
Despite Bookchin's theoretical brilliance, decades of activism and writing, and comprehensive formulation of Social Ecology, his divisiveness marred his contribution and damaged the ecological cause. His sectarianism manifested itself in his attack on Deep Ecology during the 1980s and 1990s. The ensuing conflict between Deep Ecology and Social Ecology contributed to polarizing the environmental movement into nature and social justice camps, the very schism that Bookchin was striving to supersede (Best 1998, Light 1998, Clark 2000).

Deep Ecology emerged with the work of the Norwegian ecophilosopher Arne Naess and evolved into the Deep Ecology movement through the contributions of American and Australian environmental thinkers and activists. The underlying cause of ecological destruction and of the alienation of the human species from the biosphere is identified by Deep Ecologists as anthropocentrism: the self-exultation of human beings, whose ostensible superiority and perceived entitlements sanction dominion over nature. In the culture at large anthropocentrism manifests itself as the pervasive and often unquestioned belief that nature is a domain to be used, a domain primarily of instrumental value for people.

In an effort to recover traditions of thought and practice that transcend anthropocentrism, foster biospheric egalitarianism, and celebrate the intrinsic value of nature, Deep Ecologists have formulated a syncretic platform that has integrated elements of Western philosophy, scientific ecology, conservation biology, humanistic psychology, primitive ritual, and Eastern spirituality. Those syntheses are used in an attempt to recover a biocentric sensibility that counters the supremacist tendencies of *Homo sapiens* with a vision of harmonious coexistence with all beings. In the idiom of Aldo Leopold, Deep Ecologists agitate for the day when human beings will be "plain members and citizens" rather than conquerors of the land community.

Bookchin disparaged deep-ecological thought as a random collage of ideas that was deplorable in its theoretical incoherence, mystical inclinations, inattention to social-justice issues, and denial of social domination as the root of ecological exploitation and destruction. He considered Deep Ecological philosophy a hodgepodge of "Taoist moods, Buddhist homilies, and New Age platitudes," with Spinoza, Whitehead, and Heidegger thrown into the mix, that displaces the "vigorous reasoning" and "muscularity of thought" of Western philosophical and political traditions (Bookchin 1996, p. 98ff.). Bookchin's criticisms might have inspired a dialogue between Deep Ecology and Social Ecology, but his invective proved more polarizing than constructive. The tendentious tone that Bookchin set can be seen in a deep-ecological backlash that finds little if anything to learn from his ideas.

In focusing on what repelled him in deep-ecological literature—especially appeals to spiritual transformation, invocations of mystical unity, and antirationalism—Bookchin failed to acknowledge important convergences between Deep Ecology and Social Ecology (Clark 2000). Deep Ecology has always stressed the idea that creating a balanced world will necessitate profound changes at the economic, political, cultural, and ideological levels. Social Ecologists similarly insist that real transformation will not occur without reimagining and revolutionizing all dimensions of society. Concurring with social-ecological analyses, Deep Ecologists have not shied away from criticizing capitalist wasteful production as well as the consumer culture that both is spawned by overproduction and feeds it (Roszak, Gomes, and Kanner 1995). Social Ecology and Deep Ecology share a broad vision of the ecological society, highlighting the desirability of local governance and democratic decision making,

small-scale economies of production and consumption, community spirit, lifestyles that respect cultural and natural diversity, ecological embeddedness, and care of nonhuman species both for the ways they enhance human life and for their intrinsic value.

The legacy of Social Ecology for the environmental movement and the future directions of social-ecological thought are not known. It is unclear whether Social Ecology will thrive as an ecophilosophy in its own right, whether its insights will be absorbed into new syntheses in environmental thought and activism, or whether the term *Social Ecology* will end up being applied only to analyses narrowly focused on social-justice concerns in environmental and ecological contexts. Murray Bookchin died in 2006. In the years before his death his polemics alienated him from many of his contemporaries. However, the key insights of Social Ecology continue to command attention: Social and ecological problems are inseparable, and social domination has long been implicated in the destruction of the biosphere.

SOCIETY FOR CONSERVATION BIOLOGY

The Society for Conservation Biology (SCB), established in 1986, seeks to promote the scientific study of issues pertaining to the loss, maintenance, and restoration of biodiversity. The SCB and its flagship journal, *Conservation Biology,* bring together scientists, scholars, policy makers, and members of nongovernmental organizations who share the goal of protecting and perpetuating the earth's biological diversity. Since its inception the SCB has recognized an essential role for environmental ethics in informing, shaping, and applying the science of conservation biology. Conversely, ideas and insights from conservation biology have contributed to the development of environmental philosophy and ethics.

ORIGINS AND DEVELOPMENT OF CONSERVATION BIOLOGY

The SCB was founded in 1986 in response to the increasingly urgent concern over global threats to biological diversity in the late twentieth century. More broadly, however, the emergence of conservation biology as a new interdisciplinary field reflected long-term trends in conservation science and practice. A concern with biological diversity has deep roots in the worldviews of native cultures around the world; in the scientific tradition of Europe and North America (in the fundamental contributions, for example, of Linnaeus, Charles Darwin, and Alfred Russel Wallace); and in the work of naturalists and protoconservationists of the 1800s (the writings, for example, of Alexander von Humboldt, Henry David Thoreau, and George Perkins Marsh). With the rise of the Progressive-Era conservation movement in the United States in the early 1900s, science became more intimately tied to conservation policy and practice. It

was, however, fragmented into varied disciplines, preecological in content and narrowly utilitarian in application. This scientific content both reflected and reinforced the philosophical split in the early conservation movement between the utilitarian resource-conservation ethic (often associated with forester Gifford Pinchot) and the nature-preservation ethic (often associated with naturalist John Muir).

By the 1930s ecological and evolutionary science had begun to influence various resource-management fields (including agriculture, forestry, wildlife management, range management, and fisheries management), easing this long-standing tension within the conservation movement. Early biogeographers and ecologists such as Henry C. Cowles, Frederic Clements, Henry Gleason, Victor Shelford, Charles Elton, and Ernst Mayr developed basic concepts of community ecology, ecological change, population dynamics, and plant and animal distribution, giving greater emphasis to the role of biological diversity in the structure, composition, and function of biotic communities. Aldo Leopold, applying these concepts to land management and stewardship in the 1930s and 1940s, redefined conservation as "a state of health in the land," which he further described as "the capacity for self-renewal in the soils, waters, plants, and animals that collectively comprise the land" (1991, p. 318). In thus recasting conservation's goals—most explicitly in his influential essay "The Land Ethic," published posthumously in the environmental classic *A Sand County Almanac* (1949)—Leopold wedded conservation science and conservation ethics. Leopold's land ethic implied that conservation was no longer just the purview of professional resource managers charged with the efficient production of goods from the earth, but also of individuals and institutions assuming responsibility for the health of the land. A generation later this coupling of science and ethics in the service of an ecologically robust approach to conservation provided an important cornerstone for the field of conservation biology.

In the decades following World War II, the resource-management professions faced mounting environmental and philosophical challenges in the United States and around the world. An expanding and increasingly globalized economy increased the burdens on natural communities through overexploitation; pollution; the spread of invasive species; the early indications of climate change; and widespread habitat loss, alteration, and fragmentation. These environmental changes engendered ever-lengthening lists of threatened and endangered species (later legally defined and protected) and alarm over the loss of biological diversity at various geographical scales. The world's species-rich tropical forests, for example, became a focal point of global environmental concern by the late 1970s. The traditional resource-management fields, with their inherited disciplinary boundary lines, reductionist tendencies, and commodity-dominated priorities, were ill-equipped to address these systemic challenges.

Conservation biology emerged in response to these trends. It was a part of the same process of intellectual cross-pollination that spawned such fields as environmental ethics, environmental history, ecological economics, landscape ecology, agroecology, and restoration ecology in the late 1970s and 1980s. Conservation biology was the product of a fusion of several overlapping spheres of scientific inquiry: coevolution and population biology (as developed in the 1960s by Peter Raven and Paul Ehrlich, among others); island biogeography (grounded in the landmark research of E. O. Wilson and Robert MacArthur); conservation genetics (especially as synthesized by Otto Frankel and Michael Soulé); and inquiry into the social dimensions of conservation policy and international development (through key contributors such as Thomas Lovejoy, Bruce Wilcox, and Norman Myers).

THE FOUNDING OF THE SCB

Conditions were ripe for the creation of the new field and its namesake professional society. A series of scientific workshops and conferences held between 1978 and 1985 gave the field increasing definition. In 1986 a major forum on the conservation of biodiversity—a neologism adopted in the course of planning the forum—was convened in Washington, D.C., under the auspices of the Smithsonian Institution and the U.S. National Academy of Sciences. Many of the forum's scientific leaders helped to establish the new group. In 1987 the SCB, under its first president Michael Soulé, organized its first annual meeting and published the first issue of *Conservation Biology*.

A close and continuing relationship between environmental ethics and conservation biology was forged in these early years of the SCB. The 1986 forum on biodiversity included not only a wide range of scientists but also environmental ethicists and scholars from other fields. Soulé, the central figure in defining conservation biology and organizing the SCB, credited the influential Norwegian environmental ethicist Arne Naess with shaping his priorities for the field; it was to be a "mission-driven" and "value-laden" field that accepted the moral responsibility of humans to safeguard and sustain the community of life. The bylaws required that one seat on the society's board of directors be reserved for a scholar in the humanities and environmental ethics. The first editor of *Conservation Biology*, David Ehrenfeld, had published his own contribution to environmental philosophy, *The Arrogance of Humanism*, in 1981. Beginning with Ehrenfeld's editorship, the journal regularly

featured articles on environmental ethics alongside its more customary scientific studies.

Even as conservation biology has sought to unify the disparate domains of natural-resource management, it has also significantly influenced the discourse of environmental ethics. It has raised vital issues such as the human role in shaping "natural" ecosystems; the role of biological diversity in conservation strategy; the movement toward more community-based, participatory approaches to conservation decision making; the philosophical rationales and ecological foundations of sustainability; and the role of the conservation biologist as scientist in an explicitly values-driven undertaking.

SOILS

Soil is the portion of the earth's surface that consists of a mixture of disintegrated rock and humus, or dead organic matter. Soil science, a branch of agronomy, has categorized thousands of soil types according to their physical and biochemical characteristics. In addition to its mineral substrate and humus tilth, a soil may contain 30,000 species of organisms, with a thimbleful containing billions of bacteria, fungi, algae, protozoa, and nematodes, plus virus particles. The soil microbiologist Selman Waksman received the Nobel Prize for discovering soil actinobacteria that produce lifesaving antibiotics. Soil may be critical in preventing the spread of antibiotic resistance to preserve the medical value of these soil-borne antibiotics.

VALUE AND DEGRADATION

Soil has both intrinsic and instrumental value, but modern agriculture has allowed soil degradation through erosion and contamination of soils and waters with chemicals. Though considered by some medical authorities to be a pathology, eating soil (geophagy or pica) can improve human or animal health by dissolving micronutrients. The clay mineral surfaces adsorb harmful bacteria, viruses, and toxic organic compounds and are eliminated from the body. Soil also performs a variety of ecosystem services. Soil microbes enzymatically digest the complex organic compounds of dead plants, animals, and other microbes, producing simple inorganic ions by mineralization (rotting or composting). Roots absorb those ions, and the carbon dioxide gas released enables photosynthesis. This action constitutes nutrient cycling in all terrestrial ecosystems, the study of which is a major branch of ecosystem ecology. A wide variety of toxic and hazardous organic compounds are bioremediated into harmless or beneficial inorganic substances by soil microbes. The soil biota provides biological resilience to chemical insults if it is not overwhelmed.

The "spirit of the soil" includes several extrascientific concepts. The idea of native soil has inspired patriotism for centuries, which results from the concept of soil as a symbol for the place of a person's birth and, before world trade and transport, the source of a person's nutrition. Centuries ago the apparently spontaneous appearance of mushrooms caused humans to develop the idea of vitalism, by which the soil was said to transmit a vital force from animals, through their manure, to the soil and then into the newly developing plants, once more providing sustenance for animals. The development of soilless hydroponic horticulture—plants are grown in water and supplied by dissolved inorganic fertilizers (nutrients)—developed by Justus von Leibig disproved the idea of vitalism. However, Wendell Berry and others have suggested that soil nevertheless retains a memory of its past management.

Aldo Leopold proposed a land ethic that would promote biological diversity, ranging from the humble earthworm to all other life-forms, with each one having a right to maintain a habitat within the soil. Leopold's early papers, written while he was a U.S. Forest Service

employee in the Southwest, indicate that his land ethic was rooted in concern about the soil erosion caused by the advent of fire suppression and cattle ranching in that region. Farmers holding soil in their hands often have a reverence for the plant and animal productivity developing from soil. The ancient Jewish stewardship environmental ethic emphasizes human responsibility to conserve the soil by periodically resting it because the land or soil belongs to God, not to humans. Thus, humans are caretakers of the earth.

PROBLEMS AND REMEDIES

Contemporary nonsustainable industrialized crop-production practices create serious threats to water quality, in part because they pose serious threats to soil, which modulates the flow of water and purifies it. Those nonsustainable practices also cause soil erosion, which, in addition to the loss of productive, life-sustaining soil, loads streams and reservoirs with sediments and excess nutrients, which also diminish water quality. Phosphates and pesticides move away from fields with the soil into rivers, lakes, and streams, resulting in algal blooms and fish kills or the death of a wider variety of organisms and pose threats to human health. Nitrates and herbicides are moving downward into groundwater through depleted soils, contaminating sources of drinking water.

Because of the loss of soil as a result of the use of modern tillage equipment, soil conservation practices have been a major focus of U.S. public policy. However, growers have ignored these practices in the interest of expediting farming operations and increasing short-term profits. Soil loss of one to five tons per acre per year is considered acceptable, but accelerated soil loss may occur at ten or more times that rate. A sustainable society would ensure that soil is preserved and further soil-related environmental degradation does not continue.

A major controversy surrounds the goal of nutrient replenishment. Although synthetic industrial chemical fertilizers provide the base for modern plant nutrition, more environmentally friendly sources might be reintroduced. Commercial fertilizers require extensive petroleum energy to produce, transport, and apply compared with more sustainable fertilizers, such as animal manures, that are an agricultural by-product that can be produced locally. Also, legumes used in crop rotation provide free low-energy nitrogen not only to themselves but to other plants grown on the same soil. Biodynamic microbial preparations, compost teas (composted material dissolved or suspended in water so that it can be sprayed), and greater use of animal wastes, including human waste, are key ingredients in the recipe for a postindustrial sustainable agriculture. Using more organic materials greatly enhances phosphate (the second most limiting plant nutrient after nitrogen) availability to plants. This is the key to organic agricultural production systems, including long-term sustainable practices to prevent soil and water erosion.

A holistic ecological approach to soil management requires viewing the health of the soil and the conservation of soil as a vital component of human health. Soil fertility promotes regenerative sustainable crop production, the most salient elements of which are biological nitrogen-fixing bacteria functioning inside root nodules of legumes, mycorrhizal fungi living on plant roots that serve as extra root hairs that enhance plant nutrition, and bacteria, fungi, and nematodes serving as natural biological control agents by killing insects and other plant pathogens.

The loss of soil microbial diversity may threaten future generations through loss of soil-based ecosystem services and basic biological processes and through loss of potential lifesaving antibiotics and medicines.

SONTOKU, NINOMIYA
1787–1856

Ninomiya Sontoku, also known as Ninomiya Kinjiro, a Japanese farmer-sage, was born in a small village in Odawara Han (the contemporary Kanagawa prefecture, near Tokyo) in the Edo era (1603–1867). As an orphan living in poverty, Sontoku restored his father's house and became a landowner, enlarging his estate through hard work and rational management. He served a samurai family and rescued it from debt, after which he was

sought out to restore ruined villages. He later was appointed a samurai officer and helped the government restore the Nikko area, where he died and was enshrined.

Sontoku's environmental thoughts and practices were based on the premodern ecological worldview that was characteristic of preindustrial Japanese society; it consisted mainly of Shintoism mixed with Japanese Confucianism and Buddhism. Sontoku believed that all humans and nature exist in a circle within which everything exists in fusion and unity (*ichi-en yu-go*). This is reminiscent of the Great Ultimate of Chu Hsi, the synthesizer of Neo-Confucianism in the Sung Dynasty in China, which also took the form of a circle as the monistic origin or ground from which everything was brought forth. The circle that represents the Confucian unification of humans and nature might be considered a symbol of the ecoholistic view.

The circle expresses the unity of all things. Nothing can be outside the circle, and everything is contained within it. The circle also expresses the limits of humans and nature as a whole, in which reside all dualistic principles such as yin and yang, masculine and feminine, light and dark, life and death, good and evil, and rich and poor. A circle also expresses the idea that everything within the circle will change not in the direction of progress but in a cyclical way. This holistic way of thinking leads to the conclusion that a one-sided increase in the welfare of humans or nature will destroy the balance; that is, an increase in the welfare of humans will lead to a decrease in the welfare of nature.

Sontoku's practical solution to the problem of the relationship of human beings to nature lay in the symbiotic coelaboration of both. Human beings owe gratitude (*on*) to heaven and earth (the great father and mother), to their ancestors, parents, and lords, and are obliged to repay the debt. The main virtues Sontuku practiced and recommended were diligent labor (*kin*), frugality (*ken*), and concession (*jo*) in agriculture and economics to increase natural produce by "assisting the transforming and nourishing process of Heaven and Earth" (Tu 1989, p. 86). This is part of Sontoku's teaching of "reward for virtue" (*hotoku*).

Sontoku eventually rescued more than six hundred villages and tens of thousands of people. He not only restored devastated farms but also saved people from mental collapse by helping them be financially and morally independent. To help distressed people, he used large sums of money from his successful projects, leaving none for his own family. The voluntary credit union organized by his followers, the Society for Rewarding Virtue (*Hotoku-sha*), was highly successful, with many branches throughout Japan; it continues to exist. Sontoku's achievements testified to his belief that Confucian morals ('*jen*), politics, and economics rather than Western power politics and self-interested economics can both make people happy and restore nature.

In prewar Japan, Sontoku was a national hero who was cited in elementary school textbooks on moral education called *shushin* ("cultivating oneself") as a model of Confucian and other virtues. All elementary schools had a bronze statue of him on a pedestal near the main entrance in which he carried on his back a bundle of firewood gathered in the mountains, reading a book while walking. Boys and girls were encouraged to work hard and study diligently so that they would become decent citizens and successful people. Thus, his influence was felt not only in agriculture and economics but also in moral education in Confucian virtues. In postwar Japan, he was neglected and his school of thought was almost forgotten. However, his thoughts and practices have been revived by the International Ninomiya Sontoku Association, which was founded in 2003.

SOUTH AMERICA

The cultural and biogeographic identity of South America, as well as the history of its environmental philosophy, is embodied in the Andes Cordillera, the great mountain system that crosses the continent from south to north and is home to the emblematic Andean Condor. According to Tiahuanaco pre-Inca culture, in ancestral times *Viracocha* (one of the most important deities in the Inca pantheon) emerged from Lake Titicaca in the heights of the Andes and created the sun with his light; the rain and water with his tears; the heavens, the stars, the humans and the other living beings that inhabited the region (Kusch 1962). Today, along this Andean backbone, there is a mosaic of altiplanic, rain-forest, wetland, desert, coastal, glacial, steppe, and prairie ecosystems hosting most of the world's plant and animal biodiversity (Mittermeier et al. 2003). The highest mountain peaks in the Americas, as well as the vast Amazonian basin, Pantanal wetlands, Chaco savannas, and Patagonian high latitudes

Gateway of the Sun. *The figure of* Viracocha *in the center of the Sun Gate in Tiahuanaco in the highlands of Bolivia, surrounded by human-condor guardians illustrates how deities, humans, and nature have been and are still united in Amerindians' worldviews and lives.* **© TINA MANLEY/ARCHEOLOGY/ALAMY.**

are still inhabited by endemic biological species, cultures, and languages. Amerindian people have coevolved with each of these unique and diverse landscapes, ecosystems, and biota, developing a plethora of environmental worldviews and practices that have come under consideration by South American environmental philosophers since the 1980s (Rozzi 2001).

ENVIRONMENTAL ISSUES

The principal environmental concern in South America is the threat to this, the world's treasure trove of biodiversity. The drivers of biodiversity destruction and losses of cultural diversity in South America are many (Primack et al. 2006). Global climate change is provoking a rapid retreat of high Andean glaciers. Sine 1970, glaciers in the Andes have lost 20 percent of their volume, with drastic water supply consequences that are affecting mountain communities, agriculture, and ecosystem integrity. Ozone depletion in the Earth's stratosphere has its strongest expression in the Antarctic ozone hole. At the beginning of the 2000s, in this area of the Antarctic stratosphere ozone levels have dropped 33 percent of their pre-1975 values, with a variety of human health and ecological consequences, such as increases in skin cancer, damage to plants, and reduction of plankton populations and photosynthetic capacity. Exotic invasive species represent another major threat to South American biodiversity. Exotic mammals (such as feral goats, European rabbits, or North American beavers and minks) are especially harmful in archipelagoes such as Galapagos, Juan Fernandez, and Cape Horn. Exotic predatory fish, such as trout and salmon, have a high impact on Andean and temperate freshwater ecosystems.

Mining is also a main driver of rapid and intensive changes in freshwater, marine, and terrestrial biological diversity, as well as cultural diversity involving displacement of communities from their ancestral territories, and destruction of their habitats. In addition to direct habitat destruction, mining frequently involves pollution. For example, mercury pollution caused by the amalgamation of gold in tropical regions such as the Amazon affects the health of aquatic invertebrates, fish, and humans downstream from gold-mining activities. Dams and construction of waterways represent a frequent source of social

conflicts and environmental impacts. One of the most debated mega-projects in South America is the Hidrovia, in which the Paraguay-Parana River would be dredged to let large ships carry cargo from Buenos Aires on the Argentinean coast 3000 km north to Bolivia, Paraguay, and Brazil. This project could cause significant drainage of the Pantanal, the world's largest wetland, which is the habitat of endangered jaguars, giant otters, thousands of invertebrates, and tens of Indian tribes. The latter have joined scientists, artists, humanists, and numerous non-governmental organizations (NGOs) in their protest. This type of mega-project often involves serious and rapid environmental degradation, but they have a widespread presence throughout South American geography and post-Columbian history. Currently, extensive monospecific plantations of eucalyptus are replacing native forests in Colombia, southern Brazil, Uruguay, and Chile, and large-scale plantations of genetically modified sugarcane and soybean are replacing vast areas of tropical forests. At the same time, tropical and temperate coastal marine biodiversity of South America is threatened by shrimp and salmon aquaculture, respectively.

As the process of globalization accelerated over the last quarter of the twentieth century, South America's agriculture industrialized—one element of which is an economy of scale—forcing subsistence farmers off their smallholds, for which they had no legal title. As the twenty-first century unfolds, South America not only continues to supply a hungry world with mineral, wood, and food resources, but also an energy-starved world with biofuels—more especially ethanol derived from sugar cane, further exacerbating social dislocation and environmental degradation. In spite of this pressing scenario, South America is still the home of vigorous peasant, indigenous, and diverse rural and urban communities, who value and defend their biological and cultural heritage. Thus South American environmental philosophy has from its start integrated social and often political analysis with environmental concerns. Today, they are frequently involved in conservation, ecological and social justice, and sustainable development initiatives.

SOUTH AMERICAN ENVIRONMENTAL PHILOSOPHY

There are two main sources of South American environmental philosophy (Rozzi 2001). The first is rooted in the ancient ethos and biocultural landscapes of Amerindian people, as well as African American, old peasant, and contemporary rural and urban communities. Since the 1960s these rich biocultural landscapes have been increasingly studied and valued by academics through historical and critical thinking (Mignolo 1995, Escobar 1996), liberation philosophy and theology (Boff 1995), ecofeminism (Parentelli 1996, Gebara 1999), and biocultural conservation (Rozzi 1997, 2001). The second source is the incorporation of international environmental thinking and philosophy in South American universities. This trend was first sparked in the 1970s by the United Nations Environment Programme that focused on sustainable development and interdisciplinary education (PNUMA/UNESCO 1985, Carrizosa 2001, Leff 2002, Porto-Gonçalves 2006). Second, in the 1990s, the spontaneous interest of South American scholars initiated the discussion and translation into Spanish the work of environmental philosophers in Europe, Australia and the United States, thereby introducing Deep Ecology, Social Ecology, ecocentric ethics, and animal liberation into Latin America (Sosa 1990; Bugallo 1995; Kwiatkowska and Issa 1998; Valdés 2004; Rozzi 1997, 2007).

Roots of South American Environmental Philosophy The Argentine philosopher Rodolfo Kusch was a pioneer in understanding the links between regional landscapes and Amerindian cultures in the Andean region. He realized that no genuine philosophy in the Americas can be conceived without incorporating the Amerindian cultures (1962). Kusch's efforts pitted him against the almost determined ignorance of indigenous thought and lives in South American academic philosophy.

In the1960s Kusch began to develop studies in comparative ethno-philosophy while working in northern Argentina at the University of Salta. Kusch was interested in learning how much of the Inca legacy persisted in twentieth-century peasant communities in Bolivia and northwest Argentina. In "Geoculture of the American Man" (1976) Kusch coined the term *geoculture*; thanks to the insights yielded by this concept, South American geography was no longer seen merely through "colonial lenses" as a virgin territory to be conquered and used. Instead, it was understood as a source of cultural meanings. Kusch disclosed the embeddedness of various South American ethos in the environment, "always situated, always grounded" (Gutierrez 2008, p. 2). Kusch's philosophical inquiry was motivated by a need, felt by Latin-American intellectuals since the second half of the nineteenth century, to discover or renew the cultural identity of the Americas (Mignolo 1995). The Andean biocultural geography inspired this search for identity in the southern cone of South America.

Decolonization Research Program and Environmental Philosophy In the 1980s the Argentine-Mexican philosopher Enrique Dussel developed the notion of transmodernity. This notion, combined with Kusch's geocultural approach, inspired another Argentine philosopher, Walter Mignolo, to develop the notions of *border thinking,*

An Indigenous Community in Bolivia. *Indigenous Quechua and Aymara communities in the high Andes have many celebrations and rituals to pay (*pagos*) and thank (*despachos*) the Earth or* Pachamama. *These rituals seek renovation and purification, fostering reciprocity among people, the land, and deities. border epistemology, and *pluritopic hermeneutics* (Mignolo 1995). Dussel's liberation philosophy aims to overcome eurocentric modernity not simply by negating it "but by thinking it from the underside, from the perspective of the excluded other": the colonized indigenous people, poor peasant communities, and urban marginal citizens and workers (1996, p. 14).

At Duke University Mignolo has further developed this project through the Latin American Modernity/Coloniality Research Program (LAMCRP). He affirms "the 'West and the rest,' in Huntington's phrase, provides the model to overcome, as the 'rest' . . . emerges in its diversity" (Mignolo 2000, p. 310). In contradistinction to eurocentric abstract universals, the alternative proposed by Mignolo is a kind of border thinking that "engages the colonialism of Western epistemology from the perspective of epistemic forces that have been turned into subaltern (traditional, folkloric, religious, emotional, etc.) forms of knowledge" (Mignolo 2001, p. 11). He emphasizes the need to permit the expression of "pluriversal" epistemologies and local histories and communities that exist at the borders of globalization (Mignolo 1995).

At the University of North Carolina at Chapel Hill, another LAMCRP researcher, the Colombian philosopher Arturo Escobar, has developed a geopolitical perspective by working closely with African American communities in the Colombian Pacific on projects about globalization, culture, women, environment, and place. In these communities Escobar finds powerful elements of ecological sustainability in the reinterpretation of anthropological practices related to mythical and symbolic traditions and ecosystemic contexts (Noguera 2007). However, growing violence, poverty, and environmental and social degradation in Latin America are replacing these realities. In "Invention of the Third World," Escobar affirms that "it suffices to take a quick look to the biophysical, economic, and cultural landscapes of the Third World to realize that the Development Project is in crisis" (1996, p. 9). Against this background Escobar calls for a postdevelopment era, which emphasizes local economies rather than global markets and consumerist lifestyles.

Liberation Theology and Environmental Philosophy In contrast to Escobar, Leonardo Boff, a Brazilian liberation theologian and leading environmental philosopher, asserts in his landmark book *Ecology and Liberation: A New Paradigm* (1995), that "what is today in crisis is not so much the development model, but the model of society that dominates the world" (p. 31). He proposes a holistic, ecosocial approach to environmental ethics, affirming that "the new model of society has to aim at a reconstruction of the social fabric, starting from the multiform potentialities of human beings and society" (1995, p. 36). At the same time Boff calls for broadening the spectrum of environmental ethics to encompass a notion of environmental justice that would incorporate the interests of poor people. In *Cry of the Earth, Cry of the Poor* (1997), he situates the social and political concerns of liberation theology in broader ecological frameworks: "We need to refine the concept of ecological justice, but without a minimum of social justice it is impossible to make ecological justice fully effective. The one involves the other" (p. 45). Boff's concept of ecological justice demands an overcoming of both anthropocentrism and ethnocentrism; social well-being requires consideration of biological and ecological diversity as much as of social classes, native languages, worldviews, and cultural practices.

Boff demands integration at multiple levels of relations, repeatedly calling for an interior ecology (psychological, spiritual) and a reconnection with the earth as a whole, a *dignitas terrae.* He highlights the importance of revering the masculine and feminine, a position that echoes the philosophy of leading South American ecofeminists and liberation theologians Gladys Parentelli (Uruguay and Venezuela) and Ivone Gebara (Brazil). Based on their work with poor women, Parentelli (1996) and Gebara (1999) have inaugurated a Latin American theology from the "optic" of women, pointing out that poverty is not a gender-neutral category. Frequently, poor women are victims of physical and sexual violence; they also lack control over maternity and often are left to provide the primary economic support for their children. Since the 1980s ecofeminists have created new networks and journals that explore the relationship between the oppression of women, indigenous people, and nature in Latin America. South American ecofeminists have called attention to the daily lives of women in slums, showing the ways that the exclusion of the poor is linked to the destruction of their lands. This approach concurs with the perspective that in Latin America the most negative impacts of environmental degradation affect poor people; they are the main victims, not the agents of most degradation (Rozzi 2001).

Biocultural Conservation and Environmental Philosophy Working with indigenous communities in southern South America, the Chilean ecologist and philosopher Ricardo Rozzi has integrated ecological sciences and environmental philosophy. He has developed epistemological and ethical frameworks that are designed to gain a better understanding of the differences and similarities between contemporary scientific knowledge and indigenous ecological knowledge. His work has two main goals: (1) enhancing communication and respect among different sociocultural actors and (2) promoting biocultural conservation. In South America numerous case studies show that indigenous and other local communities agree with scientists and other scholars that, where biodiversity has been protected, local communities enjoy higher levels of autonomy and social well-being (Primack et al. 2006). This convergence between indigenous and scientific views is also supported by the concept of "environmentalism of the poor" developed in South America by the Spanish ecological economist Juan Martinez Alier (2002). Likewise, Rozzi (2001) has called for a "field environmental philosophy" approach whereby philosophers participate in long-term interdisciplinary biocultural conservation projects that involve "direct encounters" with human and nonhuman beings living in their habitats. This field environmental philosophy approach aims to prevent the imposition of global epistemological and development models and to promote instead the expression of diverse ethos and traditional ecological knowledge by local communities.

ENVIRONMENTAL PHILOSOPHY AND SOUTH AMERICAN ACADEMIA

There are two main sources of the influence that environmental philosophy has come to have in South American academia: (1) UNEP's support for environmental academic programs and (2) the efforts of individual scholars.

United Nations Environment Programme (UNEP) At the beginning of the 1970s, the United Nations launched two important programs that promoted environmental thought in South American universities. In 1970 the United Nations Educational, Scientific, and Cultural Organization (UNESCO) created the Man and Biosphere Programme (MAB), which "proposes an interdisciplinary research agenda and capacity building aiming to improve the relationship of people with their environment globally" (UNESCO 2008). In 1972 UNEP was founded, and it immediately proposed to establish "an international program on interdisciplinary environmental formal and informal education" (PNUMA/UNESCO 1985).

In 1977 UNESCO and UNEP organized the International Conference on Environmental Education in Tbilisi, Russia; the conference issued a call for each continent to establish a regional network devoted to

environmental thought and education. The most successful such undertaking was the Latin American and Caribbean network, which was consolidated in 1985 at the University and Environment Conference held at the Universidad Nacional de Colombia (UNC). Three central concepts emerged from this meeting: (1) The environment includes not only biotic-physical elements but also sociocultural ones; (2) environmental problems are associated with human development; and (3) university education requires interdisciplinary approaches to address the interactions among nature, technology, and society (PNUMA/UNESCO 1985).

The University and Environment Conference triggered the creation of the Institute on Environmental Studies (IDEA) at UNC, which in 1987 gave rise to the *Pensamiento Ambiental* (Environmental Thought) working group. Since the 1990s this group has researched the relationships between environmental ethics, epistemology, and politics, questioning the technocratic character that prevails in public administration and environmental sciences (Noguera 2005). Since 2000 IDEA has collaborated with the Mexican environmental economist Enrique Leff in publishing the *UNEP Series on Environmental Thought,* an essential bibliographic source on South American environmental philosophy.

Among the philosophers from IDEA, Augusto Angel-Maya stands out for having pioneered an influential school of environmental thought in Colombia. He criticizes the rationalist tradition of philosophy that separates humans from nature. Angel-Maya affirms that "Platonism has drowned Western philosophy" (2002, p. 85). Angel-Maya urges philosophers to turn away from Platonic metaphysics by rediscovering the work of the Ionian pre-Socratic philosophers, with their immersion in the multidimensional complexities of immanent, here-and-now reality, a task he believes is best accomplished through interdisciplinary approaches.

Influences of Anglo-Saxon Environmental Philosophy As an academic subdiscipline, environmental ethics emerged during the early 1970s, mainly in U.S., British, and Australian universities (Callicott and da Rocha 1996). Since the 1990s a few South American scholars have begun to translate and discuss Anglo-Saxon environmental philosophers. In Argentina Alicia Bugallo did extensive research in Deep Ecology and published *De Dioses, Pensadores, y Ecologistas* (Of Gods, Thinkers, and Ecologists) (1995). In Uruguay Eduardo Gudynas introduced the work of the American anarchist ecologist Murray Bookchin and created the Latin American Center of Social Ecology in 1989. In Brazil Sonia Felipe has adapted the work of the animal-liberation philosophers Peter Singer and Tom Regan, participating in the journal *Revista Brasileira de Direito Animal* (Brazilian Animal Rights Review). In Chile Ricardo Rozzi has worked on ecological ethics and introduced the work of Baird Callicott and Eugene Hargrove through a collection of articles in the journal *Ambiente y Desarrollo* since 1996. To enhance the dialogue between South American and Anglo-Saxon environmental philosophers, the University of North Texas and Chilean universities have collaborated on a number of programs in environmental philosophy and biocultural conservation, including a series of occasional papers published online by the International Society of Environmental Ethics (Rozzi 2007).

Social Movements and Environmental Philosophy Since 2000 social movements have played an increasingly influential role in South American environmental philosophy. "Another world is possible" is the slogan of the World Social Forum (WSF) first held in Porto Alegre, Brazil, in 2001. The WSF has brought together countless social movements and leading environmental philosophers and scholars, helping to forge an approach to environmental philosophy that builds on the knowledge of indigenous, peasant, and other subaltern or minority groups to envision other ways of coexisting with a multiplicity of human and nonhuman beings. In the words of the "Manifesto for Life: Ethics for Sustainability," "The ethic for building a sustainable society leads to an emancipation process which, as Paulo Freire taught, recognizes that no one frees anyone else and no one frees himself alone; human beings are only freed in communion" (in Reichman 2004, p. 18). This manifesto, prepared by 35 distinguished Latin American scholars, was signed during the Thirteenth Forum of Ministers of the Environment of Latin America held in Rio de Janeiro, Brazil, in October 2001 and ratified by leading South American environmental philosophers at the Symposium on Environmental Ethics and Sustainable Development in Bogota, Colombia, in 2002; it suggests that a future of South American environmental philosophy is oriented toward a dialogue among the multiplicity of human and nonhuman forms of life.

SOUTHEAST ASIA

Southeast Asia forms a major part of the Indomalayan bioregion. Myanmar (Burma), Thailand, peninsular Malaysia, Singapore, Laos, Cambodia, and Vietnam belong to the Asian mainland, and have a biota that is similar to that of the Indian subcontinent. The insular Sabah and Sarawak (Malaysia), Brunei Darussalam, the Philippines, Indonesia, Timor-Leste, and Papua New Guinea make up most of the great Malay Archipelago, linking Indomalaya to the Australian bioregion. Southeast Asia is also usually considered to include the Andaman and Nicobar islands (India), and the Australian islands of Christmas and Cocos (Keeling).

POPULATION AND POLITICS

Geologically complex and biodiversity rich, this region is home to more than 8 percent of the world's human population and has a land area of about 5 million square kilometers (comparable to that of the European Union). With an average of about 125 people per square kilometer, its population density is similar to that of China and Europe, less than half that of India but four times greater than that of the United States. Although the two major divisions (mainland and archipelago) have many biotic and ethnic connections, the differences give rise to a variety of environmental challenges compounded by cultural diversity and a wide range of political systems: a military dictatorship (Myanmar), a communist state (Laos), a socialist republic (Vietnam), democracies (constitutional monarchies in Thailand, Malaysia, Cambodia, and Papua New Guinea; and presidencies in Singapore, Philippines, Indonesia, and Timor-Leste), and a

hereditary kingdom (Brunei). There are also pockets of unassimilated people, such as the Mangyan tribes of Mindoro (Philippines) and the totally separate Sentinelese (Andaman Islands). The recent histories of these states offer remarkable contrasts, ranging from stability to violent struggle (internal and external), including ecocide and even genocide—despite which there is evidence that both people and nature can achieve significant recovery. Most of these countries now belong to the Association of Southeast Asian Nations (ASEAN).

Although all major nations in the region are designated as "developing countries" (in terms of gross national product and population, some have had dramatic growth rates over recent decades), there are wide variations in human wealth and well-being and associated environmental problems. Singapore has attained a European standard of living, whereas in Myanmar, beyond the ruling elite poverty is widespread. Many Javanese are prosperous compared to the rural poor on other Indonesian islands. Although most areas are safe, the islands of the north Celebes Sea (southwestern Philippines) harbor many pirates and dissidents. Social unrest occurs locally, including southern Thailand, Ambon (Indonesia), Kalimantan (transmigrant and Dayak conflicts), Myanmar, and Timor-Leste (when it achieved nationhood in 2002, by some accounts it was the poorest country in the world), and many of these struggles seem likely to continue.

ENVIRONMENTAL CHALLENGES

The region faces many environmental problems. The biodiversity of Neomalaya (Malay Peninsula, Sumatra, and Borneo) has been greatly influenced by sea-level change over the last 2.5 million years, and the projected ocean rise associated with global warming would have a major impact on the densely populated coastal areas of Southeast Asia. Although much of the region has abundant rainfall, access to freshwater is threatened by climate change, agribusiness, and pollution. Loss of Tibetan glacial feed water for the great rivers of Indochina, including the Irrawaddy, the Mekong, and the Red River, will have massive impacts on humans and wildlife alike. Local rainfall patterns are often seasonal, as in central Philippines and Nusa Tenggara (Indonesia), with the effects of climate change difficult to predict. Inshore marine pollution, such as eutrophication caused by conversion of mangroves for aquaculture, is extensive. Since 1975 about half the mangrove of the Irrawaddy Delta has been cut, and the exceptional flooding caused by Cyclone Nargis in 2008 was at least partly due to this rapid and uncontrolled change.

Many areas have been affected by smoke drifting hundreds of kilometers when peat and forest fires burn out of control. In Kalimantan the so-called "El Niño fires" of 1982–83 destroyed more than 3.5 million hectares of degraded forest, and at least 200,000 additional hectares burned in 1998. These huge fires cause serious health problems, especially in megacities (where the smoke combines with vehicle and factory fumes), and economic loss (including reduced crop growth). Controversy surrounds their cause: Developers blame climate change, whereas environmentalists argue that a mixture of local uncontrolled and internationally financed forest clearance is to blame.

If all major regional forests are destroyed, these fires will eventually come to an end. But long before that point is reached, the impacts of forest destruction on local and global climate regimes, nutrient cycles, erosion, and sediment discharge into the sea are likely to be profound. Following deforestation many local soils rapidly become infertile and are abandoned, after which they are often colonized by dense siliceous grasses (notably "lalang," *Imperata cylindrica*) that inhibit natural tree regeneration. Former forest becomes anthropogenic grassland of very limited utility and greatly reduced biodiversity—as evident in the central Philippines.

UNIQUE BIODIVERSITY UNDER THREAT

These issues raise an acute challenge to the region's biodiversity. The impact of wholesale forest destruction will be massive because the region is one of the greatest biodiversity hot spots in the world. Indonesia covers less than 1.5 percent of the Earth's land surface but supports about 17 percent of all species. If there are roughly 15 million species worldwide, then probably some 2.5 million exist in Indonesia alone. Assuming a conservative 10-percent level of endemism, this means that the area is home to 250,000 species found nowhere else. For Southeast Asia as a whole, the number of endemics probably far exceeds 1 million, most of which depend on closed forest. New Guinea has the third-largest rain forest on Earth, but pressures for timber extraction and land conversion mount daily.

Myanmar, Thailand, the Malay Peninsula, and New Guinea are probably the most species-rich areas of Southeast Asia, closely followed by Vietnam and the islands of Borneo and Sumatra. If one considers marine biodiversity, the Malay Archipelago is very likely the richest on Earth, with one-third of the world's coastline and coral reefs. Nowhere is this biodiversity homogeneous—every mountain range, valley system, and shallow sea harbors a unique mix of species and, in many cases, unique endemics as well. This lack of homogeneity is shown most dramatically in the suture zone between the Asian and Australian tectonic plates occupied by the Philippines, Sulawesi, Maluku, and Nusa Tenggara (Indonesia). Biodiversity measured as species richness per unit area is lower here, but many of the species are unique to local areas. The Philippine islands, for example, are divisible (on the co-occurrence of endemic species) into six subregions, four of which make up the Philippines "proper," with many thousands of species of organisms found only there. It seems certain that many of these have

gone extinct since Magellan arrived in 1521, with the rate of disappearance accelerating sharply since 1900. Although it is a single landmass, Sulawesi offers a comparable picture of relatively low richness coupled with high endemism, including endemics restricted to particular parts of the island. To a lesser extent the same is true of northern and central Maluku, where islands such as Buru, Obi, and Seram all have a good number of endemics. The island of New Guinea (politically divided between Indonesia and Papua New Guinea) is another area of exceptional endemism.

This very high rate of change in species composition across habitats and whole regions (beta and gamma diversity, respectively) is a major challenge for conservation, especially given the wholesale conversion of lowlands for cash-crop monocultures and lumber, displacement of subsistence agriculture into montane regions, mechanized and illegal fishing, and capture of mountain water for irrigation. To conserve the region's biodiversity requires, *in extremis*, what has been called a "structural solution"; actions are required that are unique to every local ecosystem coupled with general restraint to prevent wholesale conversion to anthropogenic landscapes (already far progressed in many areas such as the Philippines, which has only 7 percent of its original forest cover left). In the archipelago in particular, because of the vast number of medium and small islands, where there is a strong tendency toward the evolution of local forms and subspecies, the threat to such "evolutionary significant units" is massive. There is every reason to expect that extensive local genetic diversity affects the majority of organisms throughout this, the greatest archipelago on Earth.

Protest Against New Forest Access Regulations. *Indonesian women protest about use of the nation's forests by mining corporations, in Jakarta on March 10, 2008. Driven by global demand for commodities, Indonesia has one of the highest rates of deforestation in the world—but public concerns about the likely consequences are growing.* **BAY ISMOYO/AFP/GETTY IMAGES.**

WHAT CAN BE DONE?

If climate change is driven by fossil fuel use, then, regardless of its own emissions, the region is largely at the mercy of China, India, Europe, and the United States. An equally potent threat to biodiversity is poverty, coupled with rising population, over which nation states have more control; Thailand, for example, has achieved some measure of population restraint through the work of the family-planning activist Mechai Viravaidya. If, however, escape from poverty depends on increased use of fossil fuel, then this policy may be self-defeating.

For many people now living in the central areas of the archipelago, such as Indonesians resettled by World Bank-funded transmigration schemes during the 1980s, primary forests appear hostile and frightening. Education, especially regarding ecological literacy, will be vital if this is to change, but opportunities are limited by persistent poverty. Many rural people now engaged in agriculture and fishing have little local or traditional ecosystem knowledge. Even though there are encouraging developments, such as dissemination of local-language guides about sustainable fisheries, these have yet to overcome the use of blast (explosive) fishing for local food needs and cyanide to collect reef fish for the international aquarium trade—both hideously destructive and all-too-common practices.

For the conservation of biodiversity, international nongovernmental organizations (NGOs) play a growing role in raising awareness and providing funds for action, although organizations such as the Nature Conservancy have been criticized for dependence on multinationals as major donors. There is increasing collaboration between Southeast Asian and international scientists concerning environmental projects, including the Millennium Ecosystem Assessment of 2001–2005.

However important NGOs, academic research, and the business world may be, any shift to a sustainable Human-Earth relationship will depend on the understanding and willingness of the mass of people. Worldviews and social aspirations, coupled with better education and relief from poverty, will largely determine the future environmental impact of *Homo sapiens* on all parts of the Earth. In Southeast

Asia there are many cultural divisions as well as demographic and economic differences, although in one respect the overall picture appears simple: On the mainland the dominant cultural outlook has been shaped by Buddhism, and in the archipelago (including the Malay Peninsula) by Islam. Christianity is a lesser but important influence throughout, with notable Roman Catholic dominance in the northern and central Philippines and in Timor-Leste. The archipelago, now dominated by monotheistic religions, has mostly had a poorer environmental record than the Buddhist-influenced mainland. However, wherever a consumer-orientated middle class has emerged, as in parts of Thailand, increasing materialism is also evident, with concomitant impacts even on areas formerly held sacred.

ENVIRONMENTAL ACTION AND PHILOSOPHY

Cultural differences, coupled with wide variations in political and economic reality, mean that structural solutions to biodiversity loss are not just desirable—they are essential. Environmental action has to deal with differences not only between but also within countries, especially in large and culturally diverse nations such as Indonesia and Vietnam. International NGOs and national and local government agencies that fail to recognize this reality (including wide variations in land tenure) are unlikely to meet with success—and could well do more harm than good.

Against this background the development of environmental philosophy within the region, including courses taught and leading figures, is vitally important as a source of insight and future leadership. Influential figures in the conservation movement include Angel Alcala (Silliman University, Philippines, a key person in marine protection), Maryati Mohamed (director of the Institute for Tropical Biology and Conservation, University of Malaysia Sabah, Kota Kinabalu), and Chris Margules (Australian team leader for Conservation International's Indo-Pacific Region program). Establishment of the ASEAN Center for Biodiversity (University of Philippines, Los Baños), and the Conservation Training and Resource Center (Bogor, Indonesia) are important steps. BirdLife International in Indochina is active in Vietnam, Cambodia, Laos, and Myanmar. There are also valuable national organizations, such as Education for Nature Vietnam; Wildlife Conservation Society of the Philippines (founded in 1992 and later a key meeting ground for government agencies, NGOs, and academics); the Malaysian Nature Society; and the Center for Environment, Technology, and Development Malaysia (founded by the renewable-energy activist Gurmit Singh).

Most of these initiatives are oriented toward technology and action, not philosophy. Few universities in Southeast Asia teach general philosophy, much less environmental values, although ethical issues are addressed within ecological and environmental courses. The International Society for Environmental Ethics does not list a single representative in Southeast Asia. The philosophy course at the National University of Singapore does include one module, taught by Cecilia Lim. International academic collaboration is likely to be critical to foster growth in environmental philosophy in the region, such as the recently established International Network of Environmental Education, led by Fumiaki Taniguchi from Konan University (Kobe, Japan) in partnership with Phranakhon Rajabhat University (Bangkok, Thailand), Peking University (Beijing, China), and University of Malaya (Kuala Lumpur, Malaysia). The Earth Charter Initiative should also play a valuable role. The effectiveness of such initiatives will hinge on sensitivity to cultural differences, a point that has been explored by Hana Panggabean, from the psychology faculty, Atma Jaya Catholic University, Jakarta (Fremerey and Panggabean 2004).

SPACE/PLACE

Humans see things and events not only as they are, but also as signs or symbols that point beyond themselves to other associated things, events, or ideas. These symbols point to meanings that might otherwise be overlooked because they are obscure, intangible, or far removed in time or space. A sign in the park warning of poison ivy points out a hazard to visitors who can read English, but not the shapes of leaves; a war memorial points back to a past event; a steeple points beyond this world to a transcendent hope.

UNDERSTANDING A SENSE OF PLACE

Such symbols are part of a public and a local vocabulary. Every day each person uses symbols in a locality to take and keep his or her physical and spiritual bearings. Understanding this local symbolic vocabulary—and the intangibles to which it points—is the first step toward sensing the locality as a place, toward feeling "in place." We can appreciate this feeling when we travel to foreign localities that are, to us, largely unintelligible, scarcely places at all. The commonalities of human life ensure that no human locality is to any other human wholly unintelligible, but to be deeply uncertain as to the meaning of many of the things and activities by which one is surrounded is to feel "out of place."

EMOTIONS, MEMORY, AND A SENSE OF PLACE

It is, of course, possible to comprehend meanings while feeling toward them intense repugnance, disapproval, or dislike. We have all understood and yet disliked a book. To understand and detest a place is not, perhaps, so common as to understand and detest a book; but there is, commonly enough, what the philosopher Roger Scruton (2007) calls *oikophobia:* antipathy toward one's home place. The oikophobe is of the place and so understands the place (detachment may enhance insight), but he is not altogether in the place. He is also, in his own way, "out of place." This is because sense of place entails empathy, affection, and understanding. The oikophobe is cut off from full understanding of the place just as the teetotaling prohibitionist, notwithstanding degrees in organic chemistry and physiology, is cut off from full understanding of wine. To understand Austria, for instance, one must not only understand the meaning and recognize the manifestations of gemütlichkeit (cordiality, friendliness)—one must also enjoy gemütlichkeit.

