and deportation of a parent may be at risk of entering the formal child welfare system. When this occurs, children in immigrant families face a number of unique challenges that threaten the child welfare system's ability to facilitate reunification with their biological parents. The achievement of reunification is largely dependent on the child welfare system's ability to provide services to families that reduce risk and ensure stability of the living situation. In families where parents have been deported, the ability to provide these services is considerably limited.

For children in the foster care system, the lack of culturally or linguistically appropriate services may also limit their ability to receive services needed to address both their physical and mental health needs. Further, when children are undocumented, funding for services may be limited due to restrictions within Title IV-E of the Social Security Act, which serves as the primary source of federal child welfare funding to states. This funding source allows states to receive federal matching funds for the care of children in state custody. However, the receipt of Title IV-E funds is restricted to children who meet eligibility requirements, which include immigration status. Immigrant children who are undocumented do not meet the eligibility requirement, and thus, states must bear the total burden of the cost of substitute care for these children. In times of shrinking resources for public child welfare systems, this may limit states' abilities to adequately care for ineligible immigrant children.

When reunification with parents or placement with relatives is not an option, undocumented immigrant children may be eligible for Special Immigrant Juvenile Status (SIJS), which makes them immediately eligible to apply for legal permanent residency in the United States. This status is available for undocumented children under the jurisdiction of a court due to dependency or delinquency. With this status, immigrant children become Title IV-E eligible and receive the other benefits of legal permanent residency, including the ability to live and work permanently in the United States. However, as SIJS is only available to children for whom reunification with their parents is not an option, the pursuit of SIJS must be done only after determining that reunification or placement with relatives in their country of origin is not in their best interest.

Hispanic Health Paradox

Flavia C. Peréa
Department of Public Health and Community Medicine, Tufts University School of Medicine, Boston, MA, USA

Research to date presents substantial evidence of a strong association between acculturation and health among the US Latino population. Generally, the research has found a negative effect on health outcomes and health behaviors with greater acculturation, whereby more optimal health outcomes have been observed among more recent immigrants to the USA from Latin America and less acculturated US-born Latinos, compared to the native-born or more acculturated members of the same ethnic/racial group or the White population. These highly provocative and controversial findings refer to the counterintuitive finding that more recent and less acculturated Latinos and immigrants in general have more optimal health, mental health, and more positive health behaviors, as well as better educational outcomes (a key determinant of health) than those who are more acculturated.

The Hispanic (or Latino) health paradox, also known as the immigrant paradox, is the phenomenon that greater acculturation to US culture, as marked by, for example, increased length of residency, and increased use of English is associated with poorer health and health behaviors, whereas foreign birth and less acculturation appear to be protective factors. Also referred to as the epidemiological paradox, the term was first coined in 1986 by Markides and Coreil in a literature review of the health status of Latinos in the US southwest. In their review they found that Latinos had lower infant mortality, a longer life expectancy, were less likely to die from cancer and cardiovascular diseases, and had better measures of functional health in spite of their low socioeconomic status and the presence of various risk factors.

Studies have found that Hispanic adults are at greater risk for cigarette smoking, alcohol and substance abuse, driving under the influence of alcohol, psychological distress, and depressive symptomatology. These paradoxical findings have been found among the larger and more diverse US immigrant demographic, not solely among Latinos. Numerous studies have documented fewer low-birthweight babies born to immigrant compared to US-born women. Similar findings have been reported for infant mortality. Immigrants are at significantly lower risk of death from cardiovascular diseases, lung and prostate cancer, chronic obstructive pulmonary disease, cirrhosis of the liver, influenza, pneumonia, unintended injuries, and suicide. More acculturated adolescents and adults have been found to have a significantly higher prevalence of overweight and obesity, perhaps a function of the increase in cardiovascular disease found with increased acculturation.

Self-selection among immigrants, that healthier and more capable people are more likely to immigrate/migrate, has been proposed as a possible explanation for the observed paradox. Nevertheless, the consistency of such findings is notable, especially considering the diversity of the populations and outcomes studied. Furthermore, studies that have examined people in the country of origin and/or across multiple generations in the USA have had similar findings and found evidence of a downward trajectory from the first generation (immigrants born abroad) to second generation (born in the USA to immigrant parents).

Similar to findings among adults, studies of adolescents from immigrant families have found they are physically healthier than nonimmigrant youth and have a lower incidence of significant emotional and behavioral problems. Youth from immigrant backgrounds as well as their parents report they are physically healthier compared to native-born youth, even though they are less likely to have health coverage or to see a health care provider on a regular basis. Second generation youth have been found more likely to engage in deviant behaviors compared to first generation immigrant youth. Similarly, marijuana and alcohol use have been found to be higher among the US-born youth compared to immigrant adolescents of similar racial/ethnic backgrounds. In education, perhaps the most important predictor of health behavior and health outcomes, studies have found that immigrant adolescents are more motivated toward school, work harder, and have higher educational aspirations, more positive academic attitudes, better academic grades, and higher math test scores compared to their peers born in the USA.

The evidence thus suggests that immigrants lose something over time in the USA and likely adopt mainstream US cultural ways that negatively impact health – for example, the loss of cultural practices, such as the consumption of traditional foods and home cooking, as they acculturate to eating highly processed and fast foods, as well as the increased stress that comes with acculturation and adjusting to life in a new country and cultural context. Research indicates that greater acculturation is associated with poorer health outcomes. These studies have observed better health outcomes among less acculturated Latino and immigrant adults and youth. These findings are important because they are contrary to dominant beliefs and are in conflict with traditional, prevailing theories of immigrant incorporation and assimilation; theories which state that immigrants who are more acculturated, those who speak English and adopt “American” cultural ways, will fare better in US society.

Although more recent and less acculturated immigrants are more likely to be poor/of low socioeconomic status, not well educated, and speak less English, evidence indicates they are healthier and engage in fewer risky health behaviors compared to immigrants or their children who have been in this country longer or are more acculturated and speak more English. That health outcomes deteriorate with greater acculturation, as length of residency in the USA goes up, is difficult to understand because as immigrants and their children acculturate to life in the USA they tend to use more English, develop social networks, acquire social capital, earn more money, and have better access to a health care provider – factors that would be expected to be associated with better health.

Foreign-born and US-born Latinos are racial/ethnic minorities in the US context, as are the vast majority of present-day immigrants to the USA who come from Latin America and, to a lesser degree, Asia. It is thus important to consider these paradoxical findings in light of the various socioeconomic and environmental factors that disproportionately impact US minorities in general, such as poverty, inadequate schools, poor access to quality health care, a lack of safe and stable housing, and exposure to hazardous environmental conditions and substances. These are contextual factors and determinants of health that disproportionately affect US minorities, which create pathways that contribute to the development and progression of disease as opposed to more optimal health.

[2]Departments of Psychiatry and Family Medicine,
University Hospitals Case Medical Center, Cleveland,
OH, USA

Background

In 2008, the US Hispanic population was 46.9 million, or 15.4% of the total US population. The term "Hispanic" is defined using the US government statistics classification, which is that of people who have ancestors from Cuba, Mexico, Puerto Rico, Spain, and countries of Central or South America where Spanish is the primary language. Race is not a factor in this definition and it does not include persons from places such as Brazil or Portugal, since Spanish is not the primary language in those countries.

Hispanics immigrate to various countries. Those from South America most often immigrate to Europe, specifically Spain, Italy, and Portugal. Mexicans and Puerto Ricans immigrate primarily to the USA. Puerto Ricans who are born in Puerto Rico and migrate to the US mainland are often referred to as migrants, rather than immigrants, because they are US citizens.

Approximately 60% of Hispanics residing in the USA were born in the USA and the remaining 40% were born elsewhere (i.e. not born as US citizens). The majority of Hispanics are of Mexican ancestry, almost 60% of the population. The remainder of this population consists of Puerto Ricans (9.7%), Central Americans (5.1%), South Americans (4%), Cubans (3.5%), Dominican (2.3%), and Spaniards (0.3%). Many Hispanics have settled in different parts of the USA based on their heritage. Almost 80% of Cubans live in the South, approximately 50% of Mexicans reside in the West and 60% of Puerto Ricans settled in the Northeast.

Hispanic health has been studied at all levels and has been included in several large national studies. One research flaw has been that often Hispanics are grouped together and not based upon their specific heritage. Newer studies have shown that often generalizations about Hispanics are not applicable to every subgroup.

Hispanics and Illnesses

It is well known that Hispanics, as a group, suffer from health disparities, which means that they have higher incidences of certain illnesses and have inequalities in the care they receive as well. They have higher mortality rates from Type II diabetes, gastric cancer, end-stage renal disease, liver disease, biliary disease, and HIV compared to all other groups in the USA. Further, they have higher rates of obesity, diabetes, and hypertension, as do both American Indians and Alaskan Natives, but at rates higher than those of non-Hispanic Whites. The top five causes of death for Hispanics in 2005 were heart disease, cancer, unintentional injuries, stroke, and diabetes. While four of these were the same for the non-Hispanic White population, diabetes was not in the top five and accidental injuries were the fifth leading cause of death. In comparison to the non-Hispanic Black population, the top five causes of death remain the same, however, not in the same rank order.

Diabetes

The rate of diabetes for Hispanics is 9.5%, which is higher than that for non-Hispanic Whites (8.7%), but lower than that of non-Hispanic Blacks (13.3%). More specifically, Mexican Americans are twice as likely to be diagnosed with diabetes than are non-Hispanic White adults. Compared to non-Hispanic White men, Hispanic men were 1.5 times more likely to start treatment for diabetic-related end-stage renal disease in 2002. In 2005, the death rate from diabetes was 1.6 times higher for Hispanics compared to non-Hispanic Whites. While it is unclear why the disparity in diabetes exists, it is likely contributed to by a combination of genetic, environmental, or metabolic differences in populations.

Heart Disease

Cardiovascular disease in Mexican American adults is found in 28.8% of males and 26.6% of females. It was found in 2007 that Hispanics as a whole were 10% less likely to have heart disease compared to non-Hispanic Whites. With regard to death rate from heart disease, Mexican American men were 30% less likely to die when compared to their non-Hispanic White male counterparts. In Mexican American adults, 4.1% of men and 1.9% of women have had a heart attack and 4.1% of men and 5.5% of women have angina, a condition of chest pain caused by reduction in blood supply to the heart muscle.

Cancer

The most common cancer found in Hispanic men is prostate cancer; however, they are 16% less likely to have this type of cancer compared to non-Hispanic White men. With regard to Hispanic women, breast cancer is the most common cause of cancer, and they are 33% less likely to have breast cancer compared to non-Hispanic White women. Both Hispanic men and women have colon and rectal cancer as the second most common type of cancer and lung cancer as the third most common cause. Hispanic men and women have higher rates of stomach and liver cancer, as well as higher mortality rates from these cancers, when compared to non-Hispanic Whites. Further, Hispanic women have twice the rate of cervical cancer compared to non-Hispanic White women.

Lung cancer is the leading cause of cancer death for Hispanic males, while breast cancer is that for Hispanic females. For non-Hispanic White women, lung cancer is the leading cause of cancer death. For the most part, the incidence and death rates from cancer in Hispanics is lower than that of non-Hispanic Whites. The exceptions are stomach, liver, cervical, acute lymphocytic leukemia, and gallbladder cancers, where Hispanics have higher rates.

In a Florida study, it was found that Hispanics living in the USA had an increased risk of cancer compared to their counterparts in the country of origin. Other than this study, the same risk factors that apply to the US population for cancer apply to the Hispanic population, such as tobacco use.

Stroke

The risk of stroke for Hispanics appears to have some variance based on age. For Hispanics between ages of 35 and 64, the relative risk of having a stroke is approximately 1.3 times greater when compared to non-Hispanic Whites. However, at age 75 or older, their risk is about half that of non-Hispanic Whites. It was found in 2005 that Hispanic men were 15% and Hispanic women were 25% less likely to die from a stroke when compared to their non-Hispanic White counterparts.

HIV/AIDS

In 2007, Hispanics made up 17% of the HIV/AIDS cases in the USA with much higher rates than that of non-Hispanic Whites. Hispanic men have almost a three times higher rate of AIDS and Hispanic women have an almost five times higher rate when compared to their non-Hispanic White counterparts. Further, Hispanic men and women have higher rates of death from HIV/AIDS, with Hispanic men being 2.5 times as likely to die and Hispanic women three times as likely to die when compared to their non-Hispanic White counterparts.

Infant Mortality

The 2005, infant mortality rates for the Hispanic subgroups varied from 4.4 to 8.3 per 1,000 live births, while the rate of infant mortality for non-Hispanic Whites was 5.8 per 1,000 live births. Puerto Ricans had an infant mortality rate that was 1.4 times that of non-Hispanic Whites. When including conditions related to low birth weight, the Puerto Rican infants were twice as likely to die compared to non-Hispanic White infants. Minimal or no prenatal care is another contributing factor for the increase in infant mortality. It was found that Mexican American women were 2.5 times as likely to begin prenatal care in the third trimester or not receive prenatal care at all, when compared to non-Hispanic White women.

Hispanic Paradox

In 1986, the concept of a “Hispanic Paradox” was first described in the literature. This concept is that while Hispanics are socioeconomically disadvantaged, they have overall better health and mortality outcomes – similar to those of non-Hispanic Whites, who do not tend to suffer from disparity in health care. This has been studied over the last two decades and the findings continue to show this mortality advantage, especially those in Mexican Americans. There are several hypotheses that attempt to explain this phenomenon. One hypothesis is that of a "salmon bias" effect, which suggests that unhealthy immigrants return to their country of origin to die, resulting in a lower mortality rate for those who stay in the USA. Another is that of a "healthy immigrant effect," in which persons in good health are able to migrate. And finally, there may be problems in how the data were collected using vital statistics records. Despite these possible explanations for the "Hispanic Paradox," none fully explain this finding.

Hispanics and Access to Medical Care

In the USA, Hispanics have the highest uninsured rate of any ethnic or racial group. Within the subgroups, 2004 data from the Centers for Disease Control and Prevention found that 37.6% of Mexicans, 20.4% of Puerto Ricans, 22.8% of Cubans, 32.3% of other Hispanic groups did not have health insurance. With regard to Medicaid coverage, 22.4% of Mexicans, 29.1% of Puerto Ricans, 17.9% of Cubans, and 20.8% of other Hispanic groups had this form of health insurance.

In 2004, a third of Hispanics in the USA did not have any health insurance, compared to 10.4% of the non-Hispanic White population. Over one fourth of Hispanic adults do not have a primary health care provider and Hispanics are much less likely to obtain health care when compared to non-Hispanic Blacks and non-Hispanic Whites. Further subgroups at higher risk for not having a usual health care provider include males, the young, those that do not speak English, the less educated, and those without health insurance.

Hispanics obtain their health information through a variety of sources. In one study, approximately 70% reported obtaining information through their physician. An equal number stated that they were able to gather this type of information through their social networks, which included friends, family, and church community. In this same study, 83% of Hispanics found health information through the media, with 79% of those acting on this information. It was found that a fourth of Hispanics felt that they received poor care during the previous 5 years and believed this to be secondary to their race, language ability, or financial situation. Despite that, 77% of Hispanics rated their health care as good or excellent.

Ethnic disparities and access to health care are influenced both by the characteristics of the person seeking care, such as language, citizenship status, sex, education, and health needs, and the characteristics of health care system itself, such as cultural competence, ethnocentrism, location, services provided, and bureaucratic barriers. Both individual factors and health system factors affect the Hispanic population.

Approximately 21% of Hispanics live at or below the poverty level for income. It has been found that poverty is a major deterrent to seeking out health care. Even when there is access to health care for minority populations, they still have worse health.

Preventive Care

Immunizations play an important role in the prevention of illnesses and Hispanics in general have lower rates of immunization. Hispanics over the age of 65 were 10% less likely to have received the flu shot in the previous 12 months and 50% less likely to have ever received the pneumonia shot when compared to their non-Hispanic White counterparts. While Hispanic children from 19 to 35 months of age have similar immunization rates for hepatitis, influenza, MMR and polio, they were slightly less likely than non-Hispanic children to be fully immunized.

Risk Behaviors

Tobacco

Approximately 24.1% of adult Hispanic men and 12.3% of adult Hispanic women are smokers. Hispanic high school students have a 34% and 31.5% smoking rate among Hispanic males and females, respectively. Further, the rate of smokeless tobacco use among Hispanic high school students is 6.1% in Hispanic males and 1.8% in Hispanic females.

Obesity

A total of 64.7% of Hispanic adult males and 56.8% of Hispanic adult females are overweight, and 18.2% of adult Hispanics are obese. Overweight is defined as having a body mass index (BMI) of 25 kg/m^2 or greater, and obesity is defined as having a BMI of at least 30 kg/m^2.

Mexican Americans have higher rates of being obese or overweight than the Hispanic averages. A total of 69.3% of both Mexican American men and women are overweight, and 24.8% of Mexican American males and 36.1% of Mexican American females are obese. In Mexican American children, ages 6–11 years old, 17.4% of males and 14.3% of females are overweight; in children 12–17 years old, 14.6% of males and 13.7% of females are overweight. There is an inverse correlation between weight and level of education for Mexican Americans. Those with less education tend to have higher BMIs (body mas index).

Diet plays a significant role in the weight status of Mexican Americans, with their average dietary cholesterol intake being 316.2 mg compared to the US average dietary cholesterol intake, which is 269.6 mg. They do have a lower average intake in saturated fat, with the US average of 27.9 g and for Mexican Americans consuming an average of 26.7 g. Mexican Americans consume more dietary fiber – on average 18.5 g, while the daily average for Americans is just 15.6 g a day, despite the recommendation of 25 g or more of daily dietary fiber intake.

Hispanics and Immigration Status

According to the 2008 census data, 28.2% of Hispanics are not citizens of the USA. It is difficult to track numbers of undocumented immigrants and it is currently believed that there are 11 million undocumented immigrants in the USA. Mexicans are estimated to make up 57% and Latin Americans 24% of the undocumented immigrant population in the US.

Hispanics and Language

The Pew Hispanic Center found that language fluency varies considerably among the Hispanic subgroups that live in the USA. Most Hispanics speak Spanish in the home, with the national level of Spanish-speaking households being 12%.

Hispanics and Education

Hispanics are less likely than non-Hispanic Whites to complete high school, with 61% of Hispanics having a high school diploma compared to 89% of non-Hispanic Whites. With regards to college, 12.5% of Hispanics have a bachelor's degree, while 30.5% of non-Hispanic Whites have a degree.

Hispanics and Occupation

A greater proportion of Hispanics live at or below the poverty level, 21.5% as opposed to only 8.2% of non-Hispanic Whites. Per the Census report of 2006, 24.4% of Hispanics work in service occupations, compared to 13.7% of non-Hispanic Whites. Hispanics hold 16.6% of management or professional occupations, while non-Hispanic Whites hold 39.9%. Fewer Hispanics earn as high a salary as non-Hispanic Whites, with 55% of Hispanic full-time employees making $35,000/year or more, while 68.2% of their non-Hispanic counterparts earn at least this much.

Summary

Hispanic immigrants face a number of challenges, including receiving adequate and appropriate health care. Work environment, availability of care, and educational level all influence the quality of health care that Hispanic immigrants receive, and influence outcomes, such as frequency of illness, and outcomes of illness that differ from that of the general population, and other immigrant populations. Despite this commonality, it is important to remember that specific country of origin often has a greater influence on health problems and outcomes than does belonging to the larger, general Hispanic population.

Hmong

Joseph Westermeyer
Departments of Psychiatry and Anthropology,
University of Minnesota, Saint Paul, MN, USA

Hmong people, numbering in the millions, inhabited remote areas of China, Burma, Thailand, Laos, and Vietnam. The Hmong who immigrated to the USA came from Laos. At the time of their flight beginning in 1975, they made up about 10% of the Laotian population, or about 250,000. About half of them fled after 1965 when communist Pathet Lao and North Vietnamese soldiers occupied Laos.

The Hmong had skills that facilitated relocation. They knew about surviving in the mountains, choosing routes to take, locating safe water, and selecting plants or animals to forage along the way. In the USA, many Hmong students and adults readily took advantage of educational and training opportunities.

However, in several urban ghettos in the USA, the Hmong experienced assault, robbery, and rape by other ethnic groups. Young Hmong men and teenagers joined into gangs to defend themselves. A Hollywood movie, *Gran Turino* (with Clint Eastwood), reflects the often-negative effects of Hmong gangs on Hmong communities.

Nuclear and extended families often pooled their savings to purchase cars, homes or trailers, and appliances. However, a significant minority of Hmong remained on welfare as compared to other immigrant groups. Factors contributing to acculturation failure included illiteracy, unfamiliarity with complex societies, difficulties applying traditional skills (e.g., gardening and animal husbandry), evolution of gangs, numerous widows from the war, and traditional retirement around age 50.

Adjustment and Psychiatric Disorders

During the first decade in the USA, the rates of major depressive disorder, posttraumatic stress disorder, social phobia, and other anxiety conditions were high in Hmong immigrants. Brain damage related to war-affected individuals ranging in age from infancy to old age. Paranoid symptoms and disorders expanded in the early years following resettlement but abated over time. Alcohol, opium, and other drug use disorders were virtually absent before and immediately following relocation but then appeared and increased over time. Many with opium addiction had previously been dependent on opium in Asia, but a large minority became newly addicted in the USA. Some young Hmong began using cannabis and other drugs with US youth.

Folie a Deux, a paranoid disorder found in two or more closely affiliated people, was particularly common among the Hmong as compared to other immigrant groups. Mistrust, projection of harm onto others, and social isolation were prominent features of *Folie*. Depression was a prominent aspect in many cases – especially in the more dependent member(s) with the shared delusional belief (which consisted of the belief that someone had given them a fatal disease, such as tuberculosis or AIDS).

Biomedical Health Problems

The Hmong brought numerous biomedical conditions from Laos, which in turn could affect mental health and social adjustment. Once a biomedical condition was identified and under treatment, some Hmong expressed the belief that doctors were experimenting on them. This mistrust was especially problematic with conditions affecting children, since courts became involved when parents refused treatment for medical conditions (e.g., middle ear disease) or surgical conditions (e.g., congenital heart disease) that could lead to chronic disability or death. Differing Hmong notions about etiology and treatment could also lead to misunderstandings with clinicians.

In general, the infectious diseases that were common in Laos also occurred in the USA, albeit with a dwindling prevalence over time. These diseases included tuberculosis, pulmonary schistosomiasis (a lung disease caused by parasites), leprosy, malaria, genital herpes, hepatitis A, and hepatitis B. Cretinism (a hormonal disorder causing mental retardation) and goiter resulting from low iodine levels in the mountainous soil of northern Laos were seen among some Hmong. Some vitamin deficiencies continued due to lack of a balanced diet. Certain cancers more common among Asian populations, such as craniopharyngioma, nasopharyngeal carcinoma, and choriocarcinoma, were initially overlooked by US clinicians unfamiliar with them. Due to frequent cross-cousin marriage in Asia, certain genetic abnormalities were common (e.g., polydactyly (finger/toe deformities), supernumerary nipples, dental abnormalities, and certain blood disorders). Enteric parasites (e.g., roundworm, hookworm, amebiasis, and tapeworm) had largely received treatment in refugee camps, so their prevalence in the USA was low.

Chronic diseases virtually absent in Laos began to appear within a few years in the USA. Epidemic obesity, hypertension, cardiovascular disease, diabetes, and metabolic syndrome became rife. As their age span increased, the Hmong developed diseases of senescence that were formerly rare and unknown (e.g., dementia, congestive heart failure, and various cancers).

Culture Clashes

Hmong and US cultures clashed in ways that could precipitate or exacerbate psychiatric and medical health conditions. Intergenerational conflict and male–female matters often dominated in these quarrels, as follows:

- Arranged marriage: Elders felt they had primary responsibility to establish successful marriages for their children, although their children and American law did not support this notion.
- Mother-in law and daughter-in-law relationships: Traditionally, daughters-in-law, coming anew to the family, had to obey their husband's mother, who had higher status in the home.
- Clan loyalty: Young people believed that their earnings belonged to them, whereas patriarchs felt the funds belonged to the clan.
- Dating and marriage: Traditional parents would often not permit their adolescent children to date or attend parties. Families did not want their offspring to date or marry non-Hmong partners.
- Marital strife: Clan elders, who typically intervened in marital problems, might be living in another state or back in Laos. American gatekeepers sometimes counseled the use of interventions that worsened family strife (e.g., shelter, restraint orders, and divorce).
- Bride capture: One means to circumvent a family's unwillingness to approve a marriage consisted of "bride capture" in which the potential bride and groom eloped. Some Hmong men in the USA actually kidnapped Hmong girls who did not want to get married.

Some problems involved the replacement of Hmong norms by American norms. Other problems resulted from the loss of traditional Hmong methods for preventing or resolving crises between generations, clans, and men and women. If Hmong families could not work out a resolution, they sometimes sought the services of a mediator. Negotiations between clan elders or through a mediator comprised means of keeping peace and avoiding smoldering hostility. This traditional method still exists to some extent in parts of the USA, with recourse to government courts if the "Hmong method" fails.

Holocaust

Delaney Smith
Timothy B Moritz Forensic Unit, Twin Valley
Behavioral Healthcare, Columbus, OH, USA

The Holocaust was the systematic murder of six million Jews by the Nazi regime. Between 1933 and 1945, two out of every three European Jews were killed. While Jews where the primary target of the Holocaust, Nazis also killed more than three million Soviet prisoners of war, approximately a half million Roma and Sinti, also known as Gypsies, a quarter million mentally or physically disabled individuals, homosexuals, Jehovah's Witnesses, and political prisoners. The Nazi ideology was based primarily on racism and a belief that Germans and the Aryan race were physically and mentally superior to all others. They felt that other "races" were a threat to the purity of the German "master race." Hitler's plan for the systematic murder of Jews was termed the Final Solution. The Schutzstaffel, or SS, served as Hitler's Praetorian Guard and along with their commander, Heinrich Himmler, were responsible for carrying out the majority of the war crimes of the Holocaust.

In 1933, The Nazis, or National Socialist German Workers Party, comprised primarily of unemployed veterans of World War I, came to power in Germany. Civil liberties in Germany were greatly curtailed under their leadership. The year 1933 also saw the opening of the first concentration camp, Dachau. The first inmates were political prisoners and opponents of the regime. The following year, Adolf Hitler combined the positions of chancellor and president, declaring himself "Fuhrer." Over the next 3 years, the rights of Jews were systematically eliminated. In 1938, Jews were made to carry identification cards, hand over driver's registrations, shut down their businesses, and attend only special Jewish schools. The assassination of a German diplomat in Paris by a German-born Polish Jew prompted the "Night of Broken Glass" (Kristallnacht) on November 9th and 10th, 1938. German and Austrian Jewish homes, businesses, and synagogues were ransacked, and 30,000 Jews were arrested and placed in concentration camps.

Hitler's invasion of Poland in 1939 marked the beginning of World War II in the European theater. At that time, Jews were forced to wear the Star of David on armbands. In 1940, German Jews began to be deported to Poland, and all Jews were forced into Ghettos which were eventually sealed off. Death camps, concentration camps with special equipment for mass murder, began to proliferate in the 1940s. In 1941, the concentration camp, Auschwitz, began experimenting with the use of the insecticide

Zyclon-B for group killings in gas chambers. Auschwitz–Birkenau became the site where the largest number of Jews were killed.

The Nazi's Final Solution is believed to have been ordered sometime between 1941 and 1942. Jews from other Nazi-occupied countries began arriving at death camps. Medical experiments at Auschwitz and sterilization of women at Birkenau began around this time. In April of 1943, Jewish fighters resisted the liquidation of the ghetto in what became known as the Warsaw Ghetto Uprising. This was the first mass revolt in Nazi Germany. Most of its survivors were taken to concentration camps. Throughout the remainder of 1943, most ghettos and many labor camps were liquidated and mass killings increased in the death camps.

On D-Day, June 6, 1944, British and American troops launched the invasion of Nazi-occupied France. This and other operations by the Allies began turning the tide of the war. As Allied forces advanced, Nazis forced evacuations of prisoners in the Auschwitz complex on foot which came to be known as death marches due to the number who died on the journey. On January 27, 1945, Soviet troops liberated the 8,000 prisoners who had been left behind. It is believed that during the time Auschwitz–Birkenau was operating, more than two million people had lost their lives there. In April 1945, US troops liberated more than 50,000 prisoners at Buchenwald and Dachau. On April 23, 1945, Soviet troops reached Berlin. A week later, on April 30, Hitler committed suicide. On May 8, 1945, Germany surrendered, marking the end of the Holocaust.

Holocaust Survivors

There is some disagreement as to who is considered a Holocaust survivor. The term has been used narrowly to refer to those Jews who were living in an area that came under Nazi control as well as broadly to refer to those who were living in these areas at the time Hitler came to power, even if they emigrated prior to the start of the war. It should be noted that under either definition, those who were never in a concentration camp are considered Holocaust survivors.