This identification with a place is often tacitly present in natives who cannot imagine themselves living anywhere else. But visitors to places with a distinctive ethos and way of life—places like New York City, New Orleans, Santa Fe, or San Francisco—sometimes feel a surge of similar affinity. Some who do will stay. Chronic homesickness afflicts anyone forced to leave a place with which they identify, because a sense of place implies desire to be in that place.

Empathy and affection may rise to the level of love. Indeed, a sense of place is often described in the language of love. Love of a place is the root meaning of *patriotism* (a word that should not be surrendered to jingoists and chauvinists or to the oikophobes who oppose them). People say that they have "fallen in love" with a place. In this, as in any loving relation, there is an interpenetration and mutual involvement that progressively knits the partners together. A husband, for instance, comes to see something of himself in his wife, as she presumably comes to see something of herself in him. The expression "grown together" is, in such cases, more than mere metaphor. Persons with a sense of place are knitted to the place in an analogous fashion. Looking at the place, they are reminded of the life they have lived there; thinking about the life they have lived, they are reminded of that place.

Memory is, therefore, the third component in a sense of place. This is not reminiscence, for sense of place does not mean that the mind is forever asking itself, "Do you remember when?" Memory is, rather, recognition that, for better or for worse (recurring to the language of love and marriage), here and nowhere else is where my life has been and is being lived. It is, in other words, love completed by conscious and demonstrated commitment to the place.

PLACELESSNESS

Understanding, affection, and memory are the three components in a sense of place. Possessing any one of these in even a small degree, one may lay claim to a sense of place, but it is doubtful that a person utterly devoid of any one of them really feels a sense of place. Localities are, for such persons, only more or less satisfactory. They are enigmas that arouse no curiosity—disposable instruments, like a parking place, a motel room, or a seat in an airport waiting area.

The geographer Edward Relph called this attitude *placelessness* (1976). Placelessness is the absence of understanding, affection, or memory. It may arise in placeless individuals who are incapable of developing a sense of place, or in placeless localities that are impossible to understand, love, or remember. Relph argued that placelessness is increasing for both reasons. There are more drifting nomads who cannot put down roots, and more impenetrable localities that do not provide fertile soil for the sinking of roots.

This argument is easily criticized as a mask for xenophobia; it is not at all clear, however, that people

with a secure sense of place are prone to xenophobia. Xenophobia is, if anything, a pathology of persons who resent unsought placelessness and blame foreigners and immigrants for this unsettled condition. This argument has also engendered a postmodern style of architecture that seeks to recover the unique and local, but the rearguard of modernism routinely denounces it as ersatz, eclectic, and kitschy. Perhaps there is something fundamentally phony about much of this superficially idiosyncratic architecture, but one can admit this and still agree with its protest against the placeless "geography of nowhere" imposed by the "international style."

THE ENVIRONMENT AND A SENSE OF PLACE

The connection between sense of place and environmental values and attitudes is complex. Clearly, persons with a sense of place will not wish to see that place destroyed; they can be expected to show more concern for stewardship of the local environment than, say, nomadic managers of global corporations. But the natural environment will be, for such proud locals, only one facet of the place, joined in complicated ways to its economy, society, and culture. The conflicts between logging communities and environmentalists in the Pacific Northwest show that residents with a sense of place may not prize environmental values. Whether understood as scenery or as natural resources, the natural environment is just one of the things these people understand, love, and remember when they experience a sense of place. They will, therefore, often accept environmental costs as tradeoffs for economic, social, or cultural benefits. Environmentalists who would harness the powerful sentiment that we call a sense of place must, therefore, learn to see and describe the ecosystem as part of the larger social and symbolic ecology of the locale. When environmental degradation can be shown to threaten a way of life and the identities of individuals who are part of it, environmentalism and a sense of place are in harmony. When environmentalism appears to threaten an established local way of life, however, environmentalism and sense of place will clash.

Regard for the viability of a place should include concern for the natural environment, as well as the larger social and symbolic ecology. Such concern is, however, sometimes coupled to indifference to the viability of the natural environment in other places. If my drinking water is safe, I may too easily grow indifferent to the quality of drinking water in other places, even when this has been rendered unsafe by my behavior as a consumer. Thus, to some ethicists attaching special value to one's local environment is a vice akin to the vice that other ethicists find in preferential regard for one's neighbors and kin. The answer to both of these challenges is the same: Abstract regard (for humanity or the environment) normally issues in a censorious attitude, whereas concrete regard (for persons and places) more often issues in constructive action.

SHRINKING SPACE AND TIME

For humans and presumably all creatures endowed with sight, the external world appears to consist of objects that occupy space. Philosophers disagree on this point: Some argue that space is itself a feature of the external world, whereas others regard space as a concept whereby the mind imagines something that is, in fact, quite different from space. Space for the second group of philosophers is analogous to color. The external world has no color, just light with different wavelengths bouncing off or being absorbed by objects: but color is the way our mind imagines these wavelengths. Whatever the answer may be to this abstruse question, there can be no doubt that it is highly practical to understand the world as objects arrayed in space. Spatial maneuvers are, after all, our most effective means of manipulating and controlling the external world.

This is why space is one of the first things the human infant learns to understand. At a young age she discovers that she can have much that she desires by reaching out for it, rolling toward it, crawling after it. This primary spatial education continues in the spontaneous play of childhood and the organized sport of adolescence. Children learn the basic nature of space (along with other things) when they run, jump, and fall; when they catch and throw balls; when they frighten their parents with tricks on their bicycles. In adulthood such exercises may continue in the spatial virtuosity of the athlete, acrobat, or dancer but are more commonly transformed into practical geometries such as navigation, engineering, and ballistics.

The mention of those three sciences should make it clear why humans seek spatial understanding. Practical geometries are instruments of power. It is no coincidence that revolutions in navigation and ballistics (as well as cartography and perspectival drawing) accompanied the birth of the modern age. Successful navigation, engineering, drawing, and ballistics demand advanced spatial understanding, but they are also means of shaping space. Navigation and ballistics, for example, shrink space. Engineering has contributed mightily to what nineteenth-century writers, thinking of trains and the telegraph, called the "annihilation of distance." Since the fifteenth century distance annihilating innovations such as highways, airplanes, and microwave transmitters have radically reduced the effective size of the earth.

The geographer Donald G. Janelle (1969) has described this shrinkage as time-space convergence, because the convergence of locations in space was a reduction in transportation

time. Time-space convergence is a pervasive fact of society. People, goods, capital, images, and ideas move through space with astonishing speed, as do pathogens, pollutants, terrorists, and intercontinental ballistic missiles. (Efforts to channel or stem these flows are another class of space-shaping technologies).

Time-space compression has profoundly transformed the global environment: first by bringing together organisms that had evolved separately—with disastrous consequences for some of those organisms (Native American populations were devastated by Old World diseases such as smallpox)—and second by bringing the farthest corners of the earth into the reach of metropolitan markets. Many critics note that the spatially extensive economy also hides from consumers the consequences of their choices, putting resource extraction, polluting factories, and waste out of sight and out of mind. Others have countered that this annihilation of distance also permits the dissemination of images of environmental degradation. Indeed, because such images often depict vivid extremes, consumers may in some instances overestimate environmental degradation.

The greatest effect of time-space compression on consumer perception of the environment is to separate degradation from the intentions of any single human actor, thereby diffusing the sense of responsibility. If someone cuts down a tree and builds a table, she has no doubt that it was she who cut the tree. If a shopper buys a table, it is much harder for her to connect her intention with the felling of any particular tree. Indeed, she never forms the intention to fell a tree—only the intention to buy a table so that she may give a dinner party for twelve. At the other end of the commodity chain, the lumberjack likewise works in a fog of abstractions. He cuts down the tree not necessarily because he wishes to but because he is impelled to do so by the market demand that reaches him through the orders and inducements of his employer. Thus, a tree is cut and no one feels that it is he or she who bears responsibility for the act. Hence environmental consciousness is not everywhere identical to a sense of place, and time-space convergence is sometimes—but not always—harmful to the environment.

SPECIES

Concern for the protection of endangered and threatened species is central to environmental ethics, and is embodied in public policy. Our moral and legal deliberations about species ought to be grounded in the best current biological and philosophical thinking about species. Unfortunately, there is no single unambiguous definition of *species* in biology, but rather a host of competing species concepts and definitions. Biologists and philosophers disagree about which, if any, is the "correct" species concept, whether we should accept a plurality of species concepts, and even whether *species* are real natural categories. These difficulties are known as "the species problem." This entry discusses various aspects of the species problem and how they impact our moral and legal thinking about species. It argues that there is a sufficiently clear account of the entities our species protection laws aim to protect, and the rationale for protecting them.

PROBLEMS WITH SPECIES

A species concept is an account of the species category. It spells out the special features that distinguish species from other groups of organisms. A species concept indicates where the boundaries are between distinct species and what makes two organisms conspecific. There are many species concepts in the biological literature; four of the most important in current use are discussed below.

The Biological Species Concept: A species is a group of interbreeding natural populations that is reproductively isolated from other such groups (Mayr and Ashlock 1991, p. 26).

The Evolutionary Species Concept: A species is a single lineage of ancestral descendant populations of organisms which maintains its identity from other such lineages and which has its own evolutionary tendencies and historical fate (Wiley 1978, p. 18).

The Ecological Species Concept: A species is a lineage (or a closely related set of lineages) which occupies an adaptive zone [ecological niche] minimally different from

that of any other lineage in its range and which evolves separately from all lineages outside its range (Van Valen 1976, p. 233).

The Phylogenetic Species Concept: A species is a group of organisms, including a common ancestor and all of its descendants (a monophyletic group), that is the smallest diagnosably distinct such group. (See Cracraft 1983; Mishler and Brandon 1987.)

These species concepts give different accounts of what makes a group of organisms a species, and generate different classifications of organisms. For example, the Biological Species Concept (BSC) does not recognize as species groups of organisms that do not interbreed, and consequently does not recognize asexual organisms as forming species. The other three species concepts recognize asexual organisms as species so long as they form ancestor-descendant lineages that meet their other criteria. The Ecological Species Concept and the Evolutionary Species Concept will lump together as a single species populations that do not exchange genetic material due to geographical isolation (unlike the BSC), so long as those populations occupy the same ecological niche, or maintain the same evolutionary tendencies, respectively. The Phylogenetic Species Concept (PSC) is the most fine-grained species concept in that it splits such populations into distinct species, so long as they are diagnosably discernible. The PSC recognizes distinct species wherever a monophyletic group of organisms is recognized as a distinct group for a variety of reasons. Subspecies, distinct forms of species often recognized by geographical or minor character differences, may be regarded as distinct species by the PSC.

Species monism is the view that there is one correct species concept, and a task of biological systematics is to determine which species concept gives the correct account of species and generates a classification that reflects true divisions in nature. Given the ongoing and unresolved dispute concerning the species concept, and the fact that biologists adopt different species concepts in different contexts, an increasingly popular alternative is *species pluralism*. Species pluralists (John Dupré 1993; Marc Ereshefsky 2001; Philip Kitcher 1984) maintain that there is more than one kind of species, and we can accept a number of different species concepts, which need not conflict. Biologists with different concerns may simply be talking about different things. For example, taxonomists employing the PSC generally follow the cladistic approach to taxonomy, which aims to reconstruct evolutionary history, while de-emphasizing the importance of similarities in classification. Those adopting the other species concepts have additional concerns and wish to retain a more intuitive classification. Pluralists have suggested we adopt explicit terminology ("biospecies," "ecospecies," "phylospecies") to make clear which things we are talking about by *species*.

Another area of contention regarding species concerns their ontological status. The traditional Platonic view considered species to be universals—abstract entities distinct from the concrete individual organisms that are their instances. The view that species are universals—eternal, unchanging, abstract entities—is thought to have no place in contemporary evolutionary biology, where species are changing, evolving units that have beginnings and go extinct. According to the class view, a species is a class or set of organisms with certain properties in common. A species concept tells us which qualitative properties (morphological, genetic, etc.) distinguish one species class from another. On one version of the class view, there are properties shared by all and only the members of a species, in virtue of which organisms belong to that species. The other version rejects precise species essences in favor of clusters of features, such that organisms belong to a species if they have a sufficient number of them. Much contemporary thinking about species has de-emphasized qualitative similarities between organisms, and focused instead on populations and the biological relations that unite them into species. This shift has caused many to adopt the species-as-individuals view—that species are concrete, persisting, particular individuals, with organisms as parts rather than members. (See works by Judith Crane 2004, Michael Ghiselin 1974, and David Hull 1978.)

A final aspect of the species problem concerns the reality of species. The difficulties in settling on a species concept and understanding the ontology of species invite this worry. Perhaps species are merely artificial categories drawn up for the sake of convenience. The idea that species gradually evolve into one another suggests that the boundaries between species are quite arbitrary, which is what led Charles Darwin to doubt the reality of species. For species to be real is for there to be an objective fact as to what the different species are, and where the boundaries are between species. Philosophers sometimes talk of "carving nature at the joints," echoing Plato's expression from *The Sophist*. If species are real, there are natural joints to be discovered, and the quest for the correct species concept is the attempt to carve nature at its joints.

CONSERVATION SPECIES

What kind of "species" matter in our efforts to protect endangered species? Consider the U.S. Endangered Species Act of 1973 (ESA). The "Definitions" section contains the following: "The term 'species' includes any subspecies of fish or wildlife or plants, and any distinct population segment of any species of vertebrate fish or wildlife which interbreeds when mature" (Section 3[16]).

The inclusion of "subspecies" and "distinct population segments" shows that the ESA is using a finer-grained

notion of species than the Biological, Ecological, or Evolutionary Species Concepts. Many of the endangered and threatened species listed under the ESA are in fact classified as subspecies in standard classifications. Perhaps the ESA is using the fine-grained Phylogenetic Species Concept (PSC), which treats many "subspecies" as species. However, the PSC's strict adherence to only monophyletic groups as species is clearly not a concern of the ESA. According to the PSC, an ancestral population that buds off a new species but persists without any noticeable change is not considered a species, since it does not include all of its descendants. The ESA's appeal to interbreeding, at least for vertebrate animals, suggests that interbreeding relations would be sufficient to unify such a group of organisms into a species, even if it were not monophyletic. That interbreeding is mentioned only in the case of vertebrate animals suggests that other biological processes, such as ecological forces, could unify a population into a species. The "species" of the ESA are finely divided populations, but the ESA does not specify which biological processes unify populations into species.

Robin Waples (1991) suggests that the protectable populations of the ESA be understood as "evolutionarily significant units" (ESUs). ESUs were introduced to capture the idea of a minimal unit of conservation, which avoids the controversial taxonomic categories of species and subspecies. This would allow ESA species to be more fine-grained than many standard species concepts. However, ESUs are identified by morphological or genetic distinctness from related populations. David Pennock and Walter Dimmick (1997) note that many populations listed under the ESA do not qualify as ESUs. Protected populations of grizzlies and grey wolves are identified by region, and do not differ genetically or morphologically from unprotected populations in other regions.

The fine-grainedness of ESA species appears to flow from the goals of slowing the current rate of extinctions, and preserving ecosystems on which species depend. Section 2(b) reads: "The purposes of this Act are to provide a means whereby the ecosystems upon which endangered species and threatened species depend may be conserved . . ." The emphasis on ecosystems accompanies a concern with regional populations. In some cases regional populations are classified as subspecies. For example, the ESA lists six subspecies of beach mice. The mice occupy similar habitats in the Southeastern United States, are closely related biologically, and are distinguished only by region and minor morphological differences. Where biological classifications do not differentiate populations as subspecies, the ESA may differentiate them nonetheless. Grizzly bears are listed as a single species (*Ursus arctos horribilis*, a subspecies of brown bear), but the ESA distinguishes and treats separately five different regional populations of grizzlies. In March 2007, the Yellowstone grizzly was removed from the threatened list, while the remaining four populations of grizzlies remained protected.

Grizzly Bear Peering Over the Grass, Yellowstone National Park. *The grizzly bear (*ursus arctos horribilis*) is a symbol of the American wilderness; it is the largest species of bear found in North America. Between 1800 and 1975, the number of grizzlies in the United States decreased from around 50,000 to fewer than 1,000. The effort to recover the number of grizzly bears, initiated in 1975, has met with some success.* **NPS.**

The ESA uses a species concept based on the idea of a regional population. How fine-grained is it supposed to be? Where do we stop dividing populations? Consider the ESA definition of "endangered species": "The term 'endangered species' means any species which is in danger of extinction throughout all or a significant portion of its range . . ." (Section 3[6]). The range of a species may be broader than an area occupied by a protected population, as in the case of grizzlies. The range of grizzlies includes Washington, Idaho, Montana, and Wyoming, but grizzlies are endangered in a portion of their range, as indicated by the four out of five regional populations protected under the ESA. But portions of ranges used to divide populations for protection must be "significant." This language is vague, as is often the case with legal language, and allows room for judgment. Clearly the status of the American red squirrel should not be based on the fate of one backyard population. Given the

concern to protect ecosystems, it is plausible that the limit of a "significant" portion of a range is an ecosystem that can be identified and discerned for the purposes of conservation. Thus the following species concept appears to be implicit in the ESA and in our practical thinking about species conservation: *The Conservation Species Concept:* A (conservation) species is a population of organisms (unified by interbreeding relations, occupation of a common ecological niche, or other biological process) that depends on a discernable ecosystem for its survival.

The Conservation Species Concept recognizes as species biologically unified populations that can be discriminated on the basis of protectable ecosystems. It is such populations that species protection laws aim to protect.

Because the Conservation Species Concept is population-based, it suggests a species-as-individuals ontology. Perhaps understanding species as individuals can help to explain the value of species and why they ought to be protected. It has been suggested that species as individuals have interests in addition to any interests of their members, and so deserve moral consideration independently of their value to humans. (See Lawrence Johnson [2003] for an attempt to show this.) But even if species are the same type of entity ontologically as organisms, given the comparative lack of cohesion and other significant differences between species and organisms, trying to establish a meaningful account of species interests still poses a substantial challenge (see Sandler and Crane 2006).

The ESA provides another account of the value of species: "These species of fish, wildlife, and plants are of esthetic, ecological, educational, historical, recreational, and scientific value to the Nation and its people" (Section 2[3]). This account of the value of species is not only human-centered, it is nation-centered, which many environmentalists may find unsatisfactory. It provides a rationale for protecting endangered populations that avoids the difficulties in giving an account of species value independently of human interests. In fact, the ESA explicitly does not recognize as endangered any species of insect that is considered a "pest" (Section 3[6]). If we rely on such an account of species value, there are no true conflicts between human interests and those of endangered species. Such apparent conflicts are between competing human interests.

The question of species realism would appear to have profound implications for efforts to preserve species. If species are not real, but merely convenient categories, are efforts to protect species misguided? No. Even biologists and philosophers who reject the reality of species can accept that populations are real. A population is a group of organisms that is integrated in some biologically interesting way—for example, by interbreeding or ecological forces. The Conservation Species Concept is based on this idea of a population. If we take a pluralist approach to species, we can accept such species concepts as legitimate. Species monists who believe there is one correct scientific concept can allow that conservationists are not talking about biological species, but populations that can be identified by the ecosystems on which those populations depend, and which we have an interest in protecting.

SPECIESISM

Richard Ryder is credited with coining the term *speciesism* in 1970 (see Ryder 1975, 1989). As Ryder himself observed, "In 1985 the *Oxford English Dictionary* defined speciesism as 'discrimination against or exploitation of certain animal species by human beings, based on an assumption of mankind's superiority.' This definition marked the official acceptance of 'speciesism' into the language" (1998, p. 320). Ryder goes on to refer to the pioneering work of Peter Singer, who has done much to both popularize the concept of speciesism and to present arguments justifying claims that speciesism is a morally odious practice.

The charge of speciesism, as it occurs in debates about the moral status of nonhuman animals, usually applies to people who attempt to justify different treatment of nonhuman animals (or who attribute to such animals different value) using the criterion of species membership. Speciesism has been compared to both racism and sexism. Racists attempt to justify different treatment and different attribution of value using race membership as a criterion, and sexists do the same using gender as a criterion. Opponents of speciesism argue that just as racism and sexism are morally odious as applied to our fellow humans, so, too, is speciesism as applied to our fellow creatures. Opponents of speciesism believe that the moral community—the community of beings that count and have moral worth—needs to be expanded to include both humans and nonhuman animals.

The debate about speciesism has been particularly intense in connection with the use of millions of nonhuman animals in biomedical experiments. As Singer has pointed out:

> The experimenter, then, shows bias in favor of his own species whenever he carries out an experiment on a non-human for a purpose that he would not think justified him in using a human being at an equal or lower level of sentience, awareness. . . . No one familiar with the kind of results yielded by most experiments on animals can have the slightest doubt that if this bias were eliminated the number of experiments performed would be a minute fraction of the number performed today. (1989, p. 80)

Bias against animals in the context of animal experimentation in turn has led to intense debates about (a) the cognitive status of nonhuman animals; and (b) the problem of cognitively marginal humans. In connection with the latter issue, some have argued that many nonhuman animals are cognitively more sophisticated than young infants, those with severe mental retardation, or advanced senility. Because these latter are included in the moral community of beings that count, why not include nonhuman animals—unless you are guilty of speciesism? Tom Regan (1979) labeled this "the argument from marginal cases," and it appears in nearly all appeals for extending the same ethical regard we accord so-called "marginal" members of our own species to cognitively equal or superior members of other species.

LaFollette and Shanks (1996) have distinguished between *bare speciesism* and *indirect speciesism*. Bare speciesism involves differential treatment of organisms simply on the basis of a biological species difference. It is hard to see how a mere species difference can possibly be morally relevant. By contrast, indirect speciesism is the view that the evolutionary changes giving rise to species differences were accompanied by changes in morally relevant cognitive properties that restrict the moral community to the human species. Issues concerning the mental lives of animals have been reviewed in the work of Niall Shanks (2002).

In an important early discussion of these matters, laid out in a footnote in *The Principles of Morals and Legislation* (1789), the utilitarian philosopher Jeremy Bentham observed:

> The day *may* come, when the rest of the animal creation may acquire those rights which could not have been withholden from them but by the hand of tyranny. The French have already discovered that the blackness of the skin is no reason why a human being should be abandoned without redress to the caprice of a tormentor. It may come one day to be recognised, that the number of legs, the villosity of the skin, or the termination of the *os sacrum* are reasons equally insufficient for abandoning a sensitive being to the same fate. What else is it that should trace the insuperable line? Is it the faculty of reason, or, perhaps, the faculty of discourse? But a full-grown horse or dog is beyond comparison a more rational, as well as a more conversable, animal than an infant of a day, or a week, or even a month old. But suppose the case were otherwise, what would it avail? The question is not, Can they *reason*? nor, Can they *talk*? but, Can they *suffer*? (1879, p. 311)

In this passage we find the earliest statement of the argument from marginal cases, in this instance "an infant of a day, or a week, or even a month old." Peter Singer, in his book *Animal Liberation* (1975), elaborated a view of the moral status of nonhuman animals along lines sketched here by Bentham, using the same utilitarian arguments. Singer focuses, as Bentham does, on the moral significance of animals' pain and suffering. As Singer observed in *Animal Liberation*, "If a being suffers, there can be no moral justification for refusing to take their suffering into consideration" (1990, p. 8). For Singer any

being capable of suffering has a place in the community of beings that have moral standing. He argues that just as racists and sexists wrongly treat certain individuals differently on the basis of morally irrelevant traits, so speciesists are guilty of a similar error. Though Singer sometimes uses the phrase "animal rights," he has made it very clear that, as a utilitarian moral theorist, he prefers not to talk about rights at all, whether animal or human.

By contrast, Tom Regan, in *The Case for Animal Rights* (1983), has developed an explicitly rights-based approach to the moral status of animals. If, as Regan argues, nonhuman animals have rights, then their interests cannot be sacrificed even if such sacrifice would greatly benefit human beings. Regan's basic idea is that creatures should be treated the same unless there is a morally relevant reason to justify a difference in treatment. A mere difference in species membership is not, in his view, a morally relevant difference. For Regan nonhuman animals have an inherent worth that trumps their instrumental value to us as subjects of painful experiments and as farm animals.

Defenders of animal experimentation such as Carl Cohen (1986) object to the comparison of speciesism with racism and sexism. For Cohen the capacity for moral judgment is what distinguishes humans from other animals. By contrast, Peter Carruthers (1992) has argued that the experiences of animals (if any) are not sufficiently like ours to confer moral standing on them.

SPINOZA, BARUCH
1632–1677

Baruch (Benedict de) Spinoza scandalized the western European world and his own Jewish community in Holland with his declaration that God is nothing other than nature. His philosophy maintains that one substance comprises all of existence. God, the force of creation, cannot be outside, above, or beyond the created world. Because God is perfect, infinite, eternal, and coextensive with all of existence, the world itself must be identical with divine perfection. God is in everything, and everything is in God (both "pantheism" and "panentheism").

According to Spinoza, God expresses himself in infinitely many ways; he has infinitely many "attributes," which are further divided into infinitely many "modes." Humans conceive two attributes, "thought" and "extension," each of which is perfect, complete, infinite, and eternal. Thus, God is not merely spiritual or mental, but equally corporeal. Infinitely many ideas comprise thought, whereas "extension" names the interactive community of infinitely many bodies. Bodies and ideas express the same order and connection of causes. This means that any individual thing in nature exists, at the same time and to the same degree, as a thinking and a bodily power. Human minds are nothing other than the ideas that correspond to human bodies. All things, including rocks, mice, and computers, have "minds," ideal powers that correspond precisely to the powers of their bodies ("panpsychism").

Such metaphysical principles inspired the Deep Ecologist philosopher Arne Naess to declare, "No great philosopher has so much to offer in the way of clarification and articulation of basic ecological attitudes as Baruch Spinoza" (1977, p. 54). Deep Ecologists are also attracted to Spinoza's doctrine of *conatus* (striving), which contends that each and every thing strives to persevere in being and enhance its existence. The recognition that all beings aim at "self-realization," in an ecological interpretation, fosters an appreciation of other beings' integrity in a way that might restrain human exploitation. Spinoza's principles and his own attitudes condemn anthropocentrism, the view that the nonhuman world exists for the use and pleasure of people (see also Sessions 1977, Mathews 1991).

Deep Ecological interpretations of Spinoza have met with criticism from several theorists, notably the philosopher Genevieve Lloyd. Lloyd notes that, although Spinoza propounds a nonanthropocentric metaphysics, his "morality" is entirely human-centered and excludes any moral consideration of nonhuman beings, affirming that "other species can be ruthlessly exploited for human ends" (1980, p. 294). Her criticism centers on Spinoza's assertion that the "rational principle of seeking our advantage teaches us to establish a bond with men, but not with the lower animals, or with things whose nature is different from human nature" (Spinoza 1985, p. 566).

Naess rebuts Lloyd's criticism by pointing out that the term "moral" is never used by Spinoza and is entirely inappropriate to his philosophy. He contends that Lloyd misleads her readers by suggesting that there is a uniquely human moral community that enjoys special "rights" separate from "natural right," the capacity to preserve and enhance one's life. The "rights" a community institutes and upholds are simply techniques humans have within their power to live well. Such forms of association are different in character, but not in kind, from, for example, packs of wolves. Although Spinoza cannot support a program of animal rights, his views allow nonhuman animals to be "members of *life communities* on par with babies, lunatics, and others who do not cooperate as citizens, but are cared for in part for their own sake" (Naess 1980, p. 319).

Nevertheless, Lloyd indicates an ambiguity in ecological philosophy; although ecological thought aims above all to undermine anthropocentrism, it often does so by "humanizing the nonhuman" (1980, p. 307). Anthropocentrism is not obviously weakened by affirming that all beings resemble us in some ways, or by viewing the universe as a great Self. Spinoza himself consistently criticized the theological tradition for imagining God in human terms. Lloyd's critique and Naess's attraction to Spinoza's antimoralism points to new directions in which Spinozism might go in support of an ecological perspective. Rather than expanding human categories to foster respect for nonhuman reality, Spinoza's philosophy suggests that we naturalize humans as thoroughly as possible. Spinoza encourages us to see that we are constituted deeply by the myriad powers we depend upon to survive and flourish, whether they are our families, the atmosphere, the military-industrial complex, or our nonhuman animal companions. Our constitutive connections complicate any boundary between the human and nonhuman, whereas a moral law upheld in the name of humanity as a special genre of being might falsely elevate people out of the rest of nature. Spinoza affirms our necessary dependence upon the human and nonhuman world, and thereby points to the importance of caring for and transforming the quality of such relationships to enjoy more vital ways of being together.

ST. FRANCIS OF ASSISI
1181 or 1182–1226

St. Francis of Assisi, patron saint of the environment and animals, was born in either 1181 or 1182 in the town of Assisi in Umbria, Italy, and was baptized as Giovanni de Bernardone. His wealthy merchant father, who was in France on business at the time, renamed him Francesco, in honor of his maternal ancestors from France. As a young man, Francis pursued an education while engaging in carousing with his friends from the nobility. Never interested in entering into his father's commercial ventures, Francis experienced a spiritual crisis in his early twenties. He began spending time as a hermit, while seeking guidance from God. Much to his father's chagrin, Francis rebuilt dilapidated churches, aided those without adequate clothes or food, nursed lepers, and abandoned his own fine garments and possessions, to cleanse himself of worldly attachments. In 1209, Francis founded the Order of Friars Minor, bound by vows of poverty, chastity, and obedience. Three years later, St. Clare of Assisi, supported by Francis, organized an order for women, the Poor Clares, based on the same principles. In 1221, St. Francis founded the Third Order open to the laity. Francis died in 1226, and was canonized a mere two years later in 1228 by Pope Gregory IX.

St. Francis of Assisi is often misunderstood as the first saint to encourage Christians to care for nature, when he is actually a participant in a long tradition of Christian protection of nature beginning with Christian monks in the third century. His medieval biographers, such as Thomas of Celano, report Francis fed bees in winter, released animals from traps, and allowed native wildflowers to remain around the edges of a cultivated garden. These practices, however,

St. Francis of Assisi. *St. Francis Preaches to the Birds, a late thirteenth-century painting by the Italian artist Giotto. In Christianity, St. Francis is considered to be the patron saint of the environment and animals.* **THE ART ARCHIVE/MUSEE DU LOURVE PARIS/ALFREDO DAGLI ORTI.**

continued the values of late ancient Celtic and desert monastics, who protected wildlife from hunting and appreciated regional flora. Francis's original contributions lie instead in his resistance to Christian treatment of nature as a mere material possession; his concern for the marginalized, whether human or in nature; and his practical approach to the social issues presented by the growth of towns and cities as Europe slowly emerged from feudalism. In his "Canticle to Brother Sun," for example, Francis exhorted Christians to a non-hierarchal valuation of nature, by identifying the planets as brother and sister. When Francis preached his well-known sermon to the birds, he not only acknowledged the worth before God of all non-human creatures, he also subtly argued for the spiritual equity of humans who were economically marginalized or socially ostracized, such as the lepers Francis physically embraced. The Franciscan friars were mendicants, which meant they were not necessarily tied to the church's estates and property holdings, and could reach out to the urban poor—who, unlike the feudal peasants, had no access to the land. Franciscans ministered to the victims of natural disasters, like earthquakes, rather than adopting the fatalistic attitude that such tragedies were God's judgment on the unrighteous.

Many stories about St. Francis's environmental ethos can be interpreted in two ways. According to legend, St. Francis tamed the wolf who had been terrifying people who ventured outside the town walls of Gubbio by striking an agreement between the wolf and the citizenry: If the wolf stopped his attacks, the town's residents would feed him. On one level this tale calls for the protection of all God's creatures, even the large predators. On another, it argues that those unable to easily feed themselves will eventually attack or harm others. Sharing resources with those who have no honest way to make a living thus will prevent the hungry from becoming outlaws and threats to the greater society.

Francis withdrew to Mount Alverna for prayer, and in doing so received the stigmata or the wounds of Christ from a seraph, an angelic being. For Christians, Christ is the Creator of the universe and his body is an analog for the cosmos. At the time, avaricious churchmen utilized the centrality of the body and blood of Christ, in the bread and wine of the Eucharist, as a rationalization for church ownership of vineyards or collection of offerings of bread or grain; Francis received the environmentally critical symbolism of Christ's suffering and death as a result of his unselfish service to others. Francis thus reminded Christians that care for the poor and needy, and for God's Creation, should be the expression of their religious faith, rather than with feudal hegemony over natural resources. In experiencing a vision at an isolated and uncultivated locale, Francis continued a Biblical tradition of encounters with the divine in wilderness settings.

After the death of Francis, Franciscan appreciation of the environment contributed to the development of modern science through the investigations of friars such as Roger Bacon, who during the thirteenth century utilized the scientific method and advocated detailed observation of nature. Today, both the Roman Catholic Church and the Anglican Communion (Episcopalians) continue to sanction Franciscan orders that champion environmental causes, work to relieve poverty, sponsor retreats in natural settings, and encourage Christians to simple living and care of the earth.

STEWARDSHIP

The term *stewardship* refers to a way of thinking about environmental responsibility that is based on the metaphor of human beings as stewards: persons who are responsible to an owner for the care or management of that person's household and goods. Environmental stewardship extends the concept of a household to include the whole earth or some part of it. It also extends the role of a steward to the human race, the present generation, an organization or agency, or an individual landowner. Synonyms or near synonyms for *steward* include *caretaker*, *curator*, *custodian*, *guardian*, and *trustee*.

THE STEWARDSHIP CONCEPT

Steward comes from the Old English word *stīweard*, from *stī*, meaning "hall," and *weard*, meaning "ward," or "guard." Its primary meaning is an official or servant who is responsible for the domestic affairs of a household, including supervising the other servants, managing money and keeping the books, and directing the serving of meals. The term also has been used to denote a ruler or highly placed noble serving as a minister to a ruler and to offices and occupations such as magistrate, labor union representative, flight attendant, shipboard caterer, and financial manager.

The two key elements of the stewardship concept are the ability to care for, manage, or control persons or things and accountability for the proper exercise of that ability. A steward exercises power and authority but does not have license to do so in a self-serving or careless manner.

Although the term *stewardship* is used widely in environmental writing, its implications and appropriateness have been debated. Critics charge that stewardship is based on the same problematic assumptions and values that underlie the environmental crisis: the idea that humans are separate from and superior to the rest of nature, which is seen as a pool of resources to be managed and controlled by the rational application of science and technology.

Defenders counter that the stewardship model recognizes that humans are unique in their power to transform, degrade, or destroy the earth and their ability to make individual and collective decisions about ways to use that power. For them, the concept of stewardship expresses a sense of responsibility for one's actions as they affect, directly or indirectly, other people and the natural environment over great distances and far into the future, a sense that has become rare in a competitive, individualistic, shortsighted, profit-oriented, and anthropocentric consumer culture.

RELIGIOUS TRADITIONS OF STEWARDSHIP

In many Western religious traditions God is the true owner of the earth and the one to whom human beings are responsible in every aspect of their lives. The stewardship concept is less prominent in or largely absent from Eastern and indigenous religious traditions. Some regard stewardship as a weak or marginal theme in Western religion, but others see it as firmly rooted in Jewish, Islamic and Christian scripture and tradition.

Psalm 24:1 declares, "The earth is the Lord's, and the fullness thereof; the world, and they that dwell therein." God tells the people of Israel, "The land is mine; with me you are but aliens and tenants" (Leviticus 25:23). Islam teaches that Allah has appointed humans as caliphs or viceroys in the earth (Qu'ran, 6:165). In Christianity the overt use of the term *stewardship* for a person's responsibility to God for the use of created things began with the sixteenth-century theologian John Calvin: "Let everyone regard himself as the steward of God in all things which he possesses. Then he will neither conduct himself dissolutely, nor corrupt by abuse those things which God requires to be preserved" (*Commentary on Genesis,* 1554). In the seventeenth-century English chief justice Matthew Hale extended the concept to human responsibility for the natural environment, writing, "In relation therefore to this inferior world of Brutes and Vegetables, the End of Man's Creation was, that he should be the vice-roy of the great God of Heaven and Earth in this inferior world; his Steward, *Villicus*, Bayliff, or Farmer of this goodly Farm of the lower World" whose charge is "to preserve the face of the Earth in beauty, usefulness, and fruitfulness" (*The Primitive Origination of Mankind* 1677).

In twentieth-century Protestantism the most common meaning of the term entailed giving a portion of one's income, volunteering one's time, or lending one's talents to the work of the church. With the rise of environmental concerns in the second half of the century, *environmental stewardship*, *stewardship of the environment*, and similar usages became increasingly common in religious and ethical literature. The concept and its scriptural roots have been used to refute the charge that rapacious domination is the orthodox Jewish and Christian attitude toward nature. It also has been used to define an ethical position between exploitive domination and subordination to nature.

Some theologically conservative Christians, especially those who expect the imminent end of the world, regard environmental stewardship as at best irrelevant to the church's mission to spread the message of salvation or at worst heretical earth worship. Political and economic conservatives criticize religious communities' advocacy for

religious environmental concern as overly influenced by "radical environmentalism." Although they may characterize their own position as stewardship (e.g., the Interfaith Stewardship Alliance), their skepticism about ecological threats and opposition to environmental regulation puts them at odds with most people who embrace that term.

In contrast, some religious writers, especially more liberal and radical theologians, have criticized stewardship language for being too hierarchical and managerial to express human solidarity with the rest of creation or God's active presence within nature.

SECULAR VERSIONS OF STEWARDSHIP

There are also significant uses of the term in secular contexts, suggesting that it need not assume a theistic or God-centered worldview. For example, there are organizations such as the Forest Stewardship Council, the Land Stewardship Project, and the Alberta Stewardship Network. Conservation programs that encourage voluntary efforts by landowner communities to promote ecological preservation and restoration on their property often are called stewardship programs, reflecting their reliance on a sense of obligation on the part of the property owner that transcends short-term economic self-interest.

What could take the place of God in a secular stewardship ethic? There are a number of human communities that environmental stewards might serve and to which they might be responsible:

1. Future generations: The present generation of human beings holds the earth in trust for those who will come after it, who are entitled to their fair share of the planet's bounty. Persons alive today thus have a responsibility to live sustainably, to use the earth's resources in ways that will not deplete them or impair the functioning of the earth's life-support systems.
2. The international community: Nations may be seen as responsible to the wider international community, including its most impoverished members, for the fair distribution of the benefits of economic development and for maintaining the quality and integrity of the global environment.
3. Citizens: Government agencies have stewardship responsibility for public lands and resources (the U.S. Bureau of Land Management, the National Park Service, etc.) on behalf of the nation's citizens.
4. Local or regional communities: Individual landowners may be held responsible to their neighbors for maintaining the ecological values (e.g., wildlife habitat, water quality, soil fertility) of their property.

Some secular stewards may see themselves as responsible not only for some portion of nature but also to nature as the whole community of life or as a cosmic creative process.

MANAGEMENT OR CARE?

Stewardship sometimes is presented as wise use of natural resources for the benefit of human beings. In contrast to such an anthropocentric, or human-centered, view, nonanthropocentric understandings of stewardship regard humans as accountable for the welfare of nonhuman individuals or communities as well. The approach that is adopted affects the characterization of stewardship: as the management of a tool or resource or as care for a loved and respected fellow being.

The term *management* suggests an effort to control someone or something to serve a purpose that is outside or separate from that entity, imposing order on activities that otherwise would be chaotic or directionless. Although one person may manage another in certain circumstances, to treat people only as tools or resources to be directed or controlled violates their inherent dignity as beings who have intrinsic value. For some, to treat animals, plants, ecosystems, or other natural entities solely as means to an end is also morally objectionable.

Whether the object of care is valued for its usefulness (a car or a tool) or loved or respected for its own sake (a child, elderly parent, or medical patient), the concept of caring implies an attempt to maintain or restore the proper functioning of a machine or the health and well-being of an organism in accordance with its inherent norms or requirements. In a nonanthropocentric definition of stewardship, *care* is a more appropriate term than *management* in defining human beings' relationship to nonhuman beings. Nonetheless, some environmental philosophers deny that humans have the right or competence to exercise power over other species. For them, care may imply a condescending, presumptuous, or paternalistic attitude toward "inferior" creatures that undercuts a proper regard for fellow beings.

INTERVENTION OR RESTRAINT?

The definition of stewardship as acting upon its object as caring or as management gives rise to the objection that stewardship is inappropriately interventionist when applied to nature. For some critics of stewardship the idea that humans have a moral responsibility to intervene in natural systems assumes that humans know what is best and that nature cannot flourish without them. Those who assume the role of steward overestimate their ability to understand and control vast, complex webs of environmental relationships and overlook the ability of ecosystems to be self-regulating. A totally managed and

humanized world also would deprive nature of its mysterious otherness and independence.

In response, advocates of stewardship argue that a hands-off policy toward nature is unrealistic and irresponsible. Very little of nature is untouched by humans, and not everything that once was thought of as "unspoiled wilderness" really was.

Humans must intervene in nature to meet their needs for survival and self-realization; stewardship means doing so in ways that will not waste resources or damage the environment to the detriment of human and other forms of life. Because so much of human activity has had destructive consequences, people have a responsibility to protect nature actively from those consequences and to reverse them where they can.

It also can be argued that humans are by nature creative transformers of their surroundings; denying them the right to do that violates their integrity and implies that they are unnatural. There is also a long-standing tradition, not necessarily embraced by all advocates of stewardship, that humans have a role in perfecting or completing an unfinished creation, carrying on the continuing work of the Creator or nature's creative powers.

The most plausible interpretations of stewardship fall between the extremes of total disengagement and total management. A restrained approach to stewardship would allow the minimum intervention necessary to maintain a sustainable, just, and dignified human civilization and protect and restore the species and ecosystems that human activity threatens or has harmed. Although human responsibility would be global in the sense that no part of the earth can be immune from being threatened or influenced by human activities, different degrees of intervention would be appropriate for different types of landscape, for example, more intervention in domesticated landscapes and less in wilderness areas.

CONTRIBUTIONS AND SHORTCOMINGS

Stewardship has contributed to the evolution of environmental ethics. It has helped draw questions about human impacts on the environment into the realm of moral and religious responsibility rather than leaving them to economists, industrialists, and engineers. It also has focused attention on the importance for environmental ethics of the choice of metaphors for defining the human place and role in nature.

As is the case with any moral model or metaphor, stewardship also has shortcomings. By itself, it does not provide criteria for good stewardship; stated in another way, its susceptibility to widely divergent interpretations offers too many possible types of criteria. It does not present a direct challenge to many of the cultural assumptions that for some philosophers and theologians lie at the roots of the environmental crisis. Even if stewardship does not require or endorse those assumptions, this ambiguity leaves it open to being reduced to more or less enlightened anthropocentric utilitarianism.

However, it is clear that for some who advocate a stewardship ethic such a reductive understanding is not adequate. To grasp how a particular stewardship ethic interprets environmental responsibility, one must look beyond its use of the word to its underlying convictions about humanity, nature, and the ultimate sources of moral obligation.

SUBSTANTIAL EQUIVALENCE

Substantial equivalence is a concept that was developed to aid in the evaluation of the safety of new food products, particularly genetically modified foods. Many traditional

foods, such as tomatoes and potatoes, contain some toxins but nevertheless have a long history of safe consumption. In evaluating the safety of novel foods, the question is not whether certain foods are completely safe but whether they are at least as safe as traditional foods.

Substantial equivalence is the principle that novel foods should be compared with traditional foods to determine whether a novel food is likely to present a new risk or a greater risk than the conventional food. The comparison involves both the biological composition of the foods and their nutrient, antinutrient, and toxin levels. Substantial equivalence is a doctrine of relative safety, not absolute safety.

If substantial equivalence is established for a novel food product, that product generally is considered to be as safe as its conventional counterpart. For many genetically modified foods, substantial equivalence can be established with the exception of the one or two specific new traits that the genetically modified food was engineered to contain. In these cases, risk assessment is directed toward those new traits. In rare instances, a novel food may be wholly unlike any traditional food and no substantial equivalence will exist, requiring extensive safety testing of the new product.

As genetically modified food products were being developed and tested in the late 1980s and early 1990s, concern arose about finding ways to evaluate their safety. The Organization for Economic Cooperation and Development (OECD) brought together a team of experts from many countries to consider how to assess the safety of genetically modified foods. One of the recommendations was the substantial equivalence concept. The principle of substantial equivalence later was endorsed by a United Nations Food and Agriculture Organization (FAO) and World Health Organization (WHO) joint expert consultation. The adoption of the substantial equivalence concept by the OECD, FAO, and WHO was not binding on any countries but did lead to the adoption of the doctrine by many member countries. The manner in which the doctrine was implemented in different countries, however, varied significantly and led to ongoing disputes about genetically modified food products.

In the United States, the Food and Drug Administration (FDA) is responsible for ensuring that all marketed food products other than meat and poultry are safe. The FDA treats genetically engineered food products the same way as traditional food products; no special requirements apply.

In general, FDA approval is necessary before a food product that contains a new additive is commercialized. This could include genetic material added to a conventional food to produce a desired trait. There is an exception to the FDA approval requirement for foods that are "generally recognized as safe" (GRAS) by experts. With respect to genetically modified foods, the FDA relied on the concept of substantial equivalence to determine that "[i]n most cases, the substances expected to become components of food as a result of genetic modification of a plant will be the same as or substantially similar to substances commonly found in food, such as proteins, fats and oils, and carbohydrates" and therefore will be GRAS (Statement of Policy 1992, 22984, 22985).

Although the FDA sets standards, the manufacturer of a food additive, not the FDA, is responsible for determining whether that additive is GRAS. A manufacturer does not need to report to the FDA that it has made a GRAS determination. As a result, use of the substantial equivalence doctrine by the FDA has produced a system in which genetically modified foods generally do not need regulatory approval prior to their commercialization.

Many European countries have adopted the substantial equivalence concept but have applied it much more stringently because of a high level of concern about the safety of genetically modified products. Many European countries generally do not permit the commercialization of most genetically engineered food products. This difference has led to ongoing international disputes between the United States and the European Union about the international shipment of and trade in genetically modified products.

The substantial equivalence concept has been criticized for lacking a definition of what precisely to compare or how similar items need to be in order to be substantially equivalent. This vagueness allows for a wide degree of flexibility in applying the doctrine, which can result in less rigorous regulation or safety evaluation than is appropriate. There are also concerns about the ability of substantial equivalence to provide an adequate basis for safety assessment for more complex next-generation genetically modified products. In 2007 the FDA issued a draft risk assessment that applied a substantial equivalence analysis to conclude that food products from cloned animals, such as meat and milk products, were as safe to eat as products from conventionally bred animals.

SUSTAINABILITY

The word *sustainability* has become ubiquitous in environmental affairs since the 1987 World Commission on Environment and Development (WCED) report *Our Common Future* popularized the concept of sustainable development. The idea, however, has a long history. The term *sustainability* has a range of definitions running into hundreds, making any preliminary definition necessarily highly abstract, but all cluster around the core idea that some system, process, range of welfare, or set of items can be maintained at a certain rate or level for the long term; the ingredients of this formulation and its applications, however, vary widely, as do their disciplinary roots and practical implications.

POLITICAL ECONOMY

The earliest clear example of the concept of sustainability in economic thought is in John Stuart Mill's (1806–1873) treatment of the "stationary state" in Book IV of his *Principles of Political Economy* (1848). In this work Mill argues that an end to economic growth is ultimately unavoidable but that this limitation need not imply a rejection progress; rather, he anticipated significant moral and emotional human improvement through a more egalitarian distribution of wealth and reduced economic competition. Although this prescription was original to Mill, in making it he acknowledged debts to Thomas Malthus's (1766–1834) earlier writings on natural limits, especially "An Essay on the Principle of Population," which had gone through six editions between 1798 and 1826 and significantly influenced opinion among Mill's utilitarian philosophical bedfellows in England. Malthus's argument, however, did not share Mill's optimism about prospects for social improvement, and was originally motivated precisely by Malthus's opposition to doctrines of human progress advanced in the wake of the French Revolution.

Malthus argued that unchecked population increases geometrically (e.g., 1,2,4,8) whereas food supply increases only arithmetically (e.g., 1,2,3,4); hence there is a constant tendency for demand on necessities to outstrip supply when population rises, along with a permanent likelihood of poverty and starvation for some section of the population, a circumstance that undercuts arguments for social improvement. This focus on population rather than differences in wealth and consumption was underscored by Malthus's opposition to contraception and was further emphasized by his supporters' tendency to concentrate on (possibly compulsory) birth control, but only for the poorer classes, priorities that were sharply condemned by the nineteenth-century radical left (e.g., Friedrich Engels's 1844 work *Outlines of a Critique of Political Economy*) and that still fuel suspicions of Malthusian influence on thinking about sustainability today.

Mill's idea of the stationary state presented a contrast to Malthus's views not only in its optimism and advocacy of contraception—Mill served two nights in prison for distributing advocacy literature on birth control methods in 1823—but also in the conditions he envisioned. Whereas Malthus saw the changes of population and resource base as a potential source of chronic instability, Mill's stationary state is stable and loosely egalitarian, and thus a progenitor of notions of a "steady-state economy" that have been popular among contemporary advocates of sustainability.

Both Malthus's outlook and Mill's utilitarian schemes grew increasingly irrelevant to mainstream political economy in the latter nineteenth and early twentieth centuries as technological improvements, along with increased agricultural and industrial productivity, appeared to dispel Malthusian gloom about an unavoidable disparity between a sprinting population and a crawling resource base. Cornucopian technological and productionist optimism were the prevailing ideas in economics at the turn of the twentieth century. Developments within economic theory also contributed, for the marginal-utility theory that arose in neoclassical economics at the nineteenth century involved a new scarcity postulate worked out simultaneously by Carl Menger, W. S. Jevons, and Leon Walras. This postulate saw need in radically subjective terms, as an internal human state rather than as the naturalistic, interactive phenomenon postulated by Mill and Malthus, and maintained that internal human desires defined need, and that satisfying these desires/needs, which themselves are stimulated by seeing desirable objects, drives human activity. This in turn means that individuals choose between satisfying various needs, with each person having an internal hierarchy of needs and endeavoring to calculatively obtain the best possible result in relation to goods that are in short supply. The existence of an infinite number of these needs places limits on any given single need at any particular moment; accordingly aggregate needs are infinitely expandable, but are rendered calculable by individuals making hierarchical choices that limit particular needs, This desocialized model of need also incorporated optimism about the functional substitutability of goods, assuming on the basis of this model that scarcity of a given

good (e.g., oil) would generate incentives to develop resource substitutes for that good (e.g., ethanol) and so absolute external scarcity could be kept at bay. This new theory came to dominate twentieth-century academic economics, pushing the consideration of external limits into the background (Xenos 1989).

The concept of hard external limits to economic expansion of a sort not amenable to technological fixes or resource substitution resurfaced with the Club of Rome's 1972 *Limits to Growth* report (Meadows et al. 1972). This report examined five variables—world population, industrialization, pollution, food production, and resource depletion—and ran these through successive computer simulations to explore possible outcomes of exponential growth combined with finite resources. The simplified models, though not aimed at explicit predictions, consistently manifested feedback loops producing dire consequences before 2100, suggesting a rate of nonrenewable resource depletion rapid enough to portend exhaustion within a little more than a century, with no likelihood of any technological rescue. The book popularized the idea of physical limits to growth and paved the way for concepts of sustainability based on that prospect. This work was still haunted by the specter of population growth, but since that time most sustainability-oriented environmentalists have increasingly emphasized the dangers of overconsumption and downplayed those of overpopulation. Nevertheless, the argument that continuous population increase will eventually place strains a depleting natural resource base, even in the most egalitarian social arrangements, remains part of environmentalist discourse. Accordingly, cornucopian and market-based critics of environmentalism such as Julian Simon (1996) and Bjorn Lomborg (2001) have characterized sustainability arguments as neo-Malthusian.

FORESTRY AND SUSTAINABLE YIELDS

Forestry has also informed modern ideas about sustainability. The work of the American forester-conservationist Gifford Pinchot (1865–1946) has been a major influence. Echoing Mill, Pinchot combined theories of resource scarcity with an anthropocentric utilitarian moral concern for human welfare. For Pinchot the forester's mission was "based on the elimination of waste, and directed toward the best use of all we have for the greatest good of the greatest number for the longest time" (Pinchot 1914, p. 25). In his autobiography *Breaking New Ground* (1947) Pinchot recounts that, upon his return to the United States in 1890 after a period of forestry training in Europe, he was horrified at American lumbermen's wastefulness. He and his allies, pointing to the dangers of timber famine, established a national U.S. Forest Service based on principles of efficient harvesting of resources through scientific forest management and replanting, and the prevention of fire, theft, improper use, and destruction. These practices aimed at preserving the resources in perpetuity. This mandate came to include economic and longterm social-justice concerns, as manifested in Pinchot's concerns about the theft of timberland land from Native Americans and his campaign in 1908 and 1909 to introduce systematic forestry on American Indian reservations. He claimed that this last measure, within eighteen months, "saved large sums of money to the Indians, gave many of them profitable employment, and by the introduction of Forestry promised to make that employment permanent" (Pinchot 1947, p. 412). Although these arrangements were truncated in 1909 by political dispute, they were resurrected in the mid-1930s under Forest Service head Ferdinand A. Silcox as the Indian New Deal, reviving ideas of social service in forestry that are still influential.

Thanks in large measure to the precedents set by Pinchot's work, the range of functions included as legally mandatory in forest planning have expanded. The Multiple Use Sustained Yield Act of 1960 formalized the U.S. Forest Service range of duties by requiring forest planning to consider issues such as outdoor recreation, location in relation to human settlements, watersheds, and fish and wildlife preservation in addition to the more familiar concerns about timber and grazing. In each case the operative principle is "sustainable yield"—the amount of a resource that can be extracted without undermining the natural system's core capacities to maintain or improve upon its full range of services.

Pinchot's original conception of forestry was anthropocentric and geared to economic development; a raft of other issues, however, has arisen in the past forty years. One major source of controversy is clear cutting, the clearing and replanting of an entire area of forest as opposed to selective felling in a given area. This practice, which had become dominant in the U.S. Forest Service by the late 1950s, is supported by timber interests (for whom it can be more profitable) and by many foresters, but most environmentalists regard it as abusive to forestlands, especially because of habitat loss, even if the species affected may be ecologically unimportant to the system's productivity. This controversy is an example of how anthropocentric and nonanthropocentric conceptions of nature's value can result in practical differences even when there is agreement among the parties about the goal of sustaining the long-term use of natural resources. The problem is most pronounced in areas where clear cutting might affect vulnerable species; not surprisingly, then, the first wave of organized opposition to Forest Service clear cutting occurred around the same time as the passage of the Endangered Species Act (1973) and the 1975 Convention on International Trade in Endangered

Species of Wild Fauna and Flora (CITES), which sought to integrate balanced species use with conservation. The latter was the first major international agreement in which the idea of sustainable use was implicit, though the phrase was not used; the convention does not expressly promote sustainable use by defining the term or demanding particular practices, but it does seek to prevent destruction and unsustainable use.

SUSTAINABILITY AND SUSTAINABLE DEVELOPMENT

Both political economy and forestry were prominent influences on the ideas sustainable development discussed in the 1987 WCED Report *Our Common Future* (often known as the Brundtland Report after its chair, the former Norwegian prime minister Gro Harlem Brundtland). Though it did not coin the phrase "sustainable development," the report furnished its basic definition as development that "meets the needs of the present without compromising the ability of future generations to meet their own needs" (WCED 1987, p. 8). It drew upon earlier precedents by linking sustainable use of resources to intergenerational, intragenerational, and international distributive justice and poverty relief, noting the extent to which poverty causes ecological depletion and linking these points to conservation concerns. The WCED sustainable-development model is, however, clearly anthropocentric, embracing technological optimism and suggesting a new kind of economic growth rather than questioning or rejecting the very idea of growth. The 1992 United Nations Conference on Environment and Development in Rio de Janeiro built upon this report in forging the Convention on Biological Diversity, the first treaty to expressly promote the idea of sustainable use as an international ideal.

A concern with yield is an important but not sufficient element of a practice of ecologically sustainable development. Ecological sustainability implies the satisfaction of three conditions in human interactions with nature: (1) Rates of use of renewable resources must not exceed their rates of regeneration; (2) rates of use of nonrenewable resources must not exceed the rate at which renewable substitutes can be developed; and (3) rates of pollution emission must not exceed the assimilative capacity of the environment (Jones 2003). Human impacts in these areas may be measured by using ecological footprint analysis, as developed by Wackernagel and Rees (1996).

VARIETIES OF SUSTAINABILITY

The concept of sustainability poses two major questions: What is to be sustained? Who or what should be the beneficiary of sustainability? In anthropocentric theories the sustaining of ecological systems aims at the flourishing of humans; indeed, some argue that a sufficiently broad conception of human fulfillment coupled with a recognition of human ignorance may lead to a policy convergence between anthropocentric and nonanthropocentric views (Norton 1991). For example, the loss of a species in a given ecosystem might superficially appear unimportant within an anthropocentric view of policy, but if the complexity of ecosystems and the possibility of human error are used to mandate caution, the sensible policy course may still be to avoid risking any possible unforeseen impacts of the loss, thus mandating the same policy as that which would come from a nonanthropocentric perspective. Alternatively it can be argued that, if some species are unnecessary to human continuity and one allows some resource substitutability (for example, moving away from consuming scarce Atlantic cod supplies and towards using more plentiful and functionally equivalent European haddock), then only natural capital critical to human survival need be sustained for future generations (Dobson 2000); such a view might call for the complement of a nonanthropocentric perspective to justify the protection of areas of nature not critical to human well-being.

A quandary of intergenerational justice is that granting equal resource access to every generation without calculating an endpoint yields absurd conclusions: Finite resources must be divided among an infinite number of claimants, and so "no one gets anything at any time" (Laslett and Fishkin 1992, p. 6). Some argue, therefore, for a compromise between discounting the future (i.e., measuring the entitlements of future people as becoming progressively smaller and less important the further away they are from us in time) and the need to impose legitimate limits on the present generation.

One option is a "just savings" solution in the manner of John Rawls's justice theory (Wissenburg 1998), whereby people of all generations are regarded as morally equal and equally entitled to a particular basic set of opportunities, thus creating an obligation for each generation to pass on that set of opportunities to the next generation. Alternatively, a moral appeal may be made to future generations' vulnerability, arguing that this vulnerability creates obligations for the current generation (Goodin 1985; Cowen and Parfit 1992; Dobson 2000). Even in purely anthropocentric terms the details of such options still need calculation, and here the distinction between weak and strong sustainability becomes significant. Weak sustainability espouses the substitutability of natural capital (i.e., naturally occurring goods that have beneficial economic effects, such as the ability of forests to produce oxygen and absorb carbon dioxide) for human-made capital (i.e., human products that may have

functionally similar economic effects to such naturally occurring goods). Weak sustainability maintains that so long as an even stock of total capital is maintained, economic growth can be beneficial and consumption rates maintained. In some formulations an even stock of welfare functions is to be maintained, and so the issue becomes still clearer: a choice between sustaining either a particular list of goods or a particular level of human welfare.

Strong sustainability insists on treating natural capital independently of human-made capital, rejecting the idea that natural capital (i.e. naturally occurring economically beneficial goods) can always in principle be substituted by man-made equivalent goods, and so strong sustainability theory advocates sustaining particular natural goods and processes (i.e., physical "stuff") rather than undifferentiated total capital or welfare (i.e., abstract measurements of welfare held at a particular level). Although weak-sustainability has been more popular among thinkers stressing the range of future individual choices, Bryan Norton has supported the strong-sustainability perspective by a series of highly ingenious arguments concerning future human options and collective goods, maintaining that future people's opportunities for living fulfilling lives mandates strong rather than weak sustainability (Norton 2005).

SUSTAINABLE AGRICULTURE

At the beginning of the twenty-first century there are renewed threats of the starvation of millions, not due to warfare but to straightforward imbalance between food production and consumption. As seen frequently in Bangladesh, starvation will occur not first in overcrowded inner cities but in the very fields where food is grown. *Sustainable agriculture* is the technical name given policies and agricultural systems whose bottom-line goal is the prevention of such systemwide failures of agriculture.

Agricultural sustainability is defined as the ability to provide sufficient, healthful, and accessible food supplies into the indefinite future for the populations that depend on the systems. Agricultural sustainability has two more particular meanings: 1) sustainability in the goal of agriculture, where it implies a permanent ability to feed its constituent populations; and 2) sustainability in the means (or tools) that actual agricultural systems use to

attain the goal of sustainable agriculture. The first goal for sustainability has a morally obligatory property: "We cannot responsibly establish a system of agriculture that is doomed eventually to fail to feed those whom the system is designed to feed." The second is a complex of technically measurable factors in the means (tools), to the goal, that enables us to confirm their success. The tools are various agricultural methods and integrated systems of agriculture. Among the factors determining the success of the means must be their ability to withstand predictable shocks such as droughts, pest invasions, and plant diseases. Some factors are directly measurable such as crop yields and rates of soil erosion (or the lack thereof). Others, noted by Richard Harwood (1990), may be more elusive such as the ability of a system to allow the nondisruptive evolution to new systems better fit to future environments and needs.

A key requirement for such future practices is that the natural and human resources needed for food production be prevented from becoming exhausted. Massive and constantly expanding use of current agricultural resources for the manufacture of biofuels is a prima facie violation of this requirement and its impact on the poor is already being felt.

OBLIGATIONS OF POLICY MAKERS

No plausible disagreement exists among agricultural professionals about the moral obligation to pursue "goal sustainability." The acrimonious debate is about whether different and often rival agricultural systems are capable of providing the means to the goal of sustainability. A constant review of agricultural systems to ascertain their current and future contribution to sustainability is a principal ethical duty of agricultural research and policy professionals. Because use of unsustainable means (tools/systems), especially on a national or large regional scale, will have tragic impacts on humans and the environment, such as those predicted for Bangladesh, the review of agricultural systems is ethically demanding. An ideal review is free of all bias, such as an unreflective preference for one's "usual way of doing things." Such a review of tools/means to a goal might be called simply "practical wisdom," a multifaceted virtue long ago identified by Aristotle. In the *Nichomachean Ethics*, Aristotle considered the nature of the intellectual virtues as well as of the moral virtues. And among the intellectual virtues, he sharply distinguished practical wisdom from scientific knowledge. The latter concerns the universal and changeless laws of nature, such as the law of gravity and the several laws of motion in physics. Practical wisdom is concerned more with doing than knowing in reference to things that are particular, not universal, and might be one way rather than another, this way, rather than that. The science of agriculture is called "agronomy." Adding the suffix "nomy"—law in Greek—to "agro" suggests that the science of agriculture is similar to astronomy, the science that discovers the universal laws of the motions of the stars and planets. But agricultural science should be conceived less like a type of Aristotelian scientific knowledge and more like a type of Aritstotelian practical wisdom. In addition to avoiding bias, the intellectual virtue of practical wisdom requires "memory," which in this context means memory of past failures that have burdened past agricultural systems (King 2004, p. 18). The function of "practical wisdom" in attaining a sustainable agriculture may be best illustrated by some history.

FAILURES IN CHOICE OF AGRICULTURAL SYSTEMS

Expensive agricultural projects by the U.S. Agency for International Development have repeatedly failed to be sustainable for the targeted populations in Asia, Africa, and Latin America because the farmers lacked access to and control of the resources needed for food production by means of those systems—such as artificial fertilizers, chemical pesticides and herbicides, and irrigation equipment. A careful review of the history of successful projects versus those that failed to provide sustainable benefits would have revealed such problems and the ways to avoid them. Further, involvement of the recipient communities in the design of their agricultural systems is vital to the long-term success of those systems (Korten 1980, Ingle 1982). The wise reviewer of tools needs to cultivate institutional memory as an essential component of the review of means and methods for sustainability.

Students of the applied sciences have noted that standard paradigms, of considerable value for efficiency in the exact sciences, like astronomy, exist also in applied sciences, like agronomy, where their function is to establish a priori categories of the "right way of doing things." What such paradigms provide in efficiency, however, they lose in efficacy, because other, more effective means lie beyond their purview. Further, prevailing agricultural paradigms can prevent a genuinely open search for optimum agricultural methods and means because, as elaborated by Thomas Kuhn (1970), the ruling paradigm shapes what subfields and competencies researchers will pursue, what equipment will be in their laboratories, and what courses they will have taken in learning to use that equipment. They will find it extremely difficult to give a fair hearing to alternative agricultural systems that use different tools and require different competencies.

The prevailing agricultural paradigm in the early 2000s is based on an industrial model and requires, among other things, the use of machinery (tractors, harvesters), fossil fuel energy (gasoline, diesel fuel), artificially

manufactured mineral fertilizers (nitrogen, potassium, phosphorous), chemical pesticides and herbicides (atrazine, Round-up), and energy- and capital-intensive irrigation systems (pumps, pipes). A paradigm suited to such high resource use shortens the amount of time it takes to produce a publishable paper because less energy-intensive, low-input systems are more time consuming to develop. Thus, the low-input systems, while plausibly more sustainable and accessible to resource- and capital-poor farmers, receive little or no attention from agricultural "experts" (agronomists) because developing them threatens the careers of young researchers. In short, it can be professionally very risky to think outside the business-as-usual agriculture box.

Genuine "practical wisdom" must consider that an eclectic tool kit assembled from elements taken from various paradigms of agricultural systems may be best to assure sustainability. For example, an "agronomist," who becomes an agro-ecologist in designing an agricultural system for an impoverished community of farmers, might substitute oxen for tractors and gravity-driven for pump-driven irrigation to reduce a local farmers' need for capital (money) while still relying on genetically modified crops engineered to be resistant to pests. Such an open review of potentially sustainable agricultural tools assembled from apparently competing paradigms implies that in the agricultural sciences there is less need for universal and unanimously accepted first principles. This is clearly abhorrent in theoretical physics but is perfectly acceptable in an applied science. The "useful good" is the object of applied science whereas physics, like astronomy, pursues something close to universal, mathematical "truth," one feature of which is self-consistency and elegant coherence. In agricultural sciences the paradigm cultivated in American agricultural schools was variously named conventional, industrial, energy-intensive, capital-intensive, or production-oriented agriculture. With the goal of increasing plant nutrition and yield improvement, influenced by the nineteenth-century chemist Justus von Liebig, the paradigm took on pretensions of an exact science. In the late twentieth century an "opposing" camp, not yet having coalesced enough to have created a recognizable paradigm of its own, began to emerge. The competing paradigm-in-the-making was variously labeled alternative agriculture, low-input agriculture, agroecology, and organic agriculture, each variant claiming to be more conservative in the use of resources, especially artificial fertilizers, chemical pesticides and herbicides, and fossil-fuel energy. Advocates of the newly emerging paradigm thus also claimed that alternative, low-input, agroecological, organic agriculture was also "sustainable agriculture." The name was offensive to conventional agronomists because it implies that conventional agriculture is unsustainable and thus in fundamental violation of a basic obligation of agriculture.

OBJECTIVE SIGNS OF SUSTAINABILITY

In any case, both conventional and alternative agriculture need something closer to the ideal of "practical wisdom." A policy maker reviewing candidate agricultural systems must require that they meet concrete criteria of sustainability. J. W. Hansen (1996), applying the rationality of conventional production agriculture, indicates that any prudent review of means to sustainability assumes that we know what we are looking for. A positive determination of "means sustainability," in other words, requires explicitly specifying objective and measurable characteristics of systems that promise goal sustainability. An example of such criteria would be the capacity to produce the same yield, year after year, without loss of soil fertility or increase in soil salinity. In the absence of such explicitly stated, objective, measurable criteria, no agricultural system can be declared to be sustainable with any certainty. And because the history of natural shocks to agricultural production, such as drought and pest invasions, warns against relying on the stability of environmental conditions, quantitative probabilities of the system's ability to withstand shocks must be determined. To this should be added Harwood's criterion: the capacity to support the evolution of new, even better, more sustainable agricultural systems, under changing environmental and cultural circumstances.

CAUTIONARY COMPLETION OF THE DEFINITION

These signs of "means sustainability" are not doctrinaire and seem intuitively obvious. But they do not deal directly with the kind of properties found in a definition coming from the alternative agriculture paradigm in which sustainable agriculture systems are defined qualitatively as ecologically sound, economically viable, socially just, culturally appropriate, and based on holistic scientific approaches, including indigenous and community-based knowledge systems. This conglomerate, qualitative definition is criticized by defenders of conventional agriculture for including extraneous, nonagricultural functions like continuity or compatibility with local cultural traditions, but above all, "community food security"—reliable access to the food produced in a region by most everyone who lives there, whether they themselves are farmers or not. Defenders of the definition respond that conventional, industrial systems have led to the worsening of poverty and hunger in less developed countries precisely because, even though such systems increased regional food production, regional increases in food production did not lead to increased local access to food. Because industrial production systems involve high costs to producers, their commodities must fetch high prices in the global marketplace, often resulting

Bangladeshi Farmers Cleaning Paddy, 2008. *For Bangladesh and other Asian countries, paddy is one of the main sources of agriculture. Researchers have been trying to promote new forms of sustainable agriculture to these and other regions around the world. Although the definition is not yet concrete, most agree that sustainable agriculture should be ecologically sound, economically viable, socially just, culturally appropriate, and based on holistic and scientific approaches.* **FARJANA KHAN GODHULY/AFP/GETTY IMAGES.**

in the export of the foods produced, which are thus unavailable, at affordable prices, to local people who are not themselves food producers. This circumstance is exacerbated by the economy-of-scale principle of conventional agriculture, which requires farmers to "get big or get out." As some farmers "get big" by acquiring the lands of their neighbors, those who are driven out fall victim to poverty and ultimately to hunger.

The qualitative definition of sustainability proffered by advocates of alternative agricultural systems, however, does not provide the quantitative measures that are vital to genuine sustainability and future food security. Organic food systems have an appeal in their conservative use of nonrenewable resources, but their capacity to provide adequate and reliable future yields needs substantiation. For there may be an unavoidable trade-off: relatively low in-put agriculture is often also relatively low-output agriculture. The inability as of the early 2000s of organic agriculture to provide for entire populations in European and North American societies does not, however, make it irrelevant to sustainability. If the failures already mentioned teach us anything, it is that in agriculture one size—that is, one system, one paradigm—does not fit all. What may work well, at least for now, in North America and Europe may be a disaster in Africa and Latin America. Today's practitioners of organic agriculture may, furthermore, be learning the arts—for practical wisdom in the area of agriculture is more an art (in the Aristotelian sense, a *techne*) than a science—needed for resilient future agricultural systems.

Agroecological systems involve harnessing ecological knowledge to food production and enhancing sustainability by reducing the need to overwhelm local ecosystems with energy and synthetic chemical inputs—for example, in weed and pest control. Such systems depend on an intimate knowledge of the local ecology and hence require a community-based approach, because local people may have a wealth of such knowledge, known as "vernacular ecological knowledge" or, more commonly, as "traditional ecological knowledge" (TEK). Traditional

agricultural societies are well suited to utilize agroecological approaches, because many have been doing so for many generations past. These approaches are not burdens on either the surrounding ecosystems or the host communities but are simply more sustainable augmentations of traditional practices or replacements for the conventional systems that involve "universal" prescriptions after they have catastrophically failed. Supporters of agroecology defend the dependence on community wisdom and labor as evidence that agroecological systems will be more responsive to community food security, the ultimate test, in their view, of true sustainability as a goal.

DEVELOPING-WORLD APPLICATIONS

Nadia Scialabba's United Nations 2007 FAO report, *Organic Agriculture and Food Security,* supplies some of the quantitative work needed on the theoretical capacity of organic agriculture to feed the world's population. She notes global models suggesting a capacity to feed the world at levels comparable to current conventional agriculture without an increase in land under cultivation and with reduced environmental impacts.

The alternative definition of "sustainable agriculture" differs from the definition given at the outset in part because it focuses explicitly on the human and environmental aspects of food production. This focus is in part due to the memory that U.S. agriculture became "unsustainable" from an ethical viewpoint at the turn of the twentieth century and again in the 1920s, when poverty, subhuman living conditions, and hunger were common in the farming communities. In efforts to find sustainable food systems, nothing could be more dangerous than leaving out the condition of the food producers and treating sustainability as a resource-input and food-output equation. Developing countries in the early 2000s provide evidence of the pervasive harm done to every kind of agricultural and environmental value when the human agents and their communities are not included in the selection of means to sustainability (Korten 1980).

It is scarcely conceivable that a global collapse of food adequacy would occur suddenly. The flip side of locally determined agricultural systems is that agricultural failure has its first visible impacts in rural locales among poor farmers who cannot feed their families. This is illustrated tragically again in Bangladesh where near famine strikes first among farm families in the months just before harvest. Neglect of political and socioeconomic factors in pursuit of sustainability will again create the environmental chaos observed by the soil scientist Charles Kellogg during one of America's brushes with unsustainability. He wrote, "The final exhaustion of the land follows, not precedes, the exhaustion of the people. In a final effort, exploited people pass their suffering to the land" (1938, p. 878).

SUSTAINABLE ARCHITECTURE AND ENGINEERING

In the late twentieth century many citizens in Western societies began to recognize that if other societies consumed resources at the same rate that they did, the ecosystem soon would be exhausted and unable to reproduce itself. That recognition motivated the United Nations to charter the World Council on Environment and Development (WCED) to investigate ways in which the apparent conflict between economic development and environmental degradation might be reconciled. Under the auspices of the Brundtland Commission, the WCED published its findings as *Our Common Future* in 1987. That document, long considered the seminal text on sustainable development, defined sustainable development as "development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (World Council on Environment and Development 1987, p. 8). In the conflict between economic development and environmental protection unsustainable development usually is associated with the industrial and transportation sectors. Although industrial wastes and automobile emissions contribute substantially to degraded environmental

Earthship in Taos, New Mexico. *One modern example of sustainable architecture is the "earthship," designed by architect Michael Reynolds since the 1970s. The low-tech designs range from multi-million dollar luxury homes to small, communal living environments.* **AP IMAGES**

and social conditions, they are not the largest source of the problem.

RESPONSES TO THE CHALLENGE

According to the U.S. Department of Energy (DOE), the production and operation of the built environment accounts for almost half of all greenhouse gas (GHG) emissions and more than half of annual energy consumption in North America. These general statistics were put in a critical context by a Brookings Institution study that projected that in 2030 about half of the buildings in which Americans live, work, study, and shop will have been built after 2000 (Nelson 2004). If these projections are accurate, the construction and operation of buildings could become the single largest threat to public health, safety, and welfare as well as the major cause of environmental degradation and threats to other species. These statistics present a serious ethical challenge to architects, engineers, and those who commission their services.

As the public conversation about sustainable development has matured, three responses to this challenge have developed: resignation, denial, and hope. If one takes these statistics as inevitable, as do neo-Malthusians such as Paul Ehrlich (1971), one tends toward resignation. If one considers them overblown or unreliable, as do those with an interest in maintaining the status quo, one tends to deny the mounting evidence that shows that people's habits are unsustainable. However, if one takes these statistics seriously but rejects historical determinism, one tends to be hopeful that environmental collapse can be avoided. This is the story line of sustainable development, a modern narrative in which people create hope for the future by taking collective actions that may alter the path of history.

MODERN ARCHITECTURE

The popular thesis among many environmentalists, that ancient architecture is the best model for sustainable development in the future, generally is accompanied by the corollary that modern architecture has been relentlessly antinature. Although many modern buildings consume vast amounts of energy because they ignore the natural energy flows of their locations, there also are buildings that look stylistically modern but act in harmony with the ecologies and cultures for which they were designed. It is inaccurate to imagine that modern and sustainable architectures embody singular and opposed sets of values; reality is far more complex.

A good example of midcentury modern architecture that works with natural forces is the Tremaine House in Santa Barbara, California (1947–1948), designed by the Austrian-American architect Richard Neutra (1892–1970). The deep overhangs of the roof shield the large expanses of glass from unwanted solar heat gain, and the operable transom panels above the sliding glass doors allow for natural cross-ventilation even when the doors are closed. Neutra (1948) referred to this system as CSSA/LS, or continuous sub-soffit airchange over a lowered spandrel. What makes Neutra's work a particularly good example of protosustainability (the initial ideas required for sustainability to emerge in the form articulated by the Bruntland Report) is the fact that he employed energy-saving technologies not only in houses for people of substantial means such as the Tremaines but also for people of modest means. This is demonstrated by his 1948 proposal that Brazilian schools be equipped with his CSSA/LS system along with technologies designed to harvest rainwater and produce electricity on site. Neutra's work demonstrates a balanced sensitivity to the competing interests of economic development, environmental preservation, and social equity—commonly referred to as the three Es—long before the Brundtland Commission declared them to be the core values of sustainable development.

Neutra was not alone in the search for environmentally and socially responsible architecture. Among his peers were the theorists Patrick Geddes (1854–1932), Lewis Mumford (1895–1990), and Frederick Keisler (1890–1965), as well as a diverse group of practitioners that included Frank Lloyd Wright (1867–1959), Alvar Aalto (1898–1976), Harwell Hamilton Harris (1903–1990), and the many practitioners of regionalism in the Bay Area of California, Texas, and Mexico, among other

places. In his collection of regionalist texts Vincent Canizaro (2007) demonstrated that some modern architects have championed the values that are associated with sustainability. In the world of engineering the appropriate technology movement that emerged in the 1960s demonstrates similar values.

After the appearance of *Our Common Future* in 1987 pressure from outside the building professions to build sustainably increased slowly; after the turn of the millennium the subject of sustainable design became a dominant discourse in both architecture and engineering. This does not imply that the legacy of Neutra and his peers dominated the theorizing and designing of sustainable environments. The sociologist Simon Guy and the architect Graham Farmer (2001) found six distinct traditions within architectural discourse, each based on differing and sometimes conflicting assumptions yet all claiming to define what sustainable design must be. Guy and Farmer's categories would include buildings as diverse as the low-tech back-to-the-land earth ships built in New Mexico by Mike Reynolds (1970), the technocratic and energy-efficient Commerzbank Tower designed for Frankfurt by Sir Norman Foster and Associates (1995–1998), and the communal solar kitchen developed for Jiutepec, Mexico, by the BaSiC Initiative (2004). Although some technocrats would prefer to standardize sustainable technologies as lists of best practices or universal technical codes, the practice of sustainable design has continued to diversify.

DISCIPLINARY APPROACHES

Another popular conception involves the division of work between architects and engineers in the planning of sustainable built environments. People are predisposed to associate architects with space planning and the superficial embellishment of building facades and engineers with technical problem solving. Although there is some truth in this categorization, reality is far more complex. Although these two modern professions emerged from a common European origin, over the last five centuries they have developed distinct cultures. Where architects tend to be expansive in their approach to problem solving—as in the arts—engineers tend to be reductive—as in the sciences. Where architects tend to emphasize the visual or communicative qualities of the environments they design, engineers tend to emphasize economic efficiency. However, the tendency to essentialize the values of the disciplines is as erroneous as it would be to characterize the visual characteristics of modern architecture as inherently antinature. The building professions are far more pluralistic than many critics suppose.

Among the diverse design practices developed in the early twenty-first century were those which derived from the critique of modern technology offered by science and technology studies (STS). Rather than focus on the expressive possibilities of building form, economic efficiency, or the artifacts themselves, STS scholars study the relationship of particular material technologies to the societies that develop, maintain, and operate them. The empirical study of the built environment as a sociotechnical system is a promising area of analysis that may influence not only the teaching of design but also the consequences of design practice.

SUSTAINABLE DEVELOPMENT

Sustainable development is designed to meet present needs without compromising the needs and aspirations of future generations. Such goals inherently pose issues of ethics and values through discussions of both intragenerational and

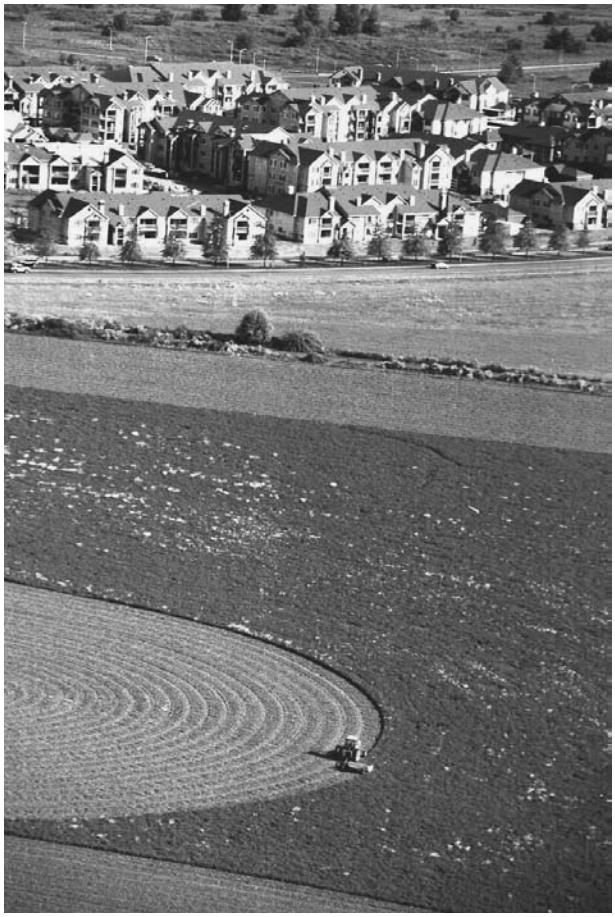
intergenerational equity; if current standards of living in some societies are unsustainable, is it possible to justify their existence in the present, much less their extension into the future?

HISTORY

Although the term *sustainable development* is often traced to the World Commission on Environment and Development's publication of *Our Common Future (1987)*, this report was the outcome of decades of concern about the impact of human beings on the natural environment. Notions of sustainable development emerged from the birth of the modern environmental movement, sparked by the work of authors such as Rachel Carson (1962), who focused on the impact of chemical pollution on the environment. These environmental concerns were linked to development as authors such Paul Ehrlich (1971) and organizations such as the Club of Rome (Meadows et al. 1972) highlighted the growth of the global human population and the stresses that growth was placing on the natural-resource base of the planet. This initial environment-development linkage was focused on the challenges human activities posed for the earth's natural-resource base. Consequently, initial efforts to address these challenges, including the United Nations Conference on the Human Environment in 1972, focused on the protection and preservation of that resource base.

Our Common Future (World Commission on Environment and Development 1987), also known as *The Brundtland Report*, reflects a shift in thinking about environment and development. By the mid-1980s, years of experience in development and international aid had demonstrated that the complexity of the connections between the environment and human well-being far exceeded the compass of analyses that were confined to the protection of natural resources. For example, it was in this period that the analysis of famine shifted from purely environmental causes (e.g., the absence of sufficient rainfall) to environmental causes as they intersect with local sociocultural factors and national and global political economies (e.g., Watts 1983). *Our Common Future* reflected this shift, turning from the previous environment-first approaches to the environment/development interface and thereby embracing a more holistic understanding of this interaction and its impact on human well-being.

The 1992 United Nations Conference on Environment and Development (UNCED) in Rio de Janeiro carried this new focus into an institutional context by producing Agenda 21, an action plan to address the interconnections between environment and development. The United Nations Commission on Sustainable Development (UNSCD) was founded to ensure appropriate follow-through after the conference. Nevertheless, the outcomes of UNCED mark something of a return to a resource-base-first approach to sustainability. For example, the Convention on Biological Diversity (CBD), a product of UNCED, focuses on the preservation of a particular key resource with the assumption that such preservation would preserve the resource in the context of development and, in so doing, improve human well-being.



The Extent of Urban Sprawl. *A tractor working in the fields near Portland, Oregon, seems dwarfed by a large tract of new apartments in the background. A study conducted by the Sierra Club reported that Oregon was ranked first in land-use planning.* **AP IMAGES.**

In later years major environmental assessments tried to better articulate the links between environmental preservation, development, and human well-being. The conceptual framework of the Millennium Ecosystem Assessment (MA) (2003) employed an ecosystem-services approach to draw this connection. Ecosystem services are the rewards human beings obtain from ecosystems, ranging from water filtration to raw materials to cultural/spiritual benefits. A change in a particular ecosystem will change the services that ecosystem provides to human beings—it will provide more

or less of a particular service and more or fewer services overall. Through this approach the MA evaluated the earth's ecosystems from an anthropocentric perspective, evaluating the current state and trends of these ecosystem services in terms of the benefits humans derive from them and projecting the future benefits that would be available from these ecosystems under current and other hypothesized policy and technological regimes. Hence the MA marks something of a return to a WCED-style understanding of sustainable development.

CONTEMPORARY TENSIONS BETWEEN ENVIRONMENT AND DEVELOPMENT

The most commonly discussed tension in the contemporary sustainable-development literature is that of intergenerational equity. The definition of *sustainable* cannot be separated from a sense of ethical responsibility to future generations. For example, does *sustainability* mean the maintenance of the basic conditions necessary for human life on earth or the maintenance of the current standard of living for future generations? The answer to this question informs choices about how to live in the present. Maintaining human life is a fairly low standard that might be achieved even with a substantially irresponsible use of natural resources. However, as the MA illustrates, the maintenance of our current standard of living into the future without substantial technological change is likely impossible because we are degrading 60 percent of the (broadly categorized) services we receive from ecosystems. If sustainable development is a worthy goal, it demands consideration of how current behavior prevents the attainment of that goal.

Less commonly discussed are the ethical dimensions of *intra*generational equity raised by contemporary thought and practice in sustainable development. Various ecological-footprint studies (e.g., Rees and Wackernagel 1995) suggest that current levels of consumption in the global north are possible only because very few people in the global south enjoy this resource-intensive standard. Furthermore, these studies make clear that it would require more than three planet earths' worth of resources to allow everyone in the world to enjoy this standard of living. This analysis points to an inherent incompatibility in the goals of environmentalists seeking the sustainable use of natural resources and those working on development efforts intended to raise the standard of living of those in the global south. Such observations have led some (e.g., Esteva 1992, Banerjee 2003) to question whether sustainable development represents a form of neocolonialism whereby those in the global south are encouraged to develop in a sustainable manner (a goal impossible under current technological regimes and societal values) so as to slow their growth and preserve the lifestyles and prerogatives of those living in the global north.

Issues of intragenerational equity are further complicated by the mainstreaming of environmental concerns into development thought and practice. Although such mainstreaming maintains environmental quality and preserves key environmental resources for human well-being, the frameworks that are emerging out of this effort may create or perpetuate challenges that hinder development efforts and maintain the difficult circumstances facing many of the world's poor. The United Nations Environment Programme's Fourth Global Environment Outlook (GEO-4), which employs a conceptual framework similar to that of the MA, is an example of the dangers of this mainstreaming. Titled *Environment for Development (UNEP 2007)*, GEO-4 uses an environmental reporting framework to evaluate sustainable development initiatives. Carr and his coauthors (2007) argue that the use of such frameworks in the evaluation of development initiatives inadvertently produces situations that disempower local communities and local knowledge in the development process, thus squandering key resources for development and losing sight of the intended beneficiaries of such efforts.

The framework employed by GEO-4 divides linked environment/development challenges into a series of causes, ranging from large-scale ultimate causes like population and economic growth to proximate causes ranging from increased sewage output into the environment to ecosystem-specific changes that affect human well-being. The responses to these changes purport to address these challenges at each of these levels. However, local actors are usually constrained in their individual efforts to responses at the ecosystem level, whereas governments and development agencies are privileged in their ability to address ultimate and proximate causes of environmental changes. This general set of outcomes is consonant with development studies that argue that contemporary development practice does not address the ideas or needs of the poor unless those ideas and needs fit into and support the ideas, values, and careers of those working for development agencies (Ferguson 1994, Escobar 1995, and Easterly 2006). For example, local (indigenous) knowledge, today a popular buzzword in development, rose to prominence only when the development community deemed such knowledge useful and/or appropriate. Before this shift in the outlook of the development community, this same local knowledge was largely ignored.

AN ETHICAL FUTURE FOR DEVELOPMENT

The mainstreaming of environmental concerns in development thought and practice remains a work in progress, and among the most significant challenges raised by this effort are the ethical issues surrounding intergenerational and intragenerational equity. In debates about tradeoffs between the present and future, work in sustainable

development has provided new openings for thinking about the ethical dimensions of environmental protection and development, and the value systems that allow unsustainable (and therefore unjust) practices to continue.

SYLVAN, RICHARD

1935–1996

Richard Sylvan was a seminal thinker in environmental philosophy. He also was known for pioneering work in logic, metaphysics, the philosophy of language, semantics, epistemology, social philosophy, political philosophy, ethics, the philosophy of science, the philosophy of mind, and computation theory.

EDUCATION AND EARLY WORKS

Sylvan was born Francis Richard Routley in Levin, New Zealand, on December 13, 1935. He met and later married the philosopher Val McCrae in 1963, and they jointly authored several works in environmental philosophy under the names R. and V. Routley. Following their separation, Val changed her name to Plumwood. Richard changed his name to Sylvan when he remarried in 1983. He studied at Victoria University, Wellington, and then Princeton before taking positions at the University of Sydney, the University of New England, and Monash University. From 1971 until his death he was a fellow at the Research School of Social Sciences at the Australian National University. Sylvan died on June 16, 1996, in Bali, Indonesia. He is buried in New South Wales at the edge of one of the forests which he cherished.

Sylvan was responsible for much of the development of environmental philosophy in Australasia. An example of his provocative style and controversial choice of topics can be found in the 1982 paper "In Defence of Cannibalism," which was published in Sylvan's *Discussion Papers in Environmental Philosophy*, one of several preprint series which he edited.

The content of "In Defence of Cannibalism" is less sensational than the title. The essay addresses the ethics of killing, in particular killing humans, and the ethics of eating dead animals, including dead humans. Sylvan carefully separated those questions. The title of the paper generated alarm among some members of the philosophical community, and Sylvan may have derived satisfaction from the unsettling effects of the paper.

DEEP GREEN THEORY

Sylvan's research program was much broader than the ambit of environmental philosophy; it was systematically linked with his and others' work in metaphysics, semantics, logic, epistemology, and value theory. He also connected it with work outside mainstream Australasian and Anglo-American philosophical inquiry as well as with work in other disciplines, including Taoism, Buddhism, nihilism, cosmology, demography, politics, and economics. Sylvan also addressed environmental policy issues in

his monograph *The Fight for the Forests* (Routley and Routley 1973), written with Val Plumwood.

Sylvan's work in environmental philosophy goes back to the early 1970s. His 1973 paper "Is There a Need for a New, an Environmental, Ethic?" is a landmark in the discussion of anthropocentrism. The last man argument presented in that paper remains an important locus of that discussion. Another important paper written in collaboration with Plumwood (Routley and Routley 1980) elaborates the argument. Sylvan's critique of anthropocentrism, or human chauvinism, aligned him with the central concerns of Deep Ecology, though he distanced himself from much of Eeep Ecology (Sylvan 1985). Sylvan went on to develop his own environmental philosophy, which he called Deep Green Theory (DGT) in *The Greening of Ethics* (1994). At the time of his death he was working on a fuller explication of DGT that was never completed. A manuscript published posthumously in 1997, *Metaphysics: From Radical to Deep Plurallism* [sic], addressed metaphysical and associated logical issues with a strong pluralist twist, which Sylvan believed was essential to providing a satisfactory foundation for environmental philosophy. Sylvan developed his views in opposition to those of his university colleague John Passmore, whose very different views were published in *Man's Responsibility for Nature* (1974), which rejected the need for radical revision in ethics to accommodate concern for the environment.

DGT aims to clear the "garbage" (Sylvan's description) from environmental philosophy and replace it with theoretical rigor. It is a pluralistic position that shares with Deep Ecology a rejection of the prevailing technocentric approach to the environment of industrial society. Although it shares a number of features with Arne Naess's eight-point platform for Deep Ecology (Naess 1989), its focus and emphasis are different. A central theme is that many environmental items are valuable in themselves; that is, their value does not depend on human values and interests. In developing his alternative position, Sylvan introduced a number of distinctions marked by a plethora of neologisms: *non-jective, gre-een, extranalities, expiricism, intraneous, extitution* (Grey 2000). Sylvan's DGT is a complex articulation of reflections which help to clarify central problems in environmental philosophy.

T

TAKINGS

The Fifth Amendment to the U.S. Constitution states that no person ''shall be deprived of life, liberty or property without due process of law; nor shall private property be taken for public use, without just compensation.'' This last clause, the ''takings clause,'' prohibits the U.S. government from seizing property without just compensation. In the United States it is this amendment that authorizes the federal government to seize properties for common use, a legal concept known as *eminent domain*. Many other nations have similar laws. The United Kingdom, New Zealand, and the Republic of Ireland have ''compulsory purchase'' laws; Australia has ''resumption or compulsory acquisition'' laws; and South Africa has ''expropriation'' laws. Takings restrictions date as far back as the Magna Carta, issued in 1215 as a curb on the absolute will of the king of England. All such laws protect property owners from unjust seizure but also allow governments to seize property in the common interest.

The requirement of compensation for the physical taking of property is uncontroversial. As regards regulations, however, the requirement is more complex. The environmental issue referred to as ''takings'' or ''regulatory takings'' relates to a property holder's claim to compensation for damages incurred or benefits forestalled, as a result of regulations—restrictions, prohibitions, or requirements—placed on the use or lease of a given parcel of property. For instance, if an owner of a piece of land is restricted from building on his or her property, say, because of an endangered-species regulation, the property owner may argue that this regulation has effectively ''taken'' the property, or taken a significant aspect of value on the property. The central theoretical question is the extent to which a given government action—or, in this case, a given regulation—constitutes a taking.

Until the late 1970s controversies over regulatory takings in the United States had been addressed chiefly by the courts. One of the earliest takings cases was *Pennsylvania Coal Co. v. Mahon* (1922). In this case the Pennsylvania legislature had prohibited the mining of coal underneath streets and houses. The controversy emerged because Pennsylvania Coal had, forty years earlier, granted strict surface rights to H. J. Mahon, under the express agreement that they would eventually mine coal under his dwelling. Pennsylvania Coal argued that the legislature's prohibition of mining under streets and houses constituted a taking because the coal company was no longer permitted to mine coal in these areas. The U.S. Supreme Court found in favor of Pennsylvania Coal, stating that ''[W]hile property may be regulated to a certain extent, if regulation goes too far it will be recognized as a taking.'' This case established the precedent that regulations, not only physical seizures of property, can constitute takings.

Since then two cases have emerged as central to modern regulatory takings law (Squillace 2008). In the first case, *Penn Central Transportation Co. v. New York City* (1978), Penn Central petitioned the city for the right to develop a high-rise tower above Grand Central Terminal. Because Grand Central had been designated by the city as an historic landmark, it was subject to zoning restrictions that prohibited such construction. The Court rejected Penn Central's regulatory takings claim, focusing on two issues: the character of the government action and whether the regulation interfered

with distinct and reasonable "investment-backed expectations." No compensation was paid.

In the second case, *Lucas v. South Carolina Coastal Council* (1992), David H. Lucas purchased two properties on the coast of South Carolina for $975,000. In 1988 the state passed the Beachfront Management Act, which restricted Lucas from developing his two properties. Lucas sued and won several critical cases, leading to a Supreme Court hearing. The Supreme Court held that the regulation had effectively deprived Lucas of all economically beneficial use of his property and therefore amounted to a "total taking." By appeal to the character of government action, the concept of reasonable "investment-backed expectations," and the notion of a "total taking," the Penn Central and Lucas cases provide a sound analytical framework for analyzing most regulatory takings cases.

Aside from this judicial history, the concept of takings has sparked heated political controversy. By the late-1970s, the United States had adopted broad-reaching environmental legislation such as the U.S. Endangered Species Act (ESA), the U.S. National Environmental Policy Act (NEPA), and the U.S. Federal Land Policy and Management Act (FLPMA). As these acts came into effect, some property owners, particularly in the western United States, began to question their legitimacy, citing as a precedent the conservationist platform of Gifford Pinchot, the first head of the U.S. Forest Service. Out of these concerns the so-called "sagebrush rebellion" or "wise use movement" was born. This political movement has influenced policy in all branches of government, but most notably in the executive and legislative branches.

For instance, when Ronald Reagan became president in 1981, he appointed James G. Watt, a central figure in the sagebrush rebellion, as secretary of the interior. Watt's appointment resulted in a series of controversial administrative decisions, the ostensible aim of which was to shore up property rights; the real aim, according to critics, was to dismantle environmental law. One of the central decisions came in 1988, when Reagan introduced Executive Order 12630, otherwise known as "Reagan's Order." This order, formally titled "Governmental Actions and Interference with Constitutionally Protected Property Rights," required all agencies in the executive branch to determine whether their proposed action may imply a taking and, if so, to conduct a takings impact assessment (TIA). If any takings implications were found, the order restricted an agency's ability to carry out that proposed action.

During the same decade, state legislatures battled over a variety of takings bills. By 1991 every state in the United States had considered some form of environmental takings legislation. The first federal takings bill had been introduced a year earlier, in 1990, by Senator Steve Symms of Idaho. Although particular bills vary widely in details, takings legislation usually seeks to establish guarantees of compensation for regulation or at least to assure that some assessment of costs and the possibility of compensation is put into place prior to the establishment of a regulation.

Regulatory takings poses complex philosophical and ethical issues, ranging from questions about the nature of private property to observations about harms to nature or to humans. At any point in the history of the "takings debate"—whether in the court decisions, in the legislation, in the policy of sitting administrations, or even in the more generalized civil sphere—philosophical issues regarding rights, harm, freedom, participation, representation, identity, self-actualization, moral status, public good, and so on, intertwine and overlap.

TAYLOR, PAUL
1923–

Paul Warren Taylor was born in Philadelphia on November 19, 1923. He is emeritus professor of philosophy at Brooklyn College, where he specialized in normative and applied ethics. The author of several works in

ethics, including *Normative Discourse* (1961) and *Principles of Ethics* (1975), Taylor is probably best known for *Respect for Nature* (1986), in which he develops and defends a sophisticated biocentric (life-centered) environmental ethic.

Taylor's egalitarian biocentric ethic (1986) synthesizes elements of classical virtue ethics with Albert Schweitzer's ethic of reverence for life, Peter Singer's egalitarianism, and Kenneth Goodpaster's account of moral considerability. Taylor contends that one who adopts the ultimate moral attitude of respect for nature will become an environmentally virtuous person. He identifies environmentally ethical conduct with conduct motivated by respect for nature. Such environmentally virtuous conduct seeks to promote the flourishing of all living organisms. In Taylor's words, "Ethical action and goodness of character naturally flow from the attitude [of respect for nature], and the attitude is made manifest in how one acts and in what sort of person one is" (1986, p. 81).

Taylor admits that "we cannot see the point of taking the attitude of respect" until we understand and accept the biocentric outlook, but he insists that "once we do grasp it and shape our world outlook in accordance with it, we immediately understand how and why a person should adopt that attitude [of respect] as the only appropriate one to have toward nature" (1986, p. 90). The biocentric outlook, a scientifically grounded view of humanity's place in the natural order, consists of the following four theses:

1. *Homo sapiens*, like all other species, emerged as a result of random genetic drift and natural selection. As such, humans are members of the earth's biotic community on a par with all other living organisms.
2. The earth's biotic community forms a complex web of functionally interdependent organisms. In this web, the survival of each organism is determined in part by its relations to other organisms.
3. Each individual living organism is a "teleological center of life" pursuing its own good in its own way.
4. Humans are not superior to other living things. Their inherent worth is no greater than that of any other living organism. (1986, pp. 99–100).

Theses 1 to 3 are solidly supported by the sciences of biology and ecology. Taylor argues that those who accept these theses are rationally committed to thesis 4, which, together, support and make intelligible the attitude of respect for nature (1981, p. 206). This outlook sees living things "as *the appropriate objects of the attitude of respect* and are accordingly regarded as entities possessing inherent worth" (1981, p. 206).

Taylor derives his biocentric egalitarianism as follows. First, he argues that all living organisms are biologically goal-directed toward goods of their own. Next, following Goodpaster, he argues that any being with a good of its own deserves moral consideration. Coupling the latter conclusion with Singer's egalitarianism, Taylor concludes that every living organism possesses equal inherent worth and deserves equal moral consideration.

Numerous objections have been raised against Taylor's biocentric ethic. Principal among them are challenges to its account of moral considerability, its egalitarianism, its individualism, and its demands, along with a worry that Taylor commits the naturalistic fallacy.

To treat these challenges in order, some critics (e.g., Singer 1975, pp. 8–9) maintain that only sentient beings have interests and that only beings with interests deserve moral consideration. Taylor argues that it is arbitrary to restrict the class of morally considerable beings to sentient beings. Since all living organisms can be harmed or benefited and what benefits them promotes their good, Taylor insists that there is no nonarbitrary reason not to extend moral consideration to all living organisms. Mary Anne Warren (1997, p. 48) rejects Taylor's reasoning on the grounds that since lower organisms do not care whether their biological interests are satisfied, neither should humans.