The emotional consequences for those who experienced the Holocaust are profound. Individuals who were able to avoid concentration camps had to either reinvent themselves as Gentile (non-Jewish), go into hiding, or find a way out of Nazi-occupied countries. No matter what option was taken, the psychological impact was profound. Guilt plagued both those who denied their true identities, as well as those who fled their country often having to leave loved ones behind. Difficulties with grief over lost friends and family became pathological in many people. This leads to increased rates of clinical depression and anxiety disorders. Posttraumatic stress disorder can be seen in this population as a result of their own near-death experiences, witnessing of traumatic events, and learning of horrors experienced by loved ones.

Individuals who were in concentration camps paid and continue to pay a heavy emotional toll. Many developed posttraumatic stress disorder associated with the reexperiencing of the trauma, avoidance of reminders of their experiences, anxiety and hyperarousal, symptoms of numbing, social detachment, and feeling a lack of a future. Depressive and anxiety disorders occur at an increased rate in this population and many developed survivor syndrome. This syndrome is a constellation of symptoms including disturbed cognition, isolation and withdrawal, identity and reality alterations, psychosomatic issues, the physical appearance of a living corpse, in addition to anxiety and depression. Elderly survivors have higher incidence of suicidal ideation and attempts. Kahana et al. compared immigrants to the USA and Israel who had experienced the Holocaust to those who had not and found that those who experienced it scored significantly higher on the Symptom Distress Scale (SCL-90) subscales of somatization, obsessiveness, depression, anxiety, hostility, and psychoticism. Survivors who immigrated to the USA also had significantly higher levels of sensitivity, phobia, and paranoia than immigrants to the USA who did not experience the Holocaust.

The physical consequences of surviving the Holocaust have been closely studied in the past several decades with results demonstrating increased morbidity and mortality. Whether in camps or in hiding, Jews and other survivors were subjected to malnutrition, injuries, and illness. In concentration camps, people were subjected to additional physical deprivations and abuse. Long-term health effects of chronic malnutrition include increased risk of infection, bone weakness and fractures, and heart disease, among others. Studies have found Holocaust survivors are more preoccupied with their psychical health, appraise their health as poor, and use medical resources more frequently. This is particularly true of survivors who lost their original identities such as names and families of origin in the war. Some studies have shown increased amounts of pain in survivors when compared to those who were not directly exposed to the Holocaust. Additionally, there have been reports of increased cardiovascular health problems, skeletal, arthritic, circulatory, gastrointestinal problems, diabetes, and ulcers in those who were directly exposed to the Holocaust. Interestingly, Kahana et al. found different physical sequelae in survivors based on what country they immigrated to.

Some concentration camp prisoners were subjected to unethical medical experimentation under the direction of Doctor Mengele and others. These included removal of organs, sterilization, exposure to extreme temperatures, genetic and twin experiments, and various other invasive procedures. Most were performed without the benefit of anesthesia. Survivors of these experiments have unique medical consequences based on the nature of the procedures they endured as well as a frequent mistrust and avoidance of medical practitioners.

In conclusion, nearly two-thirds of European Jews were killed between 1933 and 1945. The Jews and others who survived the Holocaust were exposed to emotional and physical traumas that have had long lasting effects on their health.

Homicide

SUSAN HATTERS FRIEDMAN
Departments of Psychiatry and Pediatrics, Case
Western Reserve University School of Medicine,
Cleveland, OH, USA

The term *homicide* is technically not synonymous with *murder* as *murder* would imply a criminal homicide. For example, some who commit homicide commit the dual act of homicide-suicide, in which they themselves are killed and would never be charged with *murder*. Others may kill in self-defense or in war, and these would not be considered *murder* from a legal perspective.

According to the US Centers for Disease Control and Prevention, while homicide is not in the top ten list of causes of mortality for all American men, when this is separated for race or national origin, it is the fifth leading cause of death for Black men, the sixth leading cause for Hispanic men, the ninth leading cause for Native American men, and the tenth leading cause for Asian/Pacific Islander men.

The leading cause of death in the workplace for immigrants to the USA is homicide. They may take more dangerous jobs than many natural-born Americans, such as clerking at gas stations and convenience shops, and driving taxis. For example, in 2005, 188 of

564 workplace homicides were homicides of immigrants, while they only made up 15% of workers. In the case of workplace homicide, safety measures such as protective shields for taxi drivers could make a difference.

Resettlement may lead to life improvements, but also is rife with challenges, stresses, and conflicts. One's ethnic community may be a source of great support, but there may also be struggles within the community. Persons who have immigrated to the USA are known to disproportionately become victims of homicide. However, increased death rates by homicide do not occur across-the-board for all immigrants. They may differ by ethnicity of immigrants, acculturation, and time period. For example, a study of first generation non-Hispanic White California immigrants found that immigrants had lower proportional mortality ratios. Another recent study in Israel of immigrants primarily from Russia, found that the frequency of unnatural deaths (including accidents, suicides and homicides) were more similar to rates and patterns in Israel (their new homeland) than those in Russia.

An Australian study of homicide victims found a wide range of mortality ratios depending on the immigrant group. Rates of homicide were highest for Korean male immigrants and lowest for those from Africa and America. Among women, those at highest risk of homicide were Indonesian immigrants. More than half of those who died by homicide were killed by immigrants from their homeland, but the range was vast – from none of the New Zealanders, to every Middle Eastern immigrant who was murdered.

A recent significant increase in homicide victimization has been steadily noted among undocumented workers in the American Southwest. Previously deaths occurred from exposure and dehydration, but more recently homicide has become a major factor. Those paid to lead (*smuggle*) the border-crossing undocumented workers across the border from Mexico to the USA (called *coyotes*) may attempt to extort money from families by holding border crossers hostage, and may kill the border crosser if the ransom is not paid. Members of rival gangs or vigilantes may kill border crossers as well.

On a closely related topic, one recent American study examined adult immigrants' experiences with nonfatal violence victimization and found that the prevalence of nonfatal violence was similar to that of American-born adults. Those working in farming or forestry may have higher risk of violence victimization. Another recent study found that those involved in high-risk behaviors, whether immigrant or American-born, were at higher risk for unintentional injury.

While there have been some highly publicized cases of homicide perpetrated by immigrants, such as the Virginia Tech Massacre, one must keep in mind that homicide committed by immigrants is very rare. In the evaluation for potential risk, speaking with family members and others in the cultural group may help the clinician to understand the stresses the client has been under, and to further comprehend any threats the person has made. A thorough violence risk assessment (outside the scope of this entry) should include cultural considerations.

Homosexuality

Sholeh I. Mireshghi
Department of Counseling, Clinical, and School Psychology, The Gevirtz Graduate School of Education, University of California Santa Barbara, Santa Barbara, CA, USA

In most countries around the world, homosexuality is denigrated and homosexuals are socially marginalized. Amnesty International reports abuse, torture, and sexual assault against lesbians and gay men in 30 countries, suggesting a global pattern of violence and torture against homosexuals. These acts of violence are often perpetrated with the assent of law enforcement and government officials. In more than 80 countries, homosexual relations are considered a crime. In several countries, such as Saudi Arabia, northern Nigeria, Sudan, and Yemen, the punishments for engaging in homosexual acts range from floggings, fines, and prison time up to the death penalty, whereas Iran and Mauritania mandate the death penalty.

On December 18, 2008, the United Nations General Assembly was presented a statement, signed by representatives of 66 countries, requesting that human rights protections on the basis of sexual orientation and gender identity be included in the Universal Declaration of Human Rights. Opponents of this request countered with their own statement, signed by 57 countries and brought forth by the Organization of the Islamic Conference.

The hostility and discrimination faced by many homosexuals in their native lands have prompted them to migrate to countries with more progressive legislation and greater social acceptance of homosexuality. Many have fled their home countries for fear of their physical safety and the threat of execution. Currently, 14 countries grant homosexuals asylum on the basis of membership in a particular social group, i.e., homosexuals. Countries granting sexual orientation-based asylum include Austria, Australia, Belgium, Canada, Denmark, Finland, Germany, Ireland, the Netherlands, New Zealand, Norway, Sweden, the UK, and since 1994, the USA. Applicants seeking asylum in the USA must submit their application within 1 year after the date of their arrival to the USA. Homosexuals seeking asylum must demonstrate a well-founded fear of persecution due to their sexual orientation or gender identity if forced to return to their home country.

Unfortunately, in many cases, homosexuals are denied asylum because they are unable to provide documented proof of the threat to their life or freedom in their country of origin. They are subsequently deported on grounds of lack of credibility or sole reliance on verbal testimonies to substantiate their claims. Furthermore, homosexuals who are given refugee status, compared to other refugee groups, often face additional challenges due to familial rejection, lack of familial support, lack of other social support networks, and insufficient financial resources, thereby complicating their resettlement process.

For the purposes of immigration sponsorship, a small number of countries recognize homosexual partnerships. These countries include Australia, Belgium, Canada, Denmark, the Netherlands, New Zealand, Norway, South Africa, Sweden, and the UK. All of these countries, with the exception of Canada, require that one of the partners be a citizen or permanent resident of that country before they can sponsor the other partner for immigration. Such sponsorships require proof of the existence of the couple's partnership, such as evidence of prior cohabitation for at least 2–4 years.

Hong Kong

Amy N. Sharpton
Department of Veterans Affairs, Louis Stokes DVA Medical Center Cleveland, Brecksville, OH, USA

Introduction

Hong Kong is one of two special administrative regions (SARs) of the People's Republic of China (PRC). At present, there are two SARs: Hong Kong, formerly a territory of Great Britain, and Macau, formerly a territory of Portugal. In anticipation of talks with the United Kingdom over the question of Hong Kong's sovereignty, in 1982 the provision to establish SARs was written into the constitution of the PRC. The model was envisioned as a means for reunification with Taiwan and other islands on which the PRC has resided since 1949.

By definition, a SAR is not part of any other administrative division, and each has its own chief executive and basic law. The Hong Kong Basic Law serves as the constitutional document of the Hong Kong Special Administrative Region (HKSAR) of the PRC. The document holds that the territory is *a local administrative region of the People's Republic of China, which shall enjoy a high degree of autonomy and come directly under the Central People's Government.*

History

Hong Kong became a colony of the British Empire after the First Opium War, 1839–1842. The war was fought between the United Kingdom of Great Britain and Ireland and the Qing Dynasty of China; the impetus of the conflict was the goal of securing economic benefits from trade in China. Although its boundaries were limited originally to Hong Kong Island, the colony's borders were widened in stages to include, by 1898, the Kowloon Peninsula and the New Territories, which include presently the mainland north of the Kowloon Ranges and south of the Sham Chun River, as well as the Outlying Islands. The New Territories were leased to the United Kingdom in 1898 for 99 years. Hong Kong was occupied by Japan during the Pacific War, after which the British resumed control until 1997, when, upon expiration of the lease, sovereignty was transferred to China.

Geography

Hong Kong is located on China's south coast, 60 km east of Macau on the opposite side of the Pearl River Delta. It is bordered by the South China Sea on the east, south, and west, and by the city of Shenzhen to the north. The territory's 1,104 km^2 are comprised of Hong Kong Island, the Kowloon Peninsula, the New Territories, and over 200 offshore islands. Of the total area, 1,054 km^2 is land and 50 km^2 is inland water; its land area makes Hong Kong the 179th largest inhabited territory in the world. Hong Kong claims territorial waters to a distance of 5.6 km.

A significant portion of Hong Kong's terrain is characterized as hilly to mountainous with steep slopes; less than 25% of the territory's landmass is developed. Approximately 40% of the remaining utilizable land area is designated for use as parks and nature reserves. Most of the territory's urban development exists on Kowloon peninsula, along the northern edge of Hong Kong Island, and in scattered settlements throughout the New Territories. Hong Kong's long and irregular coast provides it with many bays, rivers, and beaches.

Although Hong Kong has a reputation of being intensely urbanized, the territory has taken measures to promote a green environment. Environmental awareness is growing as Hong Kong suffers from increasing pollution, worsened by its geography and tall buildings. Approximately 80% of the city's smog originates from other parts of the Pearl River Delta.

Though just south of the Tropic of Cancer, Hong Kong has a humid subtropical climate – summer is hot and humid with occasional showers, thunderstorms, and warm air coming from the southwest. Typhoons are most likely during the summer months, sometimes resulting in flooding or landslides. Winters are mild; they usually start sunny and grow cloudier toward February. An occasional cold front brings strong, cooling winds from the north. The most temperate seasons are spring, which brings variable weather, and autumn, which generally is sunny and dry. Hong Kong averages 1,948 h of sunshine per year, while its highest and lowest temperatures on record are 36.1°C and 0.0°C, respectively.

Culture

Frequently, Hong Kong is described as a place where "East meets West," a statement reflective of the culture's fusion of the territory's Chinese roots and influences from its time as a British colony. A modernized lifestyle is balanced with traditional Chinese practices and concepts. For example, beliefs like *feng shui*, an ancient Chinese system of aesthetics believed to help one improve life by receiving positive qi, are taken very seriously. Often, expensive construction projects utilize expert consultants to incorporate feng shui ideas. Ba gua mirrors are still used regularly to deflect evil spirits, and buildings often lack any floor number that has a "4" in it, due to its similarity to the word for "die" in Cantonese.

Hong Kong is a global center of trade, a self-titled "entertainment hub." Its martial arts film genre gained a high degree of popularity in the late 1960s and 1970s, and numerous Hollywood performers, actors, and martial artists have originated from Hong Kong cinema, including Bruce Lee, Jackie Chan, Chow Yun-fat, Michelle Yeoh, Maggie Cheung, and Jet Li. A number of Hong Kong filmmakers have achieved widespread fame in Hollywood, such as John Woo, Wong Kar-wai, and Stephen Chow.

Economy

Hong Kong is one of the leading international financial centers; it has a major capitalist service economy characterized by low taxation and free trade. Its currency, the Hong Kong dollar, is the ninth most traded currency in the world, and the territory was described once by Milton Friedman as the *world's greatest experiment in laissez-faire capitalism*. It maintains a highly developed capitalist economy, ranked the freest in the world by the Index of Economic Freedom for 15 consecutive years. It is an important center for international finance and trade, with one of the greatest concentrations of corporate headquarters in the Asia-Pacific region. Between 1961 and 1997, Hong Kong's GDP grew 180 times while per capita GDP increased 87 times over.

Education

Although international systems exist, Hong Kong's education system has patterned itself after the system in England. The government maintains a policy in which instruction is in the native language, Cantonese, with written Chinese and English. In secondary schools, multilingualism is emphasized, and Mandarin language education has been increasing. The Program for International Student Assessment ranked Hong Kong's education system as the second best in the world. Hong Kong's public schools system features a noncompulsory 3-year kindergarten, followed by a compulsory 6-year primary education, a 3-year junior secondary education, a noncompulsory 2-year senior secondary education leading to the Hong Kong Certificate of Education Examinations, and a 2-year matriculation course leading to the Hong Kong Advanced Level Examinations.

The New Senior Secondary academic structure and curriculum was implemented in September 2009; it provides for all students to receive 3 years of compulsory junior and 3 years of compulsory senior secondary education. Under the new curriculum, there is the public examination only, namely the Hong Kong Diploma of Secondary Education.

Governance

In accordance with the Sino-British Joint Declaration, and the underlying principle of one country, two systems, Hong Kong has a high degree of autonomy in all areas except defense and foreign affairs. The declaration stipulates that the region maintain its capitalist economic system and guarantees the rights and freedoms of its people for at least 50 years beyond the 1997 handover. The guarantees over the territory's autonomy and the individual rights and freedoms are enshrined in a constitution, the Hong Kong Basic Law. The Basic Law outlines the system of governance but is subject to the interpretation of the Standing Committee of the National People's Congress (NPCSC).

Governing bodies include the Executive Council, the civil service, the Legislative Council, and the Judiciary. The Executive Council is headed by the Chief Executive who is elected by the Election Committee, followed by appointment by the Central People's Government. Politically neutral, the civil service implements policies and provides government services. The Legislative Council has 60 members, half of which are elected by universal suffrage, while the other half, known as functional constituencies, are elected by a smaller electorate consisting of corporate bodies and persons from stipulated sectors. The entire council is headed by the President of the Legislative Council who serves as the speaker. Judges are appointed by the Chief Executive on the recommendation of an independent commission.

Migration

Since World War II, there have been several mass waves of emigration from Hong Kong. The Hong Kong Mass Migration Wave was one such wave. The emigration trend was accelerated by the Hong Kong 1967 leftist riots and, extending into the 1980s and 1990s, was fueled further by the Tiananmen Square protests of 1989. By some estimates, the number of emigrants was in tens of thousands during this period. Canada, Australia, and the United States were the primary destinations for migrants.

The precise figure of migration is difficult to estimate. Some people had relocated overseas by studying abroad and staying after graduation, while others simply obtained returning residency visa from the destination country, which was issued by some countries with no conditions attached in the late 1980s, and then returned to Hong Kong. Informed estimates range from 250,000 to 1 million people, with the peak years of outflow between 1988 and 1994 of about 55,000/year.

As a result of failure to succeed overseas and/or the positive outlook of Hong Kong's economy after the handover, a phenomenon called the *Hong-Kong returning tidal flow* occurred approximately 1 year over the transfer.

Honor Killing

Laila Prager
Institute of Ethnology, University of Münster,
Münster, Germany

The term is usually applied in order to refer to the (intentional) act of the murdering of women who are suspected to have violated the honor of their families/kin groups by having committed sexual indiscretions and/or being involved in other "amoral" action. In most of the cases, the assaults on the unmarried or married women are undertaken by their own family members, mostly by male consanguinal relatives – father, brother, cousins. The murder is usually approved, supported, and planned by the family as a whole, often including the females (mothers, sisters, mother-in-laws, cousins, etc.), and considered as the only acceptable way to restore the family's honor and social status which was "damaged" by their murdered female relative. Honor killings may thus be expected to appear in societies and migrant communities where the idea of "honor" and the concomitant anxiety of social shame constitutes one of the focal cultural values and is being primarily attributed to the proper behavior of the consanguinal female family members. Many human rights organizations (e.g., UNICEF) argue that cases such as the killing of brides in India because their families were unable to come up for the expected dowry or the various forms of "passion crimes" performed in – or by migrants from – Latin America should also be classified as honor killings, since they are predicated on the same cultural logic according to which such crimes are usually tolerated or even endorsed by the local society. Other commentators suggest that the "acid attacks" on engaged or married women by their husbands/fiancés, known from India, Pakistan, and Bangladesh, be included as honor killings or honor crimes, although the general intention behind such attacks is not so much geared toward the actual killing of these women as to their defacement. The United Nations Population Fund estimates as 5,000 women are killed each year for "dishonoring" their families.

The term honor killing is mostly applied in the context of Middle Eastern societies while some commentators draw an additional connection with Islam. Actually, however, acts of honor killing in the Middle East are not contingent on religious convictions but are based on an overriding regional social code according to which the women are the vessel of the family's/kin groups' outward reputation. Honor killings in the USA, Canada, or Western Europe are thus committed likewise among Christian, Muslim, or heterodox migrants from this region. The reasons behind such honor killings may range from premarital sexual intercourse, sexual relations with persons who do not belong to the same ethnic or religious group, adultery, to rape, and even flirting, depending on the values of the social groups in question and varying among different families.

In most of the cases, however, dishonoring is dealt with by means other than killing. However, young women often suffer from symptoms of enduring stress and anxiety due to the possibility that their conduct may be assessed as being at odds with the family's outward reputation and thus they may eventually be victim of an attack. Apart from the physical injuries and/or the post-trauma problems suffered by those women who luckily survived an assassination attempt, the major health problems resulting from the mere threat of honor killing are situated in the domain of mental health. Frequently, young women are warned repeatedly by their relatives over a period of several years that they eventually will be killed if they dishonor the family by refusing to wear the veil, rebuffing an arranged marriage, or becoming too "Westernized." The ongoing threats and the resulting fear and insecurity may lead to protracted mental health problems, such as anxiety and panic attacks, depression, or paranoia. Moreover, the threat of murder often gives rise to a general mistrust and fear of intimate social relationships due to the menace that has been induced by the women's closest kin.

In some cases, a young woman may desperately search for assistance from a surgeon to reconstruct her hymen after she has secretly engaged in sexual intercourse. This is done to prevent potential dishonor from falling on her family if the woman has been promised in marriage or is there is a forced marriage.

Honor killings can turn out to be the final and most extreme step within a long history of previously applied forms of "honor-based violence" (HBV) such as bashing, torture, mutilation, rape, forced marriage, imprisonment at home, etc. Cases in which female victims have survived an attempted murder and openly dare to talk in public are extremely rare. The somatic and mental problems affecting the victims thus only become evident to outsiders if the women are brought to the hospital, take refuge in a women's shelter, or in cases of asylum seekers (such as Zahida Perveen from Pakistan whose face had been disfigured by her husband). Failed murder attempts may also entail severe health problems resulting from poisoning, cuts, gunshot wounds, and beating. At a later stage, the surviving women frequently fall victim to repetitive assassination attempts by their relatives, eventually leading to death.

Occasionally, health problems surrounding the issue of honor killing are considered to affect not only the victims but also the murderers, who – as some psychiatrists maintain – often are suffering from mental disorders. Indeed, in many cases, migrant families select the "weakest" member to act as the commissioned murderer, preferably a relative who already received medical treatment because of mental health problems or a physically handicapped younger brother of the victim. The intention behind such a selection is based on the expectation that a disabled person arrested for the assault will receive a more lenient sentence at court or even be declared certifiably insane due to mental disorder. Particularly in Germany and other Western European countries, lawyers in trials of honor killing increasingly employ the defensive strategy of pleading for their client's diminished responsibility resulting from mental illness, depression, or other mental health problems.

While some commentators argue that the respective social groups or migrant communities endorsing honor killing have to be informed and educated more broadly in terms of human rights and "moral" values, at present it seems that the only effective way to prevent honor killings from happening is to hide threatened women from their own families by relocating them to other regions or countries and provide them with a new identity. Such a procedure may also entail additional mental health problems for the victims.

Hospice

Moon Choi
Department of Epidemiology and Community Health, Virginia Commonwealth University School of Medicine, Richmond, VA, USA

Hospice is a program providing palliative care and supportive services that address the psychosocial, physical, financial, legal, and spiritual needs of terminally ill patients, their families, and other loved ones. The goal of hospice care is to improve the quality of life for the last days of terminally ill patients by offering comfort and dignity. Hospice care does not focus on cure-oriented treatments intended to prolong life.

A multidisciplinary hospice care team consisting of a physician, nurse, social worker, bereavement counselor, or spiritual counselor provides comfort-oriented care including pain management. Hospice is not a facility but a concept of care; thus it is available in various settings such as the patient's home, family member's home, or inpatient facility. Today a majority of hospice care patients receive care at their places of residence such as private houses or nursing homes.

St. Christopher's Hospice, which started in Great Britain in 1967, was the first formal hospice in the world. Seven years later the first hospice in the USA was established in New Haven, Connecticut. Since then the number of hospice programs has increased nationwide. Currently approximately 5,000 hospice programs exist in the United States. In the United States, individuals can choose to enroll in the Medicare Hospice Benefit if they are covered by Medicare (the federal government's insurance program for individuals over the age of 65) and have received a diagnosis of 6 months or less to live. The National Hospice and Palliative Care Organization estimated that approximately 41.6% of the deceased in 2009 received hospice care. The median length of hospice services was about 3 weeks in 2009, which means that one-half of hospice patients received care for less than 3 weeks. Length of service would be influenced by numerous factors such as type of disease, timing of referral, or patient's preference of care.

Racial and ethnic disparities have been reported in hospice use. Ethnic minority immigrants are less likely to enroll in a hospice program. This would be due to their "barriers to hospice use" such as cultural differences in coping with death and dying, limited or no knowledge of hospice, or lack of financial resources if not covered by public or private health insurance. Not-for-profit hospices will enroll uninsured individuals regardless of ability to pay for services; however immigrants may not understand the difference between not-for-profit and for-profit hospices and assume they cannot access these services due to financial restraints. Moreover, limited availability of culturally specific hospice care services also contributes to underutilization of hospice among ethnic minority immigrants.

Hospitalization

Frank C. Lemus[1], Karl Eschbach[2]
[1]Sealy Center on Aging, Department of Preventive Medicine and Community Health, University of Texas Medical Branch, Galveston, TX, USA
[2]Population Research Internal Medicine-Geriatrics, University of Texas Medical Branch, Galveston, TX, USA

Hospitalization refers to a formal admission to a medical facility or hospital for observation, diagnosis, treatment, or surgery with the expectation of an overnight stay. Generally, a formal admission is considered a stay in a hospital for at least 24 h, measured in days, and includes a baby born in a hospital. Such a stay is also known as an in-patient hospitalization and is distinguished from observation, diagnosis, treatment, or surgery done in an outpatient setting.

Hospitalization Data

Throughout the world, hospital records are maintained for all those hospitalized, regardless of their legal immigration status. Hospital discharge records or discharge abstracts contain demographic information about the person, diagnosis and procedure information, and other administrative and billing data for a stay in a hospital of at least 24 h – both in the USA and under the European rules in Europe. However, discharge records generally do not record immigration status or place of birth, making immigrant status very difficult to identify.

Hospitalizations indicate advanced disease, may signal epidemics, and help define trends in immigrant disease profiles, so complete and reliable data is critical. Frenk illustrates the importance of using international methods with country-specific data to develop major health reform affecting bordering countries such as the USA and Mexico, and by extension, other immigrant sending and receiving countries throughout the world.

Inpatient Hospitalization

Hospital utilization varies by sex, race/ethnicity, geography, and age. Throughout the world, women make up the largest number of persons hospitalized and the majority of their hospitalizations are related to pregnancy, childbirth, or post-partum complications. Studies in California and Spain illustrate this fact. For example, in 2005, six of the top ten inpatient procedures in California general acute care hospitals were related to birth, pregnancy, childbirth, or other female condition.

In the USA, Latino immigrant women have higher rates of hospitalizations than non-Hispanic White women, due to pregnancy and childbirth, which contributes to a young immigrant population, particularly among Latinos.

US studies show geographic variation in hospitalization among ethnic groups based on their concentration in certain areas such as El Paso, Texas, and Los Angeles, California, with childbirth-and pregnancy-related hospitalizations higher in these areas. Also, studies of children hospitalization show the significant variation in location of hospitalization that may be driven by source of payment. For example, a California study showed that children with public funding were hospitalized more frequently in pediatric specialty clinics than children with private funding, which suggests that fewer hospital pediatric specialty referrals are being made because they are more costly.

A recent trend has been to use the outpatient setting for care and surgical procedures previously performed in a hospital environment. This change in protocol effectively reduces the number of hospitalizations.

Immigrant Hospitalization

Limited Data in USA

While a significant body of literature has emerged about immigrant health, little exists on immigrant hospitalization, and is only available through targeted research studies that collect place of birth. One example is a study conducted in Illinois over a 10-year period, 1993–2003. In this study, foreign born persons had a lower percentage of hospital admissions and a lower proportion of admissions than did native born Americans.

With the exception for childbirth, Berk reports similar lower rates of hospitalizations among unauthorized immigrants in Los Angeles, California from 1996/1997 survey data. However, hospitalization rates among undocumented Latino immigrants in El Paso and Houston, Texas, and Fresno, California – two states with the largest concentrations of undocumented immigrants – and other Latinos and the US population as a whole were comparable (except for childbirth). In Berk's survey, rates of physician visits were much lower for undocumented immigrants than for Latinos and the US population as a whole.

Because neither hospital discharge data nor workers' compensation claims are reliable sources for hospitalization use by immigrants, Muennig recommends using small area analysis to predict hospitalization rates among immigrants. Yet, the scant data that are available to quantify immigrant hospitalizations provide preliminary insights into immigrant hospitalization, both globally and in the USA.

Challenges

Several fundamental questions emerge when comparing immigrants to other population groups. These questions underscore the complexity, importance, and challenge of understanding hospitalizations among immigrants. Are immigrant hospitalization rates high or low compared to others; and if so, why are they different from others? Do immigrants have equitable access to health care resources? Does immigrant hospitalization impose a burden on the host society; if so, why?

Controversy over immigration health pertains especially to disadvantaged laborers and undocumented populations that do not fully participate in the health care financing system of the host country. For example, in the USA, health insurance coverage rates of African and Asian immigrant populations tend to approximate those of non-Hispanic Whites. Latinos, on the contrary, have low rates of insurance coverage so that questions about both equitable access and burden on the public financial system become more important.