Some biocentrists (Goodpaster 1978, Varner 2002) take issue with Taylor's egalitarianism. They agree that all living organisms deserve moral consideration, but deny that being morally considerable entails having *equal* moral significance. These critics reject Taylor's egalitarianism in favor of a hierarchical account of moral significance.

Other critics object to Taylor's stated view that "it is the good (well-being, welfare) of individual organisms ... that determines our moral relations with the Earth's wild communities of life" (1981, p. 198). These critics contend that Taylor's focus on individual welfare fails to address the actual concerns of environmentalists. Most environmentalists are concerned not with the welfare of individual mosquitoes, dandelions, and microbes, but rather with species preservation, ecological integrity, and pollution. These critics insist that a holistic ethic can better address these environmental concerns.

The idea of extending equal moral consideration to every living organism, including every insect and plant, strikes most people as not only too demanding, but outright absurd. How can people live their lives if they must give plants and insects the same moral consideration owed humans? Taylor tries to mitigate this objection by formulating a complex set of principles (self-defense, proportionality, minimum harm, distributive justice,

and restitutive justice) for fairly resolving the conflicts that inevitably arise between humans and other equally considerable organisms. Even with these principles in place, however, Taylor's biocentric ethic remains extremely demanding, since the principle of proportionality dictates that the basic interests of plants trump the nonbasic interests of humans.

A final worry is that at some point Taylor must move from the purely descriptive aspects of his biocentric outlook to the moral attitude of respect for nature, and that in doing so he must either commit the naturalistic fallacy or beg the question by smuggling a normative judgment (thesis 4) into his biocentric outlook. Taylor recognizes, however, that the biocentric outlook "is not wholly analyzable into empirically confirmable assertions" and thus is best viewed as "a philosophical worldview" (1981, p. 205). Moreover, he never attempts to *derive* an *ought* from an *is*; rather, he seeks to provide us with a rational, coherent perspective on nature that will allow us to accurately perceive (not deduce) the inherent worth of all living beings.

Whether these objections to Taylor's biocentric egalitarianism prove insuperable remains to be seen. Regardless of whether his ethic prevails in the end or ultimately forces us to look elsewhere for an adequate environmental ethic, Taylor's biocentric outlook helps those who accept it to have a greater appreciation and respect for nature.

TECHNOLOGY

Environmental ethics often deals with the ethical and philosophical implications of human powers over the natural world. Because those powers nearly always are manifested technologically, environmental ethics is in large measure a philosophy of technology. The historical genesis of contemporary environmental ethics coincides with the unprecedented environmental impacts brought about by the advent of advanced industrial technology in the mid-twentieth century. It was also at that time that the philosophy of technology developed as a variegated research field in the English-speaking world, aspiring to comprehensive reflection on the making and using of artifacts. Although they occasionally have entered into dialogue (Ferrè 1992), these two areas of philosophy have remained largely separate despite their potential for support and synthesis.

HISTORICAL BACKGROUND

From its beginnings philosophy has included some attention to technology. However, it was only with the emergence of the industrial technosciences in the late nineteenth century that philosophers systematically turned their attention to the conceptualization and evaluation of technology (Kaplan 2004).

Premodern Socrates questioned those who pretended to wisdom: not just poets and politicians but also artisans. In Socrates's account it was the artisan practitioners of *techne* who came closest to having legitimate knowledge. The term *techne* is often translated as craft or art, but can also be seen as a practice that is grounded in theoretical knowledge, or "an account," thus linking it closely to notions of expertise or know-how. In another dialogue (*Phaedrus*) Socrates indicated that he had nothing to learn from nature. In contrast, Aristotle's philosophy included nature, or *physis,* as a fundamental theme. Aristotle did, however, maintain a strict division between natural and artificial entities. Natural entities are self-generating substantial unities of form and matter. An acorn sprouts into an oak tree, fulfilling its essence. Artifacts, by contrast, never achieve that substantial integration because the source of their being is external to them; if a bed were to sprout, it would give rise to a tree, not a bed (*Physics*). The ancient theme of *techne* and *physis* underpins contemporary work in both philosophy of technology and environmental ethics on the meaning of and proper relationships between technology and nature (McKibben 1989, Haraway 1991, Latour 1993, Rothenberg 1993, Strong 1995).

In Christian adaptations of philosophy, nature is thought of as a creation of God, who also is disclosed by means of supernatural revelation. Christian theology thus identifies two paths to insight into the ultimate nature of reality: the word of God in Scripture and the book of

nature. On neither path, however, does technical thought make a significant appearance, although historians of technology such as Lynn White, Jr. (1967) have argued that Christian theology prepared the way for modern science and technology. White claimed that the Judeo-Christian teleology—God made nature solely to serve humanity—underpins the Western technological mastery of nature.

Modern Many of the founders of modern science and technology, such as Francis Bacon, René Descartes, and Isaac Newton, were motivated partly by the aim of natural theology: As Johannes Kepler phrased it, "to think God's thoughts after him." However, the modern era also signaled a radical break from ancient and medieval religious views that valorized contemplation and the control of one's desires and maintained that technology should be subject to ethical constraints. From the Renaissance through the Enlightenment, by contrast, traditional restraints were replaced with an ethical commitment to the unfettered pursuit of technology. Bacon argued that the production of knowledge would culminate in "the conquest of nature for the relief of man's estate" (*Novum Organum*). The modern approach to the world is essentially technological because it upholds an intimate alliance between knowing and changing the world. For example, Bacon wrote that "the nature of things betrays itself more readily under the vexations of art than in its natural freedom" ("Plan of the Work," paragraph 21). It is this commitment to technology, along with its subsequent questioning in response to problems, that frames the prominence of ethical issues both in the philosophy of technology and in environmental philosophy.

Steel Mills, Pittsburgh, Pennsylvania, ca. 1920–1950. *Beginning in the nineteenth century, industrial technology, such as steel production, brought about important changes in both environmental ethics and philosophy. Some have suggested that the powerful role of technology in modern times allows for a reduction in the sense of ethical responsibility for many individuals.* **THE LIBRARY OF CONGRESS.**

In the nineteenth century, technics and science began to merge and the machine-powered industrial technology employed in capitalist systems of trade and production brought massive changes. Systematic reflection on the social organization and ethical import of technology began at that time. Social theorists such as Karl Marx and Max Weber theorized technology in terms of human activity and the causal relations between technical change and social change (e.g., technology as an autonomous determinant of human affairs or as a social construction). Weber analyzed technicalization: the movement from traditional societies, in which techniques are situated within and delimited by nontechnical values, to modern societies, in which techniques are evaluated solely in technical terms. Marx argued that material culture largely determines the character of society because it is driven by the increasing capacities of machines rather than the needs of people. Yet Marx also maintained that industrial technology could support a just and fulfilling utopia if the social organization of labor, especially ownership of the means of production, was altered. Marxism has inspired reflections on technology within critical theory, especially in the Frankfurt School and among contemporary philosophers such as Andrew Feenberg (1991).

Contemporary The late nineteenth and twentieth centuries witnessed increasingly rigorous and diverse philosophical reflection on technology. Carl Mitcham (1994) organized those works into two groups: Engineering philosophy of technology argues that technology is central to human life, and humanities philosophy of technology is concerned with the moral and cultural boundaries of technology. Representatives of the first group include Ernst Kapp (1877), the first to write a book with *philosophy of technology* in the title, who pictured all technologies as ''organ projections'' (e.g., the telegraph extends the human nervous system). Friedrich Dessauer (1972) viewed technological activity as a mystical experience involving supreme participation in reality. Dessauer argued that technological invention offers direct contact with things-in-themselves. Insofar as they make ethical judgments of technology, members of this group tend to concur with Julian Simon (1995) and other contrarians in environmental ethics who emphasize the benefits of technology and are optimistic about the prospects of managing natural systems on a large scale.

Representatives of the second group tend to adopt a more historical approach to and mixed evaluation of technology, often motivated by a concern to preserve the harmonies of nature. This viewpoint allies humanities philosophers of technology with the romantic influences in environmental ethics, including Ralph Waldo Emerson and Henry David Thoreau (Marx 1964). Lewis Mumford (1934), arguing that humans are essentially linguistic rather than engineering animals, distinguished life-oriented technologies from the bureaucratic, systemic megamachine, which diminishes human meaning and constricts personal existence. Jacques Ellul (1964) argued that *la technique*—the whole ensemble of modern technologies—operates autonomously in the modern world to reduce life to the narrow demands of efficiency. José Ortega y Gasset saw technology as central to humans' ability to transcend nature and adapt it to their needs but also expressed concern that the unlimited power of technology will lull people into a flattened existence.

Bernard Charbonneau (Cèrèzuelle 2004), who influenced Ellul's thought, was a founder of the French environmental or political ecology movement who argued that the traditional warring ideologies (e.g., liberalism and communism) were insufficient responses to industrial society because they took its basic logic of production for granted. Charbonneau's work bridges environmental and technological ethics. He argued that World War I brought about a ''great mutation'' in which human freedom has been subordinated to the logic of an ever-accelerating technological industrialism. Humans seek freedom from nature's necessities in society, but those freedoms are paid for with the additional constraints of an impersonal, bureaucratic ''societal frame.'' Charbonneau argued that embodied and personal contact with nature is as essential to human freedom as is technological escape from nature.

Many philosophers of technology follow Heidegger in treating technology as a unified system with a defining essence. This complements the thoughts of White and others in environmental ethics who attempt to situate the contemporary human condition within a broader sweep of history and a worldview that is in need of revision. Aldo Leopold, for example, argued that people need to evolve from a self-image that pictures humanity as conqueror of nature to one that pictures humanity as citizen of the biotic community. By contrast, those influenced by the more recent ''empirical turn'' in the philosophy of technology—mostly in the United States but increasingly in the Netherlands as well—tend to focus on individual technologies as they coevolve with society and express their potential uses in specific contexts (Achterhuis 2001). This approach relates to the context sensitivity of the pragmatist and policy-turn influences in environmental ethics, which are both approaches that begin inquiry with actual environmental controversies and seek to offer practical advise.

KEY CONCEPTS AND THEMES

The philosophy of technology can be discussed in terms of a number of basic issues associated with the standard branches of philosophy: logic, epistemology, metaphysics,

and ethics. In both philosophy of technology and environmental philosophy, ethical and political concerns have had primary importance.

Responsibility and Precaution Hans Jonas (1984) argued that responsibility was not a central concept in premodern ethics because of the narrow compass of scientific knowledge and technological power. For Jonas, "responsibility . . . is a function of power and knowledge," which "were formerly so limited" that consequences distant in time and space had to be left to fate as attention was focused on the present (Jonas 1984, p. 123). Modern technology, by contrast, introduces such novel actions, objects, and consequences that the old ethical frameworks are not appropriate. With the extended powers of technology, modern people face the unprecedented task of considering the global condition of human life, the well-being of future generations, and the existence of entire nonhuman species. This demands "a new conception of duties and rights" (Jonas 1984, p. 8).

Science and technology lengthen the human reach. As Jonas noted, this means that people need "lengthened foresight" to guide their actions. However, foresight is blurred by uncertainty about the consequences of people's actions. For Jonas, the correct reaction to uncertainty in the context of potentially dangerous technologies is precaution. People must apply a "heuristic of fear" that will replace predictions of hope and inform themselves about what is at stake. In this view, precaution is a noble fear grounded in an appreciation of the fragility of human existence in light of technological dangers. This position clearly situates him in the precautionary principle debates within environmental ethics.

Technosocial systems are so complex that a new ethical imperative of responsibility is not easy to implement. Moral responsibility is distributed across multiagent systems, and technologies serve as moral aggregators that turn individual morally negligible acts (driving a car) into major moral consequences (global climate change). Garrett Hardin (1968) put this in terms of the "tragedy of the commons," in which individuals immediately experience short-term benefits while creating longer-term, more diffuse costs.

Hardin's insight relates to Albert Borgmann's 1984 analysis of modern technology as a "device paradigm." Through the example of a central heating system, Borgmann demonstrates how the machinery of devices fades into the background as people increasingly confront commodities (heat, in this case) isolated from the conditions that make them possible. People flip a light switch, pull the lever on a gasoline pump, or press a button on the thermostat but do not experience the full effect of those actions. As users, people do not engender the sociotechnical systems that "lie behind" and make possible these simple actions at the user interface: People click the print icon on the computer screen but do not fell the tree, process the paper, manufacture the printer, and so on.

Thus, the conveniences afforded by technology create situations in which responsibility for the aggregate or emergent consequences seems both nowhere and everywhere. Ulrich Beck (1992) argued that many predominant techniques of risk management block out responsibility. Society is a "laboratory" in which no one has to answer for the negative effects of technological experimentation. The institutions of modern society recognize the existence of risk but permit an "organized irresponsibility."

Environmental ethics and the ethics of technology have generated the same responses to this problem, which include limiting individual freedom through expanded governmental regulations and bureaucracies and altering markets to eliminate externalities. Other proposals include enhancing individual ethical responsibility through improvements in education that incorporate expansions of affective sensibility and the cultivation of more virtuous or less consumerist character traits. Also, role responsibilities can be broadened. For example, corporations and manufacturers can adopt extended responsibility for their products and users can practice more responsible consumption. In recognition of engineering as social experimentation, engineers have shifted the interpretation of their primary responsibility from loyalty to a company or client to responsibility for public health, safety, and welfare. This is demonstrated in the growing emphasis on cradle-to-cradle design, industrial ecology, and sustainable architecture (McDonough and Braungart 2002).

Democracy and Justice Modern liberal democracy is about limits to government, yet technology has at least as much power as governments to shape people's lives—to constrain people, free them, and even constitute their identities. Richard Sclove (1995) and others argue that democracy also should be about limiting science and technology, especially by consciously guiding those increasingly powerful forces through democratic processes of foresight, reflection, participation, and discussion. This argument underpins many practical attempts to reintegrate ethics and other values into technical production processes that have become dissociated from society.

Many examples of these practices come from environmental contexts as governments routinely mandate environmental assessment processes—including public comment periods—for proposed engineering projects with environmental risks. Pointing out the inefficiencies of these processes as well as their often undesirable outcomes, others argue for increased control by those with the technical

knowledge required to ensure sustainable development or other environmental goals; this is a technocratic vision long debated in the philosophy of technology.

Proposals for the democratization of technology often are motivated by the desire to bolster human autonomy in a world largely driven by technological and growth imperatives. The human-built world is displacing and despoiling nature, prompting many people to seek greater control over technology through political processes. Such proposals often are advanced to rectify injustices stemming from the ways in which technologies shift the distribution of power. In particular, environmental burdens and benefits often are distributed unequally across lines of race, class, and gender, for example, when polluting industries are placed in impoverished neighborhoods. The Green Revolution demonstrated the ethical ambiguities of technology transfer to developing countries. The populations of those countries are also the most vulnerable to the impacts of global climate change even though they are responsible for a relatively small proportion of greenhouse gas emissions. Finally, technologies may carry certain political characteristics by their nature. A nuclear power plant, for example, requires a hierarchical distribution of power and advanced security superstructures, whereas distributed solar power generation entails far different political consequences (Winner 1986).

The Good Life The way people relate to the natural world depends on what they believe about themselves and their relationship with the environment. Thus, visions of human nature and the good life are ultimately at work—albeit implicitly—behind modern technological society. The predominant vision is that of material comfort and abundance espoused by Bacon and encapsulated in consumerism. At least for those in the developed world, modern technology has brought vast improvements in material well-being. As more people aspire to this lifestyle, environmental ruin may follow. However, fertility declines with increasing development, and greater wealth brings with it the ability to afford cleaner technologies and the possibility of caring for nature for its own sake.

However, more fundamental to this vision is the belief—coeval with human existence but now magnified beyond previous proportions—that the world as it is does not provide a suitable home for human beings; humanity must construct a home for itself. Human beings often do not find themselves at home within the worlds they create. Levels of happiness do not rise after people cross a certain income threshold, and antidepressants are among the most frequently prescribed drugs in some developed countries. Disconnected from nature and overwhelmed by the pace of modern media culture, children as well as adults tend to lead more hyperactive and desultory lives. Both romanticism and socialism critique these kinds of technological alienation. Jean-Jacques Rousseau focused on how technology alienates the individual from feelings and sentiments. Karl Marx analyzed the power of industrial capitalism to alienate individuals from their full potential and separate people from control over the tools and products of their labor.

Thus, both environmental ethics and philosophy of technology debate the merits and feasibility of alternative visions of the good life, including various types of postmaterialism, communalism, and bioregionalism. Such visions often are criticized as nostalgic idealizations of primitive existence when they are elaborated on a large scale rather than used to justify marginal or individual shifts to alternative technologies. Certainly, one would face strong humanitarian arguments against advocating anything as radical as giving up indoor plumbing or electricity as a social policy. Nonetheless, deep ecologists point out a fundamental human need when they speak of the ennobling power of wilderness. There is more to living well than material comfort, and not all burdens are odious. Indeed, in relinquishing technological aids and meeting nature on its own terms, people replenish a vital part of the human spirit. Debating the proper scope and character of technology, then, bears not just on matters of sustainability, survival, and justice but also on what it means to live well.

PRACTICAL CONTEXTS

Much of environmental ethics falls within the purview of the philosophy of technology because many of its central questions relate to the development, use, and impacts of artifacts. They also relate to the appropriate reach of technical knowledge and activities. For example, debates over sustainability in environmental ethics often stem from differences between those who picture it as a matter of technologically managing nature and those who picture it as an essential limitation on technology. This and other issues are manifested in practical contexts in which individuals and groups face decisions about technology. These contexts range from the construction of dams and power plants by societies, to business investments in new prototypes, to decisions to drive cars and run air conditioners by individuals. Thus, a focus on technology can help move environmental ethics out of academia and into the public, corporate, and private arenas in which such decisions are being made.

TELEOLOGY

The word *teleology* comes from the Greek words *telos,* meaning "end or purpose," and *logos*, meaning "word, thought, speech, principle." Teleology, as a specialty of modern philosophy, is the study of ends or purposes. With roots in Aristotle's philosophy, teleology refers both to a traditional model of scientific explanation—one that encompasses final causes—and an approach to ethics. Teleological explanations and teleological ethics have played a role, albeit a controversial one, in modern environmentalism.

ARISTOTELIAN AND MEDIEVAL ORIGINS

Based on his observations of nature, the ancient Greek philosopher Aristotle (384–322 B.C.E.) concluded that all natural objects have a characteristic and distinctive activity. Aristotle's teleological science differs from modern science in holding that one does not have a complete scientific understanding of an object until one understands this characteristic activity. The goal of this activity, what can be called its purpose or function, is identified as the object's *telos.* For example, in Aristotle's view one does not fully understand any artificial object, such as a house, until one understands the purpose it serves (shelter in the case of a house). Nor does one fully understand any natural object—including the stars, plants, and animals—until one understands the purpose it serves or the goal it strives to reach.

These brief examples demonstrate the close connection between teleological science and teleological ethics. Once one has understood the *telos* of a house or a plant or an animal (including the human animal), something one discovers through Aristotelian science, one also comes to understand what a *good* house is or what a good specimen of its species is—something with ethical implications. A good pine tree is one that grows straight and tall and produces much viable seed from which new pine trees might grow. A good pine tree is one that achieves its *telos*. Aristotle believed that this teleological framework could be applied to all natural objects, including humans. All natural objects achieve their good when they fulfill their function or achieve their *telos.*

This approach was further developed in the Middle Ages, when Christian philosophers synthesized Christian theology with Aristotle's science and ethics as the basis of natural-law philosophy. According to this perspective, as science comes to understand the natural *telos* of each living thing, the "laws of nature," it helps us understand God's "laws." Because the *telos* and purposes discovered in nature are God's purposes, the natural order can be equated with the moral order. Natural law thus has both a descriptive meaning, as the scientific laws of nature, and a prescriptive meaning, as the normative rules that we ethically ought to follow. In this ethical tradition fulfilling one's natural potential—a potential implicitly in harmony with the rest of nature—is the highest form of ethical activity.

APPLICATIONS TO ENVIRONMENTAL PHILOSOPHY

Several themes in contemporary environmental philosophy have parallels to this ethical tradition. Some environmentalists believe that ecosystems are naturally well ordered and harmonious. All parts of an ecosystem have a distinctive place and function in the overall scheme, each contributing to the natural order in its own way. Predators control the populations of their prey, bees pollinate flowering plants, and earthworms aerate the soil; hence each species has its telos in the ecological order. Undisturbed nature is thus good; ecological problems arise only when humans interfere with the natural order.

Other environmentalists have argued that all living things have moral standing because every living thing individually has a telos of its own—the end it strives to achieve—and thus a good of its own. For example, Paul Taylor argues that all living beings are ''teleological centers of life,'' and possess a good of their own that is independent of human interests or, for that matter, independent of any ecological function they may (or may not) perform in the larger ecological order (1986).

Major objections to the teleological tradition challenge its relevance to contemporary debates. Most tellingly, modern evolutionary science provides a significant and perhaps insurmountable challenge to the teleological tradition in both science and ethics. The process of evolution by natural selection offers an account of the apparent design found in nature without appealing to any purpose or *telos*. On this view the order and characteristic activity that is found in nature is not inherent in nature itself, as Aristotle thought, nor does it come from a divine plan, as the Christian Aristotelians in the Middle Ages believed; it results from random genetic mutation and natural selection.

For example, it is tempting to offer a teleological explanation for the long neck of the giraffe by claiming that the long neck exists (or was designed) in order to allow the giraffe to reach food high off the ground. Yet evolutionary biology explains that the giraffe did not develop a long neck *in order to* reach the leaves but that the longer-necked ancestors of giraffes survived and reproduced similarly longer-necked progeny because, having longer necks, they were better able to reach food high off the ground than competing organisms with shorter necks. On this view nature is aiming at nothing, and species have no assigned function in the natural order; nature is headed nowhere in particular. It is neither good nor bad; it just is.

But the appeal of the teleological tradition persists. Contemporary biologists are comfortable using teleological categories when speaking about the natural world. Even within a Darwinian framework, such teleological concepts as *function, purpose, goal,* and *design* are used regularly by scientists and philosophers. Consider the following examples: ''The purpose of the kidney is to remove waste from the blood''; ''the goal of brightly colored plumage on male birds is to attract females''; ''wetlands function as flood-control and water-filtration systems.'' In the teleological tradition, it is a reasonable inference from such purposive and functional ascriptions to a value or normative conclusion: ''This is a healthy kidney''; ''this is a successful male''; ''wetlands should not be destroyed.'' The contemporary challenge is whether such inferences are legitimate and, if so, what normative meanings inhere in them.

Many observers continue to resist any inference from natural facts to value claims. One approach is to claim that the functional language that is common and appropriate in the biological sciences is a kind of convenient shorthand and that all such ascriptions can be fully explained, albeit more awkwardly, in terms of antecedent causes. For convenience navigators treat the Earth as an object at rest, the Sun as a moving object, and the pole star as a motionless point of reference even though they know full well that the Earth orbits the Sun and turns on its axis. The science of navigation could be expressed in the language of modern astronomy, but with great sacrifice of economy and simplicity of expression. Thus, in the view of modern science, although kidneys, plumage, wetlands, and even long necks might perform a function, they do not do so out of a prior built-in purpose, as Aristotle supposed, or a divine design as his Christian exponents supposed. The functions themselves are simply the result of previous evolutionary processes. Inferring a value conclusion from these facts would require an implicit value component already assumed. For example, only by assuming that reproductive success is good could one infer that bright plumage is a good thing for male birds; and only by assuming that survival is good could one infer that long necks are good for giraffes.

Some philosophers argue that it does seem reasonable to assume that adaptation for survival and reproductive success (what biologists call ''inclusive fitness'') *is* good and therefore that it is reasonable to reach normative conclusions from biological facts. It seems reasonable to conclude that the adaptive capacity that a species has developed to outrun or hide from its predators is good for that species. It is good for the giraffe to have a long neck, and a kidney that does not filter blood effectively is bad kidney.

Assessing these debates would require carefully distinguishing between such concepts as *function, purpose, design,* and *goal.* When used in science, all of these concepts involve explaining some phenomena (kidneys, long necks, bright plumage, predators, wetlands) in terms of some future state or activity (filtering blood, reaching high food, attracting a mate, controlling prey populations, absorbing flood water). This is the essence of any teleological explanation. Aristotle's teleological science seems right in this: One has not fully understood such natural objects until one has understood how they function. But the questions remain: Are such forward-looking explanations scientifically valid? If so, is it always a good thing to attain this future state or perform this activity? Are functional explanations truly teleological? Is value built in to any notion of aiming for and attaining some future state? If so, is this value necessarily an ethically good thing?

Much modern science, particularly as it developed under the influence of physics and mechanics, argues that the only legitimate scientific explanations are those that refer back to antecedent causes, not forward to future goals, or final causes. Thus, some critics challenge the legitimacy of any teleological explanations at all in the biological sciences. Others argue that, although some teleological explanations are legitimate, others are not and that no value conclusions can be drawn from them in any case. For example, although it may be legitimate to think that the function of the kidney is to filter blood, it is not legitimate to think that the function of earth worms is to aerate soil; rather, as their digestive tracts extract nourishment from detritus, a fortuitous side effect is soil aeration. Still others argue that, although value conclusions might be drawn from biological facts, the values are always qualified and conditional. *If* you assume that survival and reproductive success is good, or *if* you assume that adaptive fit is good, then one can conclude that certain traits are good for certain species. But inclusive fitness and adaptability are not always an *ethically* good thing. That which is good for a species or an individual is not always identical with an ethical good, a distinction foreign to Aristotle. Thus, although the teleological tradition provides a framework for thinking and reasoning about relations between nature and ethics, it is fraught with philosophical and scientific controversies.

THEORY

One of the principal tasks of environmental ethics and philosophy is to posit and defend an adequate normative ethical theory. This agenda was set by two seminal essays: In "Historical Roots of Our Ecologic Crisis" (1967), Lynn White Jr. blamed the environmental crisis on the Judeo-Christian worldview, claiming that Christianity was the most anthropocentric of world religions. An environmentally friendly worldview, he implied, would have to be nonanthropocentric. But, he argued, traditional European and North American ethical theory is anthropocentric, requiring an effort at building a new ethical theory. In the 1973 essay "Is There a Need for a New, an Environmental Ethic?" Richard Routley constructed the now-famous "Last Man" thought experiment, in which the last human being "lays about him" destroying everything within reach. Routley correctly expected that most of his readers would judge the last man's behavior to be morally reprehensible, but standard European and North American ethical theory could not support such an intuition. The Last Man thought experiment claims to demonstrate that the foundations of environmental ethics must be nonanthropocentric.

This interest in theory marks environmental ethics and philosophy as distinct from the more immediate practical work of ecological restoration, the development of sustainable technologies, or the institution of ecologically informed environmental policy. In addition to the implementation of environmentally sound practices, environmental ethicists and philosophers focus on fundamental questions concerning the types of values attributed to nature, what it would mean to actually restore a landscape, what it means to engage in a sustainable technology, or what constitutes an ecologically informed policy. Underlying and motivating all of these more practical environmental aims are implicit theoretical, environmental, ethical, and philosophical assumptions about the value of the environment itself. Theoretical environmental philosophy exposes and critically engages such assumptions.

Theorists in environmental ethics and philosophy have historically been interested in both normative and metaethical theoretical questions. Metaethics addresses questions *about* ethics, whereas normative ethics focuses on questions *within* ethics. Metaethicists are interested, for example, in whether or not environmental ethical claims can be true or false, whereas normative ethicists work to formulate and defend particular systems or theories of environmental ethics.

NORMATIVE ETHICAL THEORY IN ENVIRONMENTAL ETHICS AND PHILOSOPHY

An ethical theory is an attempt to determine which entities are worthy of direct moral standing, which are worthy of only indirect moral standing, and which do not matter morally. Consider, as an illustration, a circle. If something lies within this circle of moral concern (or within the moral community), it possesses direct moral standing. Things with direct moral standing count, period. If something lies outside of the moral community, it might count,

but only indirectly at best. That is, something outside of the moral community might be tethered to (i.e., somehow important for or to) something within the moral community. It might also be the case that those things outside of the moral community possess no moral standing at all if it can be demonstrated that they serve no end for things within the moral community. So, for example, if our moral community included only human beings, then, although we would not necessarily be concerned with the loss of tropical plant species per se, we might still be concerned with them if their well-being somehow served a human end (e.g., provided chemical extracts that could treat a human illness). If, however, our moral community included all living things, then, in addition to being important as a source of medicine for humans, plants would also count directly.

Moral standing—whether direct or indirect—depends largely on what a given theory presupposes as the key to this inclusion. Typically the key to moral standing is a quality that entities possess or fail to possess. Because an entire moral-community structure depends on an established key to moral standing, normative environmental ethical theory has focused a great deal of energy on determining the nature of this key.

Although some environmental scholars downplay or dismiss the value of environmental-ethical theorizing, others point out the advantages to such theory building. First, they note that all actions and polices presuppose a theoretical foundation. Absent coercion, we are usually willing to perform only those actions that are consistent with our value assumptions. Hence, to engage in environmental ethical theory building is to engage at the same time in environmental policy making (albeit indirectly). Furthermore, given the inescapability and force of environmental ethical theory, it seems wiser to attend to such theory building than to ignore it. Second, the theoretical foundations provided by environmental ethical theory might be empowering. As opposed to environmental discourse that appears ungrounded, or environmental decision-making that happens only as the result of political maneuvering and power struggle, environmental ethical theorizing allows us to create a solid foundation from which to judge and defend a certain course of action and to understand the roots of other courses of action. Hence, even those without political power can participate in environmental discourse and possibly even in environmental decision-making. Third, environmental ethical theory provides us with at least a rough idea—but not the specific details—about how we ought to live. The application of theory, as opposed to concrete rules or policies, requires us to think for ourselves, allows us to adjust to novel situations and to consider how a given theory might manifest itself in different ways under different conditions. Finally, the establishment of an environmental ethical theory, and its corresponding notions of direct and indirect moral standing, establishes a powerful and important burden of proof. Given that those with direct moral standing would be "innocent until proven guilty," whereas those without direct moral standing would be "guilty until proven innocent," and given that the establishment of burden of proof is no small matter to those entities whose fate is thus decided, environmental ethical theory building takes on enormous importance.

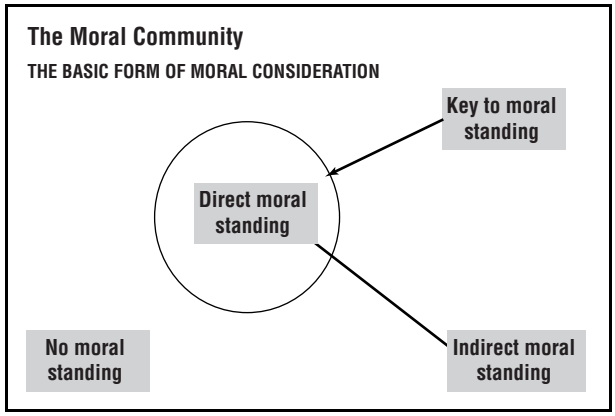

Figure 1. *Environmental ethical theories vary with regard to who or what possess direct, indirect, or no moral standing. For example, for some theories species and ecosystems might be members of the moral community directly, for others they might matter only because they support that which does count directly (i.e., they might merit only indirect moral standing), and for still others they might not matter at all. Different theories propose different relevant qualities (or keys) or moral consideration which then determines which things count (or do not count) and in what way.* CENGAGE LEARNING, GALE.

Like many disciplines, environmental ethics has its own vocabulary. Two key terms in environmental ethics are *instrumental value* and *intrinsic value*. Something is said to have instrumental value if it is a means to some other end (e.g., a child can have instrumental value if she can mow the lawn). Something is said to have intrinsic value when it possesses value that transcends its instrumental value (e.g., a child, even if she will not or cannot mow the lawn). The views of environmental ethicists differ most markedly in their attribution of either instrumental or intrinsic value to various nonhuman things in the world. These differences produce profound differences in how and to what extent one sees and likewise how one feels we ought to work to solve environmental "problems."

KEY PERSPECTIVES IN ENVIRONMENTAL ETHICS

The key perspectives in environmental ethics are the following:

1. *Anthropocentrism* is the position that all humans—and only humans—possess intrinsic value and direct moral standing. In this view, nonhumans have only instrumental value to the extent that human well-being may in some way depend on them. For the anthropocentrist, environmental ethics and policies are motivated and justified solely on the basis of their effect on humans, without regard for the nonhuman world. An anthropocentrist, for example, would be concerned about rapid global climate change only insofar as it affects the welfare of human beings. Anthropocentrists argue variously that it is either unintelligible or unnecessary to extend direct moral standing to the nonhuman world. The philosopher John Passmore (1974) represents the anthropocentric camp.
2. *Nonanthropocentrism* attributes intrinsic value to humans and to at least some nonhuman entities. Nonanthropocentrists vary in how inclusively they view the moral community. The U.S. Endangered Species Act (1973), as an example, is nonanthropocentric to the extent that it dissociates the value of a species from its economic and narrowly human-centered value. Each of the perspectives described below are types of nonanthropocentrism (except that extensionism is more general than nonanthropocentrism):
   a. *Extensionism* is exemplified by zoocentrism and biocentrism (see below). These perspectives vary according to the extent to which they argue moral consideration ought to be attributed to various kinds of other individuals. Extensionism attempts to extend traditional moral theories (such as utilitarianism or rights theory) to entities that have not traditionally been considered worthy of direct moral standing.
   b. *Zoocentrism* attributes intrinsic value only to humans and certain nonhuman animals, although adherents to this view differ about which animals possess direct moral standing and intrinsic value. A zoocentrist could, for example, be concerned about the loss of biodiversity insofar as it harms humans and nonhuman animals that possess clear indications of self-consciousness (e.g., primates). Peter Singer (1975) and Tom Regan (1983) are major proponents of zoocentric philosophy.
   c. *Biocentrism* attributes intrinsic value and direct moral standing to all individual living creatures. It takes "being alive" as the key to moral inclusion. Nonliving things (e.g., lakes or rocks) and collectives (e.g., species and ecosystems) possess only instrumental value or no value at all. Biocentrists would care, for example, about biodiversity loss because of its effect on all individual living things. The philosopher Paul W. Taylor (1986) defends this position, as do Kenneth Goodpaster, Robin Attfield, and James Sterba.
   d. *Universal consideration* is a position that attributes intrinsic value and moral standing to everything (living or not). Hence, from this perspective, biodiversity loss would be decried not only for its potential harm to all living things, but also for its negative impact on even nonliving things such as mountains, rivers, or rocks. The philosopher Thomas Birch (1993) has championed this position.
   e. *Ecocentrism* is a reaction against the atomism or individualism represented by extensionism. Adopting Charles Darwin's analysis of ethics as generated by community membership and inspired by principles of ecological science, ecocentrism reflects the social-like connectedness among individuals in nature. Emergent properties of biological wholes—such as species, biotic communities, and ecosystems—transcend the properties of the individuals that compose such collectives. Ecological collectives, ecocentrists argue, merit moral standing because of their emergent properties and connectedness. Ecocentrism thus focuses moral concern on the maintenance of biotic communities, species, and ecosystems and less on the welfare of animals and other organisms. Aldo Leopold represents ecocentrism, especially when he writes, "A thing is right when it tends to preserve the integrity, stability, and beauty of the biotic community. It is wrong when it tends otherwise." (Leopold 1949, pp. 224–225). The philosopher J. Baird Callicott (1989, 1999) is the most noted defender of Leopold's land ethic. The philosopher Arne Naess (1989) is the originator and noted defender of the ecocentric environmental ethic known as Deep Ecology, which is based on a mystical sense of self intimately connected with all of nature. Some argue that ecocentrism, taken to its logical conclusion, is equivalent to James Lovelock's Gaia hypothesis (1979), in which the entire Earth merits moral consideration.
   f. *Environmental virtue theory* began to emerge in the early part of the twenty-first century. Harking back to Aristotle's approach to ethical reasoning, environmental virtue ethicists suggest that we should focus our energies on the creation of virtuous people, or people of appropriate character, instead of on working to determine the proper key to moral consideration and membership in

the moral community. Traits such as respect, humility, caring, and attentiveness are often advanced as the key virtues. The philosophers Phil Cafaro (2001) and Ron Sandler (2007) represent this trend in environmental ethics.

METAETHICAL THEORY IN ENVIRONMENTAL ETHICS AND PHILOSOPHY

Although many metaethical questions surround environmental ethics and philosophy, three of them have been at the center of particularly robust debates. Environmental ethics is often regarded as one among several types of "applied ethics," such as biomedical ethics, engineering ethics, and business ethics. Applied ethicists rely on the prevailing European and North American ethical theories—variations on utilitarianism and Kantian deontology to new ethical questions that the eighteenth- and nineteenth-century authors of these theories could never have imagined or anticipated. Accordingly, some philosophers view environmental philosophy as work that takes traditional ethical theory and examines environmental concerns through the lens of these theories. These philosophers might therefore be concerned with what the prevailing European and North American ethical theories of utilitarianism or deontology might have to say about the rightness or wrongness of factory farming or sport hunting.

Other environmental philosophers, however, view the work of environmental philosophy and ethics as something quite beyond mere applied ethics—as work that explores new ideas about ethics and even metaphysics and that, although practical in its application, is also freshly theoretical. These philosophers might point to the unique nonanthropocentric ethical theories created by environmental philosophers or the work done in policy and philosophy or between various sciences (e.g., ecology, geography, geology, and biology) and philosophy as examples of uniquely theoretical environmental ethics. The work of Robert Frodeman has taken this approach (2003).

Second, there has been a debate between those who operate as if environmental ethicists, like classical European and North American ethical theorists, should pursue a unified ethical theory and those who recommend embracing several theories at once. The former favors ethical monism, the belief that there is only one proper ethical theory. Ethical pluralists, on the other hand, believe that there may be more than one legitimate ethical theory and a plurality of ethical truths. Pluralists worry about the homogenizing and totalizing effect of the pursuit of monism. Monists worry that pluralism is little more than ethical relativism. Pluralists deny this reduction to relativism and instead suggest that the standard of an acceptable ethic ought to shift from a focus on truth to a focus on reasonableness, pointing out that any number of ethical prescriptions can be reasonable. Are pluralists really suggesting that a number of incommensurable ethical theories can be coherently held at the same time, or are they suggesting that different persons implicitly or explicitly hold different ethical theories and that there is, therefore, no decisive way to declare that one or the other is the one true theory? Are monists really suggesting that there is only one true ethical theory or merely demanding that each person hold an internally consistent ethical point of view while allowing that there may be many self-consistent ethical theories? Synthesizing, in Hegelian fashion, monism and pluralism in environmental ethics, could a monistic theory be constructed that is sufficiently general to allow for a plurality of approaches and applications in the real world? Within the literature of environmental ethics, Christopher Stone (1987) advocates an extreme version of pluralism, whereas Peter Wenz (1993) advocates a more moderate pluralism. J. Baird Callicott (1999) has defended a moderate version of monism; Peter Singer (1990) represents a more extreme monism in his steadfast commitment to utilitarianism.

Third, there is a debate between those environmental philosophers who have focused primarily on the creation and defense of ethical theories (theories that defend the intrinsic value of nature) and environmental pragmatists who are motivated primarily by effecting environmental change in the "real world." Whereas the more theoretically motivated environmental philosophers contend that environmental philosophers should continue to create and defend abstract theories of values that underpin environmental attitudes and decision making, pragmatists contend that they should instead focus on variable and context-dependent accounts of value and truth (i.e., on solving real-world environmental problems). Pragmatists often assert that environmental ethical theorizing has had no real impact on environmental problems or policy formation and that we ought to make philosophy more practical. Although some pragmatists assert that environmental ethical theorizing is simply irrelevant or useless, some assert that it is actually counterproductive. Commonly taking a pluralist approach, some environmental pragmatists strive to marshal the values and ethical commitments of ordinary people to support of environment-friendly policies; others recommend suppressing the often conflicting values and ethical commitments of ordinary people—because they can be divisive—and focus on more situation-dependent solutions that all sides can live with. Ethical theorists might, however, argue that any such solutions cryptically rest on implicit values and ethical commitments and that the very notion of an environmental problem presupposes the significance of environmental values and ethics. Finally, although ethical

theorizing has not yet had the impact that environmental philosophers had originally hoped, it is also not clear why a pragmatist would necessarily care what ethical theorists do. It would seem that, as self-avowed pluralists, pragmatists would be content to let theorists theorize, while they, the pragmatists get on with their problem-oriented, situation-dependent solutions, What could be more unpragmatic—that is, impractical—than spending thousands of hours writing dozens of books and articles pointing out the unpragmatic product of the unpragmatic theoreticians?

THOREAU, HENRY DAVID
1817–1862

Henry David Thoreau was born in Concord, Massachusetts, and lived there all his life. A writer, naturalist, and philosopher, he was an important forerunner of American environmentalism and remains a key source of insight and inspiration for millions of environmental and political activists around the world. *Walden* is his most famous work. His influence on the development of environmental ethics has been profound.

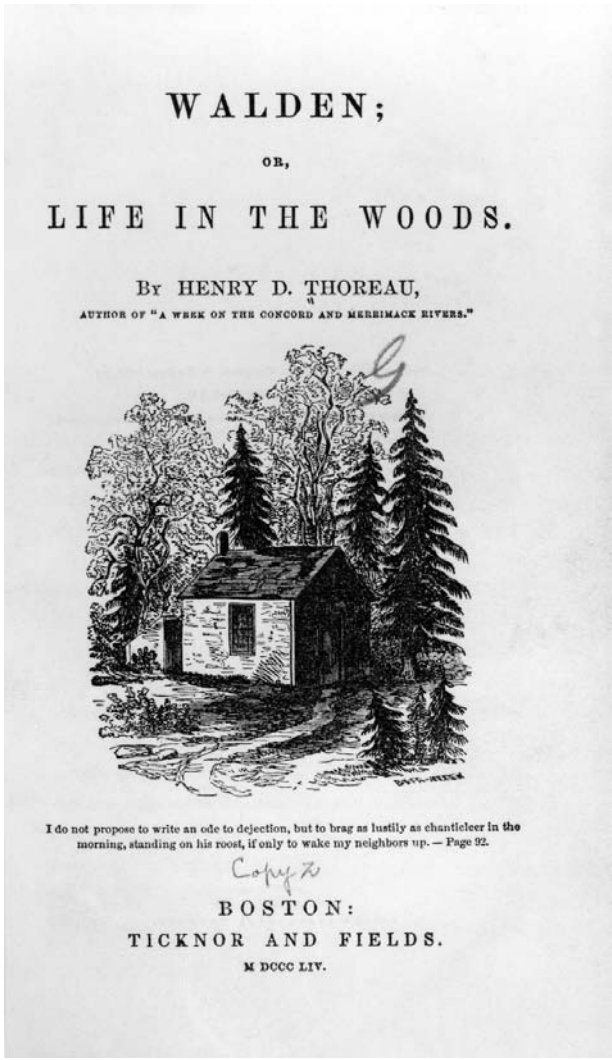
NONANTHROPOCENTRIC ETHICS

Thoreau was one of the earliest and strongest critics of anthropocentrism: the view that only human beings have rights or "intrinsic value" and that other creatures may be used in any way people see fit. For example, his first book, *A Week on the Concord and Merrimack Rivers* (1849), discussed the plight of anadromous fishes formerly found in great numbers in New England's rivers but by that time mostly blocked by dams.

One hundred thirty years before Earth First! Thoreau suggested that unjust treatment of the shad was grave enough to justify civil disobedience. This was a method of social protest which Thoreau pioneered, influencing both Mohandas Gandhi and Martin Luther King, Jr.

Thoreau made one of the earliest explicit calls for a nonanthropocentric ethic, writing: "Away with the superficial and

Henry David Thoreau. *A famous writer and philosopher and a dedicated critic of anthropocentrism, Thoreau pioneered the method of civil disobedience as a pro-environmental technique. Many of his works extoll the value of nature and the wilderness for the human experience.* **© BETTMANN/CORBIS.**



"Walden" Title Page, 1854. *One of Henry David Thoreau's most famous works, "Walden" speaks to the benefits of valuing nature and living in harmony with it. This original title page features the cabin near Walden Pond in which Thoreau lived for two years, two months, and two days while writing the book.* **LIBRARY OF CONGRESS.**

selfish phil-*anthropy* of men [emphasis and "fish" puns in the original]—who knows what admirable virtue of fishes may be below low-water mark, bearing up against a hard destiny, not admired by that fellow creature who alone can appreciate it!" (Thoreau 1849, p. 37). Reserving all love and concern for humans is both superficial, based on ignorance of what is below the surface, and selfish, an excuse for unjustified self-partiality.

WALDEN AND LATER WRITINGS

Walden represents a more searching, sustained attempt to specify and live a nonanthropocentric ethics. In that book Thoreau repeatedly asserted the intrinsic value of nonhuman nature—whether in trees, woodchucks, or Walden Pond itself—and tried to justify those assertions. However, *Walden* also discusses the benefits to people of recognizing the value of nature and living in harmony with it. Like Emerson's *Nature* (1836), but more practically and with a greater emphasis on wild nature, *Walden* teaches that nature is humankind's greatest resource. It provides all that humanity needs to flourish if people protect it and use it wisely.

However, wise use does not mean managing the whole of nature, and Thoreau's late essay "Walking" further develops the claims in *Walden* for the high value of wild nature. "In Wildness is the preservation of the World," Thoreau exclaimed there (Thoreau 1980, p. 112). "From the forest and wilderness come the tonics and barks which brace mankind" (p. 114). For Thoreau this vital connection was literal, physical, and sensual. "I think that I cannot preserve my health and spirits," he wrote, "unless I spend four hours a day at least . . . sauntering through the woods and over the hills and fields" (p. 95). This physical contact with nature revitalizes the mind, stimulating that "uncivilized free and wild thinking" at the heart of all human creativity (p. 96).

Walden and "Walking" give detailed advice for deepening one's experience of nature. However, it would be foolish to focus solely on improving the walker while failing to preserve the landscape he or she walks through, just as it would be a mistake to locate all value in the human experience and none in wild nature. The greatest value comes when one brings a lively mind to a vital place. Thoreau made much of the Concord countryside; still, as he reflected in his journal:

> I spend a considerable portion of my time observing the habits of the wild animals, my brute neighbors. . . . But when I consider [that] the nobler animals have been exterminated here,—the cougar, panther, lynx, wolverene, wolf, bear, moose, deer, the beaver, the turkey, etc., etc.,—I cannot but feel as if I lived in a tamed, and, as it were, emasculated country. (Thoreau 1906, pp. 220–221)

Thoreau wanted "to know an entire heaven and an entire earth" rather than "a maimed and imperfect nature." In the end, humanity cannot separate its own flourishing from that of nature.

One of Thoreau's major insights was that human flourishing no longer requires the further taming of nature but rather the preservation of what wildness remains. "I would not have every man nor every part of a man cultivated, any more than I would have every acre of earth cultivated," he wrote (1980, p. 126). A "true culture" must respect spontaneity as well as order, creativity and daring as well as safety and good behavior (p. 124). It also must preserve wilderness landscapes so that it can preserve wildness in people's hearts and minds: "To preserve wild animals implies generally the creation of a forest for them to dwell in or resort to. So it is with man" (p. 117).

TRADITIONAL ECOLOGICAL KNOWLEDGE

Humans have understood their environments in terms of traditional (or indigenous) ecological knowledge (TEK). TEK has been a major determinant of the ways in which people have interacted with their environment—for all peoples at some point in the past, and for many today as well, though much TEK has been lost via the diminution or disappearance of cultural groups, or greatly modified by interaction with scientific ecological knowledge (SEK), the knowledge generated by the more formal, organized investigation of the world that has become increasingly dominant.

TEK is central to environmental ethics and philosophy because understanding it opens up new perspectives on the ontology, axiology, epistemology, and praxis of ecological knowledge in general, and because understanding TEK and its similarities to and differences from modern SEK could be critical for developing and managing more sustainable ecosystems. (*Knowledge* herein is defined as consisting of values, descriptive data, and theory in a person's mind, which is shared to differing degrees within groups of different sizes to which individuals belong.)

HOW CAN WE UNDERSTAND TEK?

A major difficulty in defining and discussing TEK is that the TEKs of different indigenous groups are different because of variations in local cultural and environmental contexts; therefore, only those brought up in a specific culture and environment are likely to fully understand that culture's TEK. This insider's (*emic*) perspective contrasts with an outsider's (*etic)* perspective. Although some social scientists believe that it is fruitless for outsiders to attempt to understand TEK, others believe that it is possible to gain useful etic understanding and to generalize about TEKs, and that such work may be critical for their survival. A major challenge to generalization is the variation in TEK among individuals within local groups and in SEK within groups of scientists, e.g., plant breeders (Cleveland 2001), so that to compare TEK and SEK requires a comparison of variances and central tendencies—monolithic TEKs and SEKs do not exist.

Understanding TEK etically, however, requires a baseline for describing similarities and differences among

A San Bushman Teaching His Son to Hunt in Namibia. *Traditional Ecological Knowledge, or TEK, is an integral part of environmental philosophy. TEK is commonly understood to be based on direct interactions between humans and their environment, but what remains to be decided is whether the effects of indigenous peoples on their local ecosystems has been positive (conservationist) or negative (destructive). The UN Declaration on the Rights of Indigenous Peoples grants such native populations the right to pursue development and maintenance of their land as they see fit.* **JOY TESSMAN/NATIONAL GEOGRAPHIC/GETTY IMAGES.**

TEKs (and between TEKs and SEKs, as discussed below). Because most who have attempted this comparison have SEK, it is SEK that has provided the methodological base for comparison. (Therefore, attempts to understand TEK include the following assumptions: (a) There is an external objective reality that both TEK and SEK are based on; and (b) SEK can provide a description of this reality that can serve as an ontological comparator.)

Indeed, in an increasingly crowded and interconnected world, it is not possible to assume that each local group and its TEK and natural-resource management regimes can be understood only emically, because all activities affect other groups with different values and different management strategies. Therefore, negotiating conflicts based on some etic standards is required for the survival of TEKs and the external ecological reality they refer to.

HOW IS TEK CREATED, AND HOW IS IT RELATED TO ECOLOGY AND ETHICS?

A major controversy in the study of TEK has been whether indigenous classification of the environment is the result of the universal structure in nature that imposes itself on the human mind, perhaps facilitated by universals in human cognition (the intellectualist view), or whether it is the result of culture-dependent differences in goals, values, and theories (the utilitarian view) (Medin and Atran 1999). Boster's research with Aguaruna farmers in the Amazon is an example supporting the first view: Their cassava classification tends to classify the smallest distinct taxonomic unit in patterns similar to those of scientists. Support for the utilitarian view is a more common research finding, however: For example, the Mende of Sierra Leone use growth duration as a

major criterion for classifying African rice varieties, with a mixture of varieties of different durations managed and planted to avoid labor bottlenecks and interharvest food shortages; Hopi and Quechua farmers classify and choose maize varieties based on ceremonial and religious values (Cleveland et al. 2000).

Differences in conclusions about the basis for classifying the environment may be due in part to differences in the nature of the plants or other organisms and environments involved. For example, the pattern of phenotypic expression (the appearance of an organism) of qualitative traits (e.g. seed or leaf color) in a clonally propagated crop (cassava) is much different than for quantitative traits (e.g. plant height or yield) in sexually propagated crops (rice), especially cross-pollinated ones (maize). Indigenous people may simply enjoy "playing" with diversity, yet their perceptions of genetic variation (to the extent revealed in plant phenotypes) depend on their ability to observe it and are determined in turn by the scale at which it occurs, the extent to which it is hidden by environmental variation, and on how important it is to them.

The preceding discussion assumes that TEK is based on direct interaction of individuals with the environment. However, TEK can also be learned indirectly—through teaching or imitating a respected individual, which introduces additional challenges for understanding TEK

TEK PRACTICE AND THE ENVIRONMENT

There is evidence that indigenous peoples have had massive effects on their environments, often in ways that increased useful production for humans, as summarized for the Americas by Mann (2005). But what criteria should be used to judge whether an effect is positive in the sense of conserving ecosystem functions, or negative in the sense of disrupting them? Change in biodiversity is often used as a criterion, and it is sometimes assumed that evidence that indigenous people and biodiversity coexist in space and time means the actions of the former are responsible for the latter. For example, the Global Plan of Action for crop genetic resources of the Food and Agriculture Organization of the United Nations (FAO) calls for more emphasis on in situ conservation based on evidence that "the rich diversity that exists today offers ample testimony of what has already been achieved" through farmer management and development of their crop genetic resources (FAO 1996, para. 26). Similarly, data showing a correlation between increased human presence and loss of biodiversity support the assumption that indigenous peoples tend to destroy their environments—for example, in the massive extinctions of large mammals with the exception of Africa during the last 10,000 to 50,000 years that followed indigenous peoples movements (Koch and Barnosky 2006).

Regardless of how the effects on the environment are judged, the question remains as to the connection between peoples' action and their TEK. Those who accept the conclusion that indigenous peoples conserve their environments often assume that their TEK is accurate and "ethical" because it leads to action that conserves the environment. On the other hand, those who accept the conclusion that indigenous peoples destroy their environments often assume that their TEK relatively is inaccurate and "unethical" because it leads to action that destroys the environment. Research on the relationships among TEK, behavior, and the effects of behavior on the environment is difficult to do and has produced conflicting results, making generalizations problematic and suggesting that these relationships are often contingent on local histories, cultures, and environments.

HOW DOES TEK COMPARE WITH SEK, AND CAN THEY WORK TOGETHER?

Social scientists often contrast SEK and TEK, seeing the former as rationalistic, reductionist, theoretical, generalizable, objectively verifiable, abstract, and imperialistic—in sharp contrast to the latter, which they see as organic, holistic, intuitive, local, socially constructed, practical, and egalitarian. On the other hand, there is evidence that SEK and TEK are more similar than different (Agrawal 1995). For example, since the 1920s, work by social scientists, historians, and philosophers on the nature of SEK has explicitly explored the ways in which it is shaped by personal psychology, historical contingencies, and social context, and some current research on TEK shows that it can be theoretical and objectively verifiable. One difficulty, discussed above, is how outsiders understand TEK if communication is structured so that indigenous people cannot explain the abstract or generalized basis for their specific TEK; outsiders may assume their practices are untheorized responses to changing, unpredictable circumstances.

Soleri and colleagues (2002) used scenarios based on basic biological principles to elicit TEK from traditional farmers in different parts of the world about genotype-by-environment interaction (i.e., the relationship between nature and nurture) and heritability based on a fundamental biological model. They found patterns in TEK across different crops and countries, and between TEK and SEK that supported the hypothesis that empirical and theoretical TEK and SEK consistently reflect similar environmental patterns and relationships. However, they also found differences among farmers, and among scientists, and between TEK and SEK, which could often be explained in terms

of differences in crop varieties, environments, or cultural values.

Similarly, Ellen concluded that indigenous rain-forest peoples' observations of many individual species leads inductively to ecological models that are "privileged over accumulated inductive knowledge" (1999, p. 106). In some cases TEK may even be more complete than SEK—Malawian farmers' taxonomy of cassava varieties based on plant morphology visually distinguishes varieties between which scientists can see no differences, but whose distinctness was supported by molecular analyses for cyanogenic glucoside levels and genetic analysis (Mkumbira et al. 2003). TEK may also be less complete than SEK—Wola farmers of New Guinea are aware of geomorphological forces that destroy and renew their soil but not of processes on a geological time scale (Sillitoe 1996).

TEK IN RESEARCH, DEVELOPMENT AND POLITICAL CONTEXTS

All of the aspects of understanding TEK discussed above can be influenced by the research, development, and political contexts in which TEK is used. For example, an outside researcher's personal values and relationships with an indigenous community may affect her or his research and conclusions about TEK. Definitions of TEK in applied contexts often depend on the assumptions and goals of those in control. For example, the way in which "sustainable agriculture" is defined affects the way in which TEK is defined, which in turn leads to different roles for indigenous peoples in their development as controlled by outsiders (Cleveland and Soleri 2007).

The use of TEK in improving the well-being of local communities was pioneered by local and nongovernmental organizations and by indigenous communities themselves, but it has become institutionalized in the last two decades in mainstream economic development—for example by the World Bank and many national governments. This institutionalization has been criticized by many indigenous groups and their supporters for decontextualizing TEK and co-opting it for the goals of mainstream development, which may result in destroying TEK or even entire cultures.

Success in using TEK in "development" and applied science depends on its long-term results in social, cultural, economic, and environmental terms for local people and the world. This use of TEK challenges the cultural-relativist viewpoint that each local people's TEK is valid and should be respected by outsiders. In an increasingly crowded and interconnected world, however, TEK and natural-resource management practices cannot be judged only emically, because all activities affect other groups with different TEK and different management strategies. Therefore, we need to evaluate local solutions in global contexts of social, economic, and environmental sustainability.

TEK AND INDIGENOUS RIGHTS

Part of the problem with understanding the relationship between rights and TEK is that TEK often includes different concepts of rights than those of outsiders. It is possible, however, for outsiders to elicit indigenous peoples' knowledge of rights. For example, interviews using scenarios of potential conflicts over rights to crop genetic resources elicited consistent concepts of rights from Zuni community members (Soleri et al. 1994). There is a wide range of concepts of rights in TEK among various indigenous groups; they usually place more emphasis on community rights and on individual rights that benefit the community than SEK, which emphasizes individual rights to knowledge for personal gain and their protection through state-enforced legal systems such as patents.

Claims of indigenous farmers' rights to resources are often based on assumptions that indigenous farming is environmentally sustainable and that farmers' conservation of resources is based on accurate ecological knowledge and/or ethical principles of natural resource conservation. For example, Article 8(j) of the 1992 Convention on Biological Diversity (CBD) on in situ conservation calls for signatories to "respect, preserve and maintain knowledge, innovations and practices of indigenous and local communities embodying traditional lifestyles relevant for the conservation and sustainable use of biological diversity" and to "encourage the equitable sharing of benefits" arising from the use of those resources (CBD 1992). Yet, as discussed above, there are variations in sustainable resource use within communities and between indigenous communities.

Some arguments for indigenous peoples' human rights to land and biological resources rest on an assumption that these peoples are inherently conservationist; such arguments often mix value judgments about human rights with empirically testable hypotheses about the extent and efficacy of indigenous peoples' conservation of biodiversity. For example, indigenous rights and environmental conservation advocates may try to portray indigenous peoples in terms of European and North American environmentalist stereotypes—dubbed by some as "green Orientalism." If the empirical data do not support the claim that an indigenous people are conservators, then those who do not share the belief in their human rights—to which indigenous conservation has been linked—may deem this as sufficient justification for not recognizing indigenous rights to their traditional environments (Cleveland and Murray 1997).

On September 13, 2007, the United Nations General Assembly voted 143 to 4 (Australia, Canada, New

Zealand, United States; eleven abstentions), to adopt the nonbinding "United Nations Declaration on the Rights of Indigenous Peoples," which "sets out the individual and collective rights of the world's 370 million native peoples, calls for the maintenance and strengthening of their cultural identities, and emphasizes their right to pursue development in keeping with their own needs and aspirations," thereby ending nearly twenty-five years of "contentious negotiations" (United Nations General Assembly 2007). As this entry has shown, implementing these rights will not be easy. Successful implementation will depend on continuing research on the factors affecting variation in TEK within and among indigenous groups, and on the relationship of TEK to SEK. It will also depend on resolving conflicts over rights between individual indigenous groups and between indigenous groups and the more industrialized modern societies within which they exist. Such resolution in turn will require dealing with the reality that in an increasingly crowded and globalized world, consensus on dealing with common environmental resources will depend on some groups modifying their knowledge, including claims to rights.

David A. Cleveland

TRAGEDY OF THE COMMONS

The word *tragedy* is used to refer generically to anything really bad. As Carol Rose (1986) notes though, the word has an older meaning, referring to literary works that depict a protagonist caught up in events inexorably leading to his or her doom. Some of that older meaning is implicit in the logic of what we now call the tragedy of the commons. The phrase was invented by Garrett Hardin, who credits the idea to W. F. Lloyd. (See also the work of H. Scott Gordon.)

THE LOGIC OF THE COMMONS

Suppose there is a plot of land. The land has a *carrying capacity*: a number of animals the land can sustain more or less indefinitely. (The concept of carrying capacity is somewhat problematic. While it points to something real, because there really are limits to what the land can

support, such limits are not fixed. Carrying capacity is somewhat fluid, and a function of many variables. For example, whether Kruger National Park in South Africa can carry 15,000 elephants depends on whether we want to leave room for rhinos, which is not simply an ecological issue.) Suppose the parcel's carrying capacity is 100 animals. The land is jointly owned by ten shepherds, each of whom owns ten animals for a total flock of 100 animals. The land is thus at its carrying capacity. As things stand, each animal is worth, for example, one dollar to its owner, so that, at carrying capacity, 100 animals are worth $100. Crucially, although the ten shepherds treat their individual flocks as private property, they jointly treat the land as one large pasture, with no internal fences, so that each of their animals grazes freely.

Now suppose one shepherd adds an eleventh animal. We now have 101 animals altogether, and thus have exceeded the land's carrying capacity. There is not quite enough food per animal now; therefore they are a bit leaner, and the value per animal drops to 95 cents per head. The total stock of 101 animals is now worth $95.95, which is $4.95 less than the total stock was worth before, when it was within the land's carrying capacity.

Why would a shepherd add the extra animal, when it so clearly is a losing proposition? At the original carrying capacity, the individual flocks of ten were worth $10. Having added one more sheep, the shepherd now has eleven and each is worth 95 cents. That works out to $10.45, which means that the individual shepherd actually made a profit of forty-five cents by adding the extra animal, even though the value of the total stock went from $100 to $95.95.

Although the total cost to the group of adding the extra animal exceeded the total benefit, the individual shepherd receives 100 percent of the benefit while paying only 10 percent of the cost. The other nine shepherds own ninety percent of the animals, so they suffer ninety percent of the loss involved in the falling price per head. Individual shepherds, though, see only individual costs and benefits, and act accordingly. The logic of the commons has begun its seemingly inexorable grind toward its tragic fate.

The tragedy of the commons is one version of a more general problem of *externalities*. An externality, also called an "external" or "spillover" cost, is that portion of the cost of a decision borne by someone other than the decision-maker. We say cost is "internalized" when the arrangement is changed so that decision-makers now bear the entire cost of their decisions. One general purpose of property institutions is to internalize externalities, preventing people from shifting the cost of their activities onto others. Ideally, property regimes should evolve, internalizing externalities as they become significant—both "positive" externalities associated with productive effort and "negative" externalities associated with misuse and overuse of commonly held resources. A system is more likely to be economically and ecologically sustainable when overuse is costly not just to the community as a whole but also specifically to the individuals who decide to overuse.

PRIVATE PROPERTY AS A SOLUTION TO COMMONS PROBLEMS

In an unmanaged commons, individual shepherds are left to decide for themselves whether to step up the intensity of their resource use. They do not take full responsibility for the cost of their overuse, though, because the cost falls mainly on other members of the group of communal users. The payoff of overuse is negative for the group but positive for the individual who elects to overuse.

Is there nothing those shepherds can do? One option would be to cut their jointly owned territory into ten smaller parcels, so each shepherd owns a small parcel with its own individual carrying capacity. Under this new arrangement, instead of dispersing the environmental degradation over the entire commons, the damage is concentrated on the offender's own private land. Thus, in the hypothetical example, instead of dispersing damages worth $4.95 over a hundred animals and ten owners, the damage is concentrated within the individual shepherd's own parcel. To keep the example simple, suppose the parcel covers an area one-tenth the size of the original communal plot. Suppose also that when the damage is concentrated in one-tenth of the area, the resulting damage is ten times as great per square foot. In that case, the flock of ten, which had been worth $10, is now a starving flock of eleven, worth about $5.05. The value of each animal has been cut roughly in half, a painfully obvious mistake. Consequently, under a system of individual parcels, everyone learns in a hurry not to add an eleventh animal.

Private ownership gives an owner a right to exclude. By conferring a right to exclude, the system gives an owner the opportunity to conserve a resource. In giving such an opportunity, the system also provides an incentive, because whatever owners save, they save for themselves.

AN ALTERNATIVE SOLUTION: COMMUNAL MANAGEMENT

In a large range of cases, parcelization is a viable alternative to managing land as an unregulated commons. It is not always a viable alternative (before the invention of barbed wire, parcelizing western rangeland was not feasible), and it is not always the only viable alternative. Another option is for the shepherds to leave the territory in a common pool, and instead of each tending a small flock of ten sheep, ignoring the costs they impose on each other as they add

more sheep, they could pool their flocks and become joint owners of a single large flock of one hundred.

Each shepherd now has an interest in all of the sheep. Under a communal arrangement, a shepherd considers not whether to add the eleventh sheep, but whether to add the 101st. Adding an extra sheep means that, for each shepherd, the result is not that the value of his flock goes from \$10 to \$10.45. lnstead, the value goes from a 10 percent ownership stake in \$100 to a 10 percent stake in \$95.95. Therefore, under the communal arrangement, no one wants to add the extra sheep. Here, too, as in the case of switching to private parcels, an external cost has been internalized and each of the ten shepherds now has a self-interested reason to respect the land's carrying capacity.

Regardless of whether they cut their land into parcels, or pool their flocks of sheep, the fact remains that in the real world, a community of ten people has a good chance of being able to come together to devise and enforce rules governing the land's use that will enable them to avoid collective suicide. However, there is an additional issue to consider.

THE OPEN ACCESS COMMONS: A DIFFERENT SORT OF PROBLEM

Suppose the group has gone communal, pooling both their land and their livestock. So far, so good. Now, however, suppose that whatever rules the ten shepherds might devise to regulate the addition of extra animals, they are not able to stop an eleventh shepherd from entering the picture with yet another flock. With a fixed and known set of players, viable conventions tend to emerge, but if a community is not able to restrict the inflow of new users, then we have an *open access* commons, which makes the tragedy far more likely.

Sometimes, everything depends on whether it is possible to add the extra player rather than for existing players to add the extra animal. For a community to manage itself successfully, it must be able to control negative externalities within the community, but it is likewise critical that the community be able to restrict access, controlling the size and membership of the community of users. Robert Ellickson contrasts the unregulated or open-access commons with communes. A *commune* is a restricted-access commons. ln a commune, property is owned by the group rather than by individual members. People as a group claim and exercise a right to exclude. Typically, communes draw a sharp distinction between members and non-members, and regulate access accordingly. Access to public property tends to be restricted by time of day or year. Some activities are permitted; others are not.

Some medieval commons lasted, non-tragically, for hundreds of years. Elinor Ostrom describes a Swiss commons whose written records date back to the thirteenth century. Cattle were privately owned but grazed in communal highlands in the summer. People grew private crops on individual plots in the valleys, intending to use part of their crops to sustain their cattle over the winter. The basic limitation on communal summer grazing was that owners could send only as many cattle to the highland meadows as their private land parcel could sustain over the winter, with fodder grown during summer.

Allowing individual owners freely to decide whether to add to their individual stock is above all what governors of a commons cannot do. To avoid tragedy, governors of a common pasture must manage the overall livestock population, based on their estimate of the pasture's overall carrying capacity. There are several ways to do this. Managers can allow a given owner to graze cattle on common land only in proportion to: (a) how much hay he produces, (b) what proportion of the land belongs to him, or (c) the number of shares he owns in the cooperative.

Ostrom says, "All of the Swiss institutions that used to govern commonly owned alpine meadows have one obvious similarity—the appropriators themselves make all major decisions about the use of the common property resource. ... Thus, residents of Törbel and other Swiss villages who own communal land spend time governing themselves. Many of the rules they use, however, keep their monitoring and other transactions costs relatively low and reduce the potential for conflict" (p. 65). The lesson is that successful commons are flexible and under local control. Rules sometimes need to change in response to circumstances and local people know what needs changing locally.

In the Swiss commons, Ostrom says, no citizen could send more cows to the Alp than he could feed during the winter. As David Schmidtz and Elizabeth Willott (2003a) summarize, partners recognize an imperative to avoid the tragedy of the commons and in each case do so by taking the option of overgrazing out of the hands of individual partners. History indicates, though, that members of successful communes internalize the rewards that come with that collective responsibility. In particular, they reserve the right to exclude nonmembers. A successful commune does not run itself as an open-access commons.

Hardin himself viewed commons tragedies as problems for which there is no technical solution. To Hardin, the only solution, when there is a solution, is "mutual coercion, mutually agreed upon." Ensuing decades seem to have shown that Hardin was overly pessimistic. In particular, what Hardin deemed the ultimate commons tragedy, namely global human overpopulation, has not followed Hardin's predictions. The population is still increasing, but population growth rates have fallen everywhere, and in many countries, have fallen below zero. Part of the solution

EXCERPT FROM GARRETT HARDIN'S ''THE TRAGEDY OF THE COMMONS''

SOURCE: from Hardin, Garrett. 1968. ''The Tragedy of the Commons.'' *Science* 162:1243-1248.

was birth control technology, which on a priori grounds Hardin believed women would never use owing to the biological ''imperative to breed'' (Willott 2002).

While Hardin was overly pessimistic, it would likewise be a mistake to be overly optimistic. Society's institutions have a history of evolving in response to commons problems. Property law evolves, as do easements, nuisance law, tort law, zoning law, and regulatory agencies, along with a matrix of conventions of neighborliness. However, such remedies have a history of being imperfect. (Some small solutions turn out to be small mistakes. Some big solutions turn out to be big mistakes. And even genuine solutions can do only so much.) Although some problems get solved, others are merely mitigated. As old problems are solved or mitigated, new ones emerge. Sometimes, new problems are caused by the very regulations people devise to solve old problems. In a world filled with producers, consumers, emerging technologies, people wanting to live in neighborhoods with public spaces, and recalcitrant difficulties with enclosing such public spaces as the atmosphere itself, there will always be commons problems.

TRANSGENIC ANIMALS

Transgenic animals are animals whose genome has been changed by means of advanced biotechnology. There are several kinds of transgenic animals. An important distinction

can be made between animals that have had their genome modified by having genes knocked out, or copied, and animals that have had genes not normally found in that species inserted into their genome. (The inserted genes can come from another species or can be artificial constructs.) Technically, only the second group of animals are transgenic. The term *transgenic*, however, is used widely to refer to all animals that have had their genome modified in some way.

THE SCIENCE

Most work on transgenic animals has been carried out on laboratory mice; rats have been the second most frequently modified animal. Other species that have been genetically modified include pigs, sheep, goats, cattle, fish, rabbits, and cats. The first and still widely used method of genetic modification is so-called pronuclear microinjection, in which DNA is injected into the pronucleus of an early embryo. However, this method is not very efficient, nor is it precise, and a number of other methods of gene transfer or gene knockout have been developed. One of those methods makes use of cloning technology. In this case the genetic modifications are made on individual cells from a cell line. Afterward a genetically modified cell is inserted into an enucleated egg and turned into an embryo through the use of a cloning technique. New viral vectors and sperm-mediated DNA transfer that bring the desired genetic material into predesignated areas of the genome are other methodologies that are being developed. These technologies are likely to make the production of transgenic animals technically more efficient (Robl et al. 2007).

THE APPLICATIONS

The vast majority of transgenic animals are used in basic research or biomedical research to study biological development and function or as disease models that mimic human diseases and are therefore useful in the study of medical conditions such as Parkinson's disease, cancer, and cystic fibrosis and the testing of new drugs. A well-known example is the OncoMouse. This mouse, which was produced by Harvard University and Dupont in the late 1980s, was genetically modified to carry an activated cancer gene that significantly increases its susceptibility to cancer. Tens of thousands of animal models, mainly mice, had been developed by the first decade of the twenty-first century.

Since the early 1990s researchers have attempted to develop a new biomedical application of transgenic animals: so-called bioreactors. These are animals, typically of farm animal species, with special traits that make them useful in pharmaceutical production. An example is the goat developed by GTC Biotherapeutics that produces recombinant human antithrombin, an anticlotting protein, in its milk that can be used as medicine for humans. This product was the first of its kind to reach the market (Choi 2006).

"Britney," a Transgenic Chicken. *Dr. Helen Sang, head of the Britney research team, is shown with a third generation chicken at the Roslin Institute in Edinburgh, 2000. The scientists began the project with plans to use the protein in the eggs to treat cancer. The Roslin Institute was also the creator of probably the most famous transgenic animal to date, Dolly the sheep.* © MC PHERSON, COLIN/CORBIS SYGMA.

There is perhaps a possibility of developing transgenic animals, typically pigs, for xenotransplantation. Thus, it is envisaged that complete organs from animals will be transplantable into humans. Here the aim of modification is to make the tissue of the animal immunologically compatible with the human body to prevent rejection. Progress has been made in this area (Yamada et al. 2005), but many problems remain.

In the agricultural area attempts are being made to produce animals with traits that will allow improved production, better animal health, and/or reduced environmental impact. The Enviropig developed by researchers at the University of Guelph in Canada is an example. It has been genetically modified to be able to digest the phosphorus in a cereal grain diet. This removes the need to add phytase enzymes to the pigs' diet and reduces the amount of phosphorus released into the environment. The Enviropig thus ideally reduces production costs and environmental impact at the same time (Forsberg et al. 2003). The number of agricultural applications of transgenic animals in the research and development phase has been limited by high production costs, technical barriers, and fears of rejection by the public.

Because it is in principle possible to transfer a gene from one living organism to another regardless of species barriers and it is becoming possible to produce artificial genes on demand, the theoretical applications of the technology are limitless. Several aspects of the technology, however, remain inefficient and imprecise because many basic aspects of the function and interconnectedness of genes are poorly understood. There is little doubt, though, that the technology will play a greater role in the future,

especially in cases in which individual modified animals exhibit a trait that makes them valuable enough to cover the cost of their production, cases in which their contribution to scientific research cannot be obtained in other ways, and cases in which the use of the technology is socially acceptable. Thus, it is likely that transgenic animals will be utilized primarily for biomedical applications.

ETHICAL CONCERNS

The most common ethical concerns about transgenic animals can be divided into three main areas. Those areas and the most important issues within each of them are discussed below.

Humans and the Environment Concerns about potential risks to humans and the environment figure prominently in many discussions. Risks to humans most frequently are equated with risks to human health presented by food or medicinal products derived from transgenic animals. A very limited amount of research has been done in this area because few products have been developed. There is, however, a substantial literature on what risks should be taken into consideration when those products are evaluated. In the medical area it usually is suggested that risk assessments should follow the approach by which newly developed drugs are tested. In the food area risks arising from changes in amino acids leading to allergenicity, toxic effects, or changes in nutritional value are important parameters (National Research Council and Institute of Medicine of the National Academies 2004). At the beginning of the twenty-first century no food product from a transgenic animal had been developed far enough to necessitate serious attempts to conduct a risk assessment.

Risks relating to a specific use of transgenic animals can be found in the area of xenotransplantation. Here questions about the risk of transferring diseases from pig donors to human recipients have not been resolved. Especially important is the question whether there is a significant risk that the porcine endogenous retrovirus (PERV), which lies dormant in the pig genome, will become active after transfer to the human body. There is no doubt that this could cause serious health problems for humans, and the situation often is compared with the history of AIDS and severe acute respiratory syndrome (SARS); however, there is no agreement about how this risk should be evaluated (Moalic et al 2006; Martin et al. 2006; Levy et al. 2007).

Another risk to humans that is mentioned frequently relates to the possible socioeconomic effects of the technology, especially in agriculture, where it could accelerate the development of large-scale industrialized factory farming and deepen the divide between the developing world and richer countries. This risk is not specific to transgenic animals but relates to developments in technology in general.

There are also potential risks to the environment. The concern here is that transgenic animals might escape and breed with wild populations, thus spreading their genes in an uncontrollable environment. The most frequently cited example is transgenic fish, for example, salmon with genetic alterations that allow for faster growth. The concerns in this area can be about the indirect consequences this might have for humans (in this case economic losses for the fishing industry) or about direct concerns involving the animals and the wider ecosystem. Whether one is concerned about a particular application of the technology because it constitutes a risk to human interests or because it constitutes a risk to other species or the integrity of the ecosystem, the risk that transgenic animals will escape and evade human control and confinement is a socially important issue (PEW Initiative on Food and Biotechnology 2003).

There are also concerns about the use of transgenic animals constituting a step onto a slippery slope that will lead to unacceptable uses of biotechnology on humans. Although current uses of transgenic animals are intended primarily to gain basic scientific understanding of molecular biology and study human diseases, it is clear that the more skilled scientists become at applying biotechnology to animals, the easier it will be to apply the same technologies to humans. The factors that will prevent technologies from moving from the animal sphere to the human sphere are not the technical limitations but ethical objections, and people concerned about the slippery slope are worried that those objections eventually will be pushed aside by the appeal of the technical possibilities (Kass 1997).

Animal Welfare Transgenic animals have been used mainly in basic biological research and as disease models. Often the goal is to produce animals that underexpress or overexpress certain genes or express a mutated, disease-causing human gene. In all these cases normal body function in the organism is disrupted in some way. Modifications can involve any part of the animal genome, and the effects on the animal's phenotype range from those which are lethal to those which have no detectable effect on the health of the animal. It is therefore impossible to generalize about the effects of genetic modification on the welfare of animals.

The effects that occur can be divided into two main categories: intended and unintended. Welfare problems stemming from intended genetic change are hard to avoid because the point of inducing the change is to affect the animal. Thus, a mouse carrying the human Huntington's disease gene will inevitably suffer welfare

problems as it develops the disease, including rapid progressive loss of neural control that leads to premature death. Unintended effects are connected with the inaccuracy of the technology and insufficient understanding of the function of different genes in different organisms. Both types of effects contribute to the unpredictable nature of genetic modification at the phenotypic level.

To deal properly with both intended and unintended effects on animal welfare, it is important to monitor the animals and, when severe effects occur, take action to alleviate or end their suffering. In laboratory animal science it should be considered part of good practice to find ways to conduct experiments that minimize the discomfort and suffering imposed on animals and to define so-called humane endpoints, that is, points at which animals have to be euthanized (Olsson and Sandøe 2004).

There is wide agreement about the need to limit the discomfort and suffering imposed on animals. However, from a philosophical perspective it may be questioned whether the focus should be only on preventing pain and other kinds of suffering in animals (and perhaps promoting positive experiences). It may be argued that animal welfare is also about the extent to which an animal is allowed to fulfill its species-specific potential regardless of its subjective experience.

Very often this broader perspective on animal welfare will point to an additional group of considerations that have to be taken into account in deliberations about animal welfare. Concern about an animal's opportunity to engage in certain kinds of behavior does not prevent one from caring about its subjective experiences. Nevertheless, the two kinds of considerations sometimes are difficult to reconcile in practice. Considerations within a narrow perspective in which the subjective experiences of the animal alone matter may be outweighed by considerations in the broader perspective (Gjerris, Olsson, and Sandøe 2005).

Some of those engaged in the ethical debate on transgenic animals argue that welfare is not all that matters in dealing with animals. They may defend the view that animal integrity also must be considered.

Integrity The term *integrity* means wholeness or fullness. In the literature two notions of animal integrity are prominent. The first is based on a biological understanding, and the second on a phenomenological understanding. The first stresses the genetic integrity of the animal and therefore focuses on the importance of not changing animal genomes to suit human purposes. The obvious objection to concerns about the violation of genetic integrity through gene technology is that the genome of an animal species is in constant flux because of naturally occurring evolutionary forces and through well-established breeding practices such as conventional selective breeding. A difference between genetic changes induced by natural selective forces and human-induced changes can be stated, but it is difficult to argue for a relevant difference between introducing genetic changes with modern biotechnology and introducing changes with older, conventional methods (Rollin 1996). This has led some to conclude that transgenic animals raise no new or additional ethical concerns. Others claim that this alone constitutes a reason to reexamine conventional breeding methods with a more critical eye (Gjerris and Sandøe 2006).

The second notion of integrity is based on the experience of the animal as an inviolable whole. Animal integrity can be understood as an inherent limit in the relationship between humans and nature, a "red line" that governs what is ethically acceptable for humans to do to animals. Integrity in this case derives from an experience and understanding of animals as beings that in and of themselves set up an ethical requirement of noninterference. This requirement may be violated only if the reasons are adequate from an ethical perspective. Integrity signifies a difference between the knowledge of the animal people have through their understanding of its usefulness to humans and the knowledge people have when they conceive of the animal independently of human needs. A cow is a producer of hide, milk, and meat; it holds no surprises when it is experienced from the perspective of human need. However, when it is experienced in a nonreductionist perspective, the cow amounts to more than that. Respecting the integrity of animals is thus the polar opposite of wholesale reification of an animal as a natural resource (Gjerris and Sandøe 2006).

TRANSPORTATION

From the canal systems and railroad lines of nineteenth-century America to the current rapid growth of motorized transport in developing countries, the development and expansion of transportation systems has been a central feature of modern societies. In all its forms, transportation is the means by which human beings traverse the natural world, and is of great concern to environmental philosophy. The modes of transportation available to a population shape both the distribution of goods and services within that population and its manner of growth. Historically, advances in transportation have greatly increased the mobility of populations. For instance, in Roman times, individuals traveling on horses on Roman roads averaged around 10 miles per hour, and oxen, used for transporting many goods, averaged 2 miles per hour. Premodern sailing ships too rarely achieved average speeds of more than 9 knots (10 miles per hour). By the mid-nineteenth century, in contrast, it was not uncommon for steam-engine locomotives to move goods and passengers at speeds of over 50 miles per hour, and modern steam ships too could travel at speeds significantly faster than premodern sailing ships. By 2008, average travel times had decreased even further, with contemporary motor-vehicle travel routinely averaging 65 miles per hour and the airplanes in current use often traveling at speeds of over 500 miles per hour. Traveling by air, a contemporary individual can cross in a matter of hours distances that would have taken premodern predecessors months to traverse.

Developments in transportation have done more than just afford individuals greater mobility, though.

They have also determined the forms of human settlement. For instance, prior to modern refrigeration technologies, the transportation of perishable goods was inherently limited, and thus the areas from which food sources for urban populations could be derived was directly related to the distance that food goods could be safely transported. From early times, major population centers tended to be situated along waterways, which provided the most efficient means for transporting food and other goods. As various technological innovations in transportation occurred, developmental patterns followed suit. In the United States, many cities were founded as service hubs along the paths of the larger canals and railroad systems of the nineteenth century. As these cities grew, they in turn provided new destinations for workers and travelers in a synergistic process of expansion. In Europe and North America, the development of railroad systems in the nineteenth century had a particularly significant impact upon the movement of persons and goods. Creating an even greater change in the landscape, however, was the invention of the automobile and its rapid diffusion within Western societies in the twentieth century. With the advent of the automobile, virtually all locales became readily accessible to settlement and development. The ever increasing expansion of the roadway system and the relative affordability of automobile travel have allowed individual workers easily to commute long distances from home to work, and this ability eventually led to the suburbanization so prominent in the United States in the later half of the twentieth century. In the United States alone, there are currently over 4 million miles of public roads, and the total number of miles traveled by motor vehicles reached 2.7 trillion miles in 2000. The growth of airplane transportation has had a similar impact upon human movement, particularly at the global level, since the development of inexpensive and reliable airplane transport has allowed persons and goods to travel immense distances with little effort.

Within large urban centers, other modes of transportation have significantly affected passenger travel as well. Many modern cities developed subway or light-rail systems to move large numbers of persons, particularly commuters, more efficiently. Bicycles also provide a relatively inexpensive form of transportation for many urban dwellers, and in some countries, particularly China, bicycle traffic has constituted a major portion of intraurban transportation. While most modern technological developments have tended to encourage greater individual travel, in recent years some technological advances have had the opposite effect. Most important, the development of modern telecommunication networks and the Internet have allowed many workers to telecommute to work from their homes. Similarly, face-to-face business meetings, document transfers, and even medical diagnostics can all be done electronically in 2008, eliminating some of the need for real travel associated with such activities in the past.

The brief outline above illustrates how the history of social and economic development is tied to the history of transportation. The means of transportation available to people within a society crucially affects their access to various goods and their options concerning work and place of residence. In many ways the various technological advances in transportation that have taken place since the beginning of the modern era have undeniably provided many persons with a greater range of options concerning their choices for employment, residency, and leisure activities. This is no doubt why there exists in Western countries such a strong association between the idea of the automobile and notions of individual freedom and independence. Yet the benefits that increased mobility and greater access to goods provides for some members of society must be seen against the larger impact that various means of transportation have upon the greater good. In this sense, the ethical concerns about issues of transportation raised by environmental ethicists are best seen in terms of a discussion about the environmental costs of various modes of transportation. Unfortunately, these costs are often far less obvious to individual users of transportation than the direct benefits that such transportation provides them. Likewise, the historical and ongoing public-policy debates that deal with the environmental impact of various forms of transportation can most profitably be seen in terms of differences in how participants in those debates weight the various potential benefits and costs associated with transportation issues. Thus, to understand and evaluate such discussions and debates properly, one must first know the nature of the major environmental costs of transportation involved.

DIRECT ENVIRONMENTAL COSTS

The primary forms of direct environmental costs associated with modern forms of transportation stem from pollution. Pollution of one form or another has been associated with virtually all major forms of transportation utilized by human beings. Indeed, often the development of one form of transportation responds to problems associated with a form of pollution stemming from a previous mode of transportation, only to give rise to newer kinds of pollution. For instance, the use of horses as the primary mode of transportation in major urban centers in the nineteenth century produced such large quantities of solid waste, mainly manure, in those cities that it posed serious health risks, as well as raising quality-of-living issues, for residents. As such, the transition to the use of automobiles and rail systems in major cities represented the alleviation of one type of pollution and the problems associated with it. It was soon discovered, however, that the new forms of

Traffic Congestion in Beijing, China, 2007. *Along with the benefits provided by transportation, including increased mobilization and greater access to goods, there are a number of costs that must be considered as well, particularly negative effects to the environment. Automobiles are powered by internal-combustion engines, a major source of air pollution. Many nations have used legal measures, such as clean air acts and greater fuel-efficiency standards, in order to reduce the amount of harmful pollutants emitted by automobiles.* **AP IMAGES.**

transportation gave rise to new kinds of pollution with a fresh set of problems. This picture presents a cautionary reminder that we should carefully account for all forms of pollution associated with the development of a new transportation technology, lest we merely replace one set of environmental problems with another. Such considerations are particularly relevant to current discussions about the relative merits of various alternatives to the use of gasoline engines in automobiles, such as hydrogen-fuel-cell technologies, electric cars, and ethanol conversion.

Currently, the major direct environmental costs of transportation discussed by environmentalists center primarily around pollution generated by the use of vehicles powered by internal combustion engines, particularly automobiles and airplanes. Since these two forms of transportation account for most personal travel in the United States and for a large portion of commercial transportation as well, this focus is certainly appropriate. At the dawn of the twenty-first century, there were around 200 million automobiles in use in the United States alone, and well over 80 percent of Americans currently rely on personal automobiles or other motor vehicles, such as trucks and motorcycles, for their daily transportation needs. There has also been a significant increase in the number of airline miles traveled per capita. Indeed, in the United States, airline travel is the fastest growing segment of personal transportation. According to statistics of the U.S. Bureau of Transportation, air travel increased from 118 billion passenger-miles in 1975 to over 600 billion passenger-miles by 2000, and the number of aircraft in use by commercial carriers increased by more than 30 percent from 1990 to 2000. In 2008 there are nearly 30,000 commercially scheduled flights per day in the United States. This has resulted in a concurrent increase in the amount of pollutants produced by air transportation, which now accounts for the fastest growing source of carbon dioxide emissions, for instance. In 2000 airline traffic accounted for around 3.5 percent of

all carbon dioxide emissions, and if current trends in air travel continue, that percentage is expected to grow to 15 percent by 2050. Also, transit by motor vehicles and airplanes involves significantly more pollution problems than major alternatives, such as rail travel. Air travel produces over five times, and automobile travel over three times, the total amount of pollutants per passenger-mile as rail travel. Finally, these forms of transport are also generally less fuel-efficient, domestic airline travel averaging around 3,800 British thermal units per passenger-mile, automobile travel averaging around 3,500 British thermal units per passenger-mile, and domestic rail travel averaging around 2,100 British thermal units per passenger-mile. This is not to say that other forms of transportation do not involve any significant pollution problems, but only to emphasize that the greatest environmental problems involving transportation stem from pollution related to our reliance on motor-vehicle and air transport.

The pollution problems stemming from heavy dependence on automobiles for transit in urban areas was brought strongly to the forefront of public attention during the early environmental movement and eventually contributed greatly to the passage of clean-air acts at both the federal and state levels. Automobiles produce pollution containing lead (many countries still allow the use of leaded gasoline), benzene, carbon monoxide, nitrogen oxides, ozone, volatile organic compounds, and other environmentally harmful chemicals. These pollutants have been linked to a host of environmental problems, including smog, acid rain, low-lying ozone, and toxic air pollution. Such problems have resulted in significant damage to the environment and human health. As a result, since the 1960s there have been a number of efforts in countries such as the United States and Great Britain to reduce the level of harmful pollutants emitted by automobiles. Some of these efforts have taken the form of legislation, such as clean-air acts, that restrict levels of harmful pollutants like carbon monoxide and nitrogen oxides or mandate fuel efficiency for vehicles, while others have stemmed from industry and consumer initiatives. As a result, the motorized vehicles of today emit significantly less pollutants than their counterparts of the 1960s and 1970s. However, automobile emissions still produce significant amounts of pollutants. The Environmental Protection Agency estimates that automobiles still account for about 75 percent of all carbon monoxide emissions in the United States. The greater number of vehicles on the roads in 2008 also mitigates to some extent the emission reductions that have been gained. Furthermore, while the fuel efficiency of motor vehicles is somewhat greater in 2008 than in past decades, the fuel efficiency of many vehicles, particularly popular sport utility vehicles, remains less than optimal. In the United States, the Corporate Average Fuel Economy standard, which represents the weighted average of the fuel economy of a manufacturer's fleet of passenger vehicles, was first introduced in Congressional legislation in 1975, but since 1985 remained unchanged at 27.5 miles per gallon for passenger vehicles until 2007. Furthermore, the category of light trucks, which sport utility vehicles were categorized under, was set at the much lower standard of 20.7 miles per gallon. In view of the increase in sport utility vehicles and light trucks in the 1990s, it is perhaps not surprising then that the total fuel economy for all passenger vehicles in the United States actually peaked in 1986 at 26.2 miles per gallon. In 2005 the standard for the light-truck category was changed in part to reflect environmental concerns, and for the year 2007 the standard for light trucks has been set at 22.2 miles per gallon. A number of other countries have set fuel-efficiency standards for manufacturers that are higher than the standards in the United States, including China, which introduced a new set of standards for fuel efficiency in 2004.

Since the turn of the twenty-first century, an even greater concern about the pollution associated with petroleum-based transportation is related to global climate change. Motor vehicles are major producers of the main greenhouse gases that have been linked to global warming. In particular, such vehicles are among the primary producers of carbon dioxide, the principle greenhouse gas that contributes to global warming. Global warming occurs when greenhouse gases such as carbon dioxide build up in the atmosphere and prevent heat from leaving the earth's atmosphere. It has been estimated that in Western nations, motor-vehicle travel accounts for around 20 to 30 percent of all carbon dioxide emissions. Though there remains some debate about the extent of global warming, the potential effects upon the global environment are significant, since human, animal, and plant habitats across the globe will be altered as a result. Rising sea levels, changes in weather patterns, and alterations in the distributions of animals and plants brought about by global warming could effect agricultural practices, displace populations, and contribute to the spread of disease. Thus, even though the extent and causes of global warming are not fully known, it seems clear that the amount of carbon dioxide emissions produced by the current transportation system in countries that rely significantly on personal-motor-vehicle transit poses at least a significant risk to the environment and future generations.

As with all forms of pollution, it is the cumulative effect of the pollution associated with transportation that is particularly problematic. While the pollution produced by any particular automobile ride is unlikely to have a seriously deleterious effect upon the environment, there are significant environmental risks and potential harms to humans, animals, and ecosystems associated with the large-scale utilization of automobiles. Thus, the costs of transportation to the environment outlined above must be evaluated in terms of the total system of transportation

utilized within any given society. In the United States, that system clearly encourages the private use of automobiles as the primary mode of transportation. Since the mid-twentieth century, most governmental support and funding for transportation in the United States has gone into the construction of highways and roads, and only a small proportion has been provided for the creation and support of public transit systems, such as commuter trains or light-rail systems. Since the 1990s, some small initiatives have taken place to alleviate the impact of automobile traffic, such as the creation of high-occupancy-vehicle traffic lanes in some metropolitan areas, the expansion of light-rail systems in some urban districts, and the construction of bicycle lanes within many cities. Nonetheless, public policy on transportation in the United States still is focused on facilitating the use of automobiles, and despite the above mentioned efforts, the average commuting time has actually increased in recent years. For example, the number of drivers commuting more than sixty minutes to work by automobile rose by over 50 percent from 1990 to 2000, and the number of solo drivers commuting to work has increased by over 13 million from the 1990s.

INDIRECT ENVIRONMENTAL COSTS

While the pollution associated with contemporary forms of transportation might represent the largest and most direct impact upon the environment, many environmental ethicists have argued that it is equally important to understand the less direct effects associated with current transportation systems. First among these is the urban sprawl associated with the development of the roadway system in the United States and some other Western nations. The seemingly endless expansion of development afforded by the extension of roadway systems has raised a host of environmental concerns. Most obviously, such development makes more natural areas open to human development and thus allows the environmental degradation of those areas. The expansion of the roadway system and the accompanying development of areas along those roadways also require the use of vast amounts of resources, such as concrete and steel, and there are serious environmental impacts associated with the extraction and processing of these resources. By spreading populations out over greater distances, such sprawl creates inherent inefficiencies in the distribution of goods and services, which also entails a greater use of natural resources. In this vein, while cybercommuting might lessen the need for some workers to commute to work on a daily basis, it has the potential negative affect upon the environment of allowing individuals even greater opportunities to move into formally wild areas further away from urban centers. Finally, the reliance on petroleum inherent in a transportation system based primarily on personal motor vehicles exacerbates the well-known environmental costs related to the exploration, extraction, and refining of crude oil.

Our particular forms of transportation no doubt have other indirect environmental costs on the environment, such as those associated with invasive exotic species of plants and animals whose spread has been facilitated by various forms of modern transportation, the environmental costs related to disposing of toxic materials used in the construction of modern vehicles and vehicle-related products, and environmentally caused health problems brought about by the immense concentration of trucks and railways around major shipping ports. The point here is not to give an exhaustive list of all such costs, but merely to illustrate some of the more prominent ones and to show that a careful accounting of the environmental impact of our transportation systems needs to take in the full range of consequences that result from activities associated with the development and utilization of transportation if public policy for transportation is to be properly geared toward the overall good.

TRANSPORTATION IN A GLOBAL CONTEXT

In light of the extensive concern about the environmental effects that current modes of transportation are having within Western developed countries, it is not surprising that there is also a great deal of growing anxiety about the severe environmental impact of expanding these modes of transportation within developing nations. Within the evolving globalized economy, an ever greater amount of industry and commerce is shifting to formally less developed countries. As such countries industrialize and expand their economies, they also are taking on means of transportation that model those of the Western world, both because doing business in international markets requires having a sophisticated transportation infrastructure in place and because the creation of new wealth within these countries gives more people within their economies the ability to purchase hitherto unaffordable technologies like automobiles. The rate at which this expansion is taking place in recent years is exponential. For instance, automobile ownership in China more than tripled from the 1990s to the 2000s and has been accompanied by a corresponding and ongoing boom in the expansion of the highway system in that country. As countries such as China increasingly utilize motorized-vehicle transportation, they will incur the environmental costs that such transportation involves and can seriously aggravate global environmental problems. A particularly prominent example of this is the decline of Chinese bicycle culture. Until recent years, bicycle use dominated local travel in Chinese cities. However, with the increased use of automobiles in China, the dominance of the bicycle is beginning to fade in large urban centers. In

Beijing, for instance, bicycle travel accounted for over 60 percent of all trips within the city in 1995, whereas in 2006 that number had fallen to less than 40 percent. Other large Chinese cities have experienced a similar transition, and many Chinese cities are now even banning bicycle use on many roadways.

CHALLENGES TO DEVELOPING RESPONSIBLE TRANSPORTATION POLICY

As noted earlier, modern systems of transportation offer benefits and incur costs. At least two difficulties can make implementing transportation policies that properly balance these benefits and costs particularly troublesome. The first difficulty concerns the evaluation process itself. Transportation systems are exceedingly complex entities, and both the goods and services they engender and the problems associated with them are numerous and multifaceted. As mentioned previously, even the kinds of environmental harms associated with transportation come in a variety of forms, some of which are not readily apparent from the outset. It is no simple matter to account for all the various factors, good and bad, long-term and short-term, associated with transportation systems. Such a process also involves comparing and weighting goods and values of diverse kinds. For example, one needs to consider how values and goods such as those of environmental integrity and species welfare are to be gauged in relation to those such as individual freedom and economic growth.

The second problem is a pragmatic one. As many environmental philosophers have noted, one of the difficulties with getting people to take environmental problems seriously is the very scope of such problems. Environmental harms are often both indirect and long-term, and thus their costs are frequently ignored by the very people who bring them about. It is difficult enough to convince people to consider the long-term welfare of others in their decisions; it is even much more difficult when those considerations run contrary to the satisfaction of their immediate interests. The potential conflict between morality and self-interest becomes particularly thorny in such situations, especially because the harmful consequences are so far removed from view. This explains in part why it is difficult to get people voluntarily to change their choices of transportation, even when we can objectively evaluate the long-term consequences of the various options. As a result, it may be that societies can effect enough change in transportation to make a significant environmental difference only through public policies that involve strong incentives or strong restrictions. Because of the individualistic framework of much of modern society, restrictions on transportation choices are likely to be strongly opposed by many. Developing incentives that are comprehensive enough to alter transportation patterns and strong enough to sway individual choices will involve a degree of foresight and planning that has so far been lacking in the development of transportation policy. The task of developing effective transportation policies thus remains a difficult challenge for those concerned about the environmental impact of our transportation choices.

U

UNITED KINGDOM

The United Kingdom (England, Scotland, Wales, and Northern Ireland) is a densely populated country with a complex history of human habitation and land use. Its cultural richness is due to centuries of invasions and settlement of peoples and, in the nineteenth century, the wealth generated by the industrial revolution, which occurred against a background of colonization and plunder of other nations' resources and labor. The population density and the complex historical tensions among the different countries, religious groups, and social classes that make up the United Kingdom (UK) have been instrumental in shaping the British psyche and the relationship to nature that underlies many of that nation's contemporary responses to environmental issues.

THE OPEN SPACE MOVEMENT

Robert Hunter (1844–1913) supplied the vision and rhetorical power needed to drive what was to become the open space movement. Hunter worked for the Commons Protection Society and used his legal training and painstaking research of historical documents to resist further enclosure of common land by landowners. That drive was intended not just to protect woodland and open moors from being built on or aggressively farmed but also to keep them open for ordinary people's recreational enjoyment.

Although ancient royal parks and forests provided open space for city dwellers close to them, other burgeoning industrialized areas had no such resources. The working and living conditions of factory workers and the poor air quality led to concern for the health of city dwellers. Time spent in nature was seen as morally uplifting as well as providing fresh air, and this led to an increasing number of wealthy benefactors and city corporations creating urban parks with open or very cheap access to provide healthy recreation for the masses.

The drive for open access to countryside has persisted to the present time. In 1884 the first attempt to pass a Freedom to Roam bill in Parliament failed, as did many subsequent attempts. In 1932 six people were jailed for leading a mass trespass of four to five hundred people on Kinder Scout in the Derbyshire Peak District, England, and that led to greater public support for the "right to roam." The Ramblers Association, whose origins lay in the local walking clubs that had sprung up in the 1880s, rekindled this form of civil disobedience by holding annual mass trespass events beginning in 1985. Those unlawful but peaceful events were instrumental in providing the pressure that resulted in the Countryside and Rights of Way Act 2000. That act led to a mapping exercise culminating in the Right to Roam 2005, which gives walkers access to mountains, moor, heath, down, and common land in England and Wales. Similarly, the Land Reform Act 2003, which was implemented fully in 2005, grants the statutory right of responsible access to almost all land and water in Scotland.