Equitable access to health care services, including hospitalization, centers on two issues: cost and social justice. Immigrants often are employed, but the costs associated with insurance may preclude the employer from providing insurance; or if offered, workers may not be able to pay the premiums and co-pay amounts; or because of generally good health, the immigrant may not believe insurance is needed. Geiger points to overwhelming evidence that minorities and the poor who get medical care receive less comprehensive and lower quality diagnosis and treatment compared with others, even when confounding variables are comparable such as insurance status and severity of illness. A Canadian study noted that immigrant workers were less likely than native born workers to receive a precise diagnosis (64% vs 42%).

Numerous studies have found that the burden on the host country of immigrant hospitalization is significantly lower for immigrants than for the native-born and that immigrants do not contribute disproportionately to high health care costs in public programs such as Medicaid, including emergency department use. However, there are areas where immigrants make up a disproportionate share of the population. One example is the USA–Mexico border region, as illustrated by the University of Texas, El Paso, which incurs huge uncompensated expenses for emergency department visits and inpatient care by the uninsured, underinsured and from patients who receive hospital care because of cross-border agreements. Yet, overall, the Texas Comptroller estimates that undocumented immigrants in Texas generate more taxes and other revenue than is spent by the state on services to them.

Immigrant Flow

Number of Immigrants in USA

Passel and Cohn estimated more than 39 million immigrants (12.8% of the US population) were in the USA in 2009, both legal and unauthorized. About one-third of immigrants are estimated to be *unauthorized,* mostly Latino (nearly 75%), and mostly from Mexico (59%). The fact that nearly one-quarter of all children in the USA are in immigrant families poses a significant dilemma for the US public health system even as it underscores that the immigrant population is a young one, whose health care and hospitalization needs will extend over a considerable length of time. This trajectory of care will span the disease, injury, and illness patterns seen over the life-course from pregnancy, childbirth hospitalizations, childhood immunizations, and work-related injuries, to disability and other older age–related diseases and adverse health conditions that may lead to hospitalization. DuBard's study in North Carolina finds more rapidly increasing spending for elderly and disabled immigrants who may need frequent hospitalizations.

Healthy Immigrant Effect

Is lower hospitalization due to better health, a younger population, or barriers to accessing the health care and hospitalization system? The literature suggests that immigrants to the USA and to other countries in the world are selected because of relatively good health, and advantages in health profiles and mortality rates are attributed to what is known as the "healthy migrant effect." In the USA, this advantage is particularly evident among Latinos, who show lower mortality rates for major causes of death such as cardiovascular disease and cancer as compared to non-Hispanics, which may explain partly why they are hospitalized less frequently.

One reason for the low immigrant hospitalization is the healthy immigrant effect. Another reason is the use of alternative care settings.

Alternative Care Settings

Immigrant health care may be provided outside the medical public health mainstream by religious- and community-based organizations, through self-medication and the use of folk healers. Such alternative healthcare contributes to the challenges in studies on immigrant hospitalizations. Other challenges are that sample sizes are too small to produce reliable results, immigrants are not well identified or described in the records, and the variation in research methodologies makes comparisons between studies difficult.

Social Barriers

Fear

Regardless of legal status, immigrants are reluctant to go to the hospital for care unless absolutely necessary, for fear of deportation or of loss of employment. A Canadian study of differences between immigrant and native-born workers in the injury and illness compensation process found immigrant workers experience greater fear of reporting an injury, face greater challenges to their rights of compensation for their injuries, and by reporting their injuries they encounter greater adverse job re-hire outcomes and social exclusion from the job market than the native-born. Similar experiences by immigrants are reported in the USA and Europe, where fear of hospitalization and seeking health care occur because of numerous potential adverse consequences from such efforts.

Insurance

A principal barrier to health care and hospitalization among immigrants is lack of insurance. In 2007, the majority (59%) of unauthorized immigrants did not have insurance, and 45% of their unauthorized immigrant children were uninsured. This compares with 25% of those children born in the USA and who were US residents that year.

A 2000 study by Currie on the impact of expansion of Medicaid for children of immigrants and nonimmigrants using data from the 1989 and 1992 National Health Interview Survey showed that while children of immigrants are more likely to be eligible for Medicaid than native-born children, actual coverage is higher among native-born children. Increased *eligibility* does not necessarily mean an increase in *utilization.* The study also found that eligible immigrant children, as well as native-born children, are more likely to have at least one doctor's visit with increased Medicaid eligibility, but immigrant children are less likely to be hospitalized. This study suggests that costly hospitalizations are reduced among immigrant children with increased access to primary care doctors and preventive care. The Personal Responsibility and Work Opportunity Reconciliation Act of 1996 (PRWORA) significantly changed immigrants' access to Medicaid, excluding many new immigrants from coverage.

Medical Repatriation

Medical repatriation is a process by which hospitals discharge an immigrant patient to their home country, providing a variety of incentives to gain permission from the patient or the patient's family for the voluntary return to their home country for care that often is inferior or without needed medical care resources. Threats of reporting to immigration of those foreign individuals who have not paid their bills fuel unwillingness to seek health care.

Yet, not all medical repatriation situations are motivated by factors related to cost or other burden. For example, patients have been hospitalized in the mental health system for extended periods even though they could have been released to less-restricted environments, and have attempted medical repatriation as less onerous than the mental health facility. But because of language miscommunication and cultural misunderstanding, these medical repatriation efforts have failed.

Immigrant Hospitalization – Global

Anti-immigrant sentiment is evident throughout Europe and the USA, with Phoenix, Arizona serving as ground zero for such discord in the USA. Such sentiments influence availability of and access to primary care resources that can prevent hospitalizations used as a last resort and the attendant costs of such hospitalizations.

Infectious Disease

A study in Valencia during 2001–2002 used hospital discharge records to learn whether the rise in incidence and/or transmission of infectious diseases seen in Valencia could be attributed to the immigrant population. The authors found that the percentage of infectious and infectious–contagious diseases among immigrants did not contribute to the increase in these conditions in Valencia. Such a study reinforces the need for accurate hospitalization data that can be used to identify trends and sources of illness.

Mental Health

A review article on mental health care between 1996 and 2004, among immigrant groups in Germany, Italy, and the UK, countries with the most immigrants during the 1990s, found underutilization of mental health care services in 9 of 13 German studies. Although immigrant groups in the UK had more hospitalizations, poorer outcomes were reported. The article notes the limited research on immigrant hospitalizations to guide the development of mental health services in major countries in Europe.

Workplace Injuries

The International Labour Office estimated that, in 2000, 49% of international migrant workers were active in the labor stream, that is, either seeking work or employed. Immigrants throughout the world take high hazard, precarious jobs that are less desirable, more hazardous, and more stressful, often with few benefits (including health care) and higher risk of injury and death. Lack of regulation in this informal sector economy exacerbates the risks, and women often end up doing this work. These factors increase the hospitalization potential that is not well documented in the USA or throughout the world.

Immigrant Hospitalization – United States

Mental Health

Historically in the USA, mental health hospitalizations have been higher among immigrants during periods of high immigration. Yet, trends during the current immigration wave of Latinos and Asians show lower mental health hospitalization rates. A study in New Jersey illustrates the complexity of immigrant hospitalizations and the difficulty of doing reliable studies on this population. Researchers surveyed four of the state mental health facilities in New Jersey and identified 61 immigrant patients. Of these, 55 could have been discharged to a residential health care facility, but were not because they were ineligible for federal benefits in the community setting. On closer examination, 12 patients did have legal authorization to be in the USA and others had already initiated the process of repatriation, applied for a resident alien card, sought asylum, or had other special circumstances. However, culture and language differences and staff misunderstanding of the immigration processes kept these patients undocumented and hospitalized.

Workplace Injuries

Unauthorized immigrant workers are concentrated in occupations with greater occupational hazards and subject to conditions that cause severe neck, shoulder, and back injury. Workers and employers of immigrants are less likely to report work injuries or go to a hospital than native-born, even if the injuries are life threatening for fear of deportation, retribution, unawareness of their rights to workers' compensation, or fear of drawing unwanted attention from health and safety enforcement agencies.

Conclusion

In summary, hospitalization utilization varies by sex, race/ethnicity, geography, and age with the largest number of hospitalizations due to pregnancy- and childbirth-related conditions. Also, immigrant hospitalization rates are comparable to or lower than for the native-born, except for higher immigrant rates for pregnancy and childbirth and emergency room visits by children; lower rates of insurance among immigrants restrict their access to health care; and immigrants do not disproportionately burden the health care system.

The implications of understanding more about hospitalizations generally, and immigrant hospitalizations specifically can be embodied in these five points:

Education that targets the leading causes of workplace injury, illness, and death, and nuanced to the culture and language of the immigrant's country, even region of origin.

Enforcement of existing regulations and safety inspections throughout the world.

Underreporting of illnesses or injuries is well-known. Fears of job loss, employer retaliation, deportation, or harassment are factors influencing unwillingness to report injury and to seek hospitalization.

Improvement in data collection efforts that are country-specific, with the capacity to collaboratively link records to existing data sets in the USA and internationally.

Research studies that apply similar methodologies with adequate sample sizes to compare across regions, countries, and cultures.

Housing

Doug Brugge
Department of Public Health and Community Medicine, Tufts University School of Medicine, Boston, MA, USA

Housing is a fundamental human need that provides a critical foundation on which health is heavily determined. Without housing or with substandard housing, people are at risk for numerous health problems. Access to housing and to quality housing that is not overcrowded may be a particular problem for immigrants.

Obtaining accurate estimates of the number of people who are homeless is difficult, but homelessness is usually higher in source than in destination countries for immigrants. Of particular interest though are destination countries since that is where immigrants reside following immigration. A recent estimate suggested that over 12 months from 2006 to 2007, about 1,589,000 persons used an emergency shelter or transitional housing in the USA. In Japan, it was estimated that between 20,000 and 100,000 were homeless. In the UK an estimate was about 100,000.

There are few studies of health of homeless immigrant populations. One recent study surveyed immigrant and non-immigrant homeless people in Toronto, Canada. Chiu et al. concluded in their 2009 article that recent immigrants who are homeless constitute a distinct group and that they are generally healthier than native born homeless people. Thus recent immigrant homeless may need different services compared to other people who are homeless. The authors suggest that a "healthy immigrant," effect, which is common in immigrant populations for many illnesses, might also exist among homeless immigrants. More research is needed on the health condition and needs of homeless immigrants.

Historically, provision of decent housing has been seen as a basic step toward proper sanitation that can prevent the spread of disease. Today in much of the developed world poor housing conditions are of less concern because of the spread of disease, although that is still a concern, but more often because of exposure to toxicants and allergens that are deleterious to health through chronic disease mechanisms. In addition, injuries caused by substandard housing are also a concern. Prime examples of hazardous exposures in the home include water damage and associated mold growth; secondhand tobacco smoke; cockroach, rodent and bed bug infestations; dust mites; lead paint; indoor use of pesticides; and many more.

Because substandard housing is more common at lower socioeconomic strata and immigrants are often concentrated at lower incomes, they may be more likely than native-born populations to experience housing conditions that are unhealthy. Some immigrants may also contribute to housing problems if they have moved from, for example, rural agrarian settings to urban, multifamily housing. These immigrants may bring with them practices that while appropriate in a rural setting, are hazardous in their new housing. An example would be using open combustion for heating in poorly ventilated buildings.

Secondhand Tobacco Smoke

Secondhand tobacco smoke (SHS) is a mixture of thousands of substances, both gases and particulate matter, many of which are known or suspected carcinogens and have other toxicological properties, including effects on the cardiovascular system. Exposure to SHS has been linked to cardiovascular disease, lung cancer, asthma (both occurrence and exacerbation), middle ear infection, pneumonia, low birth weight, and sudden infant death syndrome. Of particular concern for immigrants may be that smoking norms can differ between the country of origin and the new country of residence. Immigrants may move from places with little concern about SHS to places where it is tightly regulated and even banned in some housing.

Further, some immigrant populations, many Asian immigrants in the USA, for example, have vastly different smoking patterns than native born populations. Thus, men in these immigrant populations may have a high smoking prevalence while women rarely smoke. This social pattern means that women are exposed to their husbands' and fathers' SHS more so than the other way around. Coupled with a hesitancy to challenge behavior of others in the family, especially elders, traditional approaches to educating about and discouraging smoking in the home may not be effective.

Water Damage and Mold Growth

Poorly built or maintained housing may be prone to leaks and moisture. Leaks could be from the exterior, for example, a leak through a wall or roof when it rains, or from plumbing. Inadequate ventilation in bathrooms and kitchens can also allow moisture from cooking or showers to build up. Whatever its source, if water is present where it is not supposed to be in a building it can, over time, lead to structural damage and to growth of mold. While there is mold almost everywhere, large growths may be a particular problem to health of people who are exposed. Molds produce spores and hyphae that can elicit allergic responses, including asthma, in some people. Molds also release organic compounds that have toxic properties.

Remediation of mold, once it has taken hold, is not easy. Simple cleaning is often ineffective. In some cases it may be necessary to replace structural elements that are infected with mold. A particular problem for immigrants moving from rural to urban environment might be that uncontrolled indoor moisture may not seem like a problem.

Cockroach Infestation

There are numerous species of cockroaches, but the German cockroach is a particular indoor problem in the Northeastern USA. Populations of these insects will expand to hundreds or thousands in a single apartment and the antigen they leave behind appears to increase risk of developing asthma and exacerbating asthma in some people who already have it. Controlling these infestations is especially challenging in multifamily buildings. Cleaning and eliminating these pests from one apartment is ineffective as they will simply infiltrate from other infested apartments.

Standard pesticide spraying, besides adding highly toxic chemicals to the living space, also appears to be relatively ineffective, sometimes known as, “spray and pray.” Cockroaches usually return after an absence and the space has to be continually sprayed to keep them at bay. Integrated pest management (IPM) across entire buildings seems to hold some promise for eradication of cockroach infestations. IPM uses insect toxins that have lower human toxicity and includes extensive cleaning, sealing cracks and crevices, and altering resident practices to reduce clutter, food and water sources for the insects.

Dust Mites

These arachnids are not insects, but are, instead, related to spiders. They are microscopic in size and live in bedding, carpets, and upholstery. They are highly dependent on humidity and die without enough moisture. Like cockroach antigen, antigen from dust mites is allergenic to people who are sensitive to it. Unlike cockroaches, dust mites tend to be more of a problem in middle class and suburban housing where there are more places for them to grow, including, for example, children's stuffed animals. While some in-home interventions for asthma that included multiple inventions, including dust mite control, claim that reducing dust mite antigen is beneficial for asthmatics, studies that employed these control strategies alone have failed to show consistent or statistically significant benefits.

Lead Paint

While banned for interior residential use in many countries, in the USA lead paint continued to be sold and applied in homes into the latter part of the twentieth century. The legacy of this failure to regulate residential lead paint is that approximately a quarter of a million children in the USA have elevated blood lead levels, even as evidence grows that blood lead levels below the current guideline (10 ug/dl blood) also cause neurological damage.

Residential lead paint is more prevalent in older housing stock, for instance, in the Northeastern USA, and is more likely to be deteriorated, releasing forms that can be ingested, dust primarily, in housing that is overall in poor condition, often low-income housing. A substantial problem is painted window wells. Window wells were not meant to be painted, but many were anyway. Paint in the wells is subject to regular friction when windows are opened and closed, resulting in wearing down the paint into chips and dust.

Young children spend much of their time on the floor and put things into their mouths, including their hands. In a house with lead contamination this is the main route by which lead gets into the body. At high levels lead can lead to acute illness and require immediate medical attention. At levels more common today, lead is associated with more subtle neurological damage, including changes in behavior, loss of IQ and learning difficulties.

Rodent Infestation

Rats and mice are relatively common pests in low-income housing. Like mold, cockroaches, and dust mites, they leave behind antigens that exacerbate or may cause asthma. While poisoning animal pests is an option, anything that is acutely toxic to these mammals is similarly toxic to humans. Because their numbers are usually smaller than insects or arachnids, trapping is a common approach to control. Elements of IPM described above will also help by removing paths of entry and sources of food and water.

Pesticides

Indoor use of pesticides is usually aimed at insect and arachnid infestations. Application of pesticides may be by professionals hired by the home owner or manger or by tenants on their own. Because pests are an easily observed and generally reviled presence while the toxicity of pesticides is subtle and not observable, most people will choose pesticides to address infestations. But the toxicity of pesticides, which, like lead are primarily neurotoxic, is considerable and once introduced into the home, many pesticides are stable and remain for protracted periods of time.

Julien et al. did a study in Boston, Massachusetts, USA, and found that pesticide residues in public housing often included restricted use pesticides that were not supposed to be applied in homes. Hispanic families were buying these pesticides at local bodegas and using them, undiluted and without training on their hazards, to counter cockroach infestations in their apartments.

Injuries

Houses are significant sources of injuries, especially for children and the elderly. In the USA in 2006, unintentional injuries were the leading cause of death for ages 1–44. In almost all age groups, falls were the leading cause of unintentional non-fatal injury. Many of these falls occur in the home and include falls on stairs, a common sort of fall with a high chance of injury. While much of the media attention focuses on violence (intentional injuries in this framework) and motor vehicle–related injuries, in-home injuries are also very common, if not as upsetting to us as a society.

Structural features of the home are important contributing factors to injuries. Taking stairways as an example, elements that reduce hazards of stairs include sturdy handrails, non-slip surfaces, and absence of structural damage and appropriate step lengths.

Other common in-home injuries include burns and poisonings, and cuts and abrasions.

Unlike the lead and allergen exposures described above, injuries are more easily traced to their causes. A fall on a stair is easily attributable to falling on a stair, unlike an asthma attack to which it would be difficult to assign a clear causal link. Because the source of injuries is more easily assessed, they may be easier to prevent. However, to date, attention to injuries, in-home or out of the home, has tended to attract less interest than chemical and biological exposures.

Human Immunodeficiency Virus

Daniel J. O'Shea
HIV, STD and Hepatitis Branch, Public Health Services, County of San Diego, San Diego, CA, USA

Human immunodeficiency virus (HIV) is a virus that can lead to acquired immune deficiency syndrome, or AIDS. The World Health Organization (WHO) estimated that 33.4 million people were living with HIV or AIDS at the end of 2008. In the same year, an estimated 2.7 million people became infected with HIV. The US Centers for Disease Control and Prevention (CDC) estimated that 1,106,400 persons in the USA were living with HIV or AIDS at the end of 2006, with an estimated 56,300 new HIV infections that year.

The natural history of HIV infection in adults is well documented in the medical literature. HIV damages a person's body by destroying specific blood cells, called CD4+ T cells, which are crucial to helping the body fight diseases. Within a few weeks of being infected with HIV, some people develop flu-like symptoms that last for a week or two, but others have no symptoms at all. People living with HIV may appear and feel healthy for several years. However, even if they feel healthy, HIV is still affecting their bodies. All people with HIV should be seen on a regular basis by a health care provider experienced in treating HIV infection. Many people with HIV, including those who feel healthy, can benefit greatly from current medications used to treat HIV infection. These medications can limit or slow down the destruction of the immune system, improve the overall health of the person living with HIV, and may reduce the individual's ability to transmit the virus. Untreated early HIV infection is also associated with many diseases including cardiovascular disease, kidney disease, liver disease, and cancer.

AIDS is the late stage of HIV infection, when a person's immune system is severely damaged and has difficulty fighting diseases and certain cancers. Before the development of certain medications, people with HIV could progress to AIDS in just a few years. Currently, people can live much longer – even decades – with HIV before they develop AIDS. This is because of "highly active" combinations of medications that were introduced in the mid-1990s. While current medications can dramatically improve the health of people living with HIV and slow progression from HIV infection to AIDS, existing treatments may need to be taken daily for the rest of a person's life. These treatments need to be carefully monitored, and come with costs and potential side effects. At this time, there is no cure for HIV infection. Additional information on AIDS and the impact of the worldwide HIV/AIDS epidemic can be found in the entry "acquired immune deficiency syndrome" in this encyclopedia.

Many social/psychosocial issues, including homosexuality, drug use, mental illness, racism, homelessness, and poverty, are linked inextricably to the context of HIV/AIDS by association with the communities the disease has heavily impacted, in addition to the clinical challenges of the disease itself and its toll on the health and well-being of those infected.

HIV Transmission

HIV can be transmitted through blood, semen (including pre-seminal fluid, or "pre-cum"), vaginal fluid, or breast milk. The most common modes are: sexual intercourse (anal, vaginal, or oral sex) with an HIV-infected person; sharing needles, syringes, or injection equipment with an injecting drug user (IDU) infected with HIV; and from HIV-infected women to babies before or during birth, or through breast-feeding after birth. HIV also can be transmitted through transfusions of infected blood or blood clotting factors. Some health care workers have become infected after being stuck with needles containing HIV-infected blood. Routine screening of all donated blood since 1985 has made risk by transfusion extremely low in the USA and other developed regions (Canada, Western and Central Europe, and Australia). In contrast, many developing countries have no reliable blood screening due to limited or nonexistent basic laboratory services, irregular testing supplies, poor quality test kits, poor coordination, and/or limited staff; complete, accurate data on testing of donated blood are not available from these areas.

Transmission of HIV can be influenced by several factors, including characteristics of the HIV-infected host, the recipient, and the quantity and infectivity of the virus. Having a sexually transmitted disease (STD) can increase a person's risk of becoming infected with HIV. In addition, if an HIV-infected person also is infected with another STD, that person is three to five times more likely to transmit HIV through sexual contact. HIV cannot be transmitted from casual (i.e., hugging or shaking hands) or surface (i.e., toilet seats) contact or from insect bites. Intact, healthy skin is an excellent barrier against HIV and other viruses and bacteria.

Globally, heterosexual contact between men and women accounts for approximately two-thirds of new infections; around 11% of HIV infections are among children who acquire the virus from their mothers; ten percent result from injection drug use; five to ten percent are from sex between men; and five to ten percent occur in health care settings. According to the United Nations AIDS program (UNAIDS), data on HIV transmission and risks indicate refugees and immigrants newly arriving or resettling in a new country are much more susceptible to and at greater risk for HIV infection than local general populations. The UNAIDS surveillance data attribute this phenomenon to several factors and challenges ranging from financial and environmental conditions to cultural and language barriers, stigma, discrimination, exploitation, and difficulty accessing HIV education or health services.

HIV Testing

Testing for HIV is the only way to determine for certain whether someone is infected with the virus, particularly since many infected individuals do not have symptoms for years. Commonly used tests detect antibodies produced by the body to fight HIV. Most people develop detectable antibodies within 3 months after infection, with the average at 25 days; in rare cases, it can take up to 6 months. HIV testing and counseling offers an opportunity for infected individuals to find out they are infected and gain access to treatment that may help to delay disease progression; for those not infected, counseling offers an opportunity for education on ways to prevent an infection in the future. Unfortunately, many people do not test for HIV until they or their sex or needle-sharing partner develops an AIDS-related illness. Some HIV-positive women may not be tested until they seek prenatal care or give birth.

Preventing HIV Transmission

Abstaining from engagement in any behavior that carries risk of acquiring HIV (e.g., sexual intercourse or using and injecting drugs) is the most effective way to avoid HIV, but not always the most realistic. To minimize risk for those who choose to be sexually active, the CDC recommends the following: engage in sex that does not involve vaginal, anal, or oral sex; have intercourse with only one uninfected partner; and/or use latex condoms every time you have sex. For IDUs who cannot or will not stop injecting drugs, the following steps are recommended to reduce risk: never reuse or "share" syringes, water, or drug preparation equipment; only use syringes obtained from a reliable source (such as pharmacies or needle exchange programs); use a new, sterile syringe every time to prepare and inject drugs; if possible, use sterile water to prepare drugs; otherwise, use clean water from a reliable source (such as fresh tap water); use a new or disinfected container ("cooker") and a new filter ("cotton") to prepare drugs; clean the skin with a new alcohol swab prior to injection; safely dispose of syringes after one use. If new, sterile syringes and other drug preparation and injection equipment are not available, then previously used equipment should be boiled in water or disinfected with bleach before reuse.

Medical therapy with azidothymidine (AZT) effectively reduces the chance of an HIV-infected pregnant woman passing HIV to her infant before, during, or after birth. In 1998, the US Public Health Services released updated recommendations for offering antiretroviral therapy to HIV-positive pregnant women. Unfortunately, outside of high-income countries like the USA, these drugs often do not reach high incidence regions in the developing world where they are most needed.

Care and Treatment

Early medical treatment and a healthy lifestyle can help an individual with HIV stay well, delay the onset of AIDS, and prevent life-threatening conditions. In 1987, AZT became the first approved treatment for HIV disease. Approximately 30 antiretroviral (ARV) drugs are now approved and available in the USA, with more in development. ARV drugs combat HIV disease by interrupting one of the stages of the HIV replication cycle within CD4+ T cells. There are currently five classes of ARV drugs, each of which attacks a different point in the life cycle of the virus. The standard treatment regimen comprises three different ARV drugs from two different classes in order to control the amount of virus in the body, protect the immune system, and prevent resistance. Resistance, which occurs when the virus mutates to a form that doesn't respond to an HIV medication, is less likely to occur with a three-drug combination. Recommendations for treatment continue to evolve rapidly as new medications are developed and additional data from clinical trials is presented. The most current treatment guidelines are available on the US Department of Health and Human Services' HIV/AIDS Information website.

Access to HIV Prevention, Care, and Treatment

Increasing costs of medications and related care, the eroding safety nets of the Medicaid and Ryan White federally funded programs along with reductions in general fund support from state and local governments in the context of a worldwide economic recession, and uncertainties and confusion concerning the roll-out of the Medicare drug benefit and Health Care Reform will continue to challenge many Americans living with HIV/AIDS in future years. Even so, ARV therapies are readily accessible in the USA and other developed, high-income countries (Canada, Western and Central Europe, and Australia), but remain largely unavailable to many infected individuals in the developing world.

Access to HIV prevention, care, and treatment can be particularly challenging for immigrant populations, even within high-income countries. These include asylum seekers, refugees, and undocumented migrants from Latin America, the Caribbean, sub-Saharan Africa, Eastern Europe, and Eastern and Southeastern Asia. Language barriers, marginalization, social exclusion, legal obstacles, cultural attitudes, religion, fear of discrimination, and low HIV knowledge all facilitate vulnerability to acquiring HIV infection and pose barriers to accessing care. Additional obstacles are policies, laws, lack of legal/residence status, limited or no health insurance, inadequate or lack of sustained funding, and fragmented service delivery. Provision of HIV services to immigrants is further challenged by inconsistencies between health and immigration policies regarding rights to health care. Within migrant communities themselves, access is often limited by insular culture, religion, social circumstances, fear of discrimination, and limited knowledge of available services. Within the wider society, stigma and discrimination, fueled by negative social attitudes toward migrants, sometimes exacerbated by unsympathetic media reporting, pose additional barriers. Policies that disperse immigrants within some countries may also limit access to HIV prevention and care. To address these barriers, culturally sensitive and appropriate information and interventions in relevant languages, suitably trained professionals, health and community workers, and services tailored to the specific needs of migrants are required, along with increased efforts to inform migrant communities about available services. On a larger societal scale, joint efforts are required between policymakers, health and social care professionals and civil society, with more migrant community involvement in policy processes. Clear policy and legal frameworks are needed to protect the rights of migrants, in particular undocumented and uninsured migrants, to HIV prevention, care, and treatment.

Another area of particular concern relates to HIV-positive migrants taken into custody and detained pending outcome of an immigration or deportation case. Although international law broadly protects the right to medical care for detainees, including immigration detainees, at least equivalent to that available to the general population, adequate systems are not in place in many countries to ensure HIV/AIDS treatment for detainees pending deportation. In 2007, Human Rights Watch documented substandard policies, procedures, and supervision governing HIV/AIDS care for migrants detained in US custody, leading to treatment that was delayed, interrupted, and inconsistent to an extent that endangered the health and lives of the detainees. Additionally, policies to ensure post-deportation continuity of treatment mechanisms are frequently nonexistent or extremely inadequate to protect the health of deportees, and may lead to illness, premature death, or the development of drug resistance.

HIV Immigration Bans

Since the emergence of the HIV epidemic in the 1980s, immigrants were recognized throughout the world as vulnerable for risk and spread of HIV/AIDS. Some countries sought coercive measures to prevent people living with HIV from entering or residing in their countries, whether for business, family visits, tourism, study, labor migration, or political asylum. In 1988, WHO argued that HIV-motivated travel restrictions and immigration policies were irrational and without public health justification. In 2004, UNAIDS and the International Organization for Migration officially condemned HIV immigration bans, invalidating the myths that the bans protect public health or that non-citizens with HIV place undue economic burdens on countries. In 2008, around 74 countries, including the USA at that time, were still imposing HIV-specific restrictions on entry and residence of HIV-positive people; of these, 29 countries deported people upon discovery of their HIV status.

After 22 years, on November 2, 2009, the Department of Health and Human Services (HHS) finally removed HIV from the list of "communicable diseases of public health significance" that keep non-citizens from entering the USA. The story of the US HIV travel ban illustrates how disease, domestic politics, and perceptions of sexuality and morality, rather than scientific research and public health, dictated foreign policy. In 1987, the US Public Health Service (PHS) under President Ronald Reagan officially added AIDS to the list of dangerous contagious diseases that barred aliens from entering the USA, even while noting that AIDS could not be spread casually and was not a contagious disease. Politics further trumped science when US Senator Jesse Helms proposed the "Helms amendment" to an appropriations bill that added HIV infection, whether or not there were manifestations of AIDS, to the list of excludable diseases maintained by PHS; this was approved with only a cursory discussion and became effective in December 1987. In 1990 and 1992, controversies erupted over the ban related to International AIDS Conferences held in the USA, with over 70 nations boycotting the 1990 San Francisco conference and the ultimate last-minute relocation of the 1992 conference from Boston to Amsterdam. In January 1991, the CDC called for the removal of HIV and all medical conditions other than active tuberculosis from the exclusions list. In response, a mass mailing campaign in opposition was orchestrated and US Representative William Dannemeyer and 66 fellow Republicans signed a public letter in opposition. Ultimately, the Public Health Service argued only Congress could invalidate the HIV exclusion it had adopted. The exclusion was codified in March 1993, by legislation signed by President Bill Clinton, violating a campaign promise. For the next 15 years, the USA had one of the most restrictive policies on immigration and travel of HIV-positive people in the world, compelling all non-citizens to attest they were HIV-negative before being admitted to the USA. At the same time, non-citizens living long-term in the USA were denied permanent resident categorization solely on basis of their HIV-positive status. In July 2008, Congress finally repealed the statutory HIV immigration and travel ban, and restored authority of the Secretary of Health and Human Services to remove HIV from the list of communicable diseases whose carriers are denied entry to the USA.

Human Rights

Mihaela-Catalina Vicol
Department of Bioethics, University of Medicine and Pharmacy “Gr. T. Popa”, Iasi, Romania

Human rights represent a set of universal rights to which every individual is entitled. These are absolute fundamental and inalienable rights representing the basis of individuals’ treatment by States and non-State actors.

From an historical point of view, human rights are based on three main sources:

1. Nature (natural rights). Every human being belongs to one single family that determines the essence of humanity to respect each member.
2. Divine origin (religion). This refers to the Father of every human being who imposes his indefeasible law.
3. Reason (universality). This refers to the denominator of the human being.

But there is an important distinction between natural rights and positive rights. Natural rights are those that derive from natural or divine origin; they are absolute, inalienable, and immutable. Positive rights are those rights that are recognized in a political/law context and are contained in a normative document such as a law, a treaty, a declaration, etc.

Short History

The idea that rights exist that inure only to human beings has been described in ancient cultures. In the fifth century B.C., Sophocles had illustrated in the tragedy of *Antigone* how a natural moral non-written law had been opposed to a political-based decision. Aristotle wrote about citizens’ rights to hold property and to participate in public affairs. Several philosophers, such as Aristotle, Plato, Socrates, Cicero, St. Thomas of Aquinas, Hugo Grotius, John Locke, and Immanuel Kant wrote about the existence of natural rights or divine rights. Even in medieval history there were documents that embodied and events that reflected concerns for human liberty. Examples include: the Magna Charta, issued in England in 1215; the 1776 revolution in the United States of America; and the 1789 French revolution. These latter two events led to important documents on human rights: The United States Declaration of Independence and the French Declaration of the Rights of Man and of the Citizen.

In 1948, following the Second World War and in response to the atrocities and to the absolute negation of human rights that had occurred, the General Assembly of the United Nations proclaimed The Universal Declaration of Human Rights. Through its adoption by representatives from almost every State, this document became an important instrument that guarantees human rights. Its purpose was to promote human, civil, economic, and social rights as a basis of "freedom, justice, and peace in the world." The document recognizes that "the inherent dignity and the equal and inalienable rights of all members of the human family is the foundation of freedom, justice, and peace in the world."

After The Universal Declaration of Human Rights, there have been several other important documents on human rights. These include the Convention on the Elimination of All Forms of Racial Discrimination adopted in 1966; the document entitled Human Rights and Scientific and Technological Development adopted by the U.N. in 1982; the Convention on the Elimination of All Forms of Discrimination Against Women (1981); the United Nations Convention Against Torture (1984); the Convention on the Rights of the Child (1989); the International Convention on the Protection of the Rights of All Migrant Workers and Members of their Families, adopted in 1990 and entered into force in 2003; the Universal Declaration on Bioethics and Human Rights, UNESCO, 2005; the Universal Declaration on Human Genome and Human Rights – UNESCO; and the Convention for the Protection of Human Rights and Dignity of the Human Being with Regard to the Application of Biology and Medicine of the Council of Europe, 1997.

The Content of Human Rights

The Universal Declaration of Human Rights contains a series of Articles that set forth the various rights. These can be categorized into (1) liberty rights: every person is born free, has the liberty of movement, of expression, of association, of belief; (2) security rights, such as protection of the human being against any cruel punishment or treatment and against torture; (3) social rights, such as the right to create a family, the right to work, the right to education, the right of a living standard adequate for health, the right to participate in the cultural life of the community; (4) political rights, which include the right to participate in political life; (5) judicial rights, encompassing the right to be considered a human being before the law, the right to a fair trial, and the right of presumed innocence; and (6) equity and equality rights, such as protection against discrimination.

Although the content of human rights encompasses a large number of rights, it has been criticized for its vague character and for its lack of provisions concerning the actual involvement and responsibility of States for the protection of the rights, such as the right to education, the right to a living standard adequate for health, and the nondiscrimination rights. Instead, these rights may be considered negative rights, meaning that although they exist, their protection needs no State action; consequently, they are well stipulated but there is no State action specified for their protection. At the same time, because of this absence of concrete action provisions, they are considered vague. And last, but not least, it has been argued that these rights must be prioritized, but there is no consensus on which should be considered a priority.

The Impact of Human Rights upon Immigrants

Several recognized rights may impact on immigrants' lives more immediately than others. These include the right to nondiscrimination, the right to free movement across countries, the right to seek political asylum, and the equal right to social life, cultural life, education, health, and fairness.

Although legal immigrants should enjoy the same rights as native-born citizens, some authors argue that immigrants represent a population that is rejected by both their native country and the country of immigration. For example, although the right of free political expression is a fundamental human right that encompasses the right to vote, during recent history of the 1980s, not all of the European states respected this right. Sweden recognized and respected this right for immigrants, but France and several other European countries did not adequately recognize it for immigrants.

In order to ensure that human rights are respected for all populations, especially those considered to be at a higher risk for discrimination, many countries have created agencies and commissions to address the problems of discrimination against foreign immigrants. Such examples may be seen in Australia. There, the Australian Ethnic Affairs Council functions as an advisory organism for The Minister for Immigration and Ethnic Affairs in issues regarding immigrants' integration in the community. The Multi-Cultural Resource Centre opened by the Australian Government deals with immigrants' needs and provides information related to the availability of benefits at the national and local levels. In Norway, the Norwegian Foreign Workers' Association deals with the protection of immigrants rights. In Belgium, there has been a tradition in this area since 1952.

The Right to Health

The right to health is a fundamental one, having important implications for every person's life. Starting with "the right to life" and continuing with the prohibition against slavery, torture or any cruel, inhuman or degrading punishment and with the right "to a standard of living adequate for the health and well-being," it can be seen that each of these provisions has a health impact. The Universal Declaration of Human Rights does not articulate a specific "right to health" or contain provisions that require States to protect this important right. Article 25 refers to "a standard of living adequate for the health and well-being" that includes "food, clothing, housing and medical care and necessary social services" and also "the right to security in the event of unemployment, sickness, disability, widowhood, old age or other lack of livelihood in circumstances beyond his control." The status of this right seems ambiguous; in fact, literally "the right to health" does not exist and any legal forum cannot give "health" to a person. To better understand the meaning of "the right to health," one must place it in the 1948 context. When originally declared, this right referred to the definition of health given by the World Health Organization in the introduction of its constitution on 22 July 1948: "Health is a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity. The enjoyment of the highest attainable standard of health is one of the fundamental rights of every human being without distinction of race, religion, political belief, economic or social condition."

This perspective has been further articulated in several other documents, such as those promulgated by the International Labor Organization, the U.N. Commission on Human Rights, and UNESCO. The UNESCO Universal Declaration on Bioethics and Human Rights embraces the notion of social responsibility as a factor in the actual involvement of States in promoting and protecting the right to health. The document states in Article 14, paragraph 1, "The promotion of health and social development for their people is a central purpose of governments that all sectors of society share." In addition, it articulates the importance of access to quality health care, because "health is essential to life itself and must be considered to be a social and human good." Like other documents, it underscores the importance of various factors that are determinants of health, such as adequate nutrition and water, living conditions, poverty, and illiteracy. It starts from the premise that these lifelong determinants influence health in a stronger manner than the biological and physical factors. This hypothesis is sustained also by the World Health Organization Commission on Social Determinants of Health that estimated the influence of biological factors on health as 15% and of physical factors at 10%.

All of these social determinants of health must be discussed in relation to the economic status of a person, because a low income often means a lowered quality of living conditions and reduced access to adequate medical care. Although discrimination is said to be prohibited and although every human being should enjoy human rights and, accordingly, should have the right "to a standard of living adequate for the health and well-being," inequities in this area are growing often due to poverty and a lack of access to adequate health care services. It is true that most of the documents on human rights articulate the special protection needed for certain categories of persons, e.g., "the right to security in the event of unemployment, sickness, disability, widowhood, old age or other lack of livelihood in circumstances beyond his control," but the reality is that more than one billion people live in extreme poverty, without access to minimum standard of living conditions.

From this perspective, several categories of persons distinguish themselves as vulnerable; in this domain immigrants have a special place. Immigrants, like others, have the right to health, to education, to work, and to not be subject to discrimination. However, immigrants may represent a cheap working force because they often receive less for the same job as a native-born citizen. The Soros Foundation's 2008 study *Immigrant in Romania: Perspectives and Risks* underscores the fact that foreign immigrants in Romania are an easy target for some employers, who are willing to make a good profit with a cheap work force. Factors contributing to this situation include immigrants' cultural and language differences, a lack of labor union representation, and a lack of information regarding immigrants' rights. Immigrants' low income influences their living conditions, and their access to health care (insured/uninsured status). Immigrants' access to adequate medical care may be affected not only by their economic status, but also by language differences, their legal/illegal status, and cultural differences. According to Article 2 of the Human Rights' Universal Declaration, discrimination on the basis of race, color, sex, language, religion, political or other opinion, national or social origin, property, birth or other status is prohibited, but discrimination occurs, nevertheless.

Another important aspect that interferes with immigrants' right to health is the political aspect. The report by the Office of The United Nations High Commissioner for Human Rights in collaboration with World Health Organization, on the right to health underscored the fact that States are unwilling or unable to provide the same level of medical care to immigrants as to their native-born citizens. Most of the States decided that their obligations toward foreign-born citizens in terms of medical care are limited to "essential care," or "emergency health care" domains that may vary from state to state, creating disparities and inequities in medical practices. It is that ambiguous paradox of the "right to health" taken literally as such and undermining its fundamental, inalienable, and absolute character.

The same report draws attention to identified difficulties of immigrants, especially those of the illegal immigrants with respect to their right to health. Their access to health care is limited by two important factors: they are generally inadequately covered by the State health care system and they usually cannot afford insurance. Their illegal status limits their ability to access medical care due to fear of being reported to authorities, they have less access to medical information than do native-born citizens, and their working conditions might be unsafe or unhealthy. Female working immigrants, as well as trafficked persons, may be exposed to sexual abuse and violence, and shelters for undocumented immigrants may have unhealthy conditions that could facilitate disease transmission.

The general recommendation 14/2000 of The Committee on Economic, Social and Cultural Rights, followed by the general recommendation 30/2004 (on non-citizens on the right to the highest attainable standard of health) of The Committee on the Elimination of Racial Discrimination, stipulate the involvement of States in respecting the right of non-citizens to an adequate standard of physical and mental health care. This also means that the State involvement should not be reduced only to "essential care" or "emergency care," but should be extended to provide immigrants with access to preventive, curative, and palliative health services. Additionally, the report stresses that sick asylum seekers or undocumented persons, as some of the most vulnerable persons within a population, should not be denied their human right to medical care.

Another important document regarding immigrants' right to health is The International Convention on the Protection of the Rights of All Migrant Workers and Members of Their Families. Article 25 of this document stresses that immigrants should have equal treatment with natural-born citizens, including safety and healthy working conditions. Also, Article 28 of the same document stipulates, "Migrant workers and members of their families shall have the right to receive any medical care that is urgently required for the preservation of their life or the avoidance of irreparable harm to their health on the basis of equality of treatment with nationals of the State concerned. Such emergency medical care shall not be refused them by reason of any irregularity with regard to stay or employment."

Though the framework of the right to health is encouraging for the protection of this right, many States' national provisions interpret and implement differently the terms "emergency medical care" or "essential medical care." These terms are usually defined in a number of ways that create the bases for disparities and inequities.

The goals of the 2005 United Nations' Millennium Project include the eradication of extreme poverty and hunger, the achievement of universal primary education, the promotion of gender equality and empowerment of women, the reduction of child mortality, the combating of HIV and AIDS, malaria and other diseases, the sustainability of the environment, and the establishment of a global partnership for development. Although these seem very promising, there still remains the need for significant action in order to ensure that every human benefits.

Conclusions

Human rights represent a set of norms that every person could claim by virtue of one's status as a human being. These rights are fundamental, absolute, and inalienable. Though they are well articulated and every person should enjoy them, regardless of race, sex, religion, or other factors, some of them may lack application because the documents have only proclaimed them, without requiring that States incorporate them as part of their protection for all citizens. This is why since their first proclamation many other regulations and treaties and conventions at the international level have appeared, in order to articulate more the need for their protection. Though major progress has been made, sustained efforts are needed to assure the protection of human rights for all human beings, especially for vulnerable populations such as immigrants.

Hwa-Byung

Kristi Ninnemann
Department of Anthropology, Case Western Reserve University, Cleveland, OH, USA

Hwa-Byung translates into English as anger or fire disease. Often termed a Korean folk illness, it is characterized by physical and psychological symptoms that arise as the result of chronically suppressed anger. Reported most frequently by women, *hwa-byung* is believed to develop through an interaction of culturally supported emotional repression, avoidance of conflict and external expressions of anger, and the experience of chronic hardships and oppression.

Traditionally, Korean culture discourages outward displays of conflict and emotion, particularly those labeled as negative, with a cultural emphasis placed on personal temperance and the maintenance of harmonious interpersonal relationships. Consequently, negative emotions, such as anger, disappointment, and sorrow, are internalized. *Hwa-byung* may develop due to the accumulation of internalized emotions and their interaction with the hardships many Korean women report, such as stressful familial and marital relationships, domestic abuse, discrimination, inequity, and abject poverty/deprivation. Accordingly, *hwa-byung* has been suggested by some to be a culturally sanctioned idiom of distress through which Korean women are able to express their suffering. The prevalence of *hwa-byung* has been found to be highest in middle-aged women who have emigrated from Korea. It is believed that the psychological stress and difficulties that often accompany the immigration process are correlated to this increase in cases.

There are multiple symptoms associated with *hwa-byung*. As this is a complex and varied illness, persons with *hwa-byung* present with individually unique clusters of symptomotology and may report experience through a combination of biomedical and lay/cultural terminology. Classic somatic symptoms of *hwa-byung* include the sensation of a traveling epigastric mass that may interfere with respiration and/or digestion; disturbances in the body's ability to regulate temperature, often experienced as an accumulation of heat felt in the neck, face, or head, and/or intolerance to environmental temperature changes; gastrointestinal symptoms including anorexia, stomach upset, constipation, and/or diarrhea; cardiac complaints such as heart palpitations, irregular heartbeat, and/or heart-pounding; and reports of diffuse, chronic muscle pain. Psychological symptoms of *hwa-byung* include anger, insomnia, anxiety, panic, and depression. Individuals experiencing symptoms of *hwa-byung* may seek treatment from a variety of providers including traditional healers, physicians, mental health professionals, and religious leaders.

Hwa-byung is classified as a culture-bound syndrome in the fourth edition, text revision of the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders* (*DSM IV-TR*), and it is referenced, but not independently listed, in the ICD-10 *Classification of Mental and Behavioral Disorders.*

Hypertension

Oana C. Stinga
University of Medicine and Pharmacy "Gr. T. Popa", Iasi, Romania

Hypertension or high blood pressure is a multifactorial disease. The implications of this disease in cardiovascular diseases is significant (i.e., coronary heart disease, congestive heart failure, ischemic and hemorrhagic stroke, renal failure, peripheral arterial disease, and even cerebral palsy).

Definition

Hypertension is a chronic medical condition in which registered values of blood pressure above 140/90 mmHg is considered to be hypertension.

(The normal value of blood pressure for an adult is considered to be around 120/80 mmHg; the upper number is called systolic and the lower number is called diastolic.) When the cause of hypertension is not medically known, it is called essential. When hypertension is medically proved to be caused by another condition, it is called secondary (i.e., kidney disease, pheochromocytoma, and others).

Epidemiology

This disease is wide spread in all populations except for some isolated populations living in primitive conditions, unexposed to factors such as industrialization, processed food, and others. This condition affects mostly adults, but it can be present in children also. The criteria for diagnosis of hypertension in children is based upon their age, with systolic and diastolic numbers approaching adult measurements when children are near adulthood.

Considered to be an age-related disease, high blood pressure is often associated with growth and maturation; it is usually diagnosed in the second decade of life. Both men and women seem to develop this condition, with preponderance toward men.

Signs and Symptoms

In mild or moderate forms, symptoms of hypertension are difficult to recognize or may be completely illusive. In more serious forms, high blood pressure values are associated with headache, somnolence, confusion, visual disturbances, and nausea and vomiting; in infants and neonates, failure to thrive, seizure, irritability or lethargy, and respiratory distress; in children, hypertension may cause headache, fatigue, blurred vision, epistaxis, and Bell's palsy.

Various individual features and factors have been associated with hypertension. Among risk factors: sedentary lifestyle, obesity (in individuals with a body mass index greater than 25), salt (sodium) sensitivity, alcohol intake, low calcium intake, and vitamin D deficiency. It is also related to aging and to some inherited genetic mutations. Family history of hypertension increases individual risk of developing the disease. Kidney diseases can cause disruption of renin and aldosterone equilibrium, and can predict the development of hypertension in the future. Sympathetic nerve overactivity, insulin resistance, and metabolic X syndrome (a condition which associates obesity, diabetes, dislipidemia, and arterial hypertension present in the same individual) are often associated with hypertension, and it is thought that high blood pressure levels are caused by these conditions. The external factors thought to cause this hypertension are smoking and an unhealthy diet (i.e., a diet with a high content in salt and/or saturated fats).

Secondary hypertension can also mean a disease associated with renal disease, Cushing syndrome (a condition associated with high blood levels of cholesterol), pheochromocytoma (condition in which a tumor releases increased quantities of epinephrine and norepinephrine), and coarctation of the aorta. Some drug treatments are known to induce hypertension (e.g., oral contraceptives, non-steroidal anti-inflammatory drugs such as ibuprofen), and steroids (e.g., prednisone). Some of the antihypertension drugs (beta-blockers and clonidine) are associated with rebound hypertension when they are withdrawn.

The Framingham Study launched by NIH in 1948 found that cardiovascular conditions correlate with high blood pressure, high cholesterol, smoking, diabetes, and obesity. Race and ethnicity seem to also be involved in the development of hypertension. High blood pressure is particularly more common among African American population than non-Hispanic Whites. The number of strokes and heart attacks are increased in the African American population.

Other risk factors for high blood pressure are within a person's control. For instance, lifestyle changes (i.e., an individual can improve his health by reducing the salt and/or fat intake, renouncing to smoke and sedentary habits, managing stress, reducing alcohol consumption, losing weight) may reduce blood pressure levels with 5–10 mmHg. Social stress is another factor that seems to be associated with an increased blood pressure. Since social stress represents a risk factor for developing high blood pressure, it is not uncommon for doctors to find elevated levels of blood pressure in the immigrant population.

Psychosocial stress in this category of the population takes various forms. Family separation, acculturation issues, and lack of health care or lack of access to funds for health care are only some of the psychosocial stress factors. Studies have documented that race and income levels along with limited access to health care system for this category of individuals strongly impacts on their health status. Illegal immigration is often associated with the lack of health insurance and the knowledge of immigrants about their health rights.

According to a study developed by Yechiam Ostchega and others, it was discovered that not only does age strongly correlate with hypertension, but also hypertension has a higher prevalence in the non-Hispanic Black population than the non-Hispanic White and Mexican-American populations. The prevalence was also significantly higher for the non-Hispanic White population compared with the Mexican-American population.

The risk factors mentioned above are not the only ones responsible for high values of blood pressure. Hypertension is frequently found in adult Black populations living in developed countries, and especially located in dry, hot climates and urban areas. Physiologically, this is thought to be due to a certain particularity of this population in transporting sodium from diet through the body.

Similar to social stress, some individuals' physical medical exams mislead doctors in their diagnosis if the patient registers increased blood pressure when periodic assessments are made. "White coat hypertension" represents no real threat to patient's health and does not require treatment.

In conclusion, hypertension is a multifactorial preventable and treatable disease which poses many difficulties in terms of health care due to its cardiovascular complications. Some categories are disadvantaged due to lack of full access to health care services. Between these categories, we can unmistakably name immigrants.

Hypothermia

Beatrice Gabriela Ioan
Department of Legal Medicine, Medical Deontology and Bioethics, University of Medicine and Pharmacy "Gr. T. Popa", Iasi, Romania

Hypothermia refers to the clinical condition in which the central body temperature drops below 35°C (95°F). The condition may occur in cold climates, during winter in temperate climates, and also in warm climates, especially in elderly or in young children.

Depending on the central body temperature, hypothermia can be mild (35–32°C, or 90–95°F), moderate (32–28°C, or 82–90°F) or severe (below 28°C, or below 82°F). Mild hypothermia is accompanied by shivering, which generates heat, one of the most important protection mechanisms against the decrease of central body temperature; mental confusion; slurred speech; shortness of breath; and increased heart rate. As the central temperature decreases, the individual's ability to combat hypothermia is diminished and the condition may progress to moderate hypothermia. In moderate hypothermia, shaking gradually disappears, breathing decreases, and the victim appears drowsy. Finally, in severe hypothermia the victim shows a marked decrease in brain activity, heart rate and breathing, and ultimately dies due to heart failure.

There are a number of risk factors for hypothermia. Older people can become hypothermic because of their poor economic conditions or mental deterioration, which expose them to inadequate conditions of shelter, heating, clothing, and food. Children are at increased susceptibility due to their big weight/body–surface ratio, which accelerates heat loss. Acute alcohol intoxication, which causes vasodilatation and increases cutaneous heat loss, phenothiazine intoxication, and various underlying conditions and diseases such as malnutrition, diabetes mellitus, and myxedema may also increase risk.

Significant human costs may arise as in conjunction with individuals' attempts to illegally cross international borders. Immigrants are exposed to numerous hazards, including those due to environmental factors such as extreme temperatures. As an example, the transport of

African immigrants from Sub-Saharan Africa (particularly from Senegal, Mali, and Ivory Coast) to Tenerife and Canary islands of Spain, in "Cayucos" (large vessels, of about 30 m length and 3.5 m width, which can fit up to 180 people) requires 7–10 days. During this time, migrants may have to endure extreme cold, extreme heat, dehydration, immobility, and overcrowding. A study conducted during 2005–2006 showed that 649 out of 17,164 illegal immigrants who arrived on the coast of Tenerife Island in 229 "Cayucos" needed emergency medical care (477 on site and 202 at the hospital). Most of those who received medical care were suffering from hypothermia, hypoglycemia, and dehydration. The relatively small number of people who needed medical care was largely due to the fact that they were young and theoretically healthy. To respond adequately to this genuine crisis of "Cayucos" in the Spanish Canary and Tenerife Islands, ERIE services (Immediate Emergency Response Team consisting of: a coordinator, a physician, a nurse, a social-cultural mediator and many volunteers) were created, in order to provide emergency medical care to illegal immigrants at their arrival.

Beginning in 1993, the US government has stepped up measures to prevent and combat illegal immigration from Mexico through the southwestern border, especially in urban areas. In response to increased security measures in urban areas, illegal immigrants are trying to cross the border in rural and remote areas, which are less guarded. The consequence is a marked decrease in illegal border crossing in urban areas but not in illegal border crossing in general. This option, however, involves an arduous journey through the desert and mountains, where the migrants are usually guided by paid smugglers (*coyotes*). During these exhausting trips, immigrants are exposed to a significant risk of death by hypothermia in the mountains or desert, extreme heat and dehydration in the desert, or drowning when crossing the Rio Grande or Rio Bravo. It has been estimated that during the period from 1993 to 1997, nearly 1,600 migrants died, 14% of them due to environmental factors, including extreme cold or heat. Eighty-five percent of the victims were men and the vast majority (62%) was between 20 and 30 years of age.

Sometimes the immigrants are abandoned by the smugglers, and consequently face greater risks. For instance, in May 2001, 14 migrants died in the Mexican desert near Yuma, Arizona, having been abandoned by their guide. However, the increased risk of death does not significantly influence the number of illegal immigrants trying to cross the border between Mexico and the US. Estimates suggest that the number of migrants being smuggled from Mexico into the US increased from 70,000 in 1992 to 237,000 in 2000.

The fate of immigrants trying to cross the border illegally drew attention from human rights activists worldwide. They argue that the manner in which these immigrants are treated is a violation of human rights. Human rights activists have shown that increased border security will not deter illegal immigration but will expose the immigrants to greater risks.

Identity

Cristina Gavrilovici
Department of Legal Medicine, Medical Deontology and Bioethics, University of Medicine and Pharmacy "Gr. T. Popa", Iasi, Romania

Identity formation is the process of distinct personality development. The concept of identity encompasses personal, social, cultural, political, and ethnic identities. It also refers to sexual orientation and gender identity.

On a personal level, identity has been conceptualized as a prominent aspect of self, functioning to give meaning to people and their self-images. When referring to social identity, this is often conceptualized as social roles, helping to explain how social position influences one's sense of self; it is gained from memberships in various social groups, including gender, age, profession, vocation, race, and religion. Cultural identity is a person's self-affiliation (or categorization by others) as a member of a cultural group, while national identity relates to belief in membership of a nation. Features of national identity include common myths, culture, and a homeland. Ethnic identity is one's identity or sense of self as a member of an ethnic group as well as one's thinking, perceptions, and feelings that are part of being a member of that group.

From a sociological standpoint, identity has four constructions: personal, relational, enacted, and communal identities. *Personal identity* is an individual's self-concept or self-image. It exists at the individual level of analysis, as a characteristic of individuals. *Enacted identity* is an individual's performed or expressed identity. People enact their identities and exchange the enacted identities in communication. *Relational identity* has four levels. First, an individual develops and shapes his/her identity partially by internalizing how others view him/her. Second, an individual identifies himself/herself through his/her relationships with others, such as someone's spouse and someone's friend. This is another kind of relational identity. Third, identities exist in relationship to other identities. Since people have multiple identities, they exist in relation to each other. As an example, an individual may simultaneously hold identities as a parent, a lover, an adult child, and an attorney. Fourth, a relationship itself can be a unit of identity. A couple, for instance, can establish a relational identity. The communal layer is a characteristic of the group or collectivity. This concept is similar to "collective memory" and ethno-linguistic identity. Although these four frames of identity may be considered independently for analytic purposes, they are not really separate from each other.

Identity has been also described as a key explanatory factor for poorer health. Identity is a multidimensional construct, consisting of three fundamental dimensions. Centrality refers to the extent to which one's ethnic identity is a core part of his or her self-concept. Private regard is one's affective evaluation of his or her ethnic group, while public regard refers to one's perception of how others view one's ethnic group. Individuals with positive identities (higher scores on centrality and private regard) are more likely to engage in health behaviors than are individuals with negative identities.

Two potential variables affect the relationship between identity and health: the individual's coping style and his or her identity expression. Having fewer opportunities to express one's ethnic identity than one would ideally like (expression discrepancy) is likely to lead to feelings of frustration and stress. The acceptance of one's ethnic group leads to positive self-esteem because it anchors one's relatedness to others.

When individuals migrate from one country to another, it is likely that their cultural and ethnic identity will change. When cultural groups come into contact, there is a transfer of schemes and values in both

Sana Loue & Martha Sajatovic (eds.), *Encyclopedia of Immigrant Health*, DOI 10.1007/978-1-4419-5659-0,

directions. This conception of *reciprocal* influences on cultural identities, leading to some degree of *bicultural* identity, is quite recent and it differs from an older position that viewed cultural adaptation as a unidirectional, acculturative process whereby immigrants would adapt their behavior and attitudes toward those of the host society. This unidirectional view derived from the erroneous belief that cultural changes resulted from the modification of a "primitive" culture through contact with a more advanced culture. With the process of globalization, it can be expected that most people around the world will develop a different form of bicultural identity, combining their local identity with an identity linked to the global culture.