THE NATIONAL TRUST AND OTHER NGOS

Legislation such as the Right to Roam has opened up privately owned land, but one of the most effective means of social transformation in terms of giving people access to nature and conserving natural and cultural landscapes has been to buy land and have it designated for that

purpose. The National Trust, established in 1895 by Robert Hunter, Octavia Hill, and Hardwicke Rawnsley, began doing that with the purchase of four and a half acres of coastline at Dinas Oleu, Wales. The National Trust now manages 250,000 hectares (617,761 acres) of countryside, moorland, beaches, and coastline in England, Wales, and Northern Ireland. It also owns and maintains historic houses, gardens, industrial monuments, churches, and pubs. Its focus is not just the conservation of nature but also the conservation of the historical fabric of the country and, perhaps most strikingly in the national parks of England and Wales, the conservation of the social fabric or ways of life that have shaped the cultural landscapes that characterize the UK. The National Trust for Scotland has 128 properties and a similar profile of aims and activities. Both organizations are nongovernmental charities funded by donations, legacies, and a broad membership (3.68 million combined in the first decade of the twenty-first century) and supported by volunteer labor. Although they are nongovernmental organizations (NGOs), these organizations are seen as part of the establishment: safe, nonthreatening, and often willing to compromise.

Other mainstream campaigning charity bodies have originated with visionary individuals or small groups, sometimes beginning by focusing on a small local issue in which they are out of step with public opinion. The Royal Society for the Protection of Birds began as a campaign to stop the use of grebe feathers on women's hats in 1889. It grew to have a million members, two hundred nature reserves (130,000 hectares [321,235 acres] in total), and a scope of action that is focused on protecting wildlife habitats. The larger mainstream campaigning bodies tend to work in the areas of informing the public, including educational programs for children; doing or funding research; lobbying Parliament; using the legal system to challenge damaging developments; and providing a focus for their memberships' concerns. Some focus more on lobbying and legal challenges; for example, the Campaign for the Protection of Rural England, along with its equivalent Welsh body, specializes in putting pressure on planning authorities. This organization began in 1926 and has maintained a sharp focus on resisting urban sprawl and ribbon developments: expansions of towns that eat into the countryside. Other campaigning bodies see themselves as umbrella organizations, such as Transport 2000 (and Transform Scotland), which began in 1973 and has maintained a focus on transport issues and worked to represent and inform government and other campaign groups about transport.

PUBLIC PARTICIPATION

Grassroots activity operates at a number of levels. There is mass membership in established organized campaign groups and the Green Party, where members of the public can pay for membership and see themselves as "doing their bit" for the environment. Practical volunteering is used widely; for example, the National Trust has 43,000 volunteers. More radical groups are characterized by many loose affiliations between different types of campaigns and multiple memberships by individuals, along with mass attendance at events.

An umbrella name predominant in the contemporary protest movement is Earth First! Both globally and nationally this has been a nonhierarchical rubric for other groups or individuals who use direct action to protest against destructive organizations or actions. Direct action under this name can consist in anything from a single individual stopping a shop operating for a morning by gluing his or her hands to its door to the organization of mass protests such as the 2007 climate camp to protest the addition of a new runway at Heathrow Airport. Contemporary direct action under any banner tends to consist in actions that are usually illegal but not dangerous to the public and often combine humor with a serious message. For example, critical mass cycling events involve large groups of cyclists using the same route during rush hour, clogging the road, but the cyclists are invited to wear fancy dress and create a colorful spectacle, adding an element of consciousness-raising to practical activities.

With road building protests there is more emphasis on stopping proposed projects. Direct action can involve damage to machinery or protesters placing themselves in danger to prevent tree felling or excavation. The Newberry bypass in Berkshire, England, was a new section of road intended to ease traffic congestion that ran through a designated area of outstanding natural beauty, a National Trust nature reserve, and a historic civil war battlefield. To defend those areas and protest road building in general, trees and specially dug tunnels were occupied by particularly devoted protesters (ecowarriors) and numerous camps were set up along the proposed route. Although all the camps were evacuated and work began on the bypass in 1996, the protesters received a significant amount of publicity, with the media highlighting a young man called Swampy (Daniel Hooper), the last to be evicted from the tunnels to protect Snelsmoor Common. The dedication and risk to their lives of those individuals over a long period as well as a march of five thousand people impressed the public. The cost to the construction company of delays and security, which was estimated at £23.7 million, as well as the costs of policing such protests, had an effect on plans for road building in the future.

Protests such as Newbury brought hard-core environmental campaigners who might travel from one protest to another together with local people whose concerns were more place-specific and conservation organizations

Climate Change Protesters, London, 2007. *Protestors demonstrated for the week-long Camp for Climate Action outside the BAA office near Heathrow Airport in London, England. The United Kingdom is home to many active grassroots environmental organizations, including well known groups such as Earth First! Despite the popular ethos of a love for nature, the UK deals with several environmental problems, particularly with litter.* **CATE GILLON/GETTY IMAGES.**

with specific interests. In this instance it also triggered a report from the World Wide Fund for Nature (WWF-UK) criticizing the government's watchdog for conservation, English Nature (EN). It appeared that if EN could not protect an area with the multiple designations that the Newberry site had from a stretch of road that was only 13.5 kilometers long and was predicted to be ineffective at reducing traffic elsewhere, it was powerless.

PROTESTS AGAINST GENETICALLY MODIFIED ORGANISMS

A campaign that brought together NGOs, campaigners, and the wider general public involved the introduction of genetically modified organisms (GMOs). Resistance to a new form of technology was the focus. Genetic modification (GM) was uniquely placed to bring together opposition from a number of fronts. The technology was seen as controlled and promulgated by multinational companies to the detriment of poor farmers globally, foodstuffs with GMOs were perceived by the public as dangerous, and the growing of GM crops was predicted to create "superweeds" that would have a negative impact on biodiversity.

Alongside campaigns by established groups such as Friends of the Earth, new groups emerged. One of the most effective groups at getting information to people and "outing" industry front groups was the Norfolk Genetic Information Network (now GMWatch). Another that has

worked in a scientifically literate way at the interface of science and public information is the Institute for Science in Society (I-sis), a nonprofit organization founded in 1999 by Mae-Wan Ho and Peter Saunders.

Anti-GM, like many environmental campaigns, is not just about legislating against or preventing something but also about engaging the public in decision making and encouraging informed debate. Not only did the GM issue stimulate debate across the country, the wider general public got involved by not buying GM food, much to the surprise of major UK supermarkets, which had to advertise that they were "GM free." Resistance to GM was a wider European phenomenon, and legal battles still were being waged in the first decade of the twenty-first century between the European Union and the World Trade Organization about allowing the importation of GM foods. In Britain at that time, crop trials were destroyed by protesters' direct action of pulling up the plants, sometimes at the risk of imprisonment.

ENVIRONMENTAL PHILOSOPHY AND DEBATES

A number of themes characterize environmental debates in the UK, including the layperson's love of nature. In a country dominated by cultural landscapes and with no real wilderness this speaks to a love of countryside as a place of interaction between people and nature. In farming areas and in cities and towns previous human activity provides a richness that people love and work to conserve. However, the problem of litter, which may be worse than in many other places in Europe, suggests a lack of care at even the most basic level. As in other countries, commercial forces drive developers to build uninspiring houses on greenbelt land rather than well-designed ecodevelopments on brownfield inner-city sites, and town councils do nothing to prevent historically rich and socially cohesive towns from becoming what the New Economics Forum has called "clone towns" as chain stores move in. The Transition Towns movement addresses the related problems of global climate change and community disengagement and alienation at the local level.

Environmental philosophy in the UK has emphasized approaches that are scientifically and historically informed and the creative possibilities of human-nature collaboration. There is wide recognition of romantic figures such as Ruskin and Wordsworth as a resource one can go to for inspiration. Another underlying theme is the importance of transforming rather than denying the urban experience coupled with a politically aware concern for providing opportunities for everyone to experience nature and live in socially vibrant communities.

Robin Attfield (2003) developed a biocentric practice-consequentialist line of argument and has supported and represented it as well as broadening it to include global issues. Global justice issues and international relations also appear in the work of Nigel Dower. Environmental economics is represented by figures such as John O'Neill (2006), whose virtues ethic approach is interwoven with questions of social justice. Similarly, Alan Carter combines environmental and equality concerns and combines academic work on environmental questions with work supporting policy groups or campaign organizations.

Work on animal welfare is also evident (the term *speciesism* was coined by the psychologist Richard Ryder); perhaps the most nuanced work in this area is that of Mary Midgely (1983), who has mounted a defense of a benign form of speciesism while emphasizing shared nature between humans and nonhuman animals. A mainstream philosopher who has developed arguments with regard to animals (including a defense of fox hunting) and a somewhat nostalgic approach to the countryside is Roger Scruton. The nature of the place, the richness of its nature writing, and the inspirational science of Darwin have led Alan Holland to develop the fine-grained, culturally aware, and environmentally rich notion of a worthwhile life as an approach to ethics.

The beauty of some UK landscapes also can be seen as generating the resurgence of interest in the aesthetics of nature. Ronald Hepburn was responsible for the environmental turn in the study of aesthetics, which was taken up by Emily Brady, who has focused on both cultural and natural landscapes and developed an integrated aesthetic that brings together an experiential view and an ecologically informed view. The urban situation and the densely populated nature of the country have contributed to a shift in the work of Warwick Fox. His theory of responsive cohesion is crafted to cover not just interhuman ethics and the ethics of the natural environment but also the ethics of the built environment.

Clare Palmer, the founding editor of *Worldviews: Environment, Culture, Religion,* an emigrant to the United States, has done important critical work on process philosophy and environmental ethics as well as on animal ethics. Andrew Brennan, an emigrant to Australia, has argued for a pluralist approach to environmental ethics.

Environmental philosophers in the UK have to battle against the conservative forces of philosophy as well as the current Research Assessment Exercise, which has been perceived as privileging theoretical over practical philosophy in the distribution of academic funding. However, the relative academic freedom and openness to interdisciplinarity of the higher education sector has meant that it was the first place in the world to establish a dedicated master's course in environmental philosophy. Lancaster University's degree in values and environment, which

now runs from the University of Central Lancashire, was set up in 1989, and the journal *Environmental Values* was established at Lancaster in 1992.

UNITED NATIONS EDUCATIONAL, SCIENTIFIC AND CULTURAL ORGANIZATION

The United Nations Educational, Scientific and Cultural Organization (UNESCO) was founded in November 1945 and came into force in November 1946 after ratification by twenty countries. By 2007 UNESCO had 192 member states and 6 associate members. It disseminates and shares information and knowledge in the fields of education, science, culture, communication, and information. Furthermore, it also works as a laboratory of ideas and a standard setter in forging universal agreements on emerging ethical issues, such as those concerning contemporary environmental challenges. Environmental concerns currently occupy a prominent place on the organization's agenda and generate systematic reflection on how international policy can promote an ethical approach to the environment.

UNESCO has developed international programs that help reinforce the capacities of developing countries to improve the management of the earth's resources in the fields of the natural sciences, engineering, and technology. Priorities in this area are related to capacity building in the basic and engineering sciences for the use of water and associated ecosystems, including the oceans. To complement this effort, the organization promotes the proper use and maintenance of natural resources, preparedness for and mitigation of disasters, and the use of renewable sources of energy.

The Man and Biosphere Programme, launched in the early 1970s, is especially relevant to environmental ethics. It promotes interdisciplinary research to improve people's relationship with the environment, targeting the ecological, social, and economic dimensions of the loss of biodiversity. Its World Network of Biosphere Reserves works as a vehicle for knowledge sharing, research and monitoring, education and training, and participatory decision making. Designed to balance community needs with the conservation of natural resources, these biosphere reserves seek to provide a harmonious marriage of conservation and development. With more than 480 sites in over 100 countries, the World Network of Biosphere Reserves provides context-specific opportunities to combine scientific knowledge and governance practice in order to reduce loss of biodiversity; improve livelihoods; and enhance social, economic, and cultural conditions for sustaining the environment. Thus, these biosphere reserves contribute to the pursuit of the seventh Millennium Development Goal, to ensure environmental sustainability.

The biosphere reserves can also serve as learning and demonstration sites in the framework of the Decade of Education for Sustainable Development. UNESCO assumes that education lays the ground for environmentally and ethically informed, responsible, and sound decisions and actions. The educational priorities of UNESCO include technical and vocational education, science and technology education, and education for sustainable development. UNESCO values equity for all communities and the long-term stability of the economy and ecology.

According to UNESCO, education and training are primary agents for mobilizing communities toward sustainable development. They fulfill this role by increasing people's capacities, transforming their visions for themselves and their societies into reality, and enhancing linkages between cultural and biological diversity. Yet education must respect cultural landscapes and sacred sites, promote learning about the interactions of biological and cultural diversity, and maintain biosphere reserves and World Heritage sites.

UNESCO is actively pursuing the Millennium Development Goals, especially those aiming to halve the proportion of people living in extreme poverty in

CAPE HORN BIOSPHERE RESERVE

The Cape Horn Biosphere Reserve (CHBR) protects one of the world's most pristine ecoregions, the Magellanic subantarctic rain forests, at the southern end of the Americas (Rozzi et al. 2004). It includes the archipelagoes south of Tierra del Fuego, and the fjords, ice fields, and glaciers on Darwin Cordillera, just 1,000 kilometers north of the Antarctic Peninsula. With five million hectares of marine (three million ha) and terrestrial (two million ha) ecosystems, it is the largest biosphere reserve in southern South America. The CHBR has at least three attributes that are relevant to environmental philosophers.

First, its creation in 2005 resulted from a six-year collaborative effort between the regional government and an interdisciplinary team of ecologists, artists, and humanists led by the Chilean philosopher and ecologist Ricardo Rozzi. The creation of the CHBR involved ten guiding principles, which can be adapted for interdisciplinary research and conservation work in other regions:

1. interinstitutional cooperation,
2. a participatory approach,
3. an interdisciplinary integration of environmental philosophy, sciences, arts, and policy,
4. networking and international partnership,
5. communication through the media,
6. identification of flagship species,
7. "direct encounters" with human and nonhuman beings living in their habitats,
8. economic sustainability and ecotourism,
9. territorial planning and administrative sustainability,
10. "conceptual sustainability" based on continuous long-term *in situ* research (Rozzi et al. 2006).

Second, the Research, Education, and Conservation Center of the CHBR is in the Omora Ethnobotanical Park. In 1999 Omora Park inaugurated a program in field environmental philosophy and biocultural conservation that integrates comparative ethnoecology, ecotourism, and environmental ethics. In 2004 this program was further projected through a partnership with the Department of Philosophy and Religion Studies at the University of North Texas (University of North Texas 2008).

Third, the CHBR is located in a remote region of the Americas, only 1,000 kilometers north of Antarctica. With its location at the end of the continent, it is home to a uniquely rich biological and cultural diversity (Callicott et al. 2006). For example, more than 5 percent of the world's species of mosses and lichens are found here in less than 0.01 percent of the earth's land surface. This high diversity of small flora was critical in making the case to UNESCO representatives for the establishment of the CHBR. Lichens and mosses, although very small organisms in comparison to charismatic megaflora and megafauna, can play important roles in promoting conservation when their ecological and aesthetic values are understood by the general public and by policy makers (Rozzi et al. 2008). Such a shift in the "cognitive lenses," which allows a keener assessment and greater appreciation of biodiversity, has both scientific and philosophical value.

Ricardo Rozzi

developing countries by 2015, to achieve universal primary education in all countries by 2015, to eliminate gender disparity in primary and secondary education by 2005, to help countries implement a national strategy for sustainable development by 2005, and to reverse current trends in the loss of environmental resources by 2015.

The social and human sciences have a vital role to play in helping to understand and interpret the social, cultural, and economic environment. UNESCO's priorities in the social and human sciences are advancing human rights; fighting against all forms of discrimination, racism, xenophobia, and related intolerance; and promoting ethics in science and technology, with an emphasis on bioethics (United Nations 1997).

Different solutions and alternatives started to be developed in response to environmental problems. But especially in developing countries, incipient structures of environmental and educational management have been and are exposed or vulnerable to suffering the impact of various types of economic or political crisis in those countries or regions.

One of the most frequent effects of these crises has been and continues to be the elimination of budgets or the discontinuation of funds. These irregularities have sometimes prevented governments from complying with international agreements. This happens also with UNESCO's programs, which often arise as good intentions but have hitherto been difficult to materialize. All this results in a limited development of criteria to assess the effectiveness of management, cooperation, conservation, education and training, monitoring, and participation of integrating countries. For example, in the case of Latin America and the Caribbean, there is not enough information on whether the implementation is carried out by state agencies—federal, municipal, or mixed management—or by nongovernmental institutions. Although UNESCO's programs are seen with positive expectations, they will still have to face bureaucratic structures, lack of political commitment, or insufficient human resources and institutional capacity.

UNESCO has a Division of Philosophy and Ethics, the only outpost of philosophy in the United Nations system. Through its Universal Ethics Project, this division is leading a worldwide discussion on universal ethics. Emphasis has been placed on the ethical principles at stake in environmental sciences and policies. What is the moral value of the environment? What in nature is worth protecting, preserving, and respecting? What do we mean by global sustainability? How much should we protect the interests of future generations? What are the implications of the principle of justice, for policy decisions related to environmental issues?

Here we can also find difficulties to adequately attain such valuable objectives. But, in the case of philosophy, this is not only due to institutional budgetary limitations, but also to the very nature of the philosopher's task, often linked to purely theoretical work. The UNESCO's *Courier*, published in celebration of World Philosophy Day (November 15, 2007), gathered the critical opinion of various thinkers, aiming at a strengthening of the social responsibility of the philosopher, and they recognize that the philosophical impact on society is not what it could be. The question posed here is how they could make themselves useful.

Michel Onfray (France) advocates ceasing to lecture everybody and being comfortable to remain only in the realm of the word, and trying to produce philosophical effects on the existential level. Norwegian Jostein Gaarder stresses questions as what shift in consciousness we need, what is a sustainable wisdom, what qualities of life are important, and if the unsustainable consumerism is really the only possible model of life.

Gaarder relates this to his proposal of a universal declaration of human obligations, since it is no longer meaningful to talk about rights without simultaneously stressing the individual state's or person's obligations and responsibilities.

To promote sustainable consumption, UNESCO and the United Nations Environment Programme are working together to understand young people's consumer behavior and work with them in promoting more sustainable consumption patterns for the future. Launched in March 2000, the Youth Exchange Programme, for example, includes a training guide, a Web site, online discussions, and related workshops aimed at young people's consumption.

In 2007 UNESCO undertook several important initiatives. It launched the Biosphere Connections partnership to support conservation of biodiversity and sustainable development in conjunction with the airline coalition Star Alliance, the Man and Biosphere Programme, the Ramsar Convention on Wetlands, and the World Conservation Union. The same year it also launched the International Initiative in Defence of the Quality of the Night Sky as Mankind's Scientific, Cultural, and Environmental Right. This initiative maintains that future generations have the right to skies free of light pollution.

UNESCO's Communication and Information Programme will help to build a society based on the sharing of knowledge and incorporating the sociocultural and ethical dimensions of sustainable development. The world urgently requires global visions of sustainable development based on observance of human rights, mutual respect, and alleviation of poverty—goals which lie at the heart of UNESCO's mission and activities.

UNITED NATIONS ENVIRONMENT PROGRAMME

The United Nations Environment Programme (UNEP) promotes international cooperation on the environment and serves as the focal point for environmental action and coordination within the United Nations system. Its origins can be traced back to the United Nations Conference on the Human Environment in Stockholm in June 1972. At that time it was acknowledged that a growing number of regional and environmental problems would require extensive cooperation among nations and action by international organizations in the common interest. Shortly after the Stockholm conference, the United Nations Twenty-Seventh General Assembly approved Resolution 2997 in December 1972 (United Nations 1972). In that resolution the United Nations established UNEP in the context of "the urgent need for a permanent institution within the United Nations system for the protection and improvement of the environment" (United Nations 1972, p. 43). The UNEP Governing Council is composed of fifty-eight members elected by the General Assembly for three-year terms. Seats are allocated on a regional basis.

ORIGINS AND STRUCTURE

In Resolution 2997 it was decided that UNEP should promote international cooperation on the environment; review the world environmental situation to ensure that emerging international issues would receive adequate consideration by governments; promote the acquisition, assessment, and exchange of environmental knowledge; and review the impact of environmental policies on developing countries. The mission of UNEP is "to provide leadership and encourage partnership in caring for the environment by inspiring, informing, and enabling nations and peoples to improve their quality of life without compromising that of future generations" (UNEP, "What UNEP Does," para. 2).

UNEP's headquarters are in Nairobi, Kenya. UNEP also supports six regional offices around the world and a growing number of liaison and outpost offices, collaborating centers, and convention secretariats. Based in Africa, it is positioned to have a firsthand understanding of environmental issues facing developing countries.

UNEP seeks partnerships in all sectors and describes its work as assessing global, regional, and national environmental conditions and trends; developing international and national environmental instruments; strengthening institutions for the wise management of the environment; the transfer of knowledge and technology for sustainable development; and encouraging new partnerships and mind-sets within civil society and the private sector. The implementation of this work is done through seven divisions: Early Warning and Assessment; Environmental Policy Implementation; Technology, Industry and Economics; Regional Cooperation; Environmental Law and Conventions; Global Environment Facility Coordination; and Communications and Public Information.

ACHIEVEMENTS AND PUBLICATIONS

Since its inception UNEP has been a principal actor in major international initiatives and events. Significant milestones include the Convention on International Trade in Endangered Species (1973), the Bonn Convention on Migratory Species (1979), the Vienna Convention for the Protection of the Ozone Layer (1985), the Montreal Protocol on Substances That Deplete the Ozone Layer (1987), the Intergovernmental Panel on Climate Change (IPCC) (1988), the Basel Convention on the Transboundary Movement of Hazardous Wastes (1989), the United Nations Conference on Environment and Development (1992), the Convention on Biological Diversity (1992), the Stockholm Convention on Persistent Organic Pollutants (2001), and the World Summit on Sustainable Development (2002).

UNEP promotes dialogue and cooperation among stakeholders and has assisted in the establishment of a number of notable demonstration projects, including the OzonAction program designed to help implement the Montreal Protocol, the International Coral Reef Action Network, and the Great Apes Survival Project.

In addition to a large number of books on a broad range of environmental topics, UNEP publishes annually the *UNEP Year Book*, formally known as the *GEO Year Book*; the magazine *Our Planet*; and the youth magazine *Tunza*.

UNEP's Medium-Term Strategy (2010–2013), approved in February 2008, sets out the next phase of the evolution of UNEP as it becomes more effective, efficient, and results-focused for the UNEP program of work. This focus will enable UNEP to better deliver on its mandate by building on its expertise and comparative advantage in a limited number of priority areas: climate change; disasters and conflicts; ecosystem management; environmental governance; harmful substances and hazardous waste; and resource efficiency–sustainable consumption and production.

UNEP will deliver on the six cross-cutting priorities by utilizing the capacity and expertise of UNEP divisions and regional offices and will actively reach out to government, other United Nations entities, international institutions, MEA secretariats, civil society, the private sector, and other relevant partners to support delivery of the MTS. The vision of UNEP for the medium-term future is to be "the leading global environmental authority that sets the global environmental agenda, that promotes the coherent implementation of the environmental dimension of sustainable development within the United Nations system and that serves as an authoritative advocate for the global environment" (UNEP Working Group on Medium-Term Strategy, 2010–2013, Consultation Paper No. 1).

ENVIRONMENTAL PHILOSOPHY

UNEP's values relating to environmental philosophy and ethics are stated in its founding documents and mission statement. The Declaration of the 1972 United Nations Conference on the Human Environment in Stockholm identified both natural and human-made elements of the environment as essential to human well-being and to the "enjoyment of basic human rights and the right to life itself" (UNEP 1972). In establishing UNEP, United Nations Resolution 2997 identified a need for measures designed to safeguard and enhance the environment "for the benefit of present and future generations of man [SIC]" (United Nations 1972, p. 43). UNEP's mission is "to provide leadership and encourage partnership in caring for the environment by inspiring, informing, and enabling nations and peoples to improve their quality of life without compromising that of future generations" (United National Environment Programme, "What UNEP Does"). These statements describe environmental values that direct UNEP activities. Historically, those activities primarily have been related to human rights, human rights to life, and concern for future generations.

On the 1997 World Environment Day in Korea the UNEP executive director chaired the Environment and Ethics Roundtable. The resulting document, *The Seoul Declaration on Environmental Ethics* (UNEP 1997), expanded UNEP's scope for ethical consideration. The declaration began by acknowledging that there is no choice but to redefine the values and principles that underlie human relationships with the earth. Without such fundamental changes, it suggested, further environmental degradation will lead to the collapse of the natural systems that support life. Again, there is a concern for safeguarding the rights of future generations. However, the document also rests on the assumption that the existence of all life, including human life, can be sustained only if the entire community of life on earth is sustained. *The Seoul Declaration* also stated that its framework of ideals, principles, and guidelines will evolve over time.

UNEP supported the development and publication of *Environmental Education, Ethics and Action: A Workbook to Get Started* (2006).

UNIVERSITY-INDUSTRY RELATIONSHIPS

The ties between universities and private industry have been transformed from arms-length relationships between two distinct entities with different purposes into an interaction among overlapping institutional spheres in which each side has assumed some of its partner's traditional roles and characteristics. Government, at various levels, increasingly encourages university-industry interactions in order to foster public economic goals such as job creation and economic growth. As a result, university-industry relationships have become university-industry-government relationships, sometimes referred to as the ''triple helix'' (Etzkowitz 2008).

THE GROWTH OF SCIENTIFIC RESEARCH IN THE UNIVERSITY

The university, from its medieval origins until the late nineteenth century, was devoted to the production, preservation, and transmission of culture. Since 1900, however, it has become the source of new industries and private corporations while maintaining and expanding its traditional roles. In the late nineteenth century growing science-based electrical and chemical industries initiated relations with universities to serve their research needs and to supply them with personnel.

These university-industry relations were conducted across well-defined borders between the academic and commercial domains. The university's increasing involvement in science, however, engendered a more organized approach to managing research and its practical consequences. For instance, when researchers at the University of Toronto invented an insulin treatment for diabetes in 1922, the university found that it had to patent and license the technology in order to protect itself from potentially unethical manufacturers (Bliss 2007). The University of Wisconsin encountered a similar situation when a faculty member, Harry Steenbock, in 1924 patented the irradiation process based on his work on antirachitic vitamine (Apple 1989). Thus, even before universities realized that they could earn income from inventions made on campus, they were impelled to create mechanisms to insure an orderly process of technology transfer and protect their reputations.

Traditionally, university-industry relations denoted the provision of research support from a firm to a campus-based researcher. The contemporary form, however, involves the participation of academic scientists in the formation of private companies through the use of their academic research. The university takes on an entrepreneurial role, assisting in the founding of private firms and contributing to regional economic development. As the university acquires an industrial penumbra, industry takes on some of the values of the university, sharing as well as protecting knowledge.

THE FORGING OF UNIVERSITY-INDUSTRY RELATIONSHIPS

There are both formal and informal modes of university-industry relationships. The liaison and technology-transfer offices of the university constitute the formal mechanisms through which introductions are made in seminars for potential industrial partners, disclosure statements of inventions are collected, and patents licensed and contracts are negotiated. The activities of these formal programs to paint in broad brush-strokes are similar to the informal channels, with perhaps the key difference being that financial results from the formal channels are typically shared with the university (Etzkowitz and Webster 1995).

Informal relations with industry typically occur through contacts between professors and their former students and may lead to consulting and joint-research projects with a company. Informal relations may be viewed as an ''underground economy'' that is not counted as part of official academic work. Typically, both modes are present: the formal organizations and the informal ties through which social and intellectual capital moves from graduating students into firms and back again into the university.

Traditionally, university-industry relations denoted the provision of research support from a corporation to a campus-based researcher. Though offering far fewer restrictions than government support in many cases—and finding favor with the academic research staff—such funds represented a tiny proportion of academic research support. For instance, industrial R&D support to U.S. universities and colleges was 7.4 percent in 1959; 2.7 percent in 1969; 3.6 percent in 1979; 6.6 percent in 1989; 7.4 percent in 1999; 6.7 percent in 2001; and 5.1 percent in 2006 (NSF/SRS 2006). Most of these funds flowed through consulting relationships with faculty members who provided advice on campus to company visitors and at the industrial lab, conducted tests of materials and products in their laboratories, and occasionally carried out small research projects for a company (Etzkowitz 2002). From the early years of the research university in the late nineteenth century, university-industry relationships were largely established at the behest of industry to serve the needs of existing companies. Engineering schools reorganized themselves to serve the research needs of growing

science-based electrical and chemical industries and to supply them with personnel. The linkages included cooperative programs that sent students to industry for part of their training, university professors undertaking research at the request of industry, and donations of money and equipment by industrial firms to support engineering education (Noble 1976). These relationships, however, declined in the 1930s because of the Depression, elevating foundations as important sources of sponsored research.

However, during the Depression a new series of relationship formats were being created at MIT—for example, the faculty-formed firm, an explicit role for the university in shaping regional economic development, the interdisciplinary center, and the invention of the venture capital firm (Etzkowitz 2002). The older forms of university-industry connections involved payment for services rendered, whether it was received directly in the form of consultation fees or indirectly as endowment gifts. The new formats of university-industry relationships are built upon the development of scientific-research capabilities and the creation of a series of boundary-spawning mechanisms like technology-transfer offices and spinoff firms. This institutional transformation is reflected in the enactment of the Bayh-Dole Act of 1980, which transferred ownership of intellectual property emanating from government-sponsored research to universities on the condition that they take steps to promote their utilization. Similar new legal frameworks followed in other countries, often supported by funding programs, to legitimate and foster university-industry interactions.

Contemporary university-industry relations arose from two distinct sources and an emerging third hybrid stream: basic research interests funded by research councils and similar bodies, industrial projects for which academic input is solicited and in a creative fusion, and a joint formulation of research programs with conjoint basic and applied goals and multiple funding sources. Basic research increasingly takes place in research groups that function as "quasi-firms" that have many of the attributes of a private corporation except for the profit motive.

Incubators provide a means to subsidize the infrastructure of company formation and a training mechanism to teach academics to operate a firm. Centers integrate disciplinary research groups into broader interdisciplinary collaborations and carry out "translational research" to bring research findings closer to utilization. Technology-transfer offices arrange intellectual property protection and negotiate the terms for movement of commercially promising research into private companies, including those founded by members of the university. Science parks provide a home for research units of corporations, which often emanate from universities, offering projects and collaborative opportunities to their academic counterparts.

As a "third mission" of contributing to economic and social development is integrated into the university, the dissemination of academic knowledge takes place through patents as well as publications. The hybrid forms of university-industry relationships involve the multiplication of resources through university and faculty participation in capital-formation projects such as real estate development in science parks and the formation of companies in incubator facilities. The objective is to multiply the value of intellectual property derived from academic research through the stock market, either directly or indirectly.

CONCLUSION

The university is undergoing a "second academic revolution," integrating teaching, research, and economic development. As the university engages in technology transfer, it becomes a source of new product development, which is, of course, a traditional industrial function. The growth of university-government relationship was intertwined with the formation of national identity in Germany in the early nineteenth century, with the so-called Humboltdian academic model integrating teaching and research—the first academic revolution (Jencks and Riesman 1969).

In the United States, university-government relationship transcended the emergency of World War II as academics realized, during the postwar period, that theoretical advances could arise from problem-oriented research and vice versa. As new arrangements are put in place, old formats remain in use, creating a complex interplay among organizations and roles with ensuing conflicts and confluences of interest. As the university acquires an industrial penumbra, industry takes on some of the values of the university, sharing as well as protecting knowledge. Governments assume a new role in innovation by encouraging university-industry interactions of various kinds.

The line between facts and values is in most instances blurred. But since the first expression of a plant gene in a different species of plant in 1983, ethical, environmental, and religious concerns have shaped debates over the developments in agricultural biotechnology and genetic engineering (Tokar 2001; Kleinman 2005). Environmental concerns have been at the forefront of the debates over genetically modified organisms (GMOs). The discovery in 1999 of deadly effects of pollen from genetically engineered corn on immature butterflies upped a notch the tenor of environmental consequences of genetic engineering (Tokar 2001). As a result, much of the public debate about GMO has centered on the risks of gene transfer, the role of big business, and instances of the connivance of university scientists.

Since the issues and implications of GMOs are global, such issues are best tackled within collaborative frameworks. This was illustrated by the farm-scale trials of genetically modified crops in the United Kingdom. As the exercise revealed, irrespective of the genetic design and constitution of the crop plants, ecological effects were expected to arise as a result of the conditions in which each crop was cultured (Ormerod et al. 2003, p. 940). It is plausible that any future ecological cost from genetic modification will reflect the diversifying opportunities, methods and conditions for crop growth as any other factor in the brave new GMO landscape (Ormerod et al. 2003).

The university-industry-government interaction is a global phenomenon. The increasing recognition of universities as actors in national and regional innovation systems is leading to the blurring of boundaries between corporations and the academy and their replacement with a web of ties.

URBAN ENVIRONMENTS

Born in America, Australia, and Norway, environmental philosophy has its deepest roots in the tradition of wilderness advocacy and thus has tended to focus on the value of wild nature, the interests of wild creatures, and the integrity of unaltered ecosystems. Only recently have some environmental philosophers begun to turn their attention to urban environments, broadening the field and connecting it with branches of the environmental movement other than wilderness advocacy, including the environmental justice movement and the broader discourse on sustainability.

A BLIND SPOT

From its inception environmental ethics has focused mainly on the normative status of wilderness and wildlife. The many arguments about moral standing and intrinsic value have been aimed at finding a more appropriate balance between the domestic and the wild, mainly by valorizing the wild. One example is Paul W. Taylor's theory of respect for nature, which purports to be biocentric but provides inherent worth (intrinsic value) only for wild organisms, expressly excluding domestic ones. Landscapes that have not been touched by human hands are the normative reference against which all other landscapes are to be judged not only ethically but aesthetically, according to Allen Carlson's theory of positive environmental aesthetics.

The historical alliance of environmental ethics with the tradition of wilderness advocacy once all but precluded serious direct engagement with urban environments. There is thus what Andrew Light has called "an urban blind-spot" in environmental ethics: "[B]y and large, cities are considered sources of environmental disvalue: a landscape either to be mined for examples to be avoided or ignored altogether as a product of human intentions—an artifact rather than a part of nature and so outside the proper boundaries of the discipline" (Light 2001, p. 8).

A handful of environmental ethicists have attempted to remedy that blind spot, motivated by a sense that environmental ethics is incomplete if it automatically excludes from consideration the landscapes in which people live. Roger J. H. King, for example, found a "self-destructive logic" in an approach to environmental ethics that "presupposes that humans are at best interlopers on what should otherwise have been a nonhuman scene." The one-sided valorization of wilderness yields a "halt-and-withdraw" strategy that "holds nothing open for the future; the narrative line ends in tragedy for nature and for humans." (King 2000, pp. 115–116)

The literature on urban environments has expanded in two directions. One approach focuses on the role

Aerial View of Manhattan. *The island of Manhattan, a part of New York City seen here from the Empire State Building, is the epitome of an urban metropolis in the United States. Many believe that environmental ethics have ignored urban environments until only more recently, instead choosing to focus more on wilderness habitats. Some places, like New York's Central Park, provide ta mix of both environments: a lush natural habitat in the midst of one of the largest urban centers of the world.*

urban environments can play in fostering concern for wild nature and putting that concern into practice. Light argued that in the short term at least, practicing ''ecological restoration'' in urban settings can be a means toward the goal of fostering ''ecological citizenship'' (Light 2001, p. 28). King maintained that cities should at least foster an ''environmental conscience'' and to that end proposed as a principle that ''the built environment should make nature a visible, palpable presence in daily human experience'' (King 2000, pp. 115, 130).

Another approach starts with the recognition that cities and suburbs are the environments of most direct concern to most people, with the implication that those environments should be understood and evaluated on their own account, not simply or exclusively held to the standard of wildness. In discussing long-term considerations, Light stated, ''If environmental ethics is to fully embrace the urban, then it must describe the brown space of the city to be as important a locus of normative consideration as the green space'' (Light 2001, p. 31). Alastair Gunn went so far as to redefine the natural environment in terms of the conditions for human thriving, stating that ''to the extent that human beings are able to thrive in a given environment—to live long lives, to be physically and psychologically healthy, to fulfill a significant portion of their potential—then that environment is natural for humans'' (Gunn 1998, p. 348). There is no reason in principle why a city or a suburb cannot be natural in this sense.

Taking both of these approaches into account, an urban turn in environmental ethics opens up a broad range of normative questions concerning human well-being, justice, sustainability, and political legitimacy (Kirkman, 2004).

GOOD PLACES

One set of normative considerations in urban environments concerns the conditions that contribute to or detract from human health and well-being. Those considerations need not be limited to matters of physical health, though the availability of food and clean water and protection from various kinds of risk are important. Also of interest, though, are features of the environment that contribute to or detract from mental health and personal development, including access to cultural and educational institutions, opportunities for recreation, and opportunities for economic activity. Taking all these elements together provides a basis for judging whether a particular urban setting constitutes a good place to live.

Attention to matters of human well-being in urban environments meshes with the concerns of environmentalism in a number of areas. First, attention to matters of human health in urban environments relates to the

antitoxics branch of the environmental justice movement. The signal event for the rise of antitoxics activism was the discovery of toxic waste in the soil of Love Canal, a suburban neighborhood near Buffalo, New York, and the likely effects of that waste on the health of children who lived and played there.

Second, the experiential or aesthetic richness of landscapes has long been important to environmental advocates and their conservationist predecessors. An entirely technological landscape probably would be dreary and dispiriting; this attests to the need for some measure of scenic diversity, some space left open for wild nature in the urban fabric. Ironically, much of the initial appeal of suburban development was the location of houses in a parklike setting with carefully arranged bits of wildness close by. However, a major impetus for more recent critiques of suburbanization is the perception that the resulting landscape has degraded to a dreary monoculture of lawns interrupted only by a dreary monoculture of parking lots.

Third, in addition to the provision of green space, decisions about where and where not to build mesh with broader concerns about the relationship of the domestic to the wild and the need to be attentive to nonhuman nature. In places where human well-being is at stake, it is especially important to note that inattentive building can expose people to undue risks. Examples include development in flood-prone areas or even below sea level, schools or hospitals built on ground prone to shaking during earthquakes, and neighborhoods intruding into the habitat of large predators or into landscapes subject to frequent wildfires.

JUSTICE

Landscapes in and around metropolitan areas are diverse, affording different opportunities for and obstacles to well-being. The work of establishing a particular built environment incurs costs that may be externalized to other parts of the landscape. Economic and educational opportunity has shifted to suburbs, for example, leading to deterioration of the inner city. At the same time people in one area may have to live with pollution generated in the process of providing goods and services from which people in another area derive the greatest benefit.

These are matters of justice that may be distilled into two basic questions: Who has access to good places to live, work, and play? and Who bears the costs of establishing and maintaining those good places? The answers to those questions are intertwined with matters of distribution, consent, and compensation.

A concern for justice in urban environments connects to the broader environmental movement at two points. The first involves the rise of the environmental justice movement in the 1990s. At first considerations of race and class were brought into the antitoxics movement, and it was noted that poor and minority communities are exposed to disproportionate risks in their neighborhoods and that government agencies are not evenhanded in protecting communities from those risks.

Environmental-justice theorists have looked beyond the imposition of risk to patterns of exclusion and segregation in the urban landscape. The United States, for example, has a long history of excluding minority groups from the most desirable neighborhoods: A combination of federal laws, lending practices, and personal prejudice led to concentrations of poor and minority groups in deteriorating inner cities. Laws and, to some extent, lending practices have changed, but the legacy of past discrimination persists (Torres, Bullard, and Johnson 2000). In some cases that legacy is embodied in the physical infrastructure of the city, which was put in place with the explicit intent of physically blocking the expansion of minority communities into particular areas when that was both legal and acceptable public policy (Bayor 1996).

Matters of justice are at the root of environmental ethics in its traditional guise. The built environment is a rearrangement of the existing natural environment to suit particular human ends; intentionally or not, this has the effect of including and excluding other living things and changing the composition and form of the biotic community. Aside from the long-term impact of such changes on human well-being, people may owe some consideration to nonhuman living things and systems in their own right. From this perspective it is at least possible to pose the question of whether an injustice has been done, for example, in appropriating the habitat of an animal or plant population and altering it so that that population no longer can survive there.

SUSTAINABILITY

A further set of normative considerations in urban environments concerns the degree to which human life in those environments—and civilization itself—can be sustained in the future. As environmentalists have long maintained, the domestic environment is carved out of and remains dependent on its broader environmental context, which includes not only raw materials and sources of energy but also the relatively benign and predictable setting afforded by stable landforms, stable climate, healthy ecosystems, fertile soil, and clean air and water. Patterns of human activity in a domestic environment are sustainable to the extent that they tend to conserve finite resources and maintain the dynamics that underlie the benign and predictable setting on which they depend; they are unsustainable to the extent that they tend not to do that.

Urban form is deeply implicated in charges of unsustainability leveled against contemporary civilization.

Metropolitan growth in the United States has been shaped by nearly exclusive reliance on the automobile for local transportation. As a consequence, vast areas of the American landscape are all but uninhabitable without the automobile: The functions of economic and civic life are scattered across the landscape, connected to one another and to residential areas only by roads and highways. Automobiles powered by fossil fuels are a major factor in resource depletion, local pollution, and global climate change, in effect undermining the long-term sustainability of American-style metropolitan regions.

By contrast, moderately dense urban forms in which the functions of economic and civic life are intermixed with residential areas may be more sustainable, at least by some measures. For example, residential energy use is generally lower in relatively dense urban areas than in suburban or rural areas (Light 2001), and in that setting more efficient forms of transportation become feasible, including walking, cycling, and mass transit (Gillham 2002).

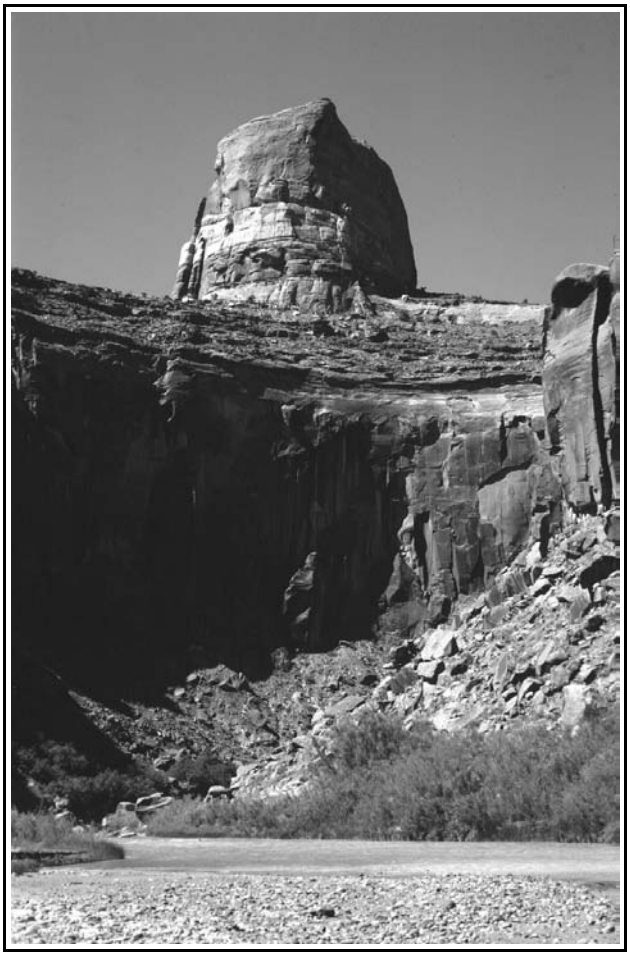
U.S. BUREAU OF LAND MANAGEMENT

The Bureau of Land Management (BLM) is responsible for managing more than 260 million acres of federal public lands, mostly scattered across the eleven western states. Created by Congress in 1946 through a merger of the General Land Office and the Grazing Service, the BLM is the largest land management agency in the Department of the Interior. Most of the BLM's acreage consists of arid and semiarid federal lands that went unclaimed during the disposal era (c. 1862–1891), when national policy was to transfer public lands into private ownership under the Homestead Act, General Mining Law, and other such laws. In addition, the BLM oversees 700 million acres of subsurface mineral resources underlying federal, state, private, and tribal lands, as well as nearly 3 million acres of timberland in western Oregon.

For its first thirty years, the BLM operated without a clear charter from Congress. In the then lightly populated West, the agency's principal focus on minerals and range resources evoked little concern among local residents, many of whom relied on mining and ranching for their economic well-being. But as the region's population expanded and urbanized and as public interest in recreation, wildlife, and wilderness grew, resource use and access conflicts became increasingly contentious, leading critics to complain that the BLM was too beholden to its traditional mineral and ranching constituencies.

In 1976 Congress responded by adopting the Federal Land Policy and Management Act (FLPMA), which is now the BLM's organic charter. The FLPMA directs the BLM to manage its lands under the "multiple-use" principle, which includes "recreation, range, timber, minerals, watershed, wildlife and fish, and natural scenic, scientific and historical values" but "without permanent impairment of the productivity of the land and the quality of the environment." To do so, the BLM must prepare comprehensive resource-management plans that effectively zone its lands for the various uses. In addition, the BLM is authorized to designate "areas of critical environmental concern" (ACECs) and was directed to inventory its lands for potential wilderness designation, a process that has placed 24 million acres in legally protected Wilderness Study Area (WSA) status. Though FLPMA includes wildlife as a delineated multiple use, it does not contain a biodiversity provision; rather, state wildlife agencies are primarily responsible for managing wildlife populations on the public lands.

Besides its FLPMA obligations, the BLM is governed by a diverse and sometimes conflicting array of resource-development and environmental laws. These laws range from the National Environmental Policy Act and the Endangered Species Act to the Mineral Leasing Act,



Grand Staircase-Escalante National Monument, Utah. *Grand Staircase-Escalante National Monument covers nearly 1.9 million acres of public land in the Unites States and serves as an outstanding source of scientific research and education. The U.S. Bureau of Land Management is responsible for managing public land, most of which consists of the arid and semi-arid land that went unclaimed in the latter half of the nineteenth century during westward expansion.* **U.S. GEOLOGICAL SURVEY.**

Taylor Grazing Act, and the Energy Policy Act of 2005. During the 1970s, once FLPMA and related environmental laws began taking hold, several western states and angry ranchers launched a political movement dubbed the Sagebrush Rebellion, which was designed to recapture control of the BLM lands. Predicated on the later-discredited theory that the states really owned the unreserved federal public lands, the Sagebrush Rebellion evaporated once Ronald Reagan was elected president in 1980 and installed James Watt as secretary of the interior to pursue an aggressive development agenda on the public lands.

During the Clinton presidency (1993–2001), however, the BLM radically changed its policy direction. Under the leadership of Secretary of the Interior Bruce Babbitt, the BLM pursued a vigorous reform agenda, not only revising its mining and rangeland regulations to incorporate new environmental standards, but also expanding the agency's wilderness review and protection authority. President Clinton created fourteen new BLM-managed national monuments (including the landmark Grand Staircase–Escalante National Monument in southern Utah) that were incorporated into a new National Landscape Conservation system, the first time that the BLM was invested with such extensive preservation responsibilities. On the BLM's Oregon and California timberlands, Secretary Babbitt instituted a new ecosystem management policy designed to promote biodiversity conservation.

But these shifts in BLM policy priorities have not held. In the aftermath of the 9/11 tragedy, the Bush administration pursued an aggressive energy-development agenda on BLM lands across the interior West. The result was an avalanche of new oil and gas leases and drilling projects that later encumber these lands. Furthermore, the BLM modified its mining responsibilities, loosened its rangeland-management regulations, and reduced its wilderness-protection obligations. Not all of these efforts succeeded, however, because the courts blocked several of these reforms. Nonetheless, the BLM remained into the early 2000s an Interior Department agency still in search of a clear identity, having been whipsawed between two very different competing visions of appropriate federal conservation policy.

U.S. DEPARTMENT OF AGRICULTURE

The act creating the U.S. Department of Agriculture (USDA) was signed by President Abraham Lincoln on May 15, 1862. In the same year Lincoln signed the Homestead Act and the Morrill Act, which created the land-grant-college system. These three acts had a significant bearing on the mission and methods of the department over the years.

The Morrill Act provided grants of federal land to states to establish colleges emphasizing agricultural and mechanic arts. The land-grant colleges developed strong research and educational ties to the agricultural communities in their states and to the USDA. Later, state-oriented systems of extension and secondary education were created to complement the university and USDA research efforts.

The USDA evolved from the U.S. Patent Office to become a research and education agency with a natural affinity to the state land-grant universities, in keeping with the mandate of the act that created the Department of Agriculture: "to acquire and diffuse . . . useful information on subjects connected with agriculture in the most general and comprehensive sense of that word, and to procure, propagate, and distribute among the people new and valuable seeds and plants" (Rasmussen 1975, Vol. 1, p. 614).

Agriculture in the United States accounts for over 933 million acres, 40 percent of America's land area. Virtually all cropland is privately owned, as is three-fifths of grassland pasture and range. Add the national forests and grasslands, which come under purview of the USDA Forest Service, and the USDA is directly involved in the land use of over 50 percent of the nation's land area. Its efforts in research, education, and cooperative extension service education indirectly affect resource use in other domains. For example, wetlands restoration affects the population size and diversity of wildlife, and wildlife can impact the income of farmers and farmland owners. Wildlife health and wellbeing is of concern to the USDA's Animal and Plant Health Inspection Service (see sidebar) and other agencies, notably the departments of the Interior and of Health and Human Services.

The USDA relates directly and indirectly to farmers; landowners; the food, fiber, and timber industries; recreationists; environmental interests; and others in rural America. The programs of the USDA are clustered under the management of seven undersecretaries: those for natural resources and environment; for farm and foreign agricultural services; for rural development; for food nutrition and consumer services; for food safety; for research, education, and economics; and for marketing and regulation. Under these clusters are many programs administered through its agencies, such as the following:

The Farm Service Agency, through its 2,346 state and county offices, is the USDA's local interface with farmers and landowners through programs affecting production management, soil conservation, and agricultural markets and finance. The agency produces and stores aerial photography and land records; administers programs on crop production, storage, finance, and insurance; provides disaster assistance and insurance; and gives technical advice and support for conservation and environmental projects.

The Food and Nutrition Service claims, "No one should go hungry in America." It administers programs affecting about one in five people, from school children to the elderly. Key operations include supplemental food for women, infants, and children; the National School Lunch Program; Food Stamps for low-income persons; child and adult food care; food assistance for disaster relief; and related research and education.

The Food Safety and Inspection Service assures the safety, quality, and labeling of meat, poultry, and eggs in the nation's food supply through research, testing, and inspection. The federal-inspection program is allied with state programs and coordinates on standards with international organizations. Under the Organic Foods Production Act of 1990, the Food Safety and Inspection

THE ANIMAL AND PLANT HEALTH INSPECTION SERVICE

The Department of Agriculture's Animal and Plant Health Inspection Service, through a system of regulations, permits, and controls, protects the health and welfare of the nation's agriculture and natural resources. Globalization and transportation has increased the exposure of America's people, animals, and plants to disease, bioterrorism, invasive or destructive species, and other threats. Since 1972, the animal- and plant-protection functions of the USDA have been consolidated under a single agency, the Animal and Plant Health Inspection Service, which monitors the condition of domestic and wild animals and plants, regulates international transportation of plants and animals, and evaluates and controls the welfare of animals in human care. (See the Web sites of the Animal and Plant Health Inspection Service and of the National Agricultural Library's Animal Welfare Information Center.)

Service is responsible for standards and labeling in the rapidly expanding organic meat and produce sector.

The Natural Resource Conservation Service (formerly the Soil Erosion Service, then the Soil Conservation Service) was formed during the drought and economic depression of the 1930s. The principal land-use-management agency of the USDA, it is a source of information and support for environmental improvement. The Natural Resource Conservation Service provides technical information and council through its Conservation Technical Assistance program. It administers resource programs such as the Wetlands Reserve Program and the National Resources Inventory, and provides technical support for resource programs in other agencies, such as the Conservation Reserve Program in the Farm Service Agency. (For an overview of conservation and other programs of the USDA, see its Web site.)

The USDA's knowledge base is rooted in the research programs of the Agricultural Research Service, the Economic Research Service, the National Agricultural Statistics Service, and the Cooperative State Research, Education, and Extension Service. Partnering with the research, education, and extension establishment in the USDA is the National Agricultural Library, with its agricultural and natural-resource collections and its information centers for alternative-farming systems and for animal welfare.

U.S. DEPARTMENT OF THE INTERIOR

Established in 1849 to oversee the young nation's internal affairs, the U.S. Department of the Interior (DOI) has evolved into the federal government's principal land-management and conservation agency. The DOI is responsible for nearly 450 million acres of federal public lands, most of which are apportioned between three agencies: the Bureau of Land Management (BLM), the National Park Service, and the U.S. Fish and Wildlife Service (FWS). In addition, the DOI houses several other agencies, including the Bureau of Reclamation, U.S. Geological Survey, Office of Surface Mining Reclamation and Enforcement, and the Minerals Management Service. Since its inception, the DOI has also handled federal relations with the nation's native inhabitants, through the Bureau of Indian Affairs (BIA). With oversight responsibility for these diverse agencies, the DOI does not have a single central mission but rather pursues an assortment of missions, some with a strong resource-development agenda and others with a much different preservationist agenda.

EARLY EVOLUTION OF THE DOI

In the beginning, the DOI had even more diffuse responsibilities. Congress created the DOI by consolidating several unrelated domestic bureaus into it to unburden the other cabinet agencies. Thus, Interior originally housed the General Land Office, Patent Office, Pensions Office, and Indian Affairs, and oversaw territorial governments and the District of Columbia jail system. Several of these bureaus were gradually incorporated into other newly established cabinet agencies, leaving Interior primarily responsible for the nation's publicly owned lands and resources. In 1905 Congress transferred the new forest reserves from Interior to the Department of Agriculture, thereby establishing the U.S. Forest Service and dividing oversight of federal public lands between these two cabinet departments. Despite periodic proposals to consolidate the four federal land-management agencies into a single Department of Natural Resources, Congress has consistently rejected this idea, leaving the bureaucratic landscape intact.

Within the DOI federal conservation policy has steadily evolved over the past 150 years. Acting through the General Land Office, DOI originally oversaw disposal of the nation's public lands into private ownership under such laws as the Homestead Act of 1862, the Pacific Railroad Act, and the General Mining Law. In 1872, however, Congress passed the Yellowstone Act and retained nearly 2 million acres of this unique landscape in public ownership as a ''public park or pleasuring ground for the benefit and enjoyment of the people,'' thus opening a new preservationist chapter in federal land policy. (Runte 1987, p. 46). In 1891 Congress authorized creation of the forest reserves, which has led to the retention of more than 150 million acres of public forest lands in federal ownership. By the beginning of the twentieth century, under the leadership of President Theodore

Roosevelt and Gifford Pinchot, federal policy had shifted away from disposal of publicly owned lands and resources to retaining and managing them under the new banner of "conservation"—a Pinchot-inspired doctrine holding that the public interest was better served by government ownership and scientific management of the nation's natural resources for utilitarian goals.

This new conservation philosophy took hold, and the DOI was soon freighted with several new professional bureaus responsible for implementing these new policies. In 1902 Congress created the Bureau of Reclamation to provide water resources for the arid West through the construction of federally funded dams and aqueducts. In 1905 Congress established the U.S. Forest Service to manage the new national forest system, but placed it in the Department of Agriculture. In 1910 the Bureau of Mines was established to promote mine safety and mineral technology. In 1916 Congress passed the National Parks Organic Act to consolidate the existing national parks and monuments into a national park system and to create the National Park Service to manage them under a strong preservation mandate. During the dust-bowl era of the 1930s, Congress adopted the Taylor Grazing Act, giving the DOI regulatory oversight of livestock-grazing practices on the public-domain lands. In 1940 the U.S. Fish and Wildlife Service was created to manage the growing national wildlife refuge system. In 1946 Congress merged Interior's General Land Office and the Grazing Service to create the Bureau of Land Management to oversee the unreserved public lands, those federal lands that were not under the aegis of the other conservation agencies.

POST-WAR

Congressional legislation since World War II has further muddled the DOI mission and aggravated the latent tensions between its resource-development and preservation-oriented agencies. The 1964 Wilderness Act not only established the national-wilderness preservation system, but it also instructed the Park Service, Forest Service, and FWS to review their undeveloped lands for possible inclusion in the system. During the 1970s a plethora of new environmental laws, including the Clean Water Act, National Environmental Policy Act, and the Endangered Species Act, required all federal agencies to take into account the environmental consequences of their actions before undertaking any action. In 1976 the Federal Land Policy and Management Act gave the BLM a new organic charter that provided for multiple-use management through an interdisciplinary resource-planning process and new wilderness review and management responsibilities. In 1980 Congress passed the Alaska National Interest Lands Conservation Act, which transferred nearly 60 million acres of Alaskan public lands into national-park, wildlife-refuge, or wilderness status.

The result for the DOI agencies has been an increasingly overt tension between preservation and utilitarian management policies. This conflict is evident in such settings as the Arctic National Wildlife Reserve, which has long been coveted by oil companies for its petroleum potential while environmental interests have sought to protect it from industrial development. Another example of this tension can be found in the BLM. Under the leadership of Secretary of the Interior Bruce Babbitt (1993–2001), the BLM was given responsibility for fourteen new national monuments as part of a new National Landscape Conservation System. But Babbitt's successor, Secretary Gale Norton (2001–2006), moved oil and gas exploration across the interior West to the forefront of its agenda.

One effort to reconcile these divergent conservation philosophies has come in the form of new ecosystem-management policies designed to achieve ecologically and economically sustainable resource-management goals at the regional or landscape scale. The efficacy of these policies is still being tested. Meanwhile, the Interior agencies are pursuing their individual missions under a welter of sometimes conflicting laws and policies, leaving the DOI a pastiche of different agencies and often clashing conservation priorities.

U.S. ENVIRONMENTAL PROTECTION AGENCY

The United State Environmental Protection Agency (EPA) was formed in 1970. As a dynamic, ever-changing, and powerful federal agency, the EPA often faces ethical choices on a range of issues, such as the mandatory

cleanup of contaminated sites and assigning liability without culpability, assessing the varying impacts of environmental regulation by race and income, whether or how to regulate nanotechnology, how to pursue and define social preferences for sustainability, and how to navigate global environmental issues like climate change. The EPA must deal with a broad range of factors in its decision making: public involvement and participation, land use, cumulative environmental impacts, the institutional ethics of economic development, legal constraints, and risk assessment processes only partially based on science.

HISTORY

Prior to the founding of the EPA, other federal agencies handled parts of some environmental issues. Their authority was often unclear, inconsistent, and sometimes conflicting. Fifteen federal agencies or parts of federal agencies handled some aspects of some environmental problems. Some states were initiating their own environmental agencies, and often-conflicting sets of regulatory procedures were beginning to emerge. There was a growing recognition of the severity, national scope, and political urgency of environmental issues.

The EPA is a creature of many federal statutes and rules. In 1970 President Nixon signed Executive Order 1110.2 which began the process of forming this new, powerful federal agency. By 1979 at least twenty-seven new environmental laws had been passed. The first waves of national environmental regulations were solidified with the passage and implementation of the National Environmental Policy Act (NEPA), the Resource Recovery Act, and the Clean Air Act in the early 1970s.

The EPA is still a relatively young and very powerful federal agency. It was designed to provide independent and objective information about the environment and to develop rules and regulations to protect it. It was also designed to have a wide purview, covering environmental issues pertaining to air, water, and land. Because of the novelty of national environmental regulations, the EPA was charged with examining new policies, assisting Congress with legal advice, and mediating political controversies.

DEVELOPMENT OF THE AGENCY

The EPA's initial tasks were massive. With every new environmental law, the EPA had to develop and enforce rules and regulations. It also had to be ready to litigate to defend these new laws and to enforce them. Many new environmental laws, such as the Clean Air Act and Clean Water Act, contain provisions that allow citizens to sue the polluter and the EPA if the EPA fails to enforce the law. Environmental groups have successfully litigated against the EPA many times on issues that lie at the foundation of modern environmental policy. For example, litigation by environmental-advocacy organizations forced the EPA to develop clean air standards.

During its first twenty years the EPA reacted to environmental issues and controversies emerging from court cases and from Congress, setting and enforcing environmental regulations that were nationally uniform and legally defensible. The early years were also notable for the cadre of dedicated senior EPA staff working to improve the presence and acceptance of the EPA from industry, states, Congress, and the public generally.

The relationship of the EPA to the states is an evolving aspect of environmental federalism. Revenue allocations flow from EPA headquarters to the ten EPA regions. Each region has from three to five states and territories within its jurisdiction. From the EPA regional offices revenue is distributed to state environmental agencies. Because many states are historically hostile to environmental regulations, EPA revenues usually make up a substantial part of many state environmental-agency budgets. States are usually free to run their programs as long as they comply with the minimum EPA requirements, although exceptions abound. If states do not want to enforce or accept a particular national program, then EPA will run it for them. States usually prefer not to lose control of regulating the environment.

The dynamic of intergovernmental relations in environmental regulatory regimes in the United States is rapidly evolving to include land-use practices that affect the environment. Ecosystems and bioregions transcend political boundaries and require cooperative national action. Protecting and preserving the environment also requires grassroots implementation at the community land-use level, a challenge not yet met by the EPA.

CHANGING MANDATES AND MERCURY MISSIONS

As the EPA has grown and evolved, so have the number of environmental laws and regulations. Often they have emerged at the EPA as part of an agency mission. Many of the early activities of the EPA involved seemingly distinct concerns about air, water, land, and solid wastes. But the environment is, in reality, multifaceted and complexly integrated. Pollution can move through an ecological cycle of land, air, and water. Along the way, it can accumulate in parts of an ecosystem and do damage to the entire system. For example, metals like mercury may accumulate in the fat and in the nervous system of fish. People who rely on these fish for food are exposed to this mercury. According to a 1969 study, the amount of heavy-metals pollution in the environment was so high that it infected mothers' milk and babies' bones to such a degree that if mothers' milk were a commercial food

item, the U.S. Food and Drug Administration would not have approved it.

The degree of danger from chemicals like DDT or metals like mercury often constitutes a separate set of controversies tied closely to concerns about liability for the damages from such exposures. There is some disparity in the degree of risk from various industrial pollutants that different cultures and communities are willing to accept, making uniform standards difficult to determine. Further, some of the cultures and communities that do not accept dangerous industrial facilities in their midst and/or require cleanup of such to residential standards of living are able to readily obtain legal remedy. Others, however, are forced into a series of "scientific" debates about the reasonability of their concern about risk. These communities end up with greater exposure to environmental risks, slower cleanup of hazardous waste sites, lower compensation and fines for environmental harms inflicted on them, and cleanups performed only to industrial, not residential, standards. These lower cleanup standards are less expensive and facilitate the sale of property. But meeting such minimal standards also keeps a higher amount of waste in those communities where such standards are imposed and makes them inappropriate for residential uses and uses for facilities for vulnerable populations like schools and hospitals

1970S: NEW LAW, RULES, AND REGULATIONS

The EPA's first public priorities were environmental protection and protecting public health, without unduly burdening the national economy. This set of priorities translated, in practice, to controlling pollution and dangerous chemicals. Standards for clean air and water were also developed and refined during the 1970s. The EPA was often sued by industries if such standards seemed too far reaching and the EPA was sued by environmentalists when it was seen to move too slowly in the development of standards or the enforcement of them.

1980S: CLEANUP

Polluting industries were not well regulated until the early 1970s, and even then regulations only partially covered some industries. Thus some egregious waste sites created before regulation was initiated or by some unregulated industries became of national concern. Mandatory cleanup laws were developed and enforced, often through the courts. As a result the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), also known as Superfund, was enacted in 1980 to, among other reasons, identify potentially responsible parties (PRPs) for the waste-site cleanup. The law required the creator, shipper, or property owner to clean up the "Superfund" site—defined as one that was egregiously polluted. Once the PRPs are found, they must either do an adequate cleanup or pay for cleaning up the site. The EPA can force any one of a group of PRPs to pay because they are jointly and severally liable. That one then may sue the other PRPs if it has to clean up more than the share of the waste for which it was responsible. If there are many PRPs, and some declare bankruptcy or are otherwise unreachable, the secondary litigation can be extensive.

If the cleanup laws required proportional sharing of responsibility for the culpable parties, there would be much less resistance against the EPA's assigning liability for cleanup when there was no other culpability than property ownership. The reason for assigning responsibility to property owners who may not otherwise be culpable is simply that unabated and unmitigated pollution can spread via the air and water to schools, organic crops and fields, and whole communities, while the actual polluters may be hard to find, bankrupt, or corporately dissolved. There is tension between U.S. traditions of private-property rights and freedom on the one hand, and the rigorous and unforgiving requirements of pollution control and abatement on the other. As many communities became concerned about accumulating emissions, impacts on the environment and human health, and other risks from the pollution of the land, air, and water, waste sites became battlegrounds pitting neighbors against one another, neighborhoods against city hall, environmentalists against industrial corporations, and parents against commercial economic development. Liability for environmental cleanup costs have followed the owner of the land, so when a municipality forecloses on a land for failure to pay taxes, the municipality may be liable for the environmental cleanup costs. On the other hand, if the land remains abandoned, it does not generate tax revenue or get cleaned up. Thus there is a chance the pollution could migrate off the polluted property and that abandoned, polluted property will suppress the property values of surrounding properties.

In the 1980s the EPA forced the clean up of Love Canal, New York, which was built on top of a chemical company's waste dump and contaminated with carcinogenic chemicals. New York State declared it a health emergency in 1978. It was one of many events that provided the political impetus to the Superfund Act. In 1983 the EPA also relocated the community of Times Beach, Missouri, near St. Louis because of excessive dioxin contamination for using waste industrial lubricants to oil the communities' roads which was then spread over the soil by floodwaters.

In the early 1980s the EPA began to respond to the environmental justice movement. Distinct from any mainstream U.S. environmental organization, environmental

justice groups were grassroots affairs, predominantly communities of color affected disproportionately by environmental harms. It had been business as usual in the United States to place toxic and noxious facilities near and around low-income and African-American communities. A study by the United Church of Christ performed in 1986 and revisited in 2006 (Bullard et al. 2007) showed that race, more than any other characteristic, indicated the likelihood of the placement of a commercial waste site, regulated or unregulated, near a community. The more African American a community was, and is, the more likely that it has one of these unwanted land uses, to a 99.9 percent certainty or one in ten thousand chance of randomness. With the rise of environmental regulation and citizen monitoring, knowledge of environmental impacts increased. With this knowledge came evidence of unequal access to legal remedy and unequal environmental results that had been previously unaddressed in U.S. environmental policy. The failure of the U.S. environmental movement to include the interests and values of oppressed people of color also contributed to the rise of environmental justice groups. Their motto, which came out of the First People of Color Environmental Leadership Summit, held in Washington, D.C., in 1991, is "We speak for ourselves." They are now formally represented by the Office of Environmental Justice, developed in the EPA during the first decade of the twenty-first century.

Lead was and is a high-priority pollutant for the EPA. Lead comes from vehicle emissions, industrial pollution, old paint in homes and on bridges, water pipes, and many other sources. It can irreversibly impair the nervous system of unborn children and children up to the age of five. It is associated with several types of cancers and other dangerous health risks. In 1985 the EPA set new limits on lead in gasoline because of air pollution. This has been one of the most successful programs implemented by the EPA. Lead emissions from motor vehicles were reduced, and lead levels in the U.S. population decreased. This measure greatly enhanced the EPA's credibility as a regulator of corporate activities in the interests of public health.

ENVIRONMENTAL INFORMATION AVAILABLE TO COMMUNITIES

Late in the 1980s the EPA began a push to make information about hazardous chemicals and pollution more available to the public. The primary concern then was with first responders to emergencies, such as fire and police personnel. With the Emergency Planning and Right to Know Act in 1986, industries that emitted over a certain threshold of chemicals from a short list of 300 had to report them annually. That list now includes over 650 chemicals. However, there are more than 80,000 chemicals used in U.S. commerce, and less than 2 percent of them have been checked for safety. Many states and some municipalities are now developing their own right-to-know laws. These often mimic the federal law. These laws have been criticized because the information is often self-reported by industry and because only when emissions exceed a certain threshold are industries required to report them. Not all industries are included. For example, universities and colleges emit significant chemicals without reporting requirements. Also, many claim that not all chemicals with significant environmental impacts are included. Despite these serious shortcomings, these laws have been a tremendous organizing tool for environmentalists and environmental justice advocates.

1990S: PREVENT THE POLLUTION

The 1990s saw environmental mandates shift to pollution prevention. The decade was inaugurated in 1990 with a major amendment to the Clean Air Act of 1963. Some 30 million tons of toxic chemicals were prevented from going into the air in the early years of its implementation. Food quality, second-hand smoke, and safe drinking water also dominated the environmental policy development at the EPA. Concern for environmental justice continued to grow in prominence, and EPA began to study issues of sustainability.

TWENTY-FIRST CENTURY: POLICIES IMPLEMENTED, GLOBAL CONCERNS LOOM

During the first decade of the twenty-first century many of the pollution-prevention, -control, and -regulation policies established over the last quarter of the previous century continued to be implemented. Like most federal agencies, the EPA responded to the 9-11 bombing of the World Trade Center towers in 2001. The EPA issued a strategic plan for homeland security in 2001 and updated it in 2004. However, because the United States did not endorse many important world environmental treaties such as Kyoto, it is difficult for the EPA to coordinate environmental policy with other countries. It is also difficult for international U.S. businesses which must comply with these global concerns in order to operate in other countries and compete internationally.

THE EPA TODAY

The strength of the EPA is its credibility here and abroad. Its information, monitoring, research, and power to control behavior through regulation in the face of unknown contingencies contribute to its credibility. Some of the vulnerabilities of the EPA stem from its lack of inclusion of all affected communities and from controversies that surround its enforcement policies. The primary enforcement theory at the EPA is compliance, not general or specific deterrence. For example, if the accused polluter simply confesses, the EPA applies a "reduction of gravity

rule" to reduce the monetary penalty by 50 to 75 percent right off the top. Citizens are often excluded from EPA decision making, even when it affects them. For example, in a federal environmental-impact statement, citizens are not given notice of a preliminary environmental assessment of their neighborhood until after it has been determined, based on this preliminary assessment, whether there are significant environmental impacts that require a full environmental-impact assessment be done or not. Citizens who may care, may know, or may simply want to participate are not given an opportunity until the process is far advanced.

Because the EPA is tied tightly to the specifics of each piece of legislation setting environmental policy and mandating its responsibilities, it is difficult for it to strategically plan for future environmental contingencies. This uncertainty makes it difficult for it to work with new, non-legislated ways of approaching environmental controversies, issues, and problems, such as the rising social concern for sustainability. However, the EPA is adaptable to changing political environments. It is exploring supplemental environmental projects (SEPs), begun in the late 1990s, so that convicted polluters can mitigate the damage they have caused in a community. By exploring collaborative, multistakeholder SEPs—SEPs with more than two stakeholders, usually community, industry, environmental, and sometimes labor organizations—the EPA is moving beyond the mandated citizen participation of the 1970s and 1980s and into citizen involvement for long-term environmental planning.

U.S. FISH AND WILDLIFE SERVICE

In the lands that later became the United States, early European settlers encountered an apparently unlimited supply of wildlife and other natural resources and often had utilitarian, negativistic, and dominionistic views of wildlife. They embarked on a process of wildlife slaughter and habitat destruction, including deforestation, on a mass scale. That process continued through much of the nineteenth century and caused the local or regional extirpation of many species, including most large predators, white-tailed deer, elk, turkey, waterfowl, and the American bison. The first conservation efforts in the United States occurred at the state level because wildlife was considered a public resource held in trust by the states for the benefit of all the people; this was known as the public trust doctrine. However, individual states struggled to protect wildlife species that crossed state and national boundaries or were in the possession of commercial hunters and trappers.

Vermont was one of the first states to face a landscape stripped of natural resources. Deforestation in that state influenced George Perkins Marsh's *Man and Nature* (1864), which suggested that societal collapse would follow environmental degradation, and led Gifford Pinchot, the first chief of the U.S. Forest Service, to craft an anthropocentric and utilitarian ethic for conservation in the United States. That ethic defined wise use of natural resources as generating "the greatest good for the greatest number for the longest time" (Pinchot 1947, pp. 325–326) and provided the context for the emergence of the U.S. Fish and Wildlife Service (USFWS).

EARLY HISTORY OF THE USFWS

The roots of the USFWS can be traced to 1871, when Congress created the U.S. Commission on Fish and Fisheries to protect rapidly disappearing food fish stocks. A parallel effort to study the food habits of migratory birds led to the establishment of the Office of Economic Ornithology in the Department of Agriculture in 1885. The U.S. Commission on Fish and Fisheries was renamed the Bureau of Biological Survey in 1905 and was given management responsibility for the U.S. wildlife refuge system that started with Theodore Roosevelt's establishment of the first Federal Bird Reservation on Pelican Island, Florida, in 1903. In 1939 the Fisheries and Biological Survey bureaus were transferred to the Department of the Interior.

In 1940 those bureaus were combined into the Fish and Wildlife Service, and in 1956 the Fish and Wildlife Act created the USFWS. During the early years the responsibilities of the USFWS reflected its utilitarian roots: It focused on enforcing the law, regulating trade, and conducting research. Those activities were intended to protect and manage game species and minimize conflicts between wildlife and agriculture. The utilitarian approach to conservation was largely responsible for the restoration of elk, white-tailed deer, the American bison, turkey, bear, and many other species throughout the United States.

CHANGES IN THE ROLE OF THE USFWS

The role of the USFWS changed drastically in the 1960s and early 1970s, when the environmental and animal rights movements began to flourish. During that period the environmental ethics guiding wildlife conservation diverged from the early anthropocentric and utilitarian focus articulated by Pinchot. Aldo Leopold's *Sand County Almanac* (1949) helped promote an ecocentric ethic—the land ethic—for wildlife conservation. The more ecocentric ethical views prevalent in the environmental movement played a role in the establishment of the Endangered Species Act (ESA) of 1973. The ESA prohibited the importation, exportation, taking, or possession of a registered endangered species and gave USFWS responsibility for listing of, recovery planning for, education about, and delisting of species.

The ESA protected animal and plant species without consideration of the economic, cultural, and social preferences of humans. The ecocentric approach to wildlife conservation taken by USFWS was responsible for some notable conservation successes, including the delisting of the American alligator, gray wolf, grizzly bear, and bald eagle. However, the tendency to subordinate human interests to the protection of listed endangered species led to conflicts between the USFWS and several rural communities. Conflicts surrounding the spotted owl in the Pacific Northwest and the coho salmon in the Klamath Basin in Oregon were among the most publicized. Those conflicts raised questions about how to integrate the interests of stakeholders at the local, regional, and national levels. In some cases the conflicts threatened wildlife management objectives by alienating private landowners. Critics of the ecocentric focus of the USFWS argued that fear of ESA-related restrictions was a disincentive for wildlife conservation on private land and might motivate landowners to get rid of threatened species before restrictions on property uses were mandated. Landowners in some areas did restrict access to their land in efforts to prevent the discovery of endangered species.

Fish and Wildlife Service Officer with Illegal Trade Items. *The responsibilities of the USFWS during their early years involved enforcing the law, regulating trade, and conducting research. Today, despite a period of a more ecocentric approach that emerged in the 1960s and 1970s, the USFWS continues to take an utilitarian approach to wildlife preservation and conservation.* **PHOTO BY CARL ZITSMAN/U.S. FISH AND WILDLIFE SERVICE.**

REESTABLISHMENT OF THE UTILITARIAN PERSPECTIVE

In the mid-1990s the ethical perspective of USFWS started moving back toward anthropocentric utilitarianism. Unlike the earlier shift to ecocentrism, this move was tied to presidential influence over the USFWS rather than to a national social movement. In the 1992 presidential race Bill Clinton promised to move the country beyond a false choice between environmental protection and economic growth. His administration pushed the Habitat Conservation Planning process to achieve that objective. Habitat Conservation Plans provided a loophole in the absolute rule of not harming endangered species. With an approved Habitat Conservation Plan, landowners, government entities, and corporations could kill individuals from a population of endangered species under the protection of incidental take permits. The 14 incidental take permits issued before the 1992 presidential race paled in comparison to the 425 approved as of July 2003.

The shift toward anthropocentric utilitarianism in USFWS operations expanded with the 1995 Safe Harbor Program and the 2007 Endangered Species Recovery Credits system. The Safe Harbor Program exempts landowners from further restrictions on their land when they agree to manage the land for endangered wildlife, and the

Credits system allows private and public entries to harm endangered species in exchange for purchasing conservation credits that require proper habitat management elsewhere.

This move back to anthropocentric utilitarianism has increased the ability of the ESA to accommodate human interests but could weaken protection for endangered species. Critics argue that sidestepping the exclusive focus on biotic integrity will allow human interests to displace the needs of other species.

U.S. FOOD AND DRUG ADMINISTRATION

The U.S. Food and Drug Administration (FDA) is responsible for protecting the public health by assuring the safety, efficacy, and security of human and veterinary drugs, the nation's food supply, medical devices, cosmetics, and several other products. The FDA is also responsible for advancing the public health by helping to speed innovations that make medicines and foods more effective, safe, and affordable (FDA Mission Statement). In the area of food safety, the FDA executes the Federal Food Drug and Cosmetic Act (FFDCA) (21 U.S.C§§ 301–399) by setting standards for food and food products, inspecting food production and distribution facilities, and ensuring proper labeling. In the area of animal health, the FDA is responsible for regulating the manufacture and distribution of food additives used in animal feed and of drugs that will be given to animals.

Under this diverse portfolio of products and activities, the FDA also has a mandate for environmental protection. The FDA is required under the National Environmental Policy Act (NEPA) (21 C.F.R. Part 25) to take environmental considerations into account in all final agency actions. For example, during the review of animal drugs under FFDCA, the FDA considers the excretion of drugs in animal waste and the effects of drug residues on the environment. NEPA requires that U.S. agencies include an environmental impact statement (EIS) with every major federal action that significantly affects the quality of the human environment. Environmental assessments (EAs) are prepared to help determine if an action will have a significant impact on the environment and whether an EIS is required.

The FDA is often faced with situations in which goals of human and animal health protection, speeding innovation, and environmental protection are at odds. Decisions under NEPA do not require that the action most beneficial to the environment be taken. For example, the FDA might be faced with a policy choice about whether to accept environmental harm from its actions to protect human or animal health or to make foods safer or more affordable. A contentious instance of this dilemma is the approval of the subtherapeutic use of antibiotics in feed to promote animal growth during agricultural production. Environmental and consumer groups have argued for a precautionary approach to limit or ban the use of antibiotics in animal feed. Concerns include the harmful effects of antibiotic residues on native species in the environment and the increased development of resistant microorganisms that cause disease.

The ethical principles of beneficence (doing good) and nonmaleficence (doing no harm) are prominent when the FDA makes decisions in the face of competing goals or interests. The distribution of risks and benefits to various stakeholder groups—the environment, animals, and humans—is an important consideration. Equity in decision making comes into play when the FDA considers this distribution. Integrity, autonomy, and justice are also prominent in how the agency makes decisions. For example, transparency in decision making, avoiding conflicts of interest in conducting safety studies, and giving consumers or users of products the right to know and choose based on good information are manifestations of these principles in the FDA's regulatory context.

An example of an emerging issue that spans environmental protection and the FDA's jurisdiction is the agency's proposal to regulate genetically engineered animals as new animal drugs (NADs) under the FFDCA. The claim by the agency is that the introduced and engineered gene is the "drug," because it alters the structure or function of the body of animals. The FDA has

been considering regulatory approval of genetically engineered (GE) fish with growth-promoting genes since the late 1990s. This decision has been stalled in part because of continuing controversy over genetically engineered organisms in food and agriculture. Environmental and consumer groups and scientists are concerned about the environmental risks of GE fish, including adverse effects on native populations, relatives, or other species of predators or prey from the introduced fish if they were to escape or were intentionally released. Many in the aquaculture industry are excited about the potential of GE fish to resist disease, grow faster, or have fewer resource needs (thus improving the environment). As the regulatory agency with primary responsibility for GE animals, the FDA will need to carefully consider its authority in this area under NEPA.

The FDA will also be faced with considering ethical principles in its decision making about GE animals. Federal agencies like the FDA are asked to weigh the risks, benefits, and costs of their decisions (to use, in effect, a utilitarian ethical framework) to comply with the order of the Executive Office of the President (1993). However, procedural justice, autonomy, inherent objections on fundamental grounds (''playing god''), and the integrity of the regulatory approval system are also prominent in GE animal oversight, as reviewed by Thompson (2007).

U.S. FOREST SERVICE

The United States Forest Service (USFS) administers 155 national forests and twenty national grasslands—some 193 million acres of land—in forty-four states, Puerto Rico, and the Virgin Islands. The USFS was established in 1905 within the U.S. Department of Agriculture to administer the nation's newly created national forests and the related forestry programs of the federal government. The creation of the USFS was a key event of the Progressive-Era conservation movement as it gained definition and broad public and political support during the presidency of Theodore Roosevelt (1858–1919, president 1901–1909). Since then the USFS has played an important role in the evolution of conservation policy, science, and practice; it has been both a generator and barometer of changing environmental values and ethics. A major force in shaping American natural-resource management, it has had a broad influence on forestry and environmental policy internationally, at other levels of government, and in the private and nongovernmental sectors.

ORIGINS AND EVOLUTION OF THE USFS

By the mid-1800s, widespread clearing of the forests of the eastern United States for farming and for timber, fuel, and other forest products had begun to raise concerns among protoconservationists. In his classic *Man and Nature; or, Physical Geography as Modified by Human Action* (2006 [1864]), George Perkins Marsh critically examined deforestation and its impact on climate, soil conditions, hydrologic dynamics, watershed function, and forest plant and animal life. Correcting the ''terrible evils'' of deforestation, Marsh wrote, was among ''the most obvious of the duties which this age owes to those that are to come after it'' (p. 279). Through his writing and his advocacy Marsh influenced those who later created the USFS, echoing his mandate to ''care for the moral and material interests of our own posterity'' (p. 279).

In the three decades following the Civil War, the rapid development of the mid-continent's cities, towns, and farms, along with the advent of new sawing, milling, and transportation technologies, led to the near-complete removal of the white pine forests of the upper Great Lakes. As these forests were depleted, devastating slash fires often followed in the wake of the loggers and fed growing fears of a ''timber famine.''

As public attitudes and political sentiment began to shift, the federal government took its first concerted actions on behalf of forest conservation. In 1876 Congress appointed Franklin B. Hough (1822–1885) as a special agent in the Department of Agriculture, charged with assessing the state of the nation's forests. In 1881 Hough's responsibilities were expanded within a new Bureau (later Division) of Forestry, the precursor to the USFS. The Forest Reserve Act of 1891 empowered the president to withdraw forestlands from the nation's public domain and to designate them as forest reserves under the administration of the U.S. Department of Interior.

Over the following fifteen years 100 million acres of forest reserves were created, primarily in the western states and territories. The Organic Act of 1897 directed the Secretary of Interior "to make such rules and regulations and establish such service as will insure the objects for which forest reservations are created . . ." (U.S. Congress 1897). Those "objects" were "to protect and improve the forests for the purpose of securing a permanent supply of timber for the people and insuring conditions favorable to continuous water flow" (U.S. Congress 1897). Under the Transfer Act of 1905, the reserves were renamed national forests. The Transfer Act shifted responsibility for their administration to the Department of Agriculture, where the old Division of Forestry was reassigned and rechristened as the U.S. Forest Service.

These developments exposed latent philosophical tensions in the emerging national conservation movement. The change in nomenclature from *forest reserves* to *national forests*, with the implication that the nation's forest estate was not to be set aside but used, revealed the movement's clashing values. Utilitarian conservationists (often identified with Roosevelt's "chief forester," Gifford Pinchot) stressed the instrumental value of the nation's forest resources and the need for efficient, scientifically informed forest management. In its classic formulation the USFS administration of the national forests was to serve "the greatest good for the greatest number over the long run." It pursued this policy by applying principles of sustained-yield silviculture developed in the European forestry tradition. By contrast, preservation-minded conservationists (often identified with the author and naturalist John Muir) emphasized the intrinsic, aesthetic, and spiritual values of forests and pushed for their protection from the incursions of settlers, loggers, grazers, miners, and dam builders. The clash of these schools played out most famously in the extended conflict over a proposed dam (eventually approved in 1913) on the Tuolumne River in Yosemite National Park's Hetch Hetchy Valley.

The timber values of the national forests dominated USFS management goals and actions through the twentieth century. The service's views and values did not, however, go unchallenged. Through the 1920s and 1930s scientists, foresters, and conservationists, within and beyond the USFS, began to champion a wider variety of forestland assets: water, wilderness lands, wildlife, and recreational opportunities. Aldo Leopold, who joined the USFS in 1909 and spent the first half of his career working in the agency, became a leading voice for recognition of the full spectrum of forest values and for their effective integration into conservation planning. Leopold's appreciation of the implications of ecology for sustainable land management drew on his own early field experience in the national forests of the American Southwest. Leopold's land ethic, by emphasizing the integrity, diversity, and self-renewing capacity of ecological communities—what he termed "land health"—sought to bridge the divergent utilitarian and preservationist strains of conservation thought; all forest values, he held, depended on the healthy functioning of the forest as a whole.

POST–WORLD WAR II DEVELOPMENTS

The end of World War II brought new pressures to bear on the national forests and the USFS. Before the war exploitation of timber resources was concentrated in the nation's private forestlands. After the war the baby boom (and the corresponding construction boom) across the United States increased demand for timber from the national forests. Large-scale industrial forestry operations became the norm, most visibly in the form of expanded clear-cutting. In the USFS narrowly defined economic values overwhelmed ecological rationales for better integrated forest management.

At the same time the more urban and suburban postwar generation took to the national forests in growing numbers for recreation, which became an increasingly important use of forestlands. This shift in turn contributed to a widening public awareness of environmental values and the rise of the environmental movement. Thus, as material and recreational demands on the national forests intensified, so did the movement for protection of roadless wildlands within the forests, culminating in passage of the Wilderness Act in 1964.

In an attempt to reconcile these competing public demands—and by implication the varied interpretations of the "greatest good"—the USFS followed the mandate of the Multiple Use and Sustained Yield Act of 1960 (MUSY). MUSY directed that the national forests be "administered for outdoor recreation, range, timber, watershed, and wildlife and fish purposes" (U.S. Congress 1960). MUSY stated that all of these uses should be accorded equal importance and directed the USFS to "[achieve] and [maintain] . . . a high-level regular output of the renewable resources of the national forest without impairment of the land's productivity" (U.S. Congress 1960). MUSY's goals proved difficult to realize. In the absence of any robust set of common values or shared commitment to land health, multiple competing interests continued to strive for predominance in national forest management, and the USFS remained a magnet for political controversy.

By the late 1980s an array of intractable forest management issues were playing out on the national stage: forest fragmentation, with its the attendant impacts on biological diversity; delineation and protection of the remaining roadless areas in the national forest system;

The Northern Spotted Owl. *In 1986 the U.S. Forest Service initiated steps to protect the spotted owl from extinction by limiting timber sales in mature portions of National Forests, the species' natural habitat. This sparked a lengthy and heated controversy between environmentalists and the timber industry when measures to protect the spotted owl may have led to layoffs and decreased business for loggers and mill workers. In 2008 the spotted owl continued to be classified as a threatened species.* **PHOTO BY JOHN AND KAREN HOLLINGSWORTH/U.S. FISH AND WILDLIFE SERVICE.**

the impacts of heavy grazing on forests, grasslands, watersheds, and riparian communities; disruption of historic fire regimes because of a century of fire suppression and postwar development at the urban/wildland interface; intensified recreational demands on forests; and local timber economies that were faltering because of mechanization, dislocation, and the impacts of the globalizing economy. Caught between the intensified scrutiny of the environmental movement (and especially the deep ecology–inspired Earth First! Movement) on the one hand and the property rights–focused wise-use movement on the other, the USFS (and other public land agencies) found itself torn between the opposing forces of forest utility and forest protection. The struggle in the late 1980s and early 1990s over the fate of the northern spotted owl and the logging economy in the national forests of the Pacific Northwest was emblematic of the broader effort to overcome conservation's philosophical divide. Out of this complex set of circumstances, foresters and other resource managers began to revisit their philosophical foundations and to search for a new management paradigm. In the USFS this trend was reflected by the formation, in 1989, of the Forest Service Employees for Environmental Ethics (FSEEE). This self-criticism within the forest service, and within professional forestry more generally, was evidenced in other land-management agencies and in the natural-resource management professions. One result was the emergence of *ecosystem management* as a potentially more integrated and unified approach to land stewardship. Embracing a broader range of intrinsic and instrumental values, recognizing the dynamic nature and scale-dependent processes of ecosystems, and acknowledging the active and mutual influence of human and natural communities, ecosystem management (and its variants) remained as of the early 2000s a work in progress, subject to varied interpretations and vulnerable to changing political forces. It has, at minimum, ushered land ethics back toward the center of discussions about national forest management, USFS decision making, the public interest, and "the greatest good."

As the USFS enters its second century, it continues to play a leading role, nationally and internationally, in shaping the ethos of the conservation/environmental movement. Even as the demand for forest products ("green"-certified or otherwise) continues, national forests are increasingly appreciated for nontimber values and services: as water sources, carbon sinks, and biodiversity repositories; as anchors for whole and sustainable landscapes; as open space and settings for healthy human communities; and as classrooms for an increasingly land-detached public. The USFS faces the challenge of managing the national forests in response to shifting demographics, new scientific knowledge, and uncertain economics, even while facing continuing threats from invasive species, habitat fragmentation, accelerating climate change, and other widespread forces of environmental change.

U.S. NATIONAL PARK SERVICE

The design of the U.S. national parks and the management philosophy of the National Park Service (NPS) have grown out of the mainstream principles and practices of American landscape design. The agency's two main missions are (a) to protect natural scenery, cultural features, and wildlife of the parklands and (b) to make them accessible for public enjoyment. The tensions between these two goals make up much of the history of the NPS and have spawned many changes and posed many challenges in the management of the National Park System.

FOUNDING VISION OF NATIONAL PARKS' DESIGN AND MANAGEMENT

The three men who most heavily influenced the initial design and management philosophy of the national parks were George Perkins Marsh (1810–1882), Andrew Jackson Downing (1815–1852), and Frederic Law Olmsted Sr. (1822–1903). Marsh advised the nation to set aside lands as public parks and preserves and to protect its natural resources (1864). Downing translated the idea of wilderness into design concepts. He was, according to NPS historian Linda Flint McClelland, ''intensely aware of the tremendous influence that primeval nature, with its dramatically changing landforms, variations of light and shadow, sounds of moving water, and enveloping vegetation could exert on the human senses'' (1997, p. 20). He introduced the picturesque style to the United States, adapting English landscape garden techniques to heighten the observer's experience of nature. Olmsted elaborated this tradition, creating systems designed to promote the circulation of human traffic amid a series of pictorially composed views. Olmsted's recommendations—which became the guiding principles of the NPS—articulated the model for national parks: Undiminished nature should be made accessible, accommodating development while subordinating it to the environment and scenic values. Accordingly, park designers adopted naturalistic approaches to landscape preservation and development, integrating roads and structures into their native surroundings and minimally disrupting topography and vegetation to provide recreational access and to educate the public about their environment's natural and cultural legacies.

ORIGINS, PUBLIC EXPECTATIONS, AND PARK MANAGEMENT

The first national park in the history of the United States—and the world—was Yellowstone National Park, created in 1872. The year 1890 saw the creation of Yosemite, Sequoia, and General Grant national parks as the idea of protecting unique natural environments became a solidly entrenched feature of U.S. policy. The park system expanded over the ensuing quarter century, culminating in the founding of the National Park Service in 1916.

J. Baird Callicott has argued that humans go to the wilderness in a spiritual quest to engage the natural world and counter the alienation fostered by modern urban civilization (1998). Fittingly, then, the law that founded the NPS, the National Park Service Organic Act of 1916, expressly set down the service's dual purposes: ''to conserve the scenery and the natural and historic objects and the wildlife'' and ''to provide for the enjoyment of same,'' but so as to ''leave them unimpaired for the

Everglades National Park. *A Great Egret (*Adrea alba*) stands among cypress trees in Everglades National Park in south Florida. The park, formally established in 1947, encompasses 2,354 square miles of mangrove swamps, pinelands, pond apple and cypress forests, and saw grass prairie. Hundreds of thousands of tourisits visit it each year.* **NPS.**

enjoyment of future generations.'' (National Park Service 2008b). Reflecting the then-fashionable aesthetic of the sublime and picturesque, America's national parks evolved as sanctified places, neither simply religious nor aesthetic (Frow 1997).

The National Park Service began to develop a transportation system in the 1920s that focused primarily on road construction to facilitate automobile usage. The early transportation planning by the Bureau of Public Roads in the 1920s sought to design a system of ''touring'' roads that connected many of the largest western parks (Hartzog 1988). As automobile usage increased, the deficiencies of the early road design became more apparent, bringing still more road design and construction. Attempting to solve automobile congestion, the NPS upgraded existing roads and infrastructure, thereby stimulating renewed cycles of increased use and ecosystem deterioration. Park visitation rose dramatically during the ensuring years: from 358,000 in 1916 to 287 million in 1999, dropping to 266 million in 2003 and rising to 275 million in 2007 (National Park Service 2008a).

FROM PRESERVATION AND CONSERVATION TO RESTORATION AND RESILIENCE

The tension between preservation of the parklands and the depredations caused by visitors' use has played out against the tradition of American Progressivism's conservation policy. As Worster (1979) has noted, in contrast to preservation, conservation holds that (a) the resources of public lands, including national parks, are abundant or renewable and thus meant to be consumed and (b) rationalized long-term practices can manage continuing production to maximize prosperity for the whole nation. An implication of conservation philosophy is that even once-ravaged parts of the natural environment can be maintained and restored (as accomplished, for example, between 1900 and 1925 with once-decimated deer herds. As sanctuaries the national parks now play a major role in restoring native species, protecting their genetic integrity, and affording the public the chance to become acquainted—or reacquainted—with them. Invasive species are removed, and the negative effects of erosion,

WOLVES RETURN TO YELLOWSTONE

Attempts to manage wildlife respond to changes in policy, practice, natural processes, and scientific knowledge. When the national parks were established, a variety of large mammals were present (gray wolves, grizzly bears, deer, and elk), although hunting and trapping almost exterminated many once-abundant creatures (deer had been killed by hunters until almost none remained by the 1880s). Changes in policy and actions based on limited observations often led to dramatic swings in the populations of individual species, oscillating from severely diminished to far in excess of a habitat's carrying capacity, with considerable variation from region to region. For example, the Progressives' view that natural resources needed to be efficiently managed included increasing "crops" such as cattle, sheep, and deer by eliminating predators. Serious predator extermination began in the late 1800s and proceeded through the early 1900s (Worster 1979). By the 1940s gray wolves were rare in the Yellowstone National Park region, with no evidence of any population (save for a random stray) by the 1970s. It appeared that the elimination of large carnivores led to the recovery of the population of deer, elk, bison, and moose (as well as to fewer lost livestock) (US–Parks 2008).

As the numbers of grazing animals increased, montane riparian willow and aspen stands became overgrazed. Because the change along rivers and streams was pronounced, the adverse effects rippled to beavers, fish, birds, and then organisms in the networks of interdependency through adjacent grasslands.

These adverse conditions prompted a turnabout in policy: It seemed a good idea to reduce the elk, bison, moose, and mule deer to remove the direct threat to vegetation and the rest of the ecosystem. There were many options—each loaded with socially charged and contested assumptions and implications—ranging from increased hunting to covert shooting by government personnel to attempts to redistribute the large animals. In 1987 the U.S. Fish and Wildlife Northern Rocky Mountain Wolf Recovery Plan experimented with the reintroduction of gray wolves; in 1991 they were restored to Yellowstone and central Montana.

The reintroduced gray wolves have thrived to the point that they have been removed from the endangered species list. There certainly are now fewer elk, and they have changed their habitat use. It is not clear, however, to what extent this is due to wolves, other predators, or changes in the weather (National Park Service 2008, US–Parks 2008). More research and interpretation need to be done to understand the impact of the wolves, not only on the entire ecosystem but on the "behaviors and life-history traits that confer resilience to environmental disturbances at various temporal and spatial scales . . . at different hierarchical levels" (Weaver et al. 1996, p. 964).

At the same time that native species have been preserved or restored, the tourist population in the parks has boomed. Since 1995 more than 100,000 visitors have swarmed over the park to observe the once-absent species. Hence the NPS still faces the perennial dilemma: developing management policies and practices that can realize its two elusive and often conflicting goals: preserving both wildlife and public access.

flooding, and other disturbances caused by human activities such as "road construction, visitor impact, and facility maintenance" are remediated (Majerus 2000, p. 77; National Park Service 2001). Such projects are undertaken in diverse environments: grassland prairies, hardwood forests, wetlands, streams, lakes, and marine systems such as coral reefs.

In the process of restoration, managers have to decide what to restore (to what state) and what to remove. Some critics have argued that NPS policies have to generate a more sophisticated idea of checks and balances among species to achieve stabilized populations and environments. They contend that management practices need to deal with the cases in which an isolated

species was restored only to have the ecosystem unpredictably collapse in new ways. Some argue that complexity theory may provide the best scientific basis for management policy: "Ecosystem restoration is invariably difficult and disturbed; . . . ecosystems often exhibit classic traits of complex systems . . . [and] responses to perturbations, including restoration efforts, can be highly nonlinear and lead to management surprises" (Gross 2004).

As Walker and Salt explain, with complexity theory comes another concept that dramatically changes goals and practices: "Resilience [is] the capacity of a system to absorb disturbance and still retain its basic formation and structure. . . . Resilience thinking presents an approach to managing natural resources that embraces human and natural systems as complex systems continually adapting through cycles of change" (2006, p. 10). They argue that, because current research usually simulates the future by extrapolating from the past (using conventional data about average conditions and incremental growth but setting aside major events), it provides an inadequate, even misleading, basis for sustainable resource management (Walker and Salt 2006, Peterson et al. 2003). There is a growing consensus that new modes of research and practice are needed (National Park Service 2000).

In the view of many policy analysts, studies and actions concerning complex, dynamic ecosystems need to respond to whole communities and events for longer periods and over wider areas (including regional variations and differences in elevation). Complexity studies often revise previous interpretations, such as the impact of pavement on stream communities: "Thresholds appear to exist, which may be catastrophic," but are not immediately apparent, because paved roads and parking lots "most likely do not cause degradation directly. Instead, [they] are a surrogate for a wide range of other variables, such as [altered water flow], increased stream temperature, enhanced erosion, habitat degradation, and so on" (Hilderbrand et al. 2001, p. 401). Sprawl reduces and fragments habitat and erodes existing buffer zones, in turn harming wildlife and plants (Trombulak 2000). The NPS has attempted to address these problems, temporarily closing areas to protect sensitive species, capping commercial development, improving wildlife corridors, and funding alternative modes of transportation, but traditional NPS management practices favoring development and some recreational activities continue to dominate park policy, perpetuating many of the threats to the ecological viability of national parks.

To be properly understood and operationalized the key concepts need to be more precisely defined and the environmental factors more thoroughly researched. For example, "habitat types are rated for development potential (e.g., camping areas and trails) on the basis of their resistance . . . (the ability of a habitat to tolerate human impacts, such as trampling, without undergoing major changes in community composition and structure) and their resilience (the ability of vegetation on a habitat to recover once it has been destroyed or severely disrupted)"; but there is no universal rule of relationship (NPS 2007, p. 4). Counterintuitively, sometimes resilience and resistance vary inversely to each other, as in the forest communities of Mount Rainier National Park or with the fauna's low resistance but high resiliency to nonnative fish introductions in Yosemite National Park lakes (Hilderbrand et al. 2001).

Complexity theory is pushing management practices away from the goal of restoration and toward resilience, resulting in a tension between these two newer approaches in both scientific research and management policy, even as the older differences between preservation and conservation persist. Although the various tasks facing the NPS do have some positive connections, they also pull in notably different directions—certainly the research and practices vary for each, thus multiplying management challenges to generate alternative scenarios that can offer satisfactory visitor experiences that will not damage the parks' ecological integrity.