These cultural and ethnic identity variations related to migration, either forced or voluntary, may impact upon individuals' mental health and both psychiatric and general medical services utilization. Cultural differences in definitions of normality and abnormality, as well as differences in explanations and presentation of mental illness, exemplify these variations.

A strong sense of ethnic identity may protect against mental health problems. Vulnerability to depression may increase for groups that face social barriers related to language and may be exacerbated by life-changing events such as immigration, which can threaten one's sense of self and mental health status. Previous research suggests that identity issues have significant implications for depression. Depression can be caused by expressing a socially desirable self while silencing an authentic self or when behaviors or ideas, including self-concept, are not reinforced by others.

Korean immigrants, who represent a recent and one of the fastest-growing minority groups in the USA, face various challenges dealing with cultural differences and outgroup immigrant status. Asian Americans, in general, tend to maintain their cultural values longer than other ethnic immigrant groups. Korean immigrants are reported to have relatively higher levels of depression compared to other ethnic groups. For instance, they reported almost twice as many depressive symptoms than did Filipino Americans, Japanese Americans, and Chinese Americans. Depression in Korean Americans may relate to several sociodemographic stress factors, including high unemployment rates, limited English-speaking abilities, and the tendency of Korean Americans to work in low-prestige jobs in comparison with other Asian groups, perhaps due to their limited English skills. Increased depression in men has been found to be significantly associated with decreased family satisfaction, lower job satisfaction, lower individual earnings, and more hours at work. Depression in women has been linked to decreased family satisfaction, less church affiliation, lower job satisfaction, and higher individual earnings. As a result, many Korean immigrants find their identities challenged in their everyday interaction with members of other ethnic groups. Without the requisite coping skills, these identity issues can be particularly problematic among members of this demographic group.

A higher level of acculturation has been associated with less acculturative stress, which, in turn, is associated with lower rates of depression. It has been found that language use and interpersonal associations are mediating influences of stress. For the dimension of acculturation that involved cultural identity and adherence to homeland traditions and values, greater assimilation to US culture resulted in higher depression scores. Maintaining traditional Korean practices and values in the US cultural context carries mental health risks. One way of understanding the mediation process in these data is to consider language-based acculturation as preceding identity-based acculturation. Studies have shown that after an average of 5–6 years in the USA, Asian immigrants showed only a moderate level of acculturation to the host culture, in that their language use, interpersonal relationships, subjective identity, and cultural practices were more likely to reflect their Korean heritage than the US culture.

Immigration is a stressful process for uprooted people adjusting to a new society in Europe as well. Research findings relating to Irish immigrants indicate that at every social level, the health and well-being of both first- and second-generation Irish immigrants are seriously compromised in comparison with both native English and non-emigrating Irish people. A number of specific explanations have been proposed: less healthy people choose to emigrate in the first instance; that first generation Irish engage more in health-compromising behavior such as heavy smoking and drinking than native equivalents; that Irish immigrants hold more fatalistic attitudes toward health and are inclined to attribute health status to external factors and, as a consequence, they are reluctant to acknowledge a developing illness and less inclined to take early counteractive measures. However, one of the most frequent explanations for the decreased well-being among Irish immigrants concerns problems in forming and maintaining a positive ethnic identity. The importance of identity is reinforced by the fact that many Irish immigrants possess inferiority feelings compared with host nationals, due in part to their history of having been colonized until relatively recently.

It has been found that the ethnic identity of immigrants' children forms at an early age, prior to adolescence. Thus, second-generation children of different ethnic groups who are living in the USA showed a high degree of awareness of their ethnic heritage and identified with being both part of their parents' culture of origin and as being American. In a study of children of first generation immigrants from three ethnic groups, all three groups reported similar levels of ethnic identity "centrality," and all reported positive feelings of pride regarding being a member of their ethnic group. Overall, older children demonstrated a greater amount of ethnic identification and exploration, and higher degree of ethnic pride. For all children, older age was associated with greater preferences to play with children of other ethnic groups. "Ingroup" social preference was positively correlated with "outgroup" social preference, demonstrating the positive connection between these two social processes during middle childhood. Thus, having a strong ethnic identity is not associated with prejudices against other groups, as some past scholars have feared.

In conclusion, a positive relationship has been demonstrated between identity and tradition-based acculturation and depression, indicating that the abandonment of the immigrants' identity and traditions may result in increased depression. Language-associated acculturation may increase depression by encouraging the abandonment of homeland identity and traditions.

Illegal Immigration

Cristina Cazacu Chinole
Center for Ethics and Public Policies,
Bucharest and Iasi, Romania

"Illegal immigrant," "undocumented migrant," or "illegal aliens" are some of the terms used to describe the immigration status of the people who do not have the required documentation that proves they are legally entitled to work, visit, or live in a certain country. "Illegal immigrants" are those who either do not have the proper visas to be in a country legally or have entered in the country legally but did not return to their native countries when their visas expired. For example, former students who do not leave a foreign country when their student visa expires fall into the latter category. Another category of illegal immigrants are those who have violated the terms of entry in a country, for example, by working without authorization, failing to attend school if admitted for that purpose, or by engaging in illegal activities. Rejected asylum seekers may also be thought of as "illegal immigrants."

Therefore, the spectrum of illegal immigration is very wide. Each State has the power to decide where illegal migration begins and ends. The restrictions imposed on entering and leaving a country, as well as the legal conditions governing access to the labor market, coexist in each country, with a lower or higher degree of tolerance on illegal immigration.

Illegal immigration often triggers the fears of governments and citizens of the target countries, as it is sometimes seen as a threat to public order and a burden to education, health care, and welfare systems. Yet, numerous studies show that the most developed nations, where the majority of illegal immigrants are looking for a better life, depend on and even thrive because of the contributions of illegal workers. Agriculture and construction and many services as cleaning and caring for young and elderly persons rely heavily on the cheap and abundant workforce provided by illegal immigrants. However, there are many who argue the opposite: that illegal immigration poses nothing other than trouble to national economies.

The exact dimension of illegal immigration is difficult to establish; according to the International Organization for Migration (IOM) data, there are 20–30 million unauthorized migrants worldwide, comprising around 10–15% of the world's immigrant total number. The majority would leave their homes from "developing" or "Third World" countries to go to developed countries on an "unauthorized," "undocumented," or "illegal" basis. In order to get into such a country, illegal immigrants may use falsified travel documents or permits obtained under false pretences, or use clandestine transportation or other methods to cross the border illegally.

Illegal or unauthorized immigrants are a heterogeneous group. Yet, there is a common factor: wherever they may be, they all have health needs but are excluded, in part or in full, from the systems of health care promotion, protection, and provision that are available for the local citizens. The provision and cost of health care for illegal immigrants is an issue of debate and concern for most of the EU Member States, the USA, and other developed nations. The most common arguments used to justify this exclusion are that national health care systems, whether publicly financed or privately run, are already strained and overburdened, and, because illegal migrants are not part of the social contracts linking States and their constituent citizens, there is no duty toward their health care needs.

Besides that, undocumented migrants, as well as asylum seekers, face practical barriers to access effective health care due to fear, lack of information, poverty, language, cultural constraints, etc. Relatively little is known, though, about the situation of undocumented migrants as the majority of national surveys do not take them into account and there is a lack of global and national statistics about their living conditions, health, and access to care.

Existing research, as fragmented as it is, demonstrates that with some minor exceptions, in most developed countries illegal immigrants are usually not entitled to receive medical care from public services, except in cases of emergencies. In the USA, illegal immigrants are not covered under the new health care plan, and they are not eligible for Medicaid. The situation is slightly different in Europe, where most EU Member States would offer health care services for children and pregnant women. In some countries medical care may be offered to illegal aliens by "alternative health care providers" such as nongovernmental organizations that are supported with public funds. Yet, such organizations, where available, cannot provide a solution to systemic problems.

Illegal Immigration Reform and Immigrant Responsibility Act of 1996 (U.S.)

Carl S. Hacker
School of Public Health, University of Texas Health Science Center, Houston, TX, USA

The United States has a long history of dealing with immigration issues through legal actions. One of the enumerated powers of the US Congress is to "…establish an uniform rule of naturalization…" (US Constitution Article I, Section 8, Clause 4). The first Congress promulgated the initial statute, "*The Naturalization Act of 1790*, which limited naturalization to free white persons of good moral character." The US Congress has pursued several policies over the following 220 years as it promulgated these "uniform rules of naturalization." The statutes that were followed varied with how persons (aliens) from certain countries and regions were favored or disfavored for eligibility of admission to the United States, and consideration for citizenship.

The 89th US Congress adopted the *Immigration and Nationality Act Amendments of 1965* (Public Law 89–236), codified in Title 8 of the US Code, that defines a lawfully admitted noncitizen or alien as either a permanent immigrant or a temporary nonimmigrant. A lawful permanent resident receives a document (card) noting this status and is eligible to work in the US and may later apply for US citizenship. The nonimmigrant can be in the United States for many different reasons and receives one of several kinds of visas. Nonimmigrants are not eligible for citizenship, but they may later apply for permanent immigrant status. All other aliens in the United States are here illegally.

The 104th US Congress began to attend to the complex matters that were emerging with illegal immigration and other immigrant matters in the *Illegal Immigration Reform and Immigrant Responsibility Act of 1996* (Public Law 104–208). This legislation emerged in response to many concerns about the number of illegal immigrants, their economic contribution or lack thereof to the nation's economy, and a concern about employment of US workers. This legislation has six titles. Title I provides for improvements of border control, facilitation of legal entry, and interior enforcement. Title II provides for enhanced enforcement and penalties against alien smuggling and deterrence of document fraud. Title III revises procedures and grounds for removing inadmissible and deportable aliens. Title IV concerns the enforcement of restrictions against employment. Title V concerns restrictions on benefits for aliens. Title VI includes several miscellaneous provisions of the Act. Highlights of each Title are noted in this suggestive sampling, not a critical analysis, of what is in the law. Examination of the law using standardized browsers offers a comprehensive and detailed review. Also, keep in mind that what the US Congress says it wants done and what it pays to have done may not coincide.

Each Title reveals with greater specificity the authorizations provided in the law. *Title I.* In this Title, the Congress uses its spending power to increase resources at the border by hiring more agents and support persons and direct how they should be deployed. It authorizes the construction of fencing and improvement of roads on the border near San Diego, California. It authorizes the acquisition of equipment that would help with detection and interdiction of illegal immigration into the United States. It asks for improved border crossing identification cards with machine readable biometric identifiers.

Civil penalties are set for illegal entry and criminal penalty for high-speed flights from immigration check points. Funds were to be appropriated to apply to nationwide fingerprinting of apprehended criminal and illegal aliens.

Funds are to be made available to have the personnel needed at border crossings during peak hours to minimize delays. Pre-inspection stations were to be added to those in existence. Additional immigration officers were to be provided to assist foreign air carriers with detecting fraudulent documents.

The Attorney General is authorized to enter into agreements with a State or any political subdivision of a State which the Attorney General determines to be qualified to perform the function of an immigration officer in relation to the investigation, apprehension, or detection of aliens in the USA.

Title II. In this Title, the Congress defines several federal crimes related to alien smuggling and specifies penalties. Wiretapping is authorized, with the expected IV Amendment limitations. An increased number of Assistant United States Attorneys is provided to handle the expected increase *in alien crimes* caseload. Increased criminal penalties are set for fraudulent use of government-issued documents and other prohibited activities under federal law (involuntary servitude, for example).

Title III. In this Title, the revised procedures for removal of an alien are laid out. Aliens who are in the USA without authorization (e.g., a "green card" or visa) are treated as not admitted. The Title lays out provisions dealing with criminal aliens including removal of aliens who have unlawfully voted, incitement of terrorist activity, falsely claiming US citizenship as examples of a longer list with a range of offenses.

Title IV. In Title IV, an employment eligibility information system is established. The statute also considers the treatment of certain documentary practices as unfair immigration-related employment practices.

Title V. In this Title, several restrictions are placed on the eligibility of aliens for public assistance and benefits. An exception is the alien who is a battered wife. Social Security benefits are not available to illegal aliens. This Title describes procedures for requiring proof of citizenship for federal benefits. Using the Attorney General's guidelines, the States can develop programs to determine whether to deny driver's licenses to unlawful aliens.

Title VI. In this Title, several Miscellaneous Provisions are laid out. Asylum granted here does not convey a right to remain permanently and may be terminated by the Attorney General under specified conditions. The section discusses several considerations and definitions on the matter of asylum. There are prohibitions concerning aliens and access to educational institutions. This title criminalizes female genital mutilation. A section of the Title IV authorizes the Attorney General to transfer and convey to the Border Patrol Museum and Memorial Library Foundation, incorporated in the State of Texas, such equipment, artifacts, and memorabilia held by the Immigration and Naturalization Service to further the purposes of the Museum and Foundation.

The events of the 11th September, 2001 led to the enactment of the Homeland Security Act of 2002 (PL-107–296). This Act established the Department of Homeland Security. This Department of a Cabinet level office in the Executive Branch was charged with the mission of securing the United States from the many threats it faces. Among other matters, this Act substantially changed how immigration is handled and by whom. The Immigration and Naturalization Service was abolished, and its functions and others were distributed among three agencies. These include:

1. *Immigration and Customs Enforcement* which enforces the nation's immigration and customs laws (www.ice.gov)
2. *Customs and Border Patrol* has a mission of keeping terrorists and their weapons out of the USA. It also has a responsibility for securing and facilitating trade and travel while enforcing hundreds of US

regulations, including immigration and drug laws (www.cbp.gov)

3. *US Citizenship and Immigration Services* which oversees lawful immigration to the United States (www.uscis.gov/portal/site/uscis)

This legislation defined and specified government responsibilities, enforcement actions, and resources to implement the provisions of the law such as border crossings. Further, it detailed the restrictions of immigrants' benefits and employment, punishments and deportations criteria. In summary, this law increased restrictions on immigrants, enhanced security measures, and reinforced legal measures to control illegal immigration to the United States.

Immigrant Health Disparities

Mark Edberg[1], Sean D. Cleary[2], Amita Vyas[1]
[1]Department of Prevention and Community Health, School of Public Health and Health Services, The George Washington University, Washington, DC, USA
[2]Department of Epidemiology and Biostatistics, School of Public Health and Health Services, The George Washington University, Washington, DC, USA

Introduction: Health Disparities and Immigrant/Refugee Populations

While the issue of ethnic health disparities in general has been discussed extensively in recent years, less attention has been focused on disparities with respect to immigrant and refugee populations. Yet it is widely acknowledged that the reduction or elimination of ethnic health disparities presents a key and continuing public health challenge. Globally, there is a vast difference in life expectancy and burden of disease between people in wealthier and poorer countries. In the USA, reduction of health disparities was encoded as the second major goal of *Healthy People 2010*, the key national planning document. There were close to 200 million immigrants worldwide in 2006, according to a UN report, where the bulk of immigrants – and refugees – came from countries with relatively high poverty rates or civil/natural crises. In the USA, the population continues to grow increasingly diverse, with much of the growth coming from immigrant populations (primarily Asian and Hispanic). While the interaction between immigration and health disparities is complex, it is clear that progress in this area is an important component of the overall effort to eliminate ethnic health disparities.

The scope of health disparities referred to above includes significant disparities pertaining to immigrant/refugee populations. Such disparities are complex: health status varies by national/ethnic group, and some immigrant groups have better health status than the general population or native-borns when they first arrive, though this often changes over time. Common health issues for immigrants/refugees include: obesity/diabetes, mental health (including depression and, for some refugees, posttraumatic stress), tuberculosis, nutritional deficiencies, intestinal parasites, chronic hepatitis B infection, and lack of immunization, though there are variations in other health and psychosocial issues, as well as cultural beliefs, among different groups. In addition, health status varies within immigrants from the same country depending upon socioeconomic circumstances.

At the same time, in what has been viewed as a "health paradox," immigrant and refugee populations often arrive in a new host country with better health status than the average native-born, yet lose this health status advantage after a number of years. There are many possible reasons – one may be self-selection for healthiness among those who emigrate (explaining better health status at time of immigration), combined with a trajectory in the host country that involves survival challenges as well as multiple barriers to health. At the same time, many immigrant and refugee groups are fleeing traumatic and severe crises, presenting yet another kind of health problem. Understanding such trajectories is a foundation for effectively addressing health problems and disparities that result.

Reasons for Health Disparities

In the USA, there have been a number of efforts to synthesize research related to the causes of health disparities in recent years, as well as an increase in funded programs specifically targeted to reducing such disparities. Some of the factors contributing to health disparities in the USA are: health care bias; racism and discrimination; lower SES as a common factor among ethnic minorities; lack of insurance; differences in knowledge; patterns of mistrust and alienation; cultural differences; language barriers; lack of culturally competent care; exposure to environmental risk; poor neighborhood conditions, including deteriorated housing, pollution, crime/violence; lack of community resources; and inadequate minority health systems, planning, and data. Several agencies in the US Department of Health and Human Services have recently developed frameworks for understanding and addressing health disparities, with a goal of fostering a systematic approach to achieving progress. Globally, the World Health Organization (WHO) Commission on Social Determinants of Health has identified many of the same kinds of issues underlying health disparities, associated with poverty, with the addition of factors such as poor drinking water, unsafe labor environments, lack of transportation, and lack of representation in governance.

For immigrant and refugee populations, a number of the factors cited above as contributing to health disparities in general are particularly salient, depending upon the population. Some of the most important factors are described in the following text.

Poverty and Lack of Resources

Research data show that a higher percentage of children in immigrant families live in poverty, compared to those in native-born families, resulting in hardships in at least three areas: food, housing, and health care. The degree of hardship is also affected by the extent to which public benefits are available to noncitizens. Some research even reports that immigrants are often staying away from public programs and assistance even when they are eligible, out of concern about the effects participation will have on their legal status or potential legal status. In addition, populations that have experienced disproportionate poverty may be less accustomed to some of the lifestyle patterns that have become commonplace among wealthier population segments. For example, *exercise* as a discrete and popular activity, not just as part of life, is a relatively recent and largely middle- or upper-class phenomenon that accompanied the rise in living standards over the past century, and the increasing separation of work from physical activity in a postindustrial, technological society.

While immigrant/refugee populations include members across socioeconomic categories, it is fair to say that these populations are over-represented in lower socioeconomic groups in host countries. Low socioeconomic status is widely associated with health risks and problems, such as nutrition, smoking, injuries, environmental pollution, lack of clean water access, unemployment, low income, family dysfunction, psychosocial stress, presence of community violence, poor neighborhood conditions, and limited recreational space. Moreover, risks such as housing segregation and lack of access to services may also be the product of discrimination against minority populations. These risks in turn have an impact on such health conditions such as obesity, violence, and substance use.

Immigrants and refugees who experience higher rates of poverty and social marginalization have little access to the interrelated systems of health, economic, and social resources. This general access-poor status generates patterns of living that tend to focus more on survival and achieving social goals (e.g., family needs, access to resources) within a very limited sphere, as opposed to maximizing health. This view is often expressed in the literature on *vulnerable populations* and on *syndemic* conditions associated with poor health. At the same time, there is also research showing that strong ethnic group identification, even in the face of discrimination and marginalization, may have some protective effect.

Lack of Health Insurance/Health Coverage and Economic Support

Access to health and social services for immigrants and refugees varies by country, and by legal status. In general, most immigrants are in working families. This does not guarantee that they will have health insurance or coverage, or enough income to afford adequate care. Immigrants who are not citizens typically face a significant lack of access to care compared to native-borns and citizens. This has serious implications for children, who may also not be covered. And of course, lack of access to care is correlated with poor health status.

Difficulties in Accessing Health Care and Treatment Bias

Financial, cultural, and language differences all make it hard for immigrants to afford care, understand medical advice, or embrace recommendations from host country providers. Even when there is access to health care, studies in the USA (by the Institute of Medicine, Kaiser Family Foundation, Commonwealth Fund, and others) have documented differential treatment for ethnic minorities in the *health care* system. Physicians and other practitioners are not always trained in competent cross-cultural care, including the provision of care to individuals with non-biomedical health beliefs or to new immigrants.

Differences in Health Knowledge and Practice

Immigrant populations may come to a host country with different understandings about health and health care. Such knowledge differences may be related to indigenous ethnomedical systems – that is, cultural systems of knowledge and practice that define the spectrum of illnesses and diseases, their causes, appropriate treatments, and appropriate treatment providers. Where these culturally specific definitions vary from Western biomedical knowledge and practice, and where immigrant and refugee populations maintain strong adherence to these definitions, a significant gap in understanding and utilization of standard medical care may result (see, e.g., Fadiman for a classic case of this kind of gap among Hmong refugees in the USA). Or, some immigrant populations may not have adequate information about available preventive and treatment procedures.

Migration and Immigration Experiences Including Acculturative Stress

Three additional and related sets of factors must be considered as unique to immigrants/refugees: home country trauma, migration trauma, and the impact of social, cultural, and economic change after arriving in the USA. Many immigrant groups – for example, Sudanese and Somalis today, Central Americans and Southeast Asians in previous years – are coming from home country situations in which there are brutal civil wars, genocide, and starvation. Moreover, the migration experience is itself dangerous and difficult for many, including persecution, pirate attacks, rape, robbery, years in refugee camps, family separation, and other experiences. Once they are in a new host country, immigrant and refugee families may then experience social role changes, generational family disruption, economic hardship, language and other difficulties. There is a high likelihood that these factors have an impact on health.

Related to these factors is the role-shifting that occurs within immigrant families. This has significant impacts on health and health care. It is often necessary for children to serve as interlocutors because they become more fluent in the host country language and familiar with public transportation and logistics. The role-shifting may in turn strain family decision making and lines of authority.

Mistrust and Other Attitudes

Mistrust of the host country health system may also exist in different forms among immigrant/refugee communities. Migrant worker populations from Central America who come to the USA, for example, are sometimes reluctant to trust government agencies and institutions (including public health clinics) due, among other things, to bad experiences during the years of civil conflict in Central America. If one adds to this a long history of dealing with health problems outside of the mainstream health care system, because of a lack of insurance or other resources to cover the cost, because of language barriers, or simply because of exclusion, it is not surprising that immigrants/refugees are often less likely than native-borns to see a doctor, even when they are in poor health.

Perceived Discrimination

Although discrimination is a complex issue with respect to immigrant/refugee communities, the negative association between perceived discrimination and health has been demonstrated across numerous studies. With respect to immigrants/refugees, the negative effects of discrimination are intermingled with political and economic contributing factors, though some research has shown that discrimination experience may be counterbalanced by the strength of ethnic identity.

Lack of Community Efficacy

One additional factor that has emerged as important is the lack of community efficacy (this can be thought of as "collective confidence") as a factor contributing to reduced access to services and to the continuation of substandard housing as well as other community conditions affecting health. Due to language barriers, unfamiliarity with supportive resources, fear, and mistrust, many immigrant community members are reluctant to take action or make complaints regarding such conditions, and may feel they cannot do anything to change the community.

Lack of Data and Systems to Address Health Needs of Immigrant and Refugee Populations

Finally, there are often few systems in a host country set up to address ethnic minority health disparities in general, and even more so for immigrant/refugee populations. Before such disparities can be addressed, they have to be identified; data need to be collected and maintained on health status and disparities among ethnic minority populations, and the data used to inform policies and programs. Currently, this is often not the case, and data that are collected may be lumped together in broad demographic categories that obscure actual conditions. In the USA, for example, peoples from Vietnam and India are both included in the "Asian" category.

Immigrant/Refugee Health Disparities as a Trajectory

The panoply of factors contributing to ethnic and immigrant/refugee health disparities most likely operates in a co-occurring and interactive fashion, as a *pathway* or *trajectory* of health for a specific population and subgroups within it. The trajectory, over time, may also shape a "way of life" with respect to health that encompasses real limitations on access to and quality of care, and higher exposure to community and environmental health risk, as well as behavior patterns and community norms that follow from expectations of high risk and limited care options, and a particular "relationship" to the health care system. For immigrant and refugee populations, such trajectories are also shaped by cultural patterns related to health, the immigration experience itself, and the dislocations and traumas that may be associated with it, as well as the socioeconomic status. The combination of *vulnerability*, *circumstance*, and *response* forms the larger set of forces that, together, create the differences in health status referred to as health disparities.

A Model for Assessing and Understanding Health Disparities Among Immigrant/Refugee Populations

Building on the general discussion of contributing factors for health disparities, below are a set of domains that can represent an *ongoing relationship between an immigrant/refugee population and the health-related system*. The term "health-related system," in this approach, refers to the combination of health services and the economic, community, social, and cultural supports necessary for their effective delivery. Health disparities experienced by immigrant/refugee populations can be seen as an outcome of these domains. [Note: This model and set of domains is adapted from Edberg et al. listed below under "Suggested Readings".] The domains are as follows:

- *Domain One – Migration Experience.* Includes the home country situation at time of emigration (crises, civil war, famine, disasters, etc.), the migration experience, including difficult or lengthy migration periods (e.g., exposure to violence, robbery, rape; extended exposure to severe conditions; and extended time in refugee camps before migration).
- *Domain Two – Social Adjustment.* Length of time in the host country, acculturation, home country social status and gender relationships, stressors created by the acculturation/adjustment process itself, regardless of migration experience. These may include: changes in social status, challenges to traditional gender roles and parental authority, change in SES (from home country), change in available social supports, and intergenerational conflict.
- *Domain Three – SES.* Economic, employment, and housing status to include economic supports for health care, such as insurance, employment with benefits, types and availability of employment, etc. (and change over time in any of these factors).
- *Domain Four – Social Supports.* Degree of cultural identity, extended family, neighborhood, cultural, employment and other important social network systems, and the degree to which any of these networks facilitate access to health care (social capital).
- *Domain Five – Neighborhood Characteristics.* Other community and neighborhood supports or barriers for health, including community organizations, social networks, recreation sites, parks, sources of healthy food (restaurants, grocery stores), etc. Presence/absence of environmental risks such as water/sanitation problems, sources of pollution, and crime and violence. The level of community efficacy fits in this category.
- *Domain Six – Health Status.* Health status (self-report), focusing on a general measure of health status (such measures could focus on health issue "clusters" that current research suggests are impacted by migration and transition – e.g., CVD/diabetes/obesity, and mental health).
- *Domain Seven – Health Knowledge and Practices.* Knowledge, attitudes, and practices with respect to health, disease, and health care treatments and utilization, including knowledge connected to indigenous ethnomedical systems and approaches to treatment and care, etc. This category should include any differences between home country health care practices and current/US practices.
- *Domain Eight – Access to Care.* Actual and perceived physical availability of and access to health care services, location of services. Actual and perceived availability of culturally competent care at service delivery settings – including language interpretation services, health care practices that recognize client cultural patterns, diverse health care staff, etc.
- *Domain Nine – Perceived Discrimination.* This is often measured as perceived level of discrimination and racism in daily experience, frequency of these experiences or events, as well as perceived acceptance, integration, and involvement in various community settings (e.g., neighborhood, school, work, health care, etc.).

These domains also set out the kinds of data that could be collected to assess a health-related *trajectory* for one or more immigrant/refugee populations, and therefore the syndemic set of circumstances, over time, that are integrated in a particular experience of health disparities. The health trajectory described through these domains incorporates a migration process beginning with a home country situation and health-related patterns, then impacted by the nature of the emigration/immigration experience itself, then impacted by an often complex and extended adjustment to life in a host country.

As a trajectory, what occurs within each of these domains may, over time, increase or decrease the "distance" between a population and the mainstream health-related system – where increased distance can be understood as *marginalization.* However, it is acknowledged that factors existing within a context of marginality may also be protective (e.g., social cohesion). Thus marginalization in itself may include positive and negative aspects. In general, however, we can hypothesize that an increase in *negative marginality*, represented by the presence or degree of negative factors in the above domains, will be associated with a decrease in health status in general and with disparities between immigrant/refugee populations and majority host country populations.

Immigrant Visa Status

Jidong Huang
Institute for Health Research and Policy, University of Illinois at Chicago, Chicago, IL, USA

In major immigrant-receiving countries, such as the United States, Canada, and Australia, immigrants who are admitted to legal permanent residence can generally be classified into three broad categories based on their types of visas at entry: (1) economic immigrants, those who migrate to seek better economic opportunities, including employer-sponsored workers, skilled professionals, entrepreneurs, and investors; (2) family reunification immigrants, those who move to reunite with one or more family members; and (3) humanitarian immigrants, such as refugees and asylees.

The selection criteria vary considerably across different visa types. While immigrants on work-/employment-related visas are selected primarily based on the skills or human capital they possess, immigrants on family reunification visas are selected because their spouse, children, siblings, or parents are permanent residents or citizens of the host country. Migrants on humanitarian visas are admitted mainly due to geopolitical, religious, and humanitarian reasons.

Because of the differences in selection criteria, immigrants differ systematically based on their visa types. As a result, the type of visa at entry has implications for immigrant health status at arrival and their long-term health adjustment in host countries. Table 1 presents immigrant self-assessed health status separated by types of visas at entry in the United States and Australia. In both countries, economic migrants reported the best health status among all three immigrant groups, while humanitarian immigrants reported

Immigrant Visa Status. Table 1 Immigrant self-assessed health status at arrival and types of visas, USA[a] (Age 18 and above) and Australia[b] (Age 15–64)

Country	Health status	Visa categories (%)		
		Economic immigrants (Independent, business skills)	Family immigrants (Concessional, preferential family)	Humanitarian immigrants
Australia	Very good	62.5	52.7	42.4
	Good	33.1	39.1	46.2
	Fair/poor/very poor	4.4	8.2	11.4
		Economic immigrants (Employment principal)	Family immigrants (Spouse of US citizen)	Humanitarian immigrants (Refugee/Asylee)
USA	Excellent/very good	85.2	75.6	73.0
	Good	13.7	20.8	20.6
	Fair/poor	1.1	3.6	6.4

[a] USA: Table 5 derived from Jasso et al. (2005)

[b] Australia: Table 2 derived from Chiswick et al. (2008)

the worst health status. In Australia, for example, the percent of immigrants who rated their health status as "Fair/Poor/Very Poor" among family migrants (8.2%) almost doubles that of economic migrants (4.4%), and among humanitarian migrants, 11.4% rated their health status as "Fair/Poor/Very Poor." A similar pattern is observed in the US data.

The selection based on health status is most intense for immigrants on work/employment visas. A few factors contribute to the better health among economic migrants. First, employers in the host country have strong incentives to sponsor healthy immigrant workers, everything else being equal, because it translates to higher productivity, less health care costs, and higher profits for employers. As a result, immigrants on work-/employment-related visas are prescreened by employers based on health status even before they obtain their visas. Second, those who are less healthy are less likely to apply for a work/employment visa to begin with. Migration is an investment in human capital whose rate of return depends on, among other things, the earnings' differentials between the country of origin and country of destination, and migration costs. Healthy persons are therefore more likely to migrate than the less healthy because the former command higher wages, and hence higher earning differentials due to the ability to work longer, more vigorously, and a longer working life. Consequently, economic migrants are favorably self-selected on the basis of health. Finally, compared with family reunification immigrants and humanitarian immigrants, economic immigrants usually migrate in their prime ages, have a higher level of education, are more prepared for moving and more proficient in the host country's language, and receive higher income. Age, education, income, and access to health care, which is facilitated by immigrant language proficiency, have been shown to be the most important determinants of health status. As a result, economic migrants tend to have better health status than other immigrant groups.

For family reunification immigrants, their primary goal is to reunite with family members, as a result, health plays a less significant role in their migration decision than it does for economic migrants. However, because of the positive assortative mating in the marriage market, and the inter-generational transfer of human capital and wealth, the spouse, children, siblings, and parents of previous migrants also tend to possess certain favorable traits, including better health. Consequently, their health profiles, though not as good as those of economic migrants, are better than those of humanitarian immigrants who are subject to the least selection on the basis of good health.

In recent years, immigrants on humanitarian visas compose about one-tenth of the total annual immigration to the United States. The majority of humanitarian immigrants are those who faced security concerns or were in need of legal protection in their countries of origin, and those who have experienced recent persecution because of their political, religious, or human rights activities. Many humanitarian immigrants are women- and children-at-risk, victims of torture or violence, physically or mentally abused persons, and persons in urgent need of medical treatment not available in their countries of origin. Moreover, administrative health requirements for obtaining a visa are relaxed for refugees. Consequently the health status of humanitarian migrants tends to be the worst among the three major immigrant groups.

In sum, there is a strong link between visa types and immigrant health. The differences in selection criteria for different types of visas result in great variations in health selection and in various human capital dimensions among immigrants, such as age, education, income, and language skills, which are the key determinants of health. The correlation between visa types and immigrant health has important public policy implications. It implies a skill-based immigration system that emphasizes migrants' educational attainment, occupational achievement, and language skills, among other productivity-related characteristics, would result in healthier immigrants and less health care costs for destination countries.

Immigration Act of 1924 (U.S.)

Bettina Rausa
Salk Institute for Biological Studies, La Jolla, CA, USA

The US government signed into law the Immigration Act of 1924, also known as The Johnson–Reed Immigration Act. This legislation was developed as a measure to control the number of immigrants entering into the USA as well as to exclude people migrating from specific countries and regions.

The Immigration Act of 1924 limited immigration visas to 2% of the total number of people from each nationality already living in the USA based on the 1890 census, inspiring the Act's more popular name, the National Origins Act. The 2% quota was actually lowered from a previously established quota of 3% based on the 1910 census. The idea of quotas was controversial. On the one hand, nativists and many politicians at the time argued that it was critical to maintain homogeneity in the USA. Those who opposed such a quota pointed out that it unfairly reduced the number of people from certain areas, such as Southern and Eastern Europe because there were fewer people from these parts of the world already living in the USA than those from Northern Europe and Britain. In addition, by going back to the 1890 census figures, it favored immigrants from Western Europe even more prominently. The other important provision of the Act was that it excluded immigrants from Asia. This did not specifically include the Japanese or immigrants from the Philippines, however. The Japanese government had voluntarily limited Japanese immigration to the USA prior to 1924 and the US Congress expected the government of Japan to honor its own promise. The Philippines were excluded because it was an American colony.

In addition to excluding entry of individuals based on national origin, certain health conditions were also considered as a basis for exclusion such as "feeble-minded, insane, narcotic drug addicts, or chronic alcoholics, those with epilepsy, psychopathic personality, a mental defect, tuberculosis, leprosy, or a dangerous contagious disease, and those whose physical defects affect their ability to earn a living." Each immigrant entering the USA had to undergo a medical examination and if determined by a US physician upon observation to be symptomatic of the health conditions on the exclusion list, he/she was separated for further examination to determine a prognosis, which may or may not have been grounds for exclusion and return to his/her country of origin.

In 1917, setting the stage for the 1924 Act, the US Congress had enacted more restrictive immigration laws driven in part by national security concerns that arose during World War I. This is also when the idea of literacy examinations for anyone over the age of 16 became mandatory. President Woodrow Wilson had vetoed a similar bill in 1922, but in 1924, the newly inaugurated President Warren Harding called a special session of Congress to pass the 1924 law. The US Department of State itself admits that the most basic purpose of the Immigration Act of 1924 was to preserve the ideal of American homogeneity. There were no revisions to the 1924 Act until 1952.

Immigration Act of 1990 (U.S.)

Bettina Rausa
Salk Institute for Biological Studies, La Jolla, CA, USA

The United States Immigration Act of 1990, signed by President George H.W. Bush, made significant changes to previous immigration legislation. The 1990 Act increased the limits on legal immigration, even compared to the significant increases allotted for by prior legislation in 1965 following the Civil Rights Era. The 1990 legislation maintained family-based criteria, that is, immediate relatives of US citizens with unrestricted numbers and placed significantly more emphasis on employment considerations for immigration, especially for highly skilled labor.

Although immigrants were considered for entry to the USA based on needed labor skills prior to 1990, this new immigration reform focused much more on making accommodations for more skill-based immigrants. Before 1990, 54,000 visas were available for occupation-based immigrants. After 1990, this number changed to 140,000. In addition, what is referred to as "diversity" immigration was introduced and designed to facilitate the entry of potential migrants that had been adversely affected by the 1965 immigration law. The diversity immigration included 55,000 visas allocated to natives of countries that had sent fewer than 50,000 immigrants to the USA over the previous 5 years. To be eligible for this particular visa, however, a prospective immigrant was required to have at least a high-school education or its equivalent, and at least 2 years of work experience or training in a particular occupation. Critics argued that this requirement would result in more overall emphasis on immigrants as skilled labor and not any other criteria which, in the end, was the major goal of the1990 law.

As intended, the 1990 immigration law amendments resulted in a significant increase in the number of employment-based immigrants. Immigrant professionals with an advanced degree increased significantly. Between 1992 and 1996, a total of 121,646 people entered into the USA from countries like China, India, and Canada via employment visas. Professionals in health care-related fields had the largest increases between 1995 and 1996, followed by other professionals like managers, executives, and those with special technical skills.

With regards to family-based immigration, or people who immigrated because they already had a close family member residing in the USA, the most notable increases were for migrants from Africa – although the total number of Africans was still small in comparison to other regions and countries. Mexico, however, was and remains the major source of immigrants to the USA with the largest immigration increases occurring between 1995 and 1996, with family-based migration accounting for almost 11.9% of those admissions.

A significant component of the 1990 Act was that it eliminated the entry ban under specified circumstances against individuals with HIV. Prior to this, those seeking entry to the USA via immigration and tested positive for HIV were excluded. The explicit HIV ban was added in 1987 in which it joined a list of other communicable diseases such as syphilis, gonorrhea and tuberculosis, originally introduced by immigration policy established in 1952. However, the lifting of the HIV ban on immigration created intense controversy, and eventually, in 1993, the US Congress conceded to pressures by those opposing the removal of the HIV exclusion and reinstated the ban. A provision was nonetheless included for immigrants to obtain discretionary wavers from the Immigration and Naturalization Service (INS). In order for an HIV positive individual to qualify for a waiver, he/she had to be "the spouse or unmarried son or daughter or the minor, unmarried adopted child of a US citizen or Lawful Permanent Resident (LPR) or have a son or daughter or lawfully adopted child who is a US Citizen or LPR; or the applicant must be eligible for classification as a self-petitioning spouse or child (including derivative children) because of abuse." Once an applicant had met these requirements, he/she was required to show that he/she would not pose more than a minimal "danger" to the public health of the USA and minimal risk for the spread of the disease. Individuals were also required to demonstrate that there would be no federal, state, or local public costs incurred by the admission of an HIV positive person. The INS issued guidelines in 1995 on how applicants could meet these caveats. The first two could be met by issuing a personal statement or a statement from a medical professional emphasizing the individual's knowledge of the disease and how it is transmitted. The third could be achieved by providing proof of private medical insurance – this one being challenging as it was unlikely that a private health insurance company would not consider HIV infection a preexisting condition, therefore excluding the individual from qualifying for insurance or, at best, excluding any treatment from the disease from an HIV positive person's insurance plan.

The HIV entry ban, even with the waivers, remained controversial with immigration and civil rights groups, along with public health professionals pushing for it to be removed from the legislation. One of the strongest points in the argument to remove the ban was that it did not prevent the spread of HIV across international boundaries. Beginning in July 2008, a series of events led to the HIV ban once again being lifted when President George W. Bush signed legislation for the President's Emergency Plan for AIDS Relief, which eliminated the provision that made individuals with HIV inadmissible to the USA. Then, in October 2009, President Barack Obama announced the final rule eliminating the ban of HIV positive individuals to the USA, effective January 4, 2010.

Immigration and Nationality Act Amendments of 1965 (U.S.)

Bettina Rausa
Salk Institute for Biological Studies, La Jolla, CA, USA

The Immigration and Nationality Act Amendments of 1965 was signed into law by President Lyndon Johnson. It phased out the use of the national origins quota which had been the basis of previous immigration legislation. Prior to 1965, immigrants were admitted to the USA based on their country of origin and race, with the vast majority of the immigrant slots allotted to people who were from Northern Europe, primarily the UK, Ireland, and Germany. The quota allowed only 2% of immigrants from each country based on the numbers of people from those countries already living in the USA. Asians, with the exception of the Japanese (whose government voluntarily prohibited it citizens from migrating to the USA) and the Philippines (a US territory), were only admitted to as immigrants beginning in 1952. In place of using nationality and racial criteria, this new legislation implemented a system based on family reunification and needed labor skills. In fact, the Immigration and Nationality Act Amendments of 1965, also known as the Hart-Celler Act, made family reunification the cornerstone for America's immigration policy.

Elected officials who were opposed to the 1965 immigration amendments feared a sudden flood of immigrants and argued that a drastic change in immigration statistics would have negative effects on the country by creating overpopulation, increasing unemployment, increasing welfare spending, and overcrowding schools, ultimately resulting in lower living standards for Americans. However, the US Civil Rights Act of 1964 was signed into law just 1 year prior and was at the heart of the changes reflected in US immigration policies in 1965. For many, the immigration amendments were seen as an extension of the civil rights movement. There were also foreign policy concerns that motivated elected officials to make some of the changes reflected in the new law. The immigration quota system based on nationality and race was now considered contrary to the civil rights movement and the image of equality and respect for all people that the USA wished to demonstrate and convey to the world.

Immigration to the USA did increase significantly during the first few years after the bill's passage, especially from Asian countries. Those escaping from war-torn Vietnam and Cambodia were particularly numerous. The Cold War also pushed millions of people fleeing from communist governments such as those in Cuba and Eastern Europe to seek refuge in the USA. More than 18 million people migrated to the USA during the three decades following the 1965 immigration amendments.

The impact of such high numbers of immigrants on the US health care system has two interesting facets. First, studies have shown that immigrants tend to have better health outcomes that their native-born counterparts. They tend to have lower morbidity rates, fewer restricted-activity days and bed disability days, fewer physician visits and lower hospitalization rates. Immigrants show a significantly lower risk of mortality not only from all causes combined, but also from several major causes of death, such as cardiovascular diseases, lung cancer, prostate cancer, COPD (chronic obstructive pulmonary disease), liver cirrhosis, pneumonia and influenza, unintentional injuries, and suicide. This suggests that immigrants place less of a burden on the US health system because they tend to be healthier than their native-born counterparts. Yet, large numbers of immigrants have less access to private health insurance for reasons of non-affordability and employment in sectors that do not traditionally offer health insurance as a benefit to employees, such as low-wage construction jobs and farming. In 1986, another obstacle to obtaining health insurance to the US immigration experience was added: except under specified conditions applicable to relatively few individuals, immigrants were prohibited from obtaining federal assistance during the first 5 years after obtaining permanent residence ("green card"). For most immigrants, this foreclosed for 5 years the possibility of receiving health care through the government-sponsored programs of Medicaid and Medicare.

Immigration and Nationality Act of 1952 (U.S.)

Bettina Rausa
Salk Institute for Biological Studies, La Jolla, CA, USA

The United States Immigration and Nationality Act of 1952, also known as The McCarran-Walter Act, upheld the national quota system put in place by the Immigration Act of 1924. The quota called for no more than a 2% increase in the number of immigrants from countries that already had established citizens in the USA. It did, however, end the exclusion of Asians as was mandated in 1924. It also introduced an immigration preference system based on both needed labor skills and family reunification.

The Immigration and Nationality Act of 1952 was influenced greatly by the US Cold War philosophy that dominated much of US foreign relations at the time. There were great concerns among elected officials that America could be infiltrated by communists and their allies from their Cold War enemies, such as the former Soviet Union. Therefore, the national origins quota of 2% established in 1924, which was a reduction from the previous quota of 3%, was maintained in 1952. The Cold War had such a great influence in the 1952 legislation that neither economic nor labor factors were considered when crafting the bill.

Although the 1952 Act now allowed Asians to migrate to the USA, using the 2% national quota system meant that immigration laws remained restrictive toward Asians because until 1952, they were completely excluded (with the exception of the Japanese and Filipino). The number of Asians already living in the USA was very low, in fact, the lowest of all ethnic and racial groups. Furthermore, language in the 1952 Act was changed from "national origin" to specific racial and ethnic terms such as "Chinese." Since there were many Chinese living in other parts of Asia, legislators argued that the quota system continued to be unfair with regards to the Chinese and considered it unnecessarily restrictive toward people of Chinese ethnicity. President Harry Truman was concerned enough about the decisions to maintain the national origins quota, especially in how it affected the Chinese, that he vetoed the bill. Congress, however, overturned his veto and the bill was passed.

Other exclusions for those wishing to immigrate to the USA during this period include those based on health. The exclusions that were implemented in the Immigration Act of 1924 were largely maintained in 1952 legislation. Exclusions included such health conditions described as "feeble-minded, insane, narcotic drug addicts, or chronic alcoholics, those with epilepsy, psychopathic personality, a mental defect, tuberculosis, leprosy, or a dangerous contagious disease, and those whose physical defects affect their ability to earn a living." Some of these conditions were subjective or broadly described, largely based on political and social ideas and opinions. Included in conditions such as "mental defect" were such traits as homosexuality. (In fact, it was not until 1973 that the American Psychiatric Association finally removed "homosexuality" from the *Diagnostic and Statistical Manual of Mental Disorders*.) As was put in practice in earlier immigration legislation, each immigrant entering the USA was required to have a medical examination by a US physician who could determine an individual to be symptomatic of the health conditions on the exclusion list and therefore considered for rejection from immigration to the USA.

Immigration and Naturalization Service

Bettina Rausa
Salk Institute for Biological Studies, La Jolla, CA, USA

The US Immigration and Naturalization Service (INS) was established in 1933 as part of the movement of immigration policies in the USA designed to regulate immigration. The first immigration act of the USA was in 1882 in which a tax was levied on each immigrant and certain persons were, for the first time, excluded from entry. Prior to this, there were no policies regulating immigration and people entered the USA freely. Subsequent immigration legislation continued to impose more restrictions on immigration especially restricting the number of immigrants based on nationality. These laws led to the federal government's creation of immigration enforcement agencies, and as early as 1891, the Immigration Service was established with the main responsibility of monitoring the entrance of immigrants and guarding against illegal entry.

In 1906, the US Congress passed the Naturalization Act with the goal of creating a uniform naturalization process. Prior to this time, each state followed its own policies. The rules established by this particular law remain in effect today. Legislation contained within the Naturalization Act of 1906 expanded the Bureau of Immigration into the Bureau of Immigration and Naturalization, which then became the Immigration and Naturalization Service in 1933.

The functions of the INS have changed over time and have included the operation of internment camps and detention centers during World War II. The INS also expanded its role by managing and operating border patrols and crackdowns on illegal immigration.

In 2003, the INS was divided into three new agencies, managed under the newly created US Department of Homeland Security. The three new agencies responsible for immigration services and enforcement are: the US Citizenship and Immigration Services (USCIS) which manages permanent residency and naturalization (granting citizenship); the US Immigration and Customs Enforcement (ICE) responsible for the investigative and enforcement functions of immigration; and the border control and enforcement roles were combined with US Customs Inspections to become the US Customs and Border Protection (CBP).

Between April 2000 and July 2009, the US Census Bureau estimates that there were 8.9 million immigrants. The three states with the highest number of immigrants during this period were California with over 1.8 million; Texas with at least 933,000; and Florida had over 851,000. The USCIS, responsible for granting legal residency and citizenship, makes information available to new immigrants in 14 different languages regarding essential services ranging from how to access health care, education, employment, housing, childcare, food stamps and other financial assistance, emergencies and safety, the role of government, and individuals' basic rights as US residents and citizens.

The healthcare section of the Department of Homeland Security, USCIS' publication "Welcome to the United States: A Guide for New Immigrants" describes how residents and citizens in the USA pay for their own health care, unless they can purchase private health insurance. It gives a general description of how private health insurance works (i.e., doctors bill insurance companies for the services rendered) and provides general information about how to obtain federal and/or state assistance obtaining health insurance if purchasing private insurance is not affordable. It also states that most hospitals with emergency rooms are obligated by law to care for people with an urgent medical need even if they do not have the ability to pay for services.

New immigrants who have been granted legal residency, often referred to as a "green card," have access to Medicaid, the US federal health insurance program, if they are permanent residents who entered the USA prior to August 22, 1996; or if they entered on or before that date and have lived in the USA for 5 years or longer. Medicare, another federal health insurance program, is available to those 65 years or older and for individuals younger if they have a qualifying disability. New immigrants also have access to State Children's Health Insurance Program (SCHIP), which is available in all 50 US states for children and youth age 18 years or younger.

Immigration Reform and Control Act of 1986 (U.S.)

Bettina Rausa
Salk Institute for Biological Studies, La Jolla, CA, USA

The US Immigration Reform and Control Act of 1986, signed by President Ronald Reagan, had the main goal of controlling unauthorized immigration to the USA. It primarily focused on the hiring of unauthorized immigrants by creating controls and restrictions for employers and financial penalties for hiring undocumented workers with the threat of imprisonment for repeat offenses.

Prior to the 1986 immigration reforms, the last major piece of legislation regarding immigration in the USA was the Immigration and Nationality Act of 1965. This was preceded by the US Civil Rights Act in 1964, and the 1965 immigration legislation established the most liberal immigration policies of the twentieth century. Immigration to the USA in the three decades following the 1965 law was more than 18 million persons. It had ended the previous policy of nationality and race quotas, and introduced a preference system based on both family reunification and needed labor skills. By the end of the twentieth century, the ethnic and racial makeup of the American population was vastly diverse. In the 1950s, more than half of all immigrants were of European origin, and only 6% were Asians as they had been excluded from immigration to the USA for at least 50 years prior. In 1965, however, new US immigration policies allowed Asians the option to immigrate to the USA which created significant increases in the number of Asians along with a large increase in the number of people from Latin America.

The Immigration Reform and Control Act of 1986 introduced the requirement on the part of US employers to verify the eligibility of each person hired after November 1986. The completion of a specific form called an I-9 was required by all employers for each employee hired with specific instructions as to which identity documents were to be verified to prove an individual's legal right to work in the USA. The law is still in effect today. Employers who hire immigrants not authorized to work in the USA face fines with the possibility of serving time in prison for repeat offenders. The 1986 changes to immigration laws also included an amnesty provision which provided legal US residency to anyone who had been living in the USA illegally but continuously since January 1, 1982, if they applied for residency by May 4, 1988. As a result, almost three million people received amnesty.

In 1987, this immigration legislation was amended to add HIV to the list of "dangerous contagious diseases," a list that was originally developed as far back as 1891. Enforcement required that all persons wishing to immigrate to the USA be subjected to HIV testing and could be denied entry if tests results were positive. However, individuals arriving in the USA as nonimmigrants, such as tourists or businesspersons, were not required to be tested for HIV. The HIV ban was controversial and spurred complaints and protests from civil rights and gay rights groups, but the USA joined 14 other countries in introducing the ban. Critics said the law failed to effectively "protect" the USA from a "dangerous contagious disease" because HIV was not spread through casual contact and the law did not deter tourists who were HIV positive from coming to the USA and spreading the disease. Furthermore, if someone tested positive and was denied entry, there were no services offered to the individual who may have just learned of the HIV status; they were simply turned away from entry. Subsequent immigration legislation included the introduction of HIV waivers so that individuals wishing to immigrate who tested positive for HIV could apply for a waiver and, if granted, were allowed entry. In 2010, the federal government eliminated the HIV immigration ban entirely.

Immigration Status

Sarah S. Willen
Department of Anthropology, University of Connecticut, Storrs, CT, USA

Immigration status can have a powerful impact upon immigrants' health and ability to access health care. This applies especially to unauthorized immigration status, or "illegality," which interacts synergistically with factors like poverty, political marginalization, and social exclusion to put unauthorized immigrants' health at risk. The forms of health-related vulnerability that result raise complex questions and challenges for scholars and practitioners in fields as diverse as medicine, nursing, health administration, public health, public policy, bioethics/public health ethics, anthropology, sociology, and law.

Some social scientists avoid terms like “illegal” status and “illegality,” which tend to carry strong pejorative connotations, whereas others argue that “illegality” constitutes a juridical, sociopolitical, and experiential condition that requires critical and comparative analysis. There are multiple pathways to “illegality,” including entry into a country without legal permission, entry with one form of legal permission and then taking on an unauthorized role (i.e., entering as a student or tourist and then seeking work), or entry with a time-bound legal permit and “overstaying.” Unauthorized immigrants tend to occupy the most “dirty, dangerous, and demeaning” roles within local labor markets, especially in gray- and black-market labor sectors.

Although unauthorized immigrants often play pivotal roles in local economies, they frequently are portrayed in public and political discourse as unwanted, undesirable, and undeserving of health-related attention, investment, or care. Moreover, they are more likely than other groups to encounter occupational hazards such as dangerous work conditions, toxic chemical exposures, lack of protective knowledge and safety equipment, and pressure to avoid reporting injury or seeking health care treatment. Structural constraints like these – along with fears of job loss and fears of arrest and deportation – prevent many from pursuing needed health care, arguing for greater worker protections, or finding safer jobs.

Beyond the workplace, immigrants’ homes may also be places of health vulnerability and risk. Many unauthorized immigrants live in workers’ camps or private dwellings that house more than the intended number of inhabitants. If a single occupant is exposed to a communicable or infectious disease, a high degree of residential density can quickly pose a health hazard for other occupants. In addition, unauthorized immigrants tend to live in low-rent neighborhoods that are more likely than affluent areas to contain toxic exposures like traffic pollution, landfills, or toxic dumping sites. They are also more likely to encounter physical and mental health risks associated with street drugs, sex work, and vulnerability to theft and other forms of crime. Although unauthorized immigrants often are held to blame for social problems like these, they are more commonly forced to seek housing in areas where such risks are already present because of their own social marginalization, political exclusion, and poverty.

Violence is also a source of health risk for many immigrants, particularly those who are undocumented. Some become targets of racially or nationalistically motivated violence, and others become embroiled in gang-related violence. Domestic violence is also a health risk of concern, especially for women. Unauthorized immigrants’ risk of serious injury or even death due to a violent encounter is exacerbated by their lack of access to health care and to other protective institutions and services like the local police and women’s shelters.

Although some unauthorized immigrants are safe from the health risks identified above, nearly all face exclusion, in part or in full, from the systems of health care promotion, protection, and provision available to local citizens and authorized residents. In many countries, health insurance is tied to authorized employment, and workers in the gray or black market are automatically excluded, as are their children. Other countries, most notably Spain and Italy, have implemented inclusive laws and policies, but their inclusionary steps are hindered by implementation challenges and exclusionary institutional and clinical practices.

When mainstream pathways to health care are blocked, unauthorized immigrants’ health-seeking pathways are limited. Available alternatives include reliance on self-diagnosis and treatment with over-the-counter or traditional remedies, consultation with folk healers or alternative medical practitioners, postponement of care seeking until a condition becomes acute, and stopgap measures like emergency rooms or clinics run by nongovernment organizations (NGOs). Since the right to emergency care is legally protected throughout North America and Western Europe, last-resort health centers like emergency rooms are vital resources for uninsured immigrants. Yet emergency rooms and NGO clinics often are not free, they cannot provide preventive or comprehensive curative care, and they are vulnerable to political, administrative, and financial constraints that may lead to reductions in available care or even to sudden closure.

Finally, linguistic and cultural obstacles to health care have received considerable attention in recent years. Although efforts to make health care for immigrants, including unauthorized immigrants, more "culturally competent" and "culturally appropriate" have yielded some positive effect, the "cultural competence" movement sometimes assumes that culture – as opposed to such structural factors as "illegality" combined with poverty, exclusion, and social inequality – is the prime cause of delayed care-seeking or "noncompliance" with medical advice. As physician-anthropologist Paul Farmer notes, it is a grave error to confuse structural obstacles – in this case, formal mechanisms of exclusion in conjunction with prohibitive cost, inability to take time away from work, lack of transportation, fear of losing one's livelihood, and the physical and mental health risks and dangers of "illegality" itself – with cultural difference.

Immunization

ECATERINA MARIANA ENACHE
Department of Microbiology, University of Medicine and Pharmacy "Gr. T. Popa", Iasi, Romania

Immunization (in common language means protection against something) is a way to control and eliminate life-threatening infectious diseases. It is considered to be one of the most cost-effective investments in health care system. It is a part of national health care programs and in some countries it is mandatory by law.

Edward Jenner demonstrated the value of immunization against smallpox in 1792. Approximately, 200 years later, in 1977, smallpox was eradicated from the world through the widespread and targeted use of the vaccine. In 1974, based on the emerging success of smallpox, the World Health Organization (WHO) established the Expanded Programme on Immunization (EPI). Through the 1980s, UNICEF worked with WHO to achieve Universal Childhood Immunization of the six EPI vaccines (BCG – bacille Calmette-Guerin for tuberculosis, OPV – oral polio vaccine, diphtheria, tetanus and measles).

Mechanism of Action

When a competent immune system is exposed to molecules that are foreign to the body, so-called antigens, it will develop an immune response that can be humoral (producing antibodies against the antigen) or cellular based on activity of cytotoxic and helper lymphocytes.

In order to achieve protection against a certain disease (to be immunized), vaccines are used. Vaccines have the characteristics to induce the immune response (forming of antibodies) but not the diseases.

In order to improve the effectiveness of immunization it is recommended to have periodic injection vaccines. A vaccine is an artificial substance that improves immunity to a particular disease when is administrated in an appropriate way. It contains the microorganism or parts of microorganism that stimulate the immune system to recognize the agent as foreign, to destroy it, and "remember" it, so that the immune system can more easily recognize and destroy any of these microorganisms to which the body will be exposed in the future.

Vaccines contributed to the eradication of smallpox, one of the most contagious and deadly diseases known to man. As long as the vast majority of people are vaccinated, it is much more difficult for an outbreak of disease to occur. This effect is called herd immunity.

Poliomyelitis, which is transmitted only between humans, is targeted by an extensive eradication campaign that has seen endemic polio restricted to only parts of four countries (Afghanistan, India, Nigeria, and Pakistan).

Types of Vaccines

Prophylactic (to prevent or ameliorate future disease)
Therapeutic (vaccines against cancer)

There are several types of vaccines currently in use (The methods used in order to obtain it have as a goal the reduction of illness and an increase in the capacity of vaccine to induce immune response.):

1. Vaccines that contain killed microorganism using chemicals or heat. Examples are the influenza vaccine, cholera vaccine, polio vaccine, and rabies vaccine.
2. Vaccines that contain live, attenuated microorganisms. Examples are the viral diseases yellow fever, measles, rubella, and mumps and the bacterial disease typhoid.
3. Toxoids are inactivated toxic compounds (toxins) in cases where these cause illness. Examples of toxoid-based vaccines include tetanus and diphtheria.
4. Vaccines that include protein subunits; examples are HBS antigen for hepatitis B virus, VLP-virus like particle for human papilloma virus, hemagglutinin and neuraminidase for Influenza virus.

Types of Immunization

1. Active immunization involves introduction into the body of a foreign substance. It happens when a person came into contact with a virus or a bacterium for the first time without having preformed antibodies against it. This stimulates an immune response and is called active natural immunization.

   Active artificial immunization refers to the situation when the microbe or parts of it are injected to human body, generating also an immune response.
2. Passive immunization involves inoculation of presynthesized elements of the immune system (usually antibodies) to a person so that the body does not need to produce these elements itself.

   There is a passive natural immunization which is physiologic when antibodies are transferred from mother to fetus during pregnancy in order to protect the child after birth against some infection. Artificial passive immunization is achieved by administration of a vaccine that contains antibodies against certain viruses or bacteria.

Vaccines can immunize against one single bacterium or virus (monovalent, univalent) or against two or more strains (multivalent polyvalent).

Effectiveness of vaccines depends on:

1. Host immune system capacity. Sometimes it cannot respond in an appropriate way probably due to special conditions such as diabetes, use of steroids, alcoholism, renal failure, live failure, and blood diseases.
2. The strain contained in the vaccine. For example, people can be vaccinated with other strains than those that are circulating in a certain period of time.
3. Time table of vaccinations has to be adhered to. (See American Academy of Pediatrics Redbook)
4. Some persons do not respond to vaccinations. There are few explanations for that. Most of the time, people do not respond to vaccinations either due to a suppressed immune system resulting from chronic diseases, different treatments, for example, for cancer, in order to retain a transplanted organ), or because the immune system is not completely developed, as is the case with young children.

Legislation Regarding Immigrants' Immunization

As of 1997, all persons who want to enter and live in USA have to be immunized. Moreover, in order to immigrate in USA, documentation is required to establish past immunization against a few diseases considered to be high risk for the general population such as hepatitis, mumps, measles, polio, whooping cough, and varicella.

INA

► Immigration and Nationality Act of 1952 (U.S.)

Inadmissibility on Health Grounds

Ireh Iyioha
University of Western Ontario, London, ON, Canada

Inadmissibility on health grounds refers to the disqualification of a visa applicant or immigrant to a country based on health-related grounds that are of public health significance. The US *Immigration and Nationality Act*, 1965 (INA) requires certain classes of visa applicants, refugees and immigrants to undergo a medical examination to identify ineligible applicants with health-related conditions for the Department of State (DOS) and US Citizenship and Immigration Services (USCIS).

Medical examination is also mandatory for foreign residents in the United States who apply for an adjustment of their immigration status to that of a permanent resident. Applicants for temporary or non-immigrant visa to the USA may be directed to undergo a medical examination at the discretion of the immigration officer at the US consular office overseas. This discretion may be exercised where there are circumstances that suggest that the applicant has an inadmissible health-related condition. Other classes of aliens, including fiancés and migrants who entered the USA without inspection and with or without proper documentation, are required to have a medical examination done before they are admitted to the USA.

Section 212(a)(1)(A) of the INA stipulates the classes of foreigners that are ineligible for visas or inadmissible to the USA based on health-related grounds. The classes of foreigners include persons with a communicable disease of public health significance, who have no documentation evidencing receipt of vaccination against vaccine-preventable diseases, who have been diagnosed with a physical or mental disorder that results in harmful behavior, and who are drug abusers or addicts. Some examples of the communicable diseases of public health significance that would cause an applicant to be ineligible to enter the USA include tuberculosis, Hansen's disease (Leprosy), syphilis, gonorrhea, and diseases that may require quarantine, such as cholera, small pox, yellow fever, and pandemic flu. Under section 212(g) of the INA, a visa applicant, refugee or status adjuster who has an inadmissible health-related condition requires a waiver to come to the USA. A waiver authorizes the applicant who is otherwise ineligible based on one or more health conditions to enter into, or remain in the USA. A waiver is granted on a case by case basis. An applicant is eligible for a waiver if the applicant is the spouse, unmarried son or daughter, or the minor adopted child of a US citizen or permanent resident; has a son, daughter, or lawfully adopted child who is a citizen of the USA or a permanent resident; or if the applicant can be classified as a self-petitioning spouse or child based on abuse.

Similarly, Canadian immigration policy establishes standards to be met by people seeking entry into Canada. These standards constitute grounds for inadmissibility under the Canadian Immigration and Refugee

Protection Act, 2001 (IRPA). Among the criteria set out under the IRPA is section 38, which outlines three health grounds under which a foreign national may be denied admission to Canada: a health condition that is likely to be a danger to public health, a condition that is likely to be a danger to public safety, and a health condition that might reasonably be expected to cause excessive demand on health or social services. The IRPA denies admission on health grounds based on two distinct rationales: the protection of public health and the public economy. A foreign national is inadmissible if his or her health condition is likely to be a danger to public health or public safety. The public health and safety policy aims to protect Canadians from a broad range of pathologies, particularly contagious or highly infectious diseases such as tuberculosis in its active state, which might pose a threat to public health.

The second rationale involves the protection of Canadian healthcare resources from unusually excessive demands on Canada's health or social services that a visa applicant might require if he or she were to be admitted to Canada. These excessive demands could take either or both of two forms. First, they could result in excessive public expenditures for the cost of the health care. Alternatively, the need to provide visa applicants with health care could result in lengthened waiting lists and increase the rate of mortality and morbidity among Canadian citizens and permanent residents as a result of the denial or delay in the provision of those services to them.

Medical and visa officers are charged with determining the inadmissibility of an applicant on health grounds. The Supreme Court of Canada in two notable cases has disapproved of speculation by medical and visa officers in determining inadmissibility. Reasons such as the likelihood of bankruptcy, mobility, school closure or parental death could be raised in relation to any applicant and are inadequate grounds for a finding of inadmissibility. Rather, medical officers must assess the applicant's likely demands on social services, not his or her eligibility for them. In making this required individualized assessment, they must consider both medical and non-medical factors, such as the availability of publicly funded services and the applicant's ability and willingness to pay for the required services.

Visa officers are now required to evaluate the intention and ability of the applicants to alleviate the burden they allegedly place on publicly funded social services before finding business class applicants or their dependants medically inadmissible for excessive demand on social services. The individualized assessment is usually made based on the likelihood of the business-class applicant accessing specific state-funded services. According to Citizenship and Immigration Canada, this approach is supported by the fact that there is a private market for some social services, and that some social services are means tested. The term "means tested" is used to determine eligibility of individuals and families for government subsidies. It involves making an assessment of a person or family's financial capacity and determining (usually according to a formula) how much of the cost of a good or service should be borne by that individual or family, and how much publicly funded subsidy the individual/family should receive.

India

Amy N. Sharpton
Department of Veterans Affairs, Louis Stokes DVA
Medical Center Cleveland, Brecksville, OH, USA

Introduction

India is a subcontinent whose history can be traced to one of the world's oldest civilizations, the Indus Valley civilization, that flourished during the third and second millennia BC. Today's classical Indian culture began to develop approximately in 1500 BC, as Aryan tribes from the northwest gained access to the subcontinent and merged with earlier Dravidian inhabitants. Uniting much of South Asia, the Mauryan dynasty ruled from 321 to 185 BC, followed by the reign of the Gupta dynasty from AD 400 to 600. The Gupta dynasty ushered in India's Golden Age, during which science, art, and culture flourished. Turks and Afghans invaded India throughout the tenth and eleventh centuries and established the Delhi Sultanate. The Emperor Babur established the Mughal dynasty in the early sixteenth century; the Mughals reigned for more than three centuries.

European explorers began establishing a presence in India during the sixteenth century, and, by the nineteenth century, Great Britain had become the dominant political power. Nonviolent resistance to British rule, led by Mohandas Gandhi and Jawaharlal Nehru, brought about India's independence in 1947. Violence and segregation resulted in India's divisions into two separate states: India and Pakistan. The two countries have fought three wars since independence, the last of which in 1971 resulted in East Pakistan becoming the separate nation of Bangladesh. Today, despite serious challenges such as overpopulation, environmental degradation, poverty, and corruption, rapid economic development has set India as a key player on the global stage.

Geography

India is located on the southern portion of the continent of Asia; it borders the Arabian Sea and the Bay of Bengal, between Burma and Pakistan. While India is the seventh largest country by geographical area – with a land mass slightly greater than one third the size of the United Sates – with more than 1.2 billion residents, it is the second most populous country and the most populous democracy worldwide. Mainland India is bounded by the Indian Ocean on the south; the Arabian Sea and Pakistan on the west; Bangladesh, Burma, and the Bay of Bengal on the east; and Bhutan, the People's Republic of China, and Nepal to the north. Geographically, India dominates the South Asian subcontinent; it is positioned near key Indian Ocean trade routes.

India's climate varies, from tropical monsoon in the south to temperate in the north. The terrain is varied also, characterized as upland plains (Deccan Plateau) in the south; flat to rolling plains along the Ganges; desert in the west; and mountainous (Himalayas) in the north. India's climate is influenced strongly by the Himalayas and the Thar Desert, both of which drive the monsoons of the area. The Himalayas prevent cold Central Asian katabatic wind from blowing in, keeping the bulk of the Indian subcontinent warmer than locations at similar latitudes. The Thar Desert plays a crucial role in attracting the moisture-laden southwest summer monsoon winds that provide the majority of India's rainfall. Natural resources include iron ore, manganese, mica, bauxite, titanium ore, chromite, natural gas, diamonds, petroleum, limestone, and arable land, as well as the fourth largest coal reserves in the world. In 1993, it was estimated that India's land usage included 56% arable land, 1% permanent crops, 4% permanent pastures, 23% forests and woodland, and 16% other.

India lies within the Indomalaya ecozone, contains significant biodiversity, and is 1 of the 17 megadiverse countries. Many of the country's ecoregions exhibit high rates of endemism; overall, 33% of Indian plant species are endemic. Potential natural disasters for the subcontinent are droughts, earthquakes, volcanic eruptions, severe thunderstorms, flash floods, as well as widespread and destructive flooding from monsoonal rains. In recent years, a volcano has been active on the Barren Island in the Andaman Sea. Currently, there are numerous environmental issues facing India, such as deforestation, soil erosion, overgrazing, desertification, air pollution from industrial and vehicle emissions, water pollution from raw sewage and runoff of agricultural pesticides, variability in tap water potability, and overstraining natural resources.

Culture

India has been home to the ancient Indus Valley Civilization, a region of historic trade routes, and many large empires. For much of its history, the Indian subcontinent was noted for its commercial and cultural wealth. Four of the world's major religions – Hinduism, Buddhism, Jainism, and Sikhism – originated here, while Zoroastrianism, Judaism, Christianity, and Islam arrived in the first millennium and shaped the region's diverse culture. Gradually annexed by the British East India Company from the early eighteenth century and colonized by the United Kingdom from the mid-nineteenth century, India became an independent nation in 1947 after a struggle for independence which was marked by a nonviolent resistance led by Mahatma Gandhi.

Characterized by a high degree of syncretism and cultural pluralism, a record of India's culture can be traced to 8000 BC. With roots based in the Indus Valley tradition, the Indian culture took a distinctive shape during the eleventh century BC Vedic Age, which laid the foundation of Hindu philosophy, mythology, literary tradition, and such beliefs and practices as dharma, karma, and yoga. It has managed to preserve established traditions while absorbing new customs, traditions, and ideas.

A chief aspect of Indian culture is formed by the various schools of thought and religious teachings developed in the region. Major dharmic religions that were founded in India include Hinduism, Buddhism, and Jainism. Hinduism has been shaped by the various schools of thought based on the *Upanishads*, the *Yoga Sutras*, and the *Bhakti* movement. Buddhism originated in India in fifth century BC, gained dominance during the Maurya empire, and played an influential role in shaping Indian philosophy and thought.

The diversity of Indian culture is reflected in its architecture, with notable references to Mughal, Dravidian, and Indian vernacular architecture. Mughal architecture, the distinctive style developed by the Mughals in the sixteenth and seventeenth centuries, is symmetrical and decorative in style. Dravidian architecture emerged thousands of years ago and consists primarily of a pyramid shaped step design consisting of many statues of deities, warriors, kings, and dancers. Indian vernacular architecture is the informal, functional architecture often found in rural areas of India. The builders of these structures are unschooled in formal architectural design and their work reflects the rich diversity of India's climate, locally available building materials, and the intricate variations in local social customs and craftsmanship.

Indian culture is reflected also in its rich literary traditions. Considered to be from the earliest and foremost era of Indian literature, the Vedic or Sanskrit literature was developed from 1400 BC to AD 1200. Prominent Indian literary works of the classical era include epics, dramas, and poetry. Sangam literature, developed between 600 BC and AD 300, consists of more than 2,000 poems and is regarded as a predecessor of Tamil literature. From the seventh century AD to the eighteenth century AD, India's literary traditions went through a period of drastic change characterized by varied thought and expression. During the nineteenth century, Indian writers took new interest in social questions and psychological descriptions and during the twentieth century, Indian literature was heavily influenced by the works of universally acclaimed Bengali poet and novelist Rabindranath Tagore.

One cannot examine current Indian culture devoid of the framework of the traditional Indian caste system, first postulated by the Brahminical texts found in Hinduism. It has been proposed by some that the initial purpose of the fourfold caste system was to categorize society in ways that furthered the well being of all of society by developing in each innate inclination toward social good. However, the practice has come to be viewed largely as a method of social stratification and social restriction. The original Indian caste system proposed in Hindu texts consists of four castes, or *varnas*: the *Brahmins* (poets, priests, teachers, scholars); the *Kshatriyas* (kings, agriculturists, and nobility); the

Vaishyas (merchants); and the *Shudras* (artisans, service providers. and laborers).

India's caste system has evolved over time to include numerous castes and subcastes, classifications that persist particularly in more rural areas and small towns. Despite recent attempts to do away with caste distinctions, to varying degrees, the practice still factors in Indian culture – in politics, for example. The Indian Government lists consist of Scheduled Castes (SC), Scheduled Tribes (ST), and Other Backward Classes (OBC).

The SC consist generally of *Dalit*, referred to also as *Outcaste*. Outcaste is a self-designation for a group traditionally regarded as untouchable and unsuitable for making personal relationships. Currently, the SC comprise 16% of the total population of India (around 160 million). Numerous castes come under the larger category of SC; for example, the Delhi state lists 49 castes as SC. The ST consist generally of tribal groups. The current ST population is 7% of the total population of India, approximately 70 million. More than 3,000 castes fall under the category of OBC. It has been estimated that this group forms between 32% and 52% of the total Indian population.

Economy

From 1947 to 1991, India was under social democratic policies and had an economy characterized by extensive regulation, protectionism, and slow growth. Continuing economic liberalization that began in 1991 has been the impetus for India's shift toward a market-based economy. The country experienced a revival of economic reforms and better economic policy in the first decade of the twenty-first century, which served to accelerate India's economic growth rate. In recent years, Indian cities have continued to liberalize business regulations. By 2008, India had established itself as the world's second fastest growing major economy.

India's large service industry generates 57% of the country's GDP, while the industrial and agricultural sectors contribute 28% and 14.6% respectively. More than half of the nation's 500 million workers are employed in agriculture; 34% are employed in the service sector; and approximately 14% are employed in the industry sector. Major agricultural products include rice, wheat, oilseed, cotton, jute, tea, sugarcane, potatoes, cattle, water buffalo, sheep, goats, poultry, and fish. Major industries include telecommunications, textiles, chemicals, food processing, steel, transportation equipment, cement, mining, petroleum, machinery, information technology-enabled services, and pharmaceuticals. During the years 2008 and 2009, India's top five trading partners were the United Arab Emirates, China, the United States, Saudi Arabia, and Germany.

Politics

India is a federation with a parliamentary government; it is a constitutional republic and a representative democracy. The Constitution of India, adopted in 1950, defines India as a sovereign, socialist, secular, democratic republic; it features a bicameral parliament that operates under a Westminster-style parliamentary system. Its form of government was traditionally described as being "quasi-federal"; however, as a result of political, economic, and social changes, it has grown increasingly federal since the late 1990s.

India's head of state, its president, is elected indirectly for a 5-year term by an electoral college. The Prime Minister is appointed by the President and is the head of the government, exercises the most executive power, and is supported by the party holding the majority of seats in the lower house of Parliament. The executive branch consists of the President, Vice-President, and the Council of Ministers. In the Indian parliamentary system, the executive is subordinate to the legislature, with the Prime Minister directly responsible to the lower house of the Parliament. The Legislature of India is the bicameral parliament, which consists of the upper house called the Council of States and the lower house called the House of People.

Education

In 2009, India passed a landmark act, the Right of Children to Free and Compulsory Education (RTE) Act. The legislation guarantees all children the right to quality elementary education by the state with the help of families and communities. India's education system has made significant progress over the past several decades. According to Education for All Mid-Decade Assessment, between 2000 and 2005, India increased primary school enrolment overall by 13.7% and by 19.8% for girls. Notably, the country has reached nearly universal enrolment in grade 1.

However, even with these commendable efforts, in 2005, one in four children left school before reaching grade 5, and almost half exited the system before reaching grade 8. Learning assessments indicate that the children who do remain in school are not learning the key skills necessary for their overall development. Although there have been significant improvements in the proportion of children from socially disadvantaged groups in school, gaps remain. Girls are still less likely to enroll in school than boys; in 2005, for grades 6–8, girls' enrolment was still 8.8% less for ST and 3.4% for SC.

Previously referred to by the British as the *depressed classes*, ST and SC are Indian population groupings that are explicitly recognized by the Constitution of India. The proportion of SCs and STs in India's population has risen steadily since independence in 1947; together, the groupings comprise over 24% of India's population. Per the 2001 Census, SCs formed 16% of India's total population, while STs made up 7.5%. Recognized as depressed or underserved, India's Constitution puts forth general principles for the policy of affirmative action for the SCs and STs.

Health Care

Health care in India is comprised of a universal health care system run by the constituent states and territories. Treatment at government hospitals is provided without charge or with a minimal charge, and most essential drugs are offered free of charge. In-hospital treatment costs are dependent on the financial condition of the patient and facility, but they are much less costly usually than the private sector.

India's health care system has improved over the last several decades, although it continues to lag behind those of its neighboring countries. The poor state of health care may be attributable to the lack of government funding on health care initiatives; estimates suggest that health care spending per capita by the Indian Government is well below international recommendations. In spite of a steady increase in medical establishments, severe shortage remains still in number of medical facilities and health care personnel. India scores poorly on most generally accepted health indicators.

Of late, as India's health care needs have increased, so has the role of the private sector. Public–private partnerships have emerged also as a potential means of growing the health care sector while keeping public goals in mind. It is expected that the private sector will continue to take on an increasing significant role in India's health care system. This growth is expected to be driven by factors that include rising life expectancy, rising income, increasing health insurance, government action, and rising incidence of lifestyle-related diseases.

Primary care is focused on immunization, prevention of malnutrition, pregnancy, child birth, postnatal care, and treatment of common illnesses. Patients who receive specialized care or have complicated illnesses are referred to secondary and tertiary care hospitals. The country suffers still from high rates of malnutrition and disease and a lack of safe drinking water and proper sanitation facilities, especially in rural areas. India suffers high incidence rates of malaria, polio, tuberculosis, and AIDS. Furthermore, according to the World Health Organization, contaminated water or air attribute to more than 900,000 deaths each year in India. As India grapples with basic health needs, new challenges are emerging with rising rates of chronic adult diseases associated with changing lifestyles. India faces significant manpower shortages. It is estimated, for example, that 700 million persons have no access to specialist care. Notably, 80% of specialists reside in urban areas. Furthermore, in terms of availability of hospital beds per 1,000 persons, with a worldwide average of 3.96 hospital beds per 1,000, India stands just a little over 0.7 hospital beds. Better policy regulations and the establishment of public–private partnerships are possible solutions to the problem of manpower shortage.

Concurrent with the gaps in health care delivery are entities that meet or exceed international quality standards, and the medical tourism business in India has been growing in recent years. The country is a popular destination for medical tourists who receive effective medical treatment at costs lower than in developed countries. Many Indian hospitals are attracting foreign patients by promoting their international quality of health care delivery and by turning to international accreditation agencies to standardize their protocols and obtain the required approvals on safety and quality of care.

Brain Drain

While India struggles with meeting the basic health needs of its population, eliminating disparities in the quality of care, and combating emerging diseases concomitant with a changing lifestyle, a disquieting potential is looming, threatening to exacerbate that country's challenge to improve the overall quality health staffing, for example, between the United Kingdom and India. India has fewer than 3,000 psychiatrists for its one billion residents compared with one psychiatrist for every 9,000 persons in the United Kingdom. This represents a 27-fold difference between the countries. Despite this inequality, however, the National Health Service (NHS) has launched a scheme to recruit senior psychiatrists and other specialists from India and other developing countries.

Although the recipient nations and the immigrating physicians benefit, the proposed recruitment plan threatens to worsen inequities in global health. Furthermore, as physicians migrate, less developed countries lose important health capabilities as a result of the increased physician shortage. One method of mitigating the brain drain phenomenon is to attach explicitly linked measures to enable the flow of doctors back to developing countries. Many familiar with the struggle of developing nations to meet health challenges have suggested that institutions in developed countries have an ethical obligation to facilitate the return of health professionals to their countries of origin. The following measures have been proposed as a means of facilitation: flexible training schemes that permit doctors from developed countries to work in developing countries; long-term partnerships to strengthen the research, clinical, and teaching infrastructure of institutions in developing countries; grants to enable returning doctors to establish personal and professional lives; and ongoing auditing of overseas doctor training schemes in terms of proportion of doctors who return home.

Migration

India has a diverse and complex migration history. In fact, since the nineteenth century, ethnic Indians have established communities on every continent of the globe. The flows have been comprised of such groups as indentured labor in far-flung colonies, postwar labor for British industry, high-skilled professionals in North America, and low-skilled workers in the Middle East. In addition, ethnic Indians in countries like Kenya and Suriname have migrated to other countries, a movement called secondary migration.

There have been several large waves of emigration from India. Upon independence from British rule in 1947, British India was divided into predominantly Hindu India and predominantly Muslim Pakistan. This division was the impetus for an enormous migration that occurred between 1947 and 1950, estimated at 12–18 million people. About half of the migrants, predominantly Muslims, moved to Pakistan and half, predominantly Hindus and Sikhs, moved in the opposite direction. This migration was accompanied by severe violence between caravans of migrants and those in the source regions; death toll estimates stand between 200,000 and 1 million people. Also, in 1971 during the war in East Pakistan that led to the formation of Bangladesh, around ten million refugees, approximately 80% of them being Hindus, crossed the border into India. It is estimated that 35,000 remained in India, mostly in West Bengal.

Internal Migration

India's Constitution guarantees its citizens the right to move freely within the country; as such, internal migration occurs within and between states. India's population, in 2009, was estimated at 1.17 billion, with an estimated 20 million internal migrants. The majority of internal migrants work as temporary migrants in construction, agriculture, and manufacturing. As for interstate migration, frequently persons from the states of Bihar, Uttar Pradesh, and Rajasthan in northern India move to New Delhi, Gujarat, or Maharashtra, while in South India, persons from Tamil Nadu move to Kerala, Karnataka, and Maharashtra. While these are the primary internal migration corridors, there are numerous secondary corridors. Although internal mobility is critical especially to the livelihoods of people from economically marginalized areas, the country's high degree of ethnic, linguistic, and religious diversity means that internal migration can have the same challenges for internal migrants, including xenophobia, as faced by internal migrants in other countries.

Refugees and Asylum Seekers in India

Although not a party to the 1951 Refugee Convention and its 1967 Protocol, traditionally India has treated refugees well. Notably, the Dalai Lama found refuge in India when he fled Tibet in 1959, as the country permitted him to set up a government-in-exile in Dharamsala. For example, while not officially recognizing it as a government, the Indian government allows the Central Tibetan Administration autonomy in public education. It is estimated that there are 110,000 Tibetans currently living in India. Approximately 80,000 Tibetans arrived in the first wave of migration. The Indian government offered permits and low-paying public works jobs; however, more recent Tibetan refugees have not been as welcome, as many have been denied resident permits.

Another wave of migrants sought refuge in India when an estimated 60,000 Afghans fled to India after the Soviet Union invaded Afghanistan in 1979, and thousands more came when the Taliban took power in 1992. Since 2001, the United Nations High Commissioner for Refugees (UNHCR) has helped some 500 return and 650 to resettle to third countries, mostly to the United States, Canada, and Australia. Recently, the Indian government has agreed to naturalize many of these Afghans who have lived in India since 1979.

Indian Student Migration

According to the United Nations Education, Scientific, and Cultural Organization (UNESCO) Institute for Statistics, the number of Indian students abroad tripled from approximately 51,000 in 1999 to over 153,000 in 2007. Thus, India ranks second among the world's largest countries sending students abroad. Five receiving countries accounted for 90% of all Indian students abroad. The United States is by far the most important destination country, receiving more than half of the worldwide expatriate Indian student force in 2006–2007, followed by Australia (16%) and the United Kingdom (15%).

Migration Outlook

Although ethnic Indian communities in receiving countries such as the United States and the United Kingdom have realized a measure of economic success and have achieved mostly peaceful integration, in many other receiving countries, millions of ethnic Indians have limited rights and less secure futures. The Indian government has demonstrated a commitment to differing groups abroad, and investment and return to India have become easier for the more well-off members of the diaspora. Those on temporary contracts have benefited from more government preparation before their departure and from more efficient remittance systems.

Although India has long served as a destination for economic migrants and refugees from neighboring countries, its policymakers have yet to address clearly the challenges related to illegal immigration. In an effort to address illegal immigration, in 2009, the government initiated a process to provide forgery-proof identity cards to all nationals. With regard to refugee-related policies, both UNHCR and India's National Human Rights Commission have urged the Indian government to ratify the refugee convention and its protocols and to enact special legislation related to refugees and child refugees. After all, India is a country people also immigrate to, rather than merely a country people leave.

Individualism

Marlene Pantin
Center for Drug Use and HIV Research, College of Nursing, New York University, New York, NY, USA

Individualism has typically been defined in terms of autonomy, individual responsibility, rights, and self-sufficiency and advocates that humans are rational beings, able to use reason to make rational decisions and personal choices. Within individualism, at the interpersonal level, social relationship ties are seen as impermanent as individuals continuously weigh the costs and benefits of social relations and transition out of them when costs are too burdensome suggesting individual initiative and choice. Individualism not only refers to the self, but also describes values, norms, attitudes, and behaviors.

Health care policies informed by the ideology of individualism are problematic particularly in the area of immigrant health. Immigrants often lack full participation in the political and economic systems that create and sustain health care. Thus, their health care choices, or rather options, are not always autonomous, voluntary, or based on equal status in the same way as native-born individuals. Individualism's focus on individual motivation, assertiveness, lifestyle, and choice obscures the role of society and its social structures in shaping health services and therefore personal health outcomes. Structural factors such as socioeconomic status, residential location, racial and ethnic discrimination, and marginalization constrain immigrant health care options. In addition, immigration status, language barriers, and issues related to acculturation further limit immigrant health care access and practices. Due to these and many other factors, immigrants utilize health services less often and have worse health outcomes than native-born individuals. Utilization and responsibility for health care framed within an individualistic model masks these structural limitations.

A changing global economy also strains opportunities of immigrants to shape their personal health. Global economic and financial pressures have resulted in more health care costs being forced onto individuals even in universal health insurance programs as a means of reducing national health care debt, as is occurring in Canada. In the US where undocumented and legal immigrants are ineligible for public health care programs such as Medicaid, individual responsibility for health care grows while government accountability declines. Such health policies are aimed at discouraging foreign-born individuals who may be interested in public health benefits from initially immigrating. Yet, restrictive health philosophies such as this miss the point. As numerous studies show, a desire for jobs and not health care fuels immigration. Limiting immigrant access to health care providers and regular care through public health care programs overwhelms secondary health care systems including emergency rooms. These health rules, as well as new immigration policies that place restrictions on immigrants' opportunities to adjust their illegal status, increase the number of undocumented immigrants and negatively influence their health care utilization and outcomes.

In the US, policies surrounding immigrant health care have paralleled general immigration policies over the past century. Individualism, informed by the ideology of traditional liberalism with its focus on individual liberty, self-definition, and moral worth, coupled with a need for populating the country at the time, was the backdrop of the early immigration policy of open borders and easy access to citizenship prior to the 1880s. But these immigration policies were eventually challenged by exclusionary impulses and practices that changed the outlook for immigrant groups. The new ideology and legal structures that emerged favored immigration less so that an individual's natural right to pursue their own self-interest were circumscribed and regulated by a new individualistic ideology focused on consent, national sovereignty, and national community. The result is that immigrants' supposed natural rights to pursue their own self-interest in the US were curbed as a result of these policy changes. Health policies in the US that favor restrictive immigrant health policies inevitably increase immigrants' vulnerabilities. Although health care in the US, and in many other nations, is embedded in individualistic values, the status of immigrant health care demonstrates that the principles of individualism such as personal independence and decisions, and rights and responsibility for health care choices are more often absent and ineffectual with regard to immigrant health experiences. Ultimately, national health and immigration policies such as those in the US, as well as structural constraints inhibiting immigrant access to adequate health services, may have greater influence in shaping health outcomes than individual expressions of free will and choice.

Infant Mortality

Richard J. David
Division of Neonatology, Stroger Hospital of Cook County, Chicago, IL, USA

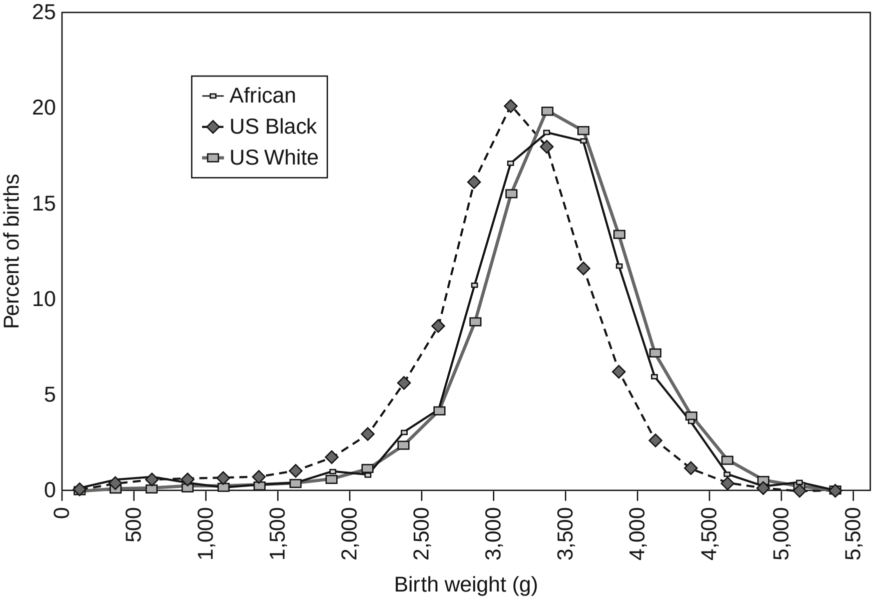
Infant mortality, that is, the number of deaths in the first year of life per 1,000 live births, more than any other population health indicator, reflects the well-being of a society. It is intimately connected to the rate of preterm birth (and its proxy, low birth weight) since the organism's maturity at the moment of biological separation from its mother to a great extent determines the success of the transition to independent existence. The relation between the rate of first year deaths and social conditions in which the birth occurs has been written about at least since the publication of Engels's classic *The Condition of the Working Class in England* in 1845. Unlike the situation prevailing in the nineteenth century, however, a full picture of population health today requires a study of social conditions in more than one country. This reflects the large and growing number of people who emigrate from their country of birth to a new land. Immigrant women give birth to about one quarter of infants born in the United States and some European countries each year, increased from under 10% just 30 years ago.

The range of infant mortality rates in different countries is quite wide, reflecting the wide gulf between social and economic conditions in different parts of the world. According to the World Health Organization, the risk of death for a newborn baby ranges more than 20-fold between countries. International comparisons are complicated because of different levels of accuracy and completeness in recording of vital events, but clearly huge differences exist between different parts of the world and societies of different levels of wealth. Interestingly, among countries of a moderate to high economic level income inequality in the population, as opposed to average income, becomes an equal or stronger predictor of first year death. Of course, within-country rates also vary strikingly by social class and by "race" or ethnic group. Finally, within a given ethnic group giving birth in a given country, there are differences between outcomes of women born in that country and those who have immigrated there from their country of birth. The specific issues surrounding infant mortality among immigrants, compared to the population of their host country and to their population of origin, are the focus of this article.

Racialist theories to explain health problems in immigrants were popular in the receiving countries in the late nineteenth and early twentieth century. For example, the high rate of rheumatic heart disease in Irish immigrants to the USA, now understood to be mediated by higher prevalence of rheumatic fever caused by crowded living conditions, was at one point hypothesized to be a constitutional predisposition linked to the gene for red hair. Similar theories to explain health disparities between people of European and those of African ancestry continue to be advanced, although they have been repeatedly shown to be at odds with most empirical research from population genetics and epidemiology. The genetic theory of "racial" differences in birth weight has been seriously challenged by observations that women immigrating to the USA from Africa have infants with a birth weight pattern closer to that of US-born White women than that of US-born Black women (Fig. 1).

In many respects, immigrants in various countries fare better than expected for their level of income and education. In many cases they are healthier than native-born individuals of a comparable socioeconomic stratum. This is true for a variety of health measures but clearly the case for birth outcomes. A number of theories have been advanced to explain this so-called "epidemiologic paradox." It is likely that more than one hypothesized process is at work in various national contexts. For example, women immigrating to Taiwan were less likely than Taiwan-born women to have an infant of low birth weight. In that case, selective immigration of healthier individuals, the "healthy migrant" theory, appears to fit the data best. In the United States, birth weight advantage in the immigrant generation is related to the country of origin. Women whose race is listed as "White" on the birth certificate (the US still records "race" on its vital records) and who immigrated from Europe enjoy a negligible advantage compared to US-born White women, approximately 15 g. In contrast, Mexican immigrants have about a 60 g advantage over US-born women of Mexican descent. Black women immigrating from African or Caribbean countries have about a 180 g birth weight advantage over US-born Black women. All of these differences disappear in the next generation. The correlation of the protective birth weight effect in the immigrant generation with the socioeconomic hierarchy of ethnic groups that obtains in US society has led investigators to interpret these observations as reflecting the physiologic effects of perceived racial discrimination and institutional racism, leading to chronic stress.

Support for the discrimination-stress hypothesis also comes from studies of birth outcomes in women with different lengths of time between immigration and giving birth. In a study of approximately 75,000 women immigrating to Canada, compared to about 400,000 Canada-born women, there was a measurable birth weight advantage from 0 to 5 years after



Infant Mortality. Fig. 1 Distribution of birth weights among infants of U.S.-born White and Black women and African-born Black women in Illinois, 1980–1995 (David & Collins, 1997, © 1997 Massachusetts Medical Society. All rights reserved.)

immigrating, decreasing in the 5–10 year post-immigration group and becoming a disadvantage in those with Canadian residence more than 10 years. This was true for women coming from a variety of home countries, although the protective effect in the early years was strongest for women from sub-Saharan Africa or the Caribbean.

A meta-analysis of 133 reports of birth outcomes among immigrants does show an overall trend toward higher infant and fetal death rates among some immigrants to the USA and Europe, especially those from sub-Saharan Africa and the Caribbean. This is interesting since no birthweight disadvantage (or often an advantage) was noted when compared to the population of the receiving country. One possible explanation for this apparent contradiction would be the combined effects of two epidemiologic phenomena related to immigration. The mass of immigration into many host countries is driven by economics, with immigrants seeking improved opportunities for their families. However, superimposed on this migration are special situations such as refugees and asylum seekers, many of whom may have health and nutrition problems related to internment prior to arrival in their new country. There is also anecdotal evidence for "medical migration" in which individuals at risk for adverse health outcomes arrange to give birth in a country with more sophisticated healthcare services. Support for this notion was reported in a large study of African immigrants to the USA. These investigators showed overall similarity of birth weight distribution between Africa-born Black women and US-born White women as noted above, but also a high rate of very low birth weight premature infants, a group with 15-times higher mortality than the general birth population. African immigrant women giving birth to these very small infants were more likely to have had prior pregnancy losses. Selective "medical immigration" is speculated to have played a role in some of those cases.

With almost 200 million people migrating between countries every year by some estimates, the impact of immigration on the health of the migrants and the populations they merge into will be of increasing importance. Infant mortality and related birth outcomes are increasingly viewed from a life-course perspective. The physiological, nutritional, and psychosocial influences on females from fetal life through infancy, childhood, and adolescence impact childbearing health. That these factors will be significantly different for women born, and perhaps raised, in a very different national context is clear. However, much work remains to sort out the most important factors and their mechanisms of action. Implications for clinical management as well as targeted public health interventions are only beginning to become clear as research in this important area begins to accumulate.

Introduction

Infectious diseases are a significant cause of morbidity and mortality worldwide, with the major burden occurring in developing countries. human immunodeficiency virus (HIV), tuberculosis (TB), malaria, and respiratory and diarrheal illnesses have led to over five million deaths each year. Developing countries are both the source and host to most of the global population of refugees, who are at risk of these and other infections.

Refugees have multiple risk factors for infectious diseases in their countries of origin, transit, and settlement. Source countries are typically characterized by conflict, with the disruption of basic infrastructure such as sanitation, health services, and vaccination programs. Living conditions in transit countries, both in refugee camps, or other situations, are frequently crowded and unsafe. People may also lack basic requirements, such as access to clean water, a regular food supply and health care. Other risk factors for infectious diseases in refugees include inadequate immunization, lack of access to barrier contraception and exposure to sexual violence. Stress associated with trauma and migration may affect the manifestation of infectious diseases; for example, the risk of developing tuberculosis disease is highest in the initial years after migration.

Refugees settling in more economically developed countries may have undiagnosed and/or untreated infections, which can cause long-term complications and chronic ill health. Some of these infections are latent, meaning the person feels well and may not seek assessment. Health screening and disease prevention may be a low priority for refugees arriving in a new country, especially in the early stages of settlement and diagnosis, and treatment of infectious diseases is often poor. Health providers in the country of settlement may be variably familiar with infectious diseases in refugee populations, and may not consider relevant differential diagnoses, or perform appropriate screening. Refugees may face barriers to accessing health care in their country of settlement. In general, the risk of transmission of infectious diseases to others in the host country is very low.

Health Screening in Refugee Populations

There is general consensus that refugees settling in developed countries need health screening. Screening protocols vary depending on the countries of origin/transit and the country of settlement. Health screening may be completed offshore (prior to leaving for the country of settlement) or after arrival in the new country (onshore or domestic screening) and may include presumptive treatment for infectious diseases. Many countries use a combination of both offshore and domestic health screens. Examples of current protocols are shown in Table 1.

Health screening also varies according to how refugees arrive in a new country. The majority of the world's refugees are hosted by neighboring developing countries and do not have specific health screening based on their refugee status. A small number of refugees applying for resettlement through the United Nations High Commissioner for Refugees (UNHCR) are offered permanent resettlement in a developed country and may undergo offshore screening. Alternatively, refugees may arrive in a developed country by boat, or on a short-term visa or permit, and then seek asylum (onshore processing). In this situation, access to health screening depends on their asylum status and access to local health services.

Infectious Diseases in Refugees

Infectious diseases in refugees can be considered in six main groups: Tuberculosis, blood-borne viruses, parasitic infections, other gastrointestinal infections, vaccine-preventable diseases, and sexually transmitted infections. There may be multiple concurrent infectious diseases to consider in a refugee patient, in addition to their other health issues.

Tuberculosis

Tuberculosis (TB) is caused by organisms from the *Mycobacterium Tuberculosis* complex and is the second most common cause of death from infectious diseases worldwide. In 2008, there were an estimated 9.4 million incident cases of TB, 11.1 million prevalent cases of TB and 1.3 million deaths from TB in HIV negative people, and an additional 0.52 million deaths from TB in people with HIV.

One third of the world's population has been exposed to TB, however only 5–10% of those exposed will develop active disease. People can develop TB disease after their initial exposure (primary disease) or after a period of latent infection (reactivation disease). Latent TB infection (LTBI) refers to the situation where a person is infected with small numbers of TB organisms, but does not have symptoms or features of TB disease. TB disease occurs most commonly in the lungs (pulmonary TB), but may occur at any site in the

Infectious Diseases. Table 1 Health screening for infectious diseases in refugee populations: examples of protocols

Country and approximate annual intake	Offshore screening	Presumptive treatment	Onshore	Specific details
USA 60,000	Medical examination: all ages	Directly observed treatment for malaria with artemether-lumefantrine completed within 3 days of departure, directed treatment used for pregnant women or babies <5 kg weight	TB – follow-up for treated active disease, LTBI and contacts	HIV testing no longer required in offshore screening (from January 2010)
	TB screening:			
	Age < 2 years: where clinical assessment suggests TB, or HIV positive: TST or IGRA, CXR and 3 sputum samples		HIV testing aged 13–64 years, and aged $\leq$ 13 years unless maternal status negative and no risk factors	
	Age 2–14 years: TST or IGRA, CXR if +	Treatment for intestinal parasites varies with area of origin (CDC 2010):	Presumptive treatment for malaria for refugees from sub-Saharan Africa if not given offshore	Culture of sputum specimens, drug susceptibility testing, and use of DOTS introduced since 2007
	Age $\geq$15 years: CXR, TST, or IGRA based on prevalence area origin, if assessment suggestive three sputum samples with culture, drug susceptibility testing if +	Middle East, South/Southeast Asia: Albendazole/Ivermectin	Screening for intestinal parasites varies with offshore screening completed and presence of eosinophilia	
	TB disease treated using DOTS predeparture, no travel until treatment completed	Africa (areas without Loa loa): Albendazole, ivermectin, praziquantal	Serologic testing for syphilis aged $\geq$ 15 years (regardless offshore results) and age $<$15 years with risk factors	
	Malaria screening for pregnant/lactating women and children $<$5 kg (otherwise presumptive treatment)	Africa (areas with Loa loa) Albendazole, praziquantal	Chlamydia NA amplification tests females $\leq$25 years, or older females/children with risk factors	
	Serologic testing for syphilis		Gonorrhea NA amplification tests in people with symptoms or urine dipstick suggestive and children with risk factors	
	Clinical examination for other STIs		Vaccination requirements must be met to obtain legal permanent resident status (12 months after arrival)	
	Vaccination proof not required for refugees (required for other permanent immigrants)			

Australia 13,500	Medical examination: all ages	Additional predeparture medical screen (not universal) includes albendazole and MMR vaccination, also RDT malaria and	Recommended (ASID 2009):	A diagnosis of tuberculosis disease in off shore screening delays travel
	FWTU aged $\geq$5 years		Hepatitis B serology	
	CXR aged $\geq$11 years		Hepatitis C serology	
	HIV aged $\geq$15 years		HIV testing	
	Hepatitis B pregnant women, UHM		TB screening

	Syphilis serology aged $\geq$15 years from refugee camps		Strongyloides serology	
			Syphilis serology	
			Malaria films/RDT	
			Fecal specimen	
			Urine chlamydia	
			Urine gonorrhea	
			Other tests frequently performed include:	
			Full blood count, glucose, ferritin, folate, B12, vitamin A, vitamin D, Measles, rubella, tetanus serology, chest X-ray	
Canada 11,000	Medical examination: all ages	No	No standardized post arrival health screening recommendations	Positive HIV status does not preclude migration
	CXR aged $\geq$ 11 years			
	FWTU aged $\geq$ 5 years			
	Syphilis serology aged $\geq$ 15 years			
	HIV testing			
	TB disease treated prior to travel			

Infectious Diseases. Table 1 (continued)

Country and approximate annual intake	Offshore screening	Presumptive treatment	Onshore	Specific details
UK	No	No	TB screening (CXR) at ports of entry on arrival for people staying in the UK for longer than 6 months	
Few UNHCR refugees, large numbers onshore asylum seekers			Routine health care generally provided through the National Health Service for asylum seekers (free of charge) Voluntary HIV screening for asylum seekers coming into the UK Comprehensive screening for infectious diseases encouraged as part of an integrated primary care resource. Health screening offered to those asylum seekers in designated reception centers	
European Union 330,000 asylum claims	Generally not used	No	Varies. A 2004 survey reported:	
			TB screening in 22 countries (compulsory in 12)	
			HIV screening in 19 countries (compulsory in 5)	
			Emergency care at time of arrival only – 12 countries	

Based on 2008 UNHCR figures

Note: only screening directly related to infectious diseases included in this table, other health checks recommended

Albendazole used for presumptive treatment of helminths

Ivermectin used for presumptive treatment of strongyloides

Praziquantal used for presumptive treatment of schistosomiasis

UHM unaccompanied humanitarian minors

NA nucleic acid

body. The classic presentation of pulmonary TB is a productive cough associated with fevers, malaise, and weight loss. Children aged less than 5 years are at higher risk of developing TB after exposure and have a higher risk of disseminated TB disease.

Screening for tuberculosis is a cornerstone of health assessments for all new migrants in many countries (not just refugee entrants). Protocols vary, but most include a chest X-Ray (CXR) for adolescents and adults, with further investigations based on the results of a medical assessment and the CXR findings. Mantoux testing (a skin test) and/or interferon gamma release (IGRA) assays may also be used in predeparture screening for people from areas with a high prevalence of TB. The assessment of children is usually limited. People diagnosed with active TB disease may be offered treatment. Successful completion of treatment is a mandatory condition of immigration for countries such as the USA and Australia.

LTBI can be identified by scarring on a chest X-ray, a positive Mantoux test or a positive IGRA test in a person without features of active TB disease. People with LTBI have a lifetime risk of developing TB disease of up to 10%, although the risk is higher in children, adolescents, and people with HIV. This risk can be reduced by preventive treatment with an anti-TB medication over 6–9 months. Treatment of LTBI is generally recommended in developed countries.

Refugees are at high risk of developing TB disease. They have often lived in countries with high rates of TB infection, crowded living conditions facilitate transmission, access to adequate treatment is variable for cases, and the risk of developing TB disease is increased in the first years after migration. Recent research has shown that low vitamin D is associated with both active tuberculosis and latent TB infection in refugees from sub-Saharan Africa settling in Australia. Low vitamin D is increasingly recognized as a health issue in dark-skinned refugees settled in areas of high or low latitude, and in women who wear covering clothing for religious or cultural reasons.

The prevalence of positive TB screening results in refugee groups settling in developed countries is high, and foreign-born people account for over half the cases of TB disease in the USA, Canada, and Australia. Refugees have a higher prevalence of TB disease than other migrants. A large study of US-bound migrants over 1999–2005 found the prevalence of smear negative TB disease in refugees was 1,036 cases per 100,000 people and the prevalence of inactive TB (CXR suggestive of old TB changes) was 2,838 per 100,000 people, which was threefold higher than other immigrants. Other studies have examined TB screening tests and found the prevalence of positive results (suggesting LTBI) was 35–60%.

Blood-Borne Viruses

HIV/AIDS

The human immunodeficiency virus (HIV) invades specific cells of the immune system, leading to the acquired immune deficiency syndrome (AIDS). The World Health Organization (WHO) estimates that in 2008 there were 33.4 million people living with HIV, 2.7 million new infections with HIV, and 2 million AIDS-related deaths worldwide; the majority of HIV is acquired by heterosexual sexual contact, although a significant number of children acquire HIV "vertically" (at birth or by breast feeding from an HIV-infected mother). In many parts of the world, injecting drug use and unsafe medical practices are additional routes of acquisition.

Many refugees come from countries with high rates of HIV infection. Although refugees are often screened prior to arrival, and a positive test may preclude immigration, cases of HIV are still identified in refugees after settlement. This can be due to poor test quality, delay between the time of testing and the time of arrival, or infection with HIV during return trips or while living in the new host country.

Very effective treatment is available for HIV; however this is expensive, and can have significant side effects. There is no cure or vaccine, despite ongoing research.

Hepatitis B

Hepatitis B is a viral infection that primarily affects the liver, causing inflammation. Worldwide, two billion people have been infected with the virus and 350 million have chronic infection. Up to 1.2 million people die each year from the complications of hepatitis B, including liver failure, cirrhosis, and liver cancer.

Hepatitis B can be acquired sexually, by contact with infected blood, or transmitted vertically (from mother to child) or horizontally (between children or household contacts). In developing countries, the majority of infection occurs at birth or in early childhood. People who acquire hepatitis B at birth or in early childhood are less likely to have symptoms when they acquire the infection, but are much more likely to develop chronic infection that persists for life. Hepatitis B infection can be prevented by vaccination; however, most refugee source countries in recent years do not include hepatitis B vaccination in their national immunization schedules.

Refugees have high rates of chronic hepatitis B infection and should be offered screening. The prevalence of hepatitis B infection in refugee cohorts settling in developed countries is generally reported at 5–9% although a prevalence of over 10% is noted in some groups. Many refugees originate from countries with a high prevalence of hepatitis B, especially those from Asia, the Middle East, and Africa. If refugees do not have evidence of infection or immunity to the virus, they should be offered vaccination.

People with chronic hepatitis B infection require long-term follow-up, monitoring, and surveillance for complications. Chronic hepatitis B can be treated with antiviral medications or interferon; however, these treatments are expensive and have side effects.

Parasite Infections

Malaria

Malaria is a potentially fatal parasitic infection spread by mosquitoes. Some forms of the parasite can lay dormant in the liver for extended periods. Over half of the world's population lives in malaria-endemic areas, and in 2008 it was estimated there were 247 million cases worldwide, leading to nearly 1 million deaths. Refugees who arrive from malaria-endemic areas should be screened for malaria. Symptoms of malaria can be nonspecific; people may present with cough, abdominal pain, headache, or vomiting. Young children (below 5 years) have a higher risk of rapid deterioration and severe disease. It is crucial for clinicians to consider the possibility of malaria in any new immigrant who has a fever, even after more than a year in the new country. Treatment is readily available and very effective.

Schistosomiasis

Schistosomiasis (also called bilharzia) is a trematode (fluke) infection transmitted by skin contact with contaminated fresh water. Schistosomiasis affects over 200 million people worldwide, with the greatest burden of disease in Africa. Five main species cause disease in humans. The parasite lives in the blood vessels around the gut or urinary system (depending on species) and can survive for many years after the initial infection. The manifestation of disease is determined by the species and the immune response to the parasite. Schistosoma infection may be asymptomatic, or it may cause gastrointestinal symptoms (such as abdominal pain, diarrhea, or blood in the feces) or urinary symptoms (blood in the urine). Chronic *schistosoma* infection is associated with liver disease, portal hypertension, and bladder cancer.

Schistosomiasis is common in refugees who have arrived in developed countries, even years after resettlement. Around 20% of African refugees have schistosomiasis in studies from Australia, New Zealand, and the USA, although a higher prevalence (up to 44%) is reported in Sudanese refugees arriving in the USA. Schistosomiasis is also occasionally seen in refugees from the Middle East and South Asia. Predeparture empiric treatment with the medication praziquantel may be used; however, many refugees remain untreated. Screening recently arrived refugees and treating people with positive results with a short course of cheap and effective medication is an appropriate strategy to prevent long-term disease complications.

Strongyloidiasis

Strongyloides stercoralis is a helminth (worm) that is transmitted by skin contact with soil containing infective larvae. Humans are the definitive host. Strongyloides infection is endemic in tropical regions; worldwide, 100 million people are thought to be infected. The parasite can reproduce within the human host and infection can persist for more than 40 years if left untreated. People with Strongyloides infection can develop a hyperinfection syndrome (with overwhelming fatal infection) if they become immunosuppressed for any reason.

Predeparture presumptive treatment with single-dose albendazole therapy is used by several countries. This reduces infections with other soil-transmitted helminths; however, it is inadequate treatment for Strongyloides infection. Newer predeparture protocols include ivermectin, which is a more effective treatment for Strongyloides. Refugees should be screened for Strongyloides infection after arrival, unless they have clear documentation of predeparture treatment. Infected individuals should be offered a course of treatment and followed up, to document cure.

Other Gastrointestinal Parasites

People in the developing world frequently have infestation with other intestinal helminths (worms) or protozoan parasites such as *Giardia intestinalis* or *Entamoeba histolytica*. Other helminths include roundworms (*Ascaris lumbricoides*), whipworms (*Trichuris trichiura*), and hookworms (*Necator americanus* and *Ancylostoma duodenale*). These infections are spread in conditions of poor sanitation. They may be asymptomatic, or they may cause diarrhea, abdominal pain, malaise, weakness, and poor nutrition, depending on the type of infection(s). Anemia is a significant problem with hookworm infestation.

Treatment is generally straightforward, and in immigrants who have moved to conditions of good sanitation, reinfection is unlikely. Many refugees who have a health check overseas are given empiric treatment for gut parasites. This treatment is generally more effective for helminths than protozoal infections. Refugees with gastrointestinal symptoms after settlement require further screening and treatment.

Other Gastrointestinal Infections

Helicobacter pylori

Helicobacter pylori is a bacterium that colonizes the stomach. Half of the world's population is thought to be infected with *H. pylori* and most *H. pylori* are acquired in childhood. The bacteria are found in all populations worldwide and colonization can be lifelong. Rates are much higher in the developing world. Infection with *H. pylori* causes gastritis (inflammation of the lining of the stomach), peptic ulcer disease, and gastrointestinal malignancy. Currently, most guidelines do not recommend screening for *H. pylori* in adults without symptoms; however, we would recommend a low threshold for testing in refugees with gastrointestinal symptoms, and treatment for people found to have *H. pylori* infection. The significance of *H. pylori* infection in children and the relationship between infection and symptoms is not clear.

Vaccine-Preventable Diseases

Many refugees who arrive in the developed world have not had complete vaccination, and very few have written records of immunization. Refugees are at high risk for inadequate immunization for many reasons, including disruption of health services in their countries of origin, poor-quality vaccines, reduced access to vaccines, and difficulties completing catch-up vaccination after settlement. Studies have shown that catch-up vaccination is often not considered and that rates of vaccine coverage in immigrants are low.

All refugees should have an assessment of their vaccination status. Catch-up immunization is recommended if there is no written record of immunization, although a BCG scar is considered adequate evidence of BCG vaccination (for tuberculosis). Catch-up immunization will vary depending on national protocols; however, it usually includes coverage against tetanus, diphtheria, pertussis (whooping cough), measles, mumps, rubella, and polio, and can also include other vaccines such as *Haemophilus influenzae* type B, meningococcal, pneumococcal, and hepatitis A and B vaccines. Clinicians need to be alert to the development of vaccine-preventable diseases in the immigrant population due to the low vaccination rates.

Sexually Transmitted Infections

Many refugees have been exposed to sexually transmitted infections (STI) before arrival in a developed country. There are many reasons for this, including lack of education, poor availability of barrier contraception, and high rates of exposure to sexual violence, although this history may not be disclosed. Screening for sexually transmitted infections should be part of routine refugee health assessment for people who have been sexually active. This includes a clinical assessment and urine testing for gonorrhea and chlamydia, as well as blood testing for syphilis, HIV, and hepatitis B. Most of these infections are easily treated. If they are not treated they can have significant long-term consequences, including adverse effects on fertility. When assessing refugee patients for STI, providers should be particularly aware of protecting patient confidentiality, and using an appropriate interpreter.

Conclusions

Infectious diseases are common in refugees and may have long-term effects on health. Detection and treatment of infectious diseases is an important part of the post arrival health screen, and many of these conditions may not be associated with symptoms.

A refugee patient is unique in that he or she has often been exposed to a large range of infections in the course of his or her lifetime and may present with diseases that are rarely, if ever, seen in people who have always lived in a developed setting. Clinicians need to be alert to the possibility of unusual infections, and know how to assess refugee clients for these conditions, and when to refer to an infectious disease specialist. A number of excellent guidelines are available to assist the clinician and these should be used whenever possible.

Significant improvements are occurring in health care provision for refugees who arrive in developed countries. Fortunately, the infectious diseases described in this entry can be effectively cured or managed, allowing better health and well-being for people of a refugee background after settlement.