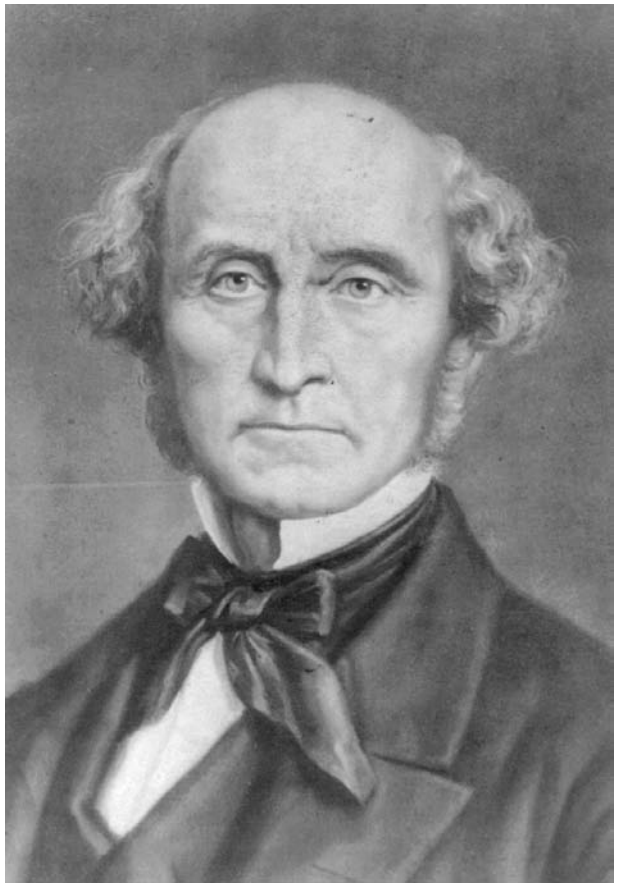
UTILITARIANISM

Utilitarianism is a popular ethical theory that has greatly influenced the development of law, economic theory, and many areas of public policy, including technological and environmental planning. Along with rights theory, it may be said to form the ethical basis of modern liberal democracy. This entry explores the possibility of basing environmental ethics on utilitarianism.

According to the most famous advocate of utilitarianism, John Stuart Mill, "The creed which accepts as the foundation of morals, Utility, or the Greatest Happiness Principle, holds that actions are right in proportion as they tend to promote happiness, wrong as they tend to produce the reverse of happiness. By happiness is intended pleasure, and the absence of pain; by unhappiness, pain, and the privation of pleasure" (2001 [1863], chap. 2).

Utilitarianism is the most widely accepted consequentialist theory. Consequentialism is the approach to ethics that considers that the rightness of an act is determined by the good achieved by that act for those affected, and by nothing else. Thus no act is inherently right or wrong, and the rightness or wrongness of an act is independent of such factors as the motive or character of the agent. The British jurist Jeremy Bentham (1789) is usually considered to be the founder of utilitarianism. He, Mill, and Henry Sidgwick (the third great classical utilitarian) believed that nothing is good in itself except happiness, which they identified with pleasure; they are thus known as hedonistic utilitarians, from the Greek word for pleasure. Everything else is valuable only instrumentally, as a means to producing pleasure. Thus utilitarians reject claims about the intrinsic value of environmental objects, species, and ecosystems, which are commonly believed to be central to environmental ethics.



John Stuart Mill, 1884. *Mill (1806–1873) is considered one of the greatest advocates of the ethical theory of utilitarianism. Mill attempted to defend the controversial theory against its critics. For example, his idea of "rule utilitarianism" qualified the belief that an act is good or bad based only on the amount of happiness it produces, by suggesting that an actor must consider whether an experience shows an action to produce positive consequences for it to be "right."* **THE LIBRARY OF CONGRESS.**

More recently, utility has been seen as the satisfaction of interests or preferences. Its proponents, notably the celebrated Australian philosopher Peter Singer (1993), regard it as a complete theory of ethics, that is, as capable of identifying the right thing to do in every conceivable situation.

SOME PROBLEMS

From the beginning, utilitarianism was controversial, for several reasons. First, many people were offended by the determinedly secular nature of the theory. It was not so much that it questioned the widely accepted idea that

morality was a function of divine command, but that it left no room for it or any other moral authority.

Second, since the amount of happiness is all that counts, ethically it does not matter whose happiness is affected. Insofar as institutions such as slavery and racist and sexist practices diminish the happiness of their victims (a reasonable thing to suppose), slavery and racism and sexism must be abolished. Thus utilitarianism is profoundly democratic and egalitarian, unlike the society of the day.

Third, conservative moralists were shocked by utilitarianism's implicit acceptance of behavior that was widely regarded as sinful. If pleasure is the only good, then any activity that gives pleasure must be good, and the more pleasure it gives, the better it is. The only moral or legal constraint that utilitarians accept is what Mill called the "Harm Principle": An act is wrong only if it causes avoidable nontrivial harm to others.

Fourth, if only pleasure is valuable in itself, then no source of pleasure is any better or worse than any other. As Bentham put it, "Quantity of pleasure being equal, pushpin [a children's game played with pins and a hat] is as good as poetry." Not only that, the pleasure of torture afforded a sadist is not bad in itself; torture is abominable only because it inflicts great pain on the sadist's victim. Worse still, the ideal life could be achieved by plugging people into a computer-generated reality-simulation system (as in the film *The Matrix*) or a pleasure machine (which would constantly stimulate the pleasure center of the brain).

Finally, Bentham's *act utilitarianism* seems to require that in each situation the agent should predict the consequences of an action and calculate the effects on happiness, but, it was argued, this would cripple decision making because it is not possible to make any such calculation.

Classical utilitarians ignored or dismissed the first three criticisms, which are less relevant at the beginning of the twenty-first century. Mill attempted to deal with the fourth by arguing that as well as degrees of *quantity* there are also degrees of *quality* of pleasure, and that those who have experienced both lower and higher pleasures will acknowledge that, say, philosophical speculation is superior to mud wrestling. Most commentators have considered this argument elitist and unconvincing. Logically, it appears to involve a contradiction, for pleasure per se is acknowledged to be the only good, but if some pleasures are qualitatively better than others, then some other standard of good appears to be implicitly invoked.

Mill addressed the fifth concern by proposing what has become known as *rule utilitarianism*: The right act is the one that follows a rule that experience has shown to have positive consequences. This gets around the problem that act utilitarianism requires the agent successfully to figure out the consequences of an action, thus requiring what is often referred to as moral luck. This solution, however, is bought at the expense of also requiring the agent to ignore special features of a situation. Experience suggests that adherence to the rule "Do not murder" has good consequences overall, but surely a utilitarian would accept that it would have been ethical to take out the Nazi high command in the early days of World War II, thus perhaps saving many lives and much misery. Rule utilitarianism, it is said, thus collapses into act utilitarianism.

ANIMALS AND THE ENVIRONMENT

Utilitarianism is usually associated with anthropocentrism, for instance in the work of William Baxter (1974), who famously claimed that penguins are valuable only because people happen to enjoy watching them walk about on rocks. However, Bentham argued that since pain and suffering are inherently bad, it is as wrong to inflict suffering on any sentient beings (animals capable of feeling pleasure or pain) as it is to inflict it on humans. This idea was largely ignored until it was taken up by Singer (1975). Singer argued that since it is wrong to discriminate on the grounds of sex (sexism) and race (racism), it is equally wrong to discriminate on the grounds of species membership (speciesism). Suffering is bad, regardless of the species of the suffering organism. Many of our uses of animals cause suffering, and hence Singer advocates that we should cease animal farming, research and testing involving animals, and hunting, fishing, and other recreational use of animals.

Singer's utilitarian position has both positive and negative implications for environmental protection. On the one hand, protection of the interests of animals often happens to coincide with protection of the environment. For instance, industrial agriculture, as exemplified by giant pig-raising operations, may be condemned because it causes the animals to suffer, has effects injurious to humans, and destroys natural values. On the other hand, the interests of individual animals may happen not to coincide with the protection of the environment. Advocates for animals and advocates for the environment can and do find themselves in opposition, as in the case of invasive introduced species. The eastern brush-tail possum, an Australian marsupial that was introduced to New Zealand in the mid-nineteenth century, has now reached plague proportions, with a population of up to 70 million in a country with an area of some 269,000 square kilometers, the size of Colorado. These possums destroy entire areas of native forest, and the only way to protect the forest is to kill millions of the animals, which, even with the most humane methods, inevitably involves

the suffering of many animals. In Singer's view, killing possums to protect forests cannot be justified, because trees, not being sentient, do not have interests.

A number of other problems may be briefly mentioned. First is the problem of predation in nature. This undoubtedly causes considerable suffering. For instance, African wild dogs in pursuit of their prey rip chunks of flesh out of the latter. Some chimpanzees reportedly captured a living bonobo, ripped the arm from the creature, and ate it while the bonobo screamed in agony. Domestic cats are not the only animals that play with their food while it is still alive. Killer whales toss around their favorite prey, seal pups, in a similar manner. We could reduce this suffering by painlessly eliminating predators, though of course we would then have to painlessly cull prey animals to keep them from overpopulating. Alternatively, we could painlessly kill grazing animals and feed them to predators. Indeed, utilitarianism would seem to require that we engage in these or similar activities.

Second, if we could increase total utility by transforming natural areas for the benefit of sentient beings, this might be permissible or even obligatory. Mark Sagoff (1984) argues that wilderness areas and national parks could be converted into game parks, where animals could be fed and receive veterinary care. This would also solve the predation problem.

Third, because utilitarianism focuses entirely on the interests of sentient individual organisms, it does not attach any value to species or ecosystems, except insofar as these can be reduced to the aggregated value of individuals. Thus, for a utilitarian, it is no worse to kill a member of a common species, such as a minke whale or a black bear, than to kill a member of an endangered species, such as a blue whale or a polar bear.

For these and other reasons, Sagoff (1984) has argued that animal liberation and environmental ethics are fundamentally incompatible. Similarly, utilitarianism cannot recognize value in naturally occurring inanimate objects, such as rock formations and caves, or in the built environment and works of art, except insofar as sentient beings happen to enjoy or prefer them. Even then, if something is valued only instrumentally, there is no reason why it cannot be substituted for by something providing equal or greater happiness. Thus if the Board of Trustees of Britain's National Gallery were dedicated utilitarians, they might decide secretly to sell one of the Gallery's more celebrated paintings—Leonardo da Vinci's *Madonna of the Rocks*, say—to a wealthy collector, replacing it with a perfect copy and using the proceeds to add to its collection.

PUBLIC POLICY

Utilitarianism has been very influential in shaping public policy, in particular through risk-cost-benefit analysis. Such analysis operates by identifying all the risk, costs, and benefits of a proposed action, assigning a dollar value to each, and summing them. One then accepts only proposals with a favorable risk-cost-benefit balance (or, in the case of competing proposals, the one with the most favorable balance). Risk-cost-benefit analysis is widely used to evaluate and rank projects such as dams and new highways, regulations of emissions and food additives, social programs such as free mammograms for women of varying ages, environmental actions such as endangered-species management plans, and so on. The best known philosophical advocate of risk-cost-benefit analysis is Kristin Schrader-Frechette (2001).

Bentham and Singer notwithstanding, risk-cost-benefit analysis is anthropocentric. This is because the methods used in such analysis—such as calculations based on the economic value of a life predicted to be saved by highway improvements or industrial health and safety standards, and willingness to pay—can be applied only to humans. This does not mean that endangered species, forests, and ecosystems are not valuable, but it does mean that their value effectively depends on human preferences.

Despite the theoretical defects that many philosophers see in utilitarianism, in practical terms it may turn out to be an effective basis for environmental policy. This is because its egalitarianism implies intergenerational equity, and therefore an obligation to future generations to leave the earth in at least as good a condition as we inherited it in. True, we do not have detailed knowledge of what will make future generations happy or what their preferences will be. However, we can be reasonably certain that these will not include exposure to a toxic environment, drowned coastlines, desertification, and mass species extinction. Since we do not wish these things on ourselves or our direct descendents, we should not wish them on future generations as a whole. This has profound implications for our consumerist lifestyles.

VEGANISM

SEE *Vegetarianism.*

VEGETARIANISM

In the United States, between 2 percent and 5 percent of the population "classify themselves as *vegetarians*; of that number perhaps five percent are strict vegans" (Koerner 2007). Although vegetarians renounce animal flesh, they consume animal fluids (milk and milk-derivates such as cheese, yogurt, butter, and ice cream) and/or eggs.

TYPES OF VEGETARIANISM

Thus the vegetarian tribe is divided into "lacto-ovo" vegetarians; "lacto-vegetarians," who eat dairy but no eggs; and "ovo-vegetarians," who eat eggs but no dairy. Some describing themselves as vegetarians eat fish ("pesco-vegetarians") or chicken ("pollo-vegetarians") or both ("pesco-pollo vegetarians").

There are many reasons for choosing a vegetarian diet: personal distaste for meat; a personal health, especially avoidance of saturated animal fats (a concern that is similar to the avoidance of saturated vegetable fats); or ethics. Although eating yogurt and/or egg whites, chicken and/or fish may be either preferable to or more healthful than eating beef or pork, from an ethical point of view, many strict vegetarians consider these eaters of animal products and/or animals such as fish and chickens to be carnivores whose claim to vegetarianism depends on equating "meat" with "red meat."

Vegetarianism itself has been criticized as ethically inadequate and inconsistent by a more radical group known as "vegans." The same ethical considerations that lead vegetarians to renounce meat-eating lead vegans to repudiate dairy, cheese, eggs, and honey; clothing items such as fur, leather, wool, and silk; and animal-tested products, including shampoo, cosmetics, and, drugs. Vegans believe that vegetarians only partially— and therefore inconsistently—break from a cruel, violent, and ecocidal system of food production. Milk cows and birds in battery cages—no less than veal calves—are confined for "lacto-ovo" consumption; and dairy and egg farms pollute the air and water.

The vegan pioneer Donald Watson (1910–2005) disparaged vegetarianism as "but a half-way house between flesh eating and a truly humane, civilised diet" (1944, p. 1).

As with vegetarianism, there are subcategories of vegans, including fruitarians, raw-food vegans, and freegans (who practice a minimal consumption, "dumpster-diving" lifestyle).

HISTORY OF VEGETARIANISM

Vegetarianism (which will be used here to include veganism) has a long and rich history that is as old as European and American cultures (see Berry 1998, Iacobbo and Iacobbo 2004, Spencer 2002, Walters and Portmess 1999 and 2001, Spencer 2004, Tristram 2007). As a health-promoting diet and an ethic rooted in compassion for all living beings (*ahimsa*), vegetarianism emerged more than 3,000 years ago as a philosophy and practice of the ancient South Asian religions: Hinduism, Jainism,

and Buddhism. The vegetarianism of the Greek philosopher Pythagoras (ca. 496–552 BCE) and animal-protectionist ethics spread throughout the ancient world and resurfaced in the seventeenth century (indeed, until the mid-nineteenth century, those who abstained from meat were called "Pythagoreans"). At the dawn of modernity, vegetarianism became increasingly influential throughout European society; radicals deployed its nonviolent and egalitarian outlook as a critical weapon against class rule and what they viewed as European barbarism, and prominent medical figures espoused it as ideal for health as well as morality (Stuart 2007).

VEGETARIANISM AND THE ENVIRONMENT

As the twentieth century unfolded, however, the influence of vegetarianism in the United States began to wane as the livestock industry became increasingly powerful and meat became an affordable staple for working-class families (Rifkin 1992). In a culture trained in the mindset that meat promotes strength and vegetarianism fosters weakness, a dramatic revival, growth, and broadening of vegetarianism began in 1971, with the publication of Francis Moore Lappé's book *Diet for a Small Planet*. In this and subsequent books (1977, 1998, 2003), Lappé described a corporate-controlled, industrialized, factory-farmed system of animal agriculture that is inefficient, wasteful, cruel, and destructive to every facet of the environment. The global livestock industry is, she argued, a vehicle of European-American imperialism that displaces millions of people from the land, destroys the livelihood of independent farmers, exacerbates poverty and inequality, and aggravates world hunger by diverting resources into producing feed rather than food. To this destructive, unethical, unjust, and unsustainable system of agriculture, Lappé contrasted a vegetarian mode of farming that produces maximum output with minimum input; that promotes health, rights, justice, and democracy; and that is environmentally sound and sustainable.

Lappé's work—along with Peter Singer's *Animal Liberation* (2001 [1975]), Singer's and Jim Mason's *Animal Factories* (1990 [1980]), and John Robbins's *Diet for a New America* (1998 [1987])—vividly portrays the human, animal, and environmental costs of the global meat culture, and this systemic outlook inspired the *vegetarian environmental* movement. This movement has fused issues of health, animal rights, social justice, world hunger, violence, globalization, and environmental concerns into a holistic theory unrivaled in depth, comprehensiveness, and awareness of the multidimensional crisis—health, moral, social, and environmental—facing humanity. Pursuing the lead of these theorists, a number of books have documented the central role of the livestock industry in the devastation of the social and natural worlds (see Mason and Singer 1990 [1980], Jacobs 1992, Rifkin 1992, Hill 1996, Robbins 2001, Lyman 2001, and Jacobson 2006).

By 2000 growing alarm over the human, animal, and environmental toll of the global meat, dairy, and egg industries percolated into scientific sectors, international government bodies, and—in a slow and hesitant way—some mainstream environmental groups such as the Sierra Club. Throughout 400 pages, a landmark 2006 United Nations report, "Livestock's Long Shadow," identified the livestock industry "as one of the top two or three most significant contributors to the most serious environmental problems, at every scale from local to global" (Steinfeld et. al. 2006). The data compiled in this report and countless thousands of corroborating studies leave little room for doubt that the livestock industry is a significant threat to the planet. The number of farmed animals (including fish) in the world has quadrupled in the last fifty years, putting a great strain on air, land, and water. Livestock uses 70 percent of all agricultural land and 30 percent of the earth's entire land surface (Steinfeld et. al. 2006). Crops grown for animal feed rather than human food consume 87 percent of the nation's fresh water, 90 percent of the soy crop, 80 percent of its corn, and 50 percent of all grains (Vesterby and Krupa 1997, Pimentel 1997). Compared to a vegetarian diet, meat production demands seven times more land (Leckie 2007), eight times more fossil fuel energy (Pimenel 1997), and ten times as many crops (Pimentel 1997; Robbins 1998 and 2001; Horrigan et. al. 2002). In this system of carnivorous consumption, 41 million tons of plant protein for cows returns 7 million tons of protein for humans (Pimentel 1997).

The livestock industry is a major cause of air pollution, soil erosion, desertification, water pollution, and acid rain. U.S. farms generate 130 times as much excrement as the nation's entire human population (Worldwatch Institute 1998). Factory farm effluvia—a slurry of manure, pesticides, antibiotics, hormones, and fertilizers—poison water supplies, decimate fish populations, degrade coral reefs, and have contributed to the emergence of more than 150 oxygen-starved "dead zones" in the oceans (Larsen 2004).

Moreover, 70 percent of the Amazon rain forest has been slashed and burned to graze cattle, and much of the remainder has been converted to fields for growing feed. In addition to being a principal cause of forest destruction and species extinction, the livestock industry is a significant factor in global climate change (Steinfeld et. al. 2006). Meat, dairy, and egg industries emit 18 percent of all carbon dioxide, 37 percent of the methane gas (a heat-trapping gas that is twenty times stronger than

carbon dioxide), and 65 percent of nitrous oxide gases (300 times more potent than carbon dioxide). The UN report concluded that the livestock industry produces more greenhouse gases than all the world's transportation systems (Steinfeld et al. 2006).

CONFLICTS BETWEEN VEGETARIANS AND ENVIRONMENTALISTS

These facts suggest the possible importance of vegetarianism and animal rights for the environmental movement and the urgency of finding common ground for a triangular alliance. Yet rather than uniting in the war to prevent massive species extinction, catastrophic ecological breakdown, and irreversible climate change, vegetarian and environmental camps remain divided by deep differences in philosophy and lifestyle (Motavalli 2002, Sapontzis 2004). Both camps break with anthropocentrism (the belief that only human beings deserve ethical consideration). Environmentalists advocate a new holistic "ecological consciousness" and "land ethic" but often neglect to advocate concern for individual sentient or conscious nonhuman beings. Whereas vegetarians now identify themselves as ipso facto environmentalists, certainly not all environmentalists embrace vegetarianism. At stake are competing views on animal rights, whether or not hunting and meat-eating are ethical and compatible with environmental values, and how to balance the values of individuals and ecosystems.

Ethical vegetarians shift the criterion for having rights from rationality to the far broader characteristics of consciousness or sentience. For Singer (1975) and Regan (1983) a necessary and sufficient condition of meriting moral consideration is the capacity to experience pleasure and pain, although both place a moral premium on advanced levels of consciousness and intelligence. If it is a fundamental moral axiom that it is wrong to cause injury, suffering, or death to another individual unless there is a compelling reason to do so, ethical vegetarians argue that—except in very rare cases such as self-defense—we never have adequate reason to harm animals. This is true not only for exploiting animals for "sport," "entertainment," and fur, but also for killing them for food, because humans cannot only live but flourish on a purely plant-based diet.

Many environmentalists opposed to industrial agriculture agree that factory farming is cruel and unethical but nonetheless assert that raising animals on small "family" farms without intensive confinement and manipulation is acceptable and good. Their justifications for raising animals for slaughter include the argument that such animals would not live at all if not bred for food, that they live a satisfying and worthy life on nonindustrial farms, and that killing and consuming other animals is a natural fact of life. This position turns on a "welfare" rather than "rights" position (see Regan 2004); it contends that the moral wrong lies in causing animals severe or unnecessary suffering (such as on factory farms) rather than in exploiting them for human purposes. On the welfare view, slaughtering animals for food is ethical if done "humanely"—a concept ethical vegetarians dismiss as Orwellian doublespeak, arguing that there is nothing humane about any kind of killing and taking a being's life against its will.

Whereas vegetarians view hunting as unnecessary and therefore unjustifiable killing, some environmentalists support hunting as a means of affirming our evolved human place in the biotic community. And some argue that hunting has positive ecological benefits by stabilizing "game" (prey) populations such as deer that would otherwise overpopulate (Lott 2007, Miniter 2007). Vegetarians respond that hunting in fact is the prime cause of deer overpopulation and argue that hunters' predilection for killing large, healthy males over weaker individuals and females disrupts ecological and evolutionary dynamics (Pickover 2005). Unlike the animal-rights ethic that defends the rights of sentient individuals as inviolable, environmental ethics is often holistic, valuing ecosystems and species populations over individuals. Whereas many environmentalists champion Aldo Leopold's "land ethic" (1970) as the most comprehensive embrace of the biotic community (Callicott 1993), the animal-rights philosopher Tom Regan (1983) has denounced it as "environmental fascism" that sacrifices the individual to the good of the whole. Other environmental ethicists have worked to reconcile these contrasting positions (Jamieson 1997).

Although, some environmentalists agree with vegetarians that factory farming is cruel, they also support obtaining meat from noncommercial wild sources through sustainable hunting and fishing, just as they might argue that small-scale, organic farming is humane and beneficial for the environment (Pollan 2007). Some land spaces—such as high-elevation, short-grass prairies and steppes—are unsuited for cultivation but can support cows and sheep; thus it might be argued that their highest use is meat production (*Science Daily* 2007). Rebutting vegetarians who boast the ecological virtues of a plant-based diet, environmentalists point out that a frugal organic farmer who consumes modest amounts of meat from his or her own livestock can leave a lighter "ecological footprint" than a vegetarian who drives a Hummer, is a frequent flyer, and buys produce from global rather than local sources.

Vegetarians counter that such environmentalists have not explained how their vision of a global network of small farms can satisfy the competitive need for profits

(Collin 2003), much less the surging demand for meat—especially in the world's most populous nations, China and India, and a burgeoning overall population projected to double to 12 billion by 2050 (Worldwatch Institute 1998, Steinfeld et. al. 2006, Freston 2007). Moreover, vegetarians argue, environmentalists' uncritical praise for organic farming is naïve and romantic because organic-farm products are satisfying high-end consumer demand and becoming just another form of mass production and large-scale killing of animals (Cienfuegos 2004, Davis 2007, Lucas 2007, PETA n.d.)

CONCLUSION

Vegetarianism is not a panacea for ever-worsening social and environmental crises, but it could be a significant part of major changes that people—especially those in the developed world—can make to avert ecological disaster. These changes include reducing consumption and shifting from industrial to local agriculture, from chemically intensive to genuinely organic farming, and from fossil-fuel to alternative energy. The shift from a meat-based to a vegetarian diet would not only benefit the environment but also save billions of animals from suffering in factory farms and slaughterhouses, keep small-scale farmers from being displaced from their land, and protect billions of people against the suffering of diseases of excess (in the developed world) and of lack (in the undeveloped world).

VIRTUE ETHICS

Virtue ethics is the branch of ethics that focuses on issues of character, excellence, and human flourishing. Some philosophers believe that virtue ethics is the correct approach to ethics in general; other philosophers see it as a necessary supplement to Kantian and utilitarian approaches that focus on the treatment of others (Swanton 2003). In recent years more philosophers have come to believe that virtue ethics is a valuable approach to environmental issues, although they have different reasons for that belief.

THE VALUE OF VIRTUE ETHICS

Some philosophers see standard attempts to prove the intrinsic value or moral considerability of nonhuman beings as inconclusive or failed. In embracing environmental virtue ethics they seek a more solid grounding for environmentalism, arguing that protecting the environment is necessary to promote human well-being or flourishing (Hursthouse 2007). Other philosophers find some intrinsic value claims convincing but believe that appeals to human flourishing provide further arguments for environmental protection. They attempt to supplement appeals to altruism with appeals to people's enlightened self-interest (O'Neill 1993). Yet other philosophers see an urgent need to specify the kinds of character traits that are needed to live environmentally sustainable lives. For this group environmental virtue ethics is the proper framework in which to discuss the creation of sustainable societies (Newton 2003).

INFLUENTIAL WORKS

Four books have been particularly influential in the development of environmental virtue ethics. John O'Neill's *Ecology, Policy, and Politics* (1993) was an early attempt to ground environmentalist claims in human flourishing. Rejecting accounts of human well-being based on subjective states or mere preference satisfaction, O'Neill developed an Aristotelian conception of well-being in terms of objective goods such as health,

friendship, knowledge, and the ability to develop people's natural capacities. Nature must be protected both to preserve the basic resources people need to live and to protect opportunities for people to develop their higher capabilities, such as scientific knowledge, artistic creation, and personal connection to the natural world. Like many environmental virtue ethicists, O'Neill attempted to rein in an overly economic view of the world. He questioned the wisdom of cost-benefit analysis, asserting that it provides "policy without [political] debate" (O'Neill 1993, p. 78), and argued that people must limit the power of markets through regulations that will uphold strong conceptions of the common good.

Louke van Wensveen's *Dirty Virtues* (2000) showed philosophers that popular and scholarly environmental discourse already contained discussions of virtue and character (an appendix lists 189 virtues and 174 vices mentioned in the previous three decades of environmental literature). She found this environmental virtue discourse to be productive and dynamic both in its discussion of new ecological virtues such as attunement and earthiness and in its reinterpretation of established virtues such as frugality and gratitude in an ecological context. Wensveen's analysis attempted to bring order to that discourse by developing criteria for what should count as genuine ecological virtue. Her procedure was a mixture of the old and the new; to Aristotelian criteria focused on the social sustainability of various human qualities she added the newer criteria of psychological and ecological sustainability.

Philip Cafaro's *Thoreau's Living Ethics* (2004) argues that Henry David Thoreau's life and writings provide a coherent and inspiring environmental virtue ethic that links attentiveness to nature to human excellence and flourishing. Thoreau thus points the way toward a comprehensive, life-affirming environmental ethics in which the traditional "thou shalt nots" of environmentalism are complemented by a description of positive ideals of character. By recognizing nature's value, people enrich their lives. By restraining physical consumption, people are more likely to lead healthy and enjoyable lives and allow future generations to do the same thing. By devoting themselves to pursuits higher than moneymaking, they act in their enlightened self-interest, with great benefits for the many other species with which they share the earth.

Cafaro also argued that Thoreau's evolutionary experimentalism—in which human nature and hence human virtue may change over time, and our particular virtue judgments are always assumed fallible and hence must be tested in life—provides a more plausible foundation for environmental virtue ethics than do the unchanging human nature and timeless objectivity to which many contemporary virtue ethicists subscribe (following Aristotle).

Ronald Sandler's *Character and Environment* (2007) is a theoretically rigorous defense of environmental virtue ethics that contains detailed positions on issues such as the proper criteria for judging right action and whether virtue ethics approaches are necessarily anthropocentric. It provides a naturalistic account of the proper characterization of virtue that is grounded in a broad sense of human flourishing but leaves open the possibility that virtues may be virtues because they recognize or promote other goods, such as the intrinsic value of nonhuman beings. Surveying the many accounts of environmental virtue, Sandler developed a typology that does justice to the many ways in which character traits may be environmental virtues. His typology includes virtues of sustainability (temperance and frugality), communion with nature (attentiveness and wonder) and respect for nature (care, compassion, and ecological sensitivity), stewardship (honesty and diligence), and environmental activism (cooperativeness, perseverance).

CRITICISMS AND DEFENSES

One criticism of environmental virtue ethics is that its account of environmental virtues is undertheorized and ad hoc. In light of Wensveen's list of 189 environmental virtues, it is not clear how to make sense of such a plenitude. Environmentalists can identify their favorite virtues and exhort like-minded people to cultivate them, but what imposes discipline on discussions of particular virtues? What allows philosophers to put those accounts together into a cohesive whole, whether in an account of general human virtue or in terms of particular lives well lived? Because environmental virtue ethicists see the need for new virtues and the reinterpretation of old ones, they cannot rely on accepted accounts of virtue from general ethical theory; in addition, general virtue theorists disagree about what makes a virtue a virtue.

Environmental virtue ethicists have tried to answer this criticism by developing specific criteria for what makes a virtue a virtue. Wensveen (2000) argued that genuine virtues must contribute to ecological sustainability because environmental degradation undermines the ability to live and pursue virtue. Most proponents of environmental virtue ethics attempt to ground their general accounts of virtue in a substantive account of human flourishing; the virtues are those qualities which constitute or contribute to that flourishing. Their accounts of this flourishing differ, however, and more work needs to be done to generate an account of human flourishing that also upholds diversity and possibility. Moving beyond exhortation, the hope is to converge on the personal

qualities that make people good people who are likely to live well and protect nature.

Reflecting a criticism of virtue ethics in general, some argue that environmental virtue ethics is not sufficiently action-guiding. They claim that virtue ethics tells people what sort of character to cultivate but cannot do what an ethical philosophy must do: tell people how to act in particular situations. One response to this criticism is that it is not the job of ethics to provide rules and that the failure of deontology and utilitarianism to supply compelling rules for dealing with hard ethical cases shows that such a goal is impossible to reach (Hursthouse 2007). Cultivating the virtues, especially practical wisdom, will put people in the best position to make good moral decisions in hard cases and act on them. Another response is to develop "v-rules" that specify how people with the requisite virtues would respond to particular ethical challenges (Sandler 2007). Thus, it is possible to say something about how a temperate person might respond to the blandishments of modern commercial society or how someone with the virtues of attentiveness and ecological sensitivity might decide which forms of recreation are acceptable in natural areas.

Perhaps the strongest answer to the objection that virtue ethics is not sufficiently action-guiding is to remove the focus from virtue and place it on the notion of flourishing. Peter Wenz (2005) argued that there is evidence that the excesses of modern consumerism harm human health, distract people from more enjoyable activities, and impede human flourishing in other ways; thus, there are good reasons to rein them in. Cafaro argues that the pursuits of the naturalist lead to greater health, happiness, knowledge, and wisdom; thus, there are good reasons to explore and protect nature (Cafaro 2001). Once the definition of human flourishing is broadened to include the flourishing of all living things, people have even stronger guidance in limiting environmentally destructive practices and protecting nature.

The most persistent criticism of environmental virtue ethics states that it is anthropocentric because it stresses the contribution of environmental protection to people's well-being and focuses excessively on human character. This focus on people leads to the same human selfishness that created contemporary environmental problems. Holmes Rolston makes this criticism in "Environmental Virtue Ethics: Half the Truth but Dangerous as a Whole" (Sandler and Cafaro 2005): If people protect nature solely to help themselves live better lives, they are not acting from correct motives. Even worse, they will sacrifice nature if it is in their own selfish interests to do so.

In response, a few environmental virtue ethicists embrace anthropocentrism. Yes we are anthropocentric, they concede, but any reasonable ethics necessarily focuses on human needs and wants. They claim that those considerations provide powerful reasons for environmental protection that will actually motivate people to protect nature.

Most environmental virtue ethicists, however, make a place in their philosophies for the intrinsic value or moral considerability of nonhuman nature. Some say that they ground ethics in human and nonhuman flourishing; the virtues are those qualities which further both (Cafaro 2004). Others say that people can best get from the "is" of nature's intrinsic value to the "ought" that compels people to protect that value, by bringing in issues of human flourishing (O'Neill 1993). Still others argue that a pluralistic account of moral considerability in which different kinds of entities are considered from the perspective of the appropriate virtues is more plausible and accurate than monistic accounts of intrinsic value (Sandler 2007). All these approaches emphasize that human flourishing and the flourishing of nature are necessarily intertwined; the same actions and personal characteristics allow people to be good neighbors and citizens and good environmentalists.

APPLICATIONS

Ethical approaches should not just be judged by how well proponents respond to criticisms, or defend the weakest links in their arguments. Perhaps more important is how well they help philosophers explore new areas and illuminate old ones. Some of the best work in environmental virtue ethics has focused on giving detailed "thick" accounts of particular environmental virtues. This includes Geoffrey Frasz on "Benevolence as an Environmental Virtue" (Sandler and Cafaro 2005) and on friendship ("What Is Environmental Virtue Ethics That We Should Be Mindful of It?" Cafaro 2001); and Louke van Wensveen on temperance ("Attunement: An Ecological Spin on the Virtue of Temperance," Cafaro 2001) and on the Seven Deadly Sins (Wensveen 2000). It includes Thomas Hill, Jr. on humility ("Ideals of Human Excellence and Preserving Natural Environments," Sandler and Cafaro 2005), Philip Cafaro on wisdom ("The Naturalist's Virtues," Cafaro 2001), and Rosalind Hursthouse (2007) on wonder. This work can deepen people's understanding of environmentalism and provide a better sense of what it would mean to be benevolent, temperate, properly humble, and wise people.

Lisa Newton's textbook *Ethics and Sustainability* (2003) provides another example of applied philosophy built on a base of environmental virtue ethics. After giving an account of environmental virtue grounded in Aristotle and Aldo Leopold, among others, Newton works out the kinds of technological, social, and economic policies needed to create sustainable, flourishing

societies. She also discusses the sorts of lives people will have to lead to make those societies work. The book culminates in an account of simplicity as the virtue most in demand at this point in societal evolution. Newton's work shows that environmental virtue ethics can help specify the sorts of lives people need to live to do justice to nature and live good lives within it. It thus helps people think comprehensively and practically about how to make sustainable, just, generous human societies a reality.

VON HUMBOLDT, ALEXANDER
1769–1859

Alexander von Humboldt, who was a polymath, an explorer, and one of the founders of modern geography, was born in Berlin on September 14, 1769, the year in which James Cook sailed the *Endeavour,* and died in that city on May 6, 1859, the year of publication of Charles Darwin's *Origin of Species*. A Prussian, he received training in biology, geology, and political economy at Göttingen and Frankfurt. After a period in the Prussian civil service, he sailed with Aimé Bonpland for South America in 1799 and travelled across the llanos, the Andes, and Mexico. On that journey (Von Humboldt and Bonpland 1881 [1852]) he determined heights and positions by using a barometer and a chronometer, developed ideas about the geography of plants (Von Humboldt and Bonpland 1977 [1805]), and made an innovative attempt to relate the political and economic conditions of New Spain to its physical geography and to natural and human resources (Von Humboldt 1988 [1811]). Later in his life he visited the Urals and the Altai.

In *Cosmos,* which was published between 1845 and 1862, von Humboldt stressed relationships between phenomena and attempted to explain the links between phenomena in different climatic zones. He believed that the earth is an integrated organic whole. He also had a vision of man as a part of nature:

> The general picture of nature which I have endeavoured to delineate would be incomplete if I did not venture to trace a few of the most marked features of the human race, considered with reference to physical gradations—to the geographical distribution of contemporaneous types, to the influence exercised upon man by the forces of nature and the reciprocal, although weaker, action which he in his turn exercises on these natural forces. Dependant, although in a lesser degree than plants and animals, on the soil, and on the meteorological processes of the atmosphere with which he is surrounded, escaping more readily from the control of natural forces, by activity of his mind, and the advance of intellectual cultivation, no less than, by his wonderful capacity of adapting himself to all climates—man everywhere becomes most essentially associated with terrestrial life. (Von Humboldt 1850–1859, vol. 1, pp. 360–361)

Von Humboldt, as D. N. Livingstone pointed out, "constantly sought for the universal behind the particular, for underlying patterns and unities that tied nature together in such a beautiful, functioning system" (1992, p. 135).

Cosmos included a survey of the current theories about the structure of the universe, a sketch of the historical progress of science and of geographical exploration and discovery, an exposition of the content of the disparate sciences, and a discussion of nature poetry, aesthetics, and landscape painting.

Von Humboldt was influenced by many other thinkers—Kant, Rousseau, J. G. Forster, Agassiz, Ritter,

Goethe, von Liebig, and Schiller, among others—and had a strong influence on scientists such as Darwin and Alfred Russel Wallace. His holistic views were fundamental for the development of geography (Mathewson 2006), but he also demonstrated the importance of detailed and reliable measurements, established many of the basic tenets of plant geography, and was a founder of global and regional climatology, a term he probably coined (Dickinson 1969). In his essay on Mexico he demonstrated that he was a regionalist, illustrating the interrelated conditions that give its character to an area. This was a striking contrast to the encyclopedic compilations of many previous geographers, topographers, and explorers.

Von Humboldt's work spawned what has been termed Humboldtian science:

> To signify a scientific style that conducted observations with the latest instruments, corrected measurements for errors, and linked these to mathematical laws; constructed maps of isolines connecting points with the same average values; identified large, even global, units of investigation; and used nature rather than the laboratory as a site of investigation. The term as applied to nineteenth century science has since acquired other connotations, including connecting different types of large-scale phenomena, demonstrating their independencies, seeking a universal science of nature, and using large-scale international organisational structures to execute local readings as part of a global effort. (Olesko 2003, p. 384)

Von Humboldt was the last truly universal man. His funeral was one of the most imposing state funerals in the history of Berlin, and his name is given to over a thousand places in the world.

W

WAR

War, armed conflict with the intent to kill and destroy, has been pursued between groups, societies, and nations throughout human history. Such activity, with all of its associated devastation, continues into the twenty-first century, despite a widespread international attempt in 1928 to renounce for all time at least war between nations. Its brutality also continues into the 2000s, despite a lengthy series of intergovernmental attempts—especially in 1899, 1907, 1929, 1949, and 1977—at constraining the more vicious and pernicious aspects of international war. Its frequency notwithstanding, few comparable attempts have been made over the years to constrain internal (noninternational, civil, insurgency) war.

The environment—that is, the world at large, encompassing the atmosphere, lithosphere, hydrosphere, and biosphere, upon which all humankind depends for its well-being and very survival—is undergoing ever more serious deterioration by the civil sector of society. It is thus particularly troubling that damage to the environment is also an inevitable consequence of warfare. Such wartime damage can be incidental or intentional. It occurs within the theater of military operations and beyond it. Moreover, environmental damage occurs not only during wartime, but also as a result of preparing for war and as a result of some postwar recovery efforts. Perversely, it must be noted that war can also lead to a number of beneficial environmental outcomes.

This entry covers both the environmental consequences of war and the environmental causes of war. It further examines the ethical development and implications of wartime environmental protection, whether as an anthropocentric extension of social justice or perhaps in part as an ecocentric concern in its own right, and briefly also religious norms related to war and the environment.

INCIDENTAL ENVIRONMENTAL IMPACT ON THE BATTLEFIELD

Incidental environmental damage to the battlefield is an inevitable outcome of war. Such incidental damage can result from the profligate use of high-explosive munitions against enemy personnel and matériel. Another common source of incidental damage is the use of tanks and other heavy off-road vehicles. These environmental insults are especially disruptive of local habitats and the wildlife depending on them. Battle-related actions can also result in less persistent local soil, water, and air pollution.

Conversely, a theater of military operations often precludes the usual peacetime exploitation (often overexploitation) of a rural area by hunting, logging, fishing, grazing, or farming. This permits population recoveries of the local flora and fauna, the most notable case being in the demilitarized zone between North and South Korea.

INTENTIONAL ENVIRONMENTAL IMPACT ON THE BATTLEFIELD

Intentional environmental impact in a theater of military operations can take various forms, including especially forest clearing, oil releases, area denial (e.g., land mines), and on occasion even the use of chemical, biological, or nuclear weapons.

Intentional forest destruction is carried out during wartime primarily to deny the enemy cover and concealment.

Agent Orange. *The aftermath of a herbicidal attack with agent orange by the United States during the Vietnam conflict of 1961–1975 against a lush mangrove forest for the immediate purpose of denying the enemy cover and concealment is depicted here. It was U.S. actions of this sort that awoke a widespread revulsion against massive military disruption of the environment and, more generally, contributed significantly to ushering in the newly emerging environmental ethic in the world at large.* **PHOTO TAKEN BY ARTHUR H. WESTING IN GIA DINH PROVINCE, SOUTH VIETNAM, AUGUST 15, 1970.**

This has been accomplished by spraying the area with herbicides (including the notorious agent orange), by using heavy tractors equipped with special forest clearing blades (so-called Rome plows), by saturation bombing, and, at propitious times and places, by setting self-propagating wild fires. Depending upon the site and severity of attack, recovery from any such assault can take years to decades. Indeed, it was U.S. forces' sustained use of all of these tactics during the Vietnam War of 1961–1975 that alerted the world to the levels of environmental destruction that can be associated with war.

Intentional oil releases are possible in certain theaters of military operation for purposes of enemy harassment or area denial as well as for punitive purposes. This can be variously accomplished by sabotaging oil wells; by breaching pipelines, collection centers, and storage tanks; and by attacking oil tankers—in each instance with or without igniting the escaping oil. The most spectacular example of such action was by Iraqi forces during the Persian Gulf War of 1991. Much rural surface area, groundwater, and Persian Gulf seawater and shoreline became severely contaminated with liquid oil, and the torched escaping oil heavily contaminated the regional atmosphere with dense smoke (soot plus combustion gases), with adverse health effects on wildlife, livestock, and humans.

Area denial with land mines (both antivehicle and antipersonnel) or with remotely delivered scatterable mines and cluster-bomb submunitions is a common military practice for purposes of hindering, slowing down, or channeling the movements of enemy forces, as well as of sapping their morale. Such area denial is a pernicious military tactic because the area remains perilous for years, even decades, after its battlefield use, thereby hindering subsequent forestry, herding, farming, or other development. Postwar rehabilitation efforts are a daunting task that is technically difficult, time-consuming, expensive, exceedingly dangerous, often environmentally disruptive,

and never fully successful. On the other side of the ledger, after a war, previously overgrazed or otherwise overexploited minefields can undergo considerable habitat recovery, both floral and faunal. For example, such recovery occurred following World War II in the heavily mined rangelands in Libya and elsewhere in North Africa. A somewhat comparable maritime example was the recovery during World War II of the drastically depleted North Sea fishery, where a combination of naval actions and sea mines made it long impossible for fishing boats to enter.

Chemical, biological, and nuclear weapons are weapons of mass destruction that lead to intentional environmental disruption. Antipersonnel chemical agents were used extensively (and openly) by both Allied and Axis forces during World War I, but not before or since on such a grand scale. Antiplant chemical agents are covered above. Biological agents have been used essentially only once in modern times, on a relatively minor scale (and secretly) by Japanese forces during World War II. Nuclear weapons have also been used only once, by U.S. forces during World War II over Hiroshima and Nagasaki. The potential for long-term environmental disruption by any of these so-called unconventional weapons is truly enormous.

INTENTIONAL RELEASE OF DANGEROUS FORCES

Under certain conditions, it is possible for a belligerent to manipulate some component of the natural or built environment so as to result in the release of pent-up energy, so-called dangerous forces. This sort of hostile action—often referred to as *environmental warfare*—becomes especially tempting when the hostile manipulation involves a relatively modest expenditure of effort (i.e., of triggering energy) leading to the release of a substantially greater amount of directed destructive energy. Environmental modifications of particular concern here involve the pent-up forces contained in fresh-water impoundments, nuclear power stations, certain industrial facilities, and, to a lesser extent, forest and other wild lands.

Water impoundments formed by the many hundreds of major dams that have been constructed throughout the world contain enormous quantities of water. Many such dams could be breached with relative ease either through direct attack or sabotage, and the release of the impounded reservoir would cause immense levels of death and destruction. Hostile actions of this nature have been spectacularly successful in various wars, for example, the Sino-Japanese War of 1937–1945, World War II, and the Korean War of 1950–1952.

Nuclear facilities have become essentially permanent additions to the human environment. Almost two hundred clusters of nuclear power stations, plus a number of additional nuclear reprocessing plants and nuclear waste repositories, are distributed in over thirty nations. These sites are amenable to direct attack or sabotage, with the possible attendant release into the surrounding area, measurable in thousands to millions of hectares, of iodine-131, cesium-137, strontium-90, and other radioactive elements. What has been learned from the aftermath of U.S., British, and French nuclear testing on several Pacific islands in the 1940s and 1950s and from the Soviet Chernobyl accident of April 1986 is that the contaminated zone essentially defies rehabilitation. Thus, both the Pacific islands and the region surrounding Chernobyl remain uninhabitable despite massive attempts at decontamination.

Certain industrial facilities, if attacked, can release a cloud of toxic chemicals spreading over hundreds of hectares and proving variously detrimental to plants, animals, and humans. Providing ample evidence of this source of wartime danger are the horrifying releases into the air in Seveso, Italy, of dioxin from a factory explosion in July 1976, and similarly in Bhopal, India, of methyl isocyanate in December 1984, as well as the catastrophic explosion in Mexico of a huge liquefied-natural-gas storage facility in Mexico City in November 1984.

Wild fires can be started and become self-propagating over large areas under special habitat and weather conditions in forest, grassland (prairie), and tundra ecosystems. Initiated by napalm or other incendiary munitions (and sometimes preconditioned by herbicidal attack), such fires have the potential to cause extensive damage to wildlife, livestock, and humans, and under certain site conditions lead to severe soil erosion and loss of nutrients (so-called *nutrient dumping*). Grassland recovery is measurable in years, forest recovery in decades, and tundra recovery in many, many decades.

WARTIME ENVIRONMENTAL IMPACT BEYOND THE BATTLEFIELD

Environmental disruptions caused by military activities during wartime but beyond the theater of military operations can be more or less severe, and are generally excused as part and parcel of the necessities of war. These disruptions derive from the construction of base camps, fortifications, and lines of communication, and also often from armed forces' heavy exploitation of timber, food, and feed. Preemptive self-inflicted scorched-earth tactics in anticipation of an enemy advance can be utterly devastating, as exemplified during World War II by such actions carried out by Soviet forces in western Russia and also by German forces in northern Norway. Finally, persons displaced from a war zone and concentrated into refugee camps can cause severe environmental damage to

the surrounding flora and fauna, as seen during and following a number of early-twenty-first-century internal wars in Africa.

PREWAR AND POSTWAR ENVIRONMENTAL IMPACTS

Whether at peace or war, most nations continually maintain armed forces. Such armed forces are kept for various reasons, especially (1) to deter an attack from outside the country's borders or, failing that, to defend against such an attack; (2) to threaten an attack on another nation in support of some foreign-policy objective or, failing that, to carry out such an attack; and (3) to deter or quell internal uprisings. In fact, a majority of the wars since the 1980s have fallen into the third of these categories.

There are manifold environmental ramifications of nations' maintaining armed forces for any or all of the three reasons mentioned above. Environmental disruption can result from any of the following:

- Establishing military fortifications and other military facilities
- Equipping and supplying armed forces with weapons and other military needs
- Disposing of those items once they become obsolete or otherwise unwanted
- Training armed forces and testing the weapons they use
- Routine deployment of armed forces nationally, in other nations, and in areas beyond any national jurisdiction.

Among benefits, the often large exclusion zones surrounding nuclear and other sensitive military facilities, especially in the industrialized nations, often become important de facto nature reserves and wildlife sanctuaries. Moreover, during peacetime, a number of nations (India being a prime example) employ a portion of their armed forces to police their nature reserves, controlling wildlife and timber poachers and other harmful trespassers.

ENVIRONMENTAL CAUSES OF WAR

Over the past nine millennia or more, war has been widely recognized as a successful societal strategy for acquiring needed or desired land and other natural resources. So it should come as no surprise that environmental scarcities, especially in the nonindustrialized world, lead to human violence—and indeed already have in such diverse places as Haiti, Pakistan, the Philippines, and South Africa.

The growing numbers of people, especially in the nonindustrialized world—together with their ever expanding demands for such increasingly scarce natural resources as cropland, forestland, freshwater supplies, and ocean fish—have increasingly significant social consequences. In many such impoverished nations, the social consequences are certain to cause further internal unrest, population movements, and even occasional insurgencies. And in many instances the adversities of climate change exacerbate this intractable problem of growing environmental scarcities. Indeed, among military planners, climate change is already identified as a threat multiplier, perhaps even promoting terrorism, within many of the more fragile and unstable regions of the world.

SOCIETAL CONSTRAINTS ON ENVIRONMENTAL DAMAGE IN WARFARE

Social values and environmental values have been of philosophical and religious concern to both Western and non-Western cultures since ancient times. But only since the late twentieth century have social and environmental concerns begun to intersect and become mutually reinforcing, for example, in the emerging ethical norms related to the notion of sustainable development. Modern tangible manifestations first of social values and subsequently of environmental values did not arise until the after World War II. And (as indicated earlier) the widespread emergence of recognizable ethical concerns over wartime environmental damage had to await the depredations of the Vietnam War of 1961–1975.

It was the human atrocities associated with World War II that fostered and crystallized worldwide ethical concerns and gave rise to meaningful expression of those concerns. Such concerns were first tangibly expressed through passage of the 1948 Convention on the Prevention and Punishment of the Crime of Genocide (UN Treaty Series No. 1021), soon followed by adoption of the 1948 Universal Declaration of Human Rights (United Nations General Assembly, resolution 217 A [III]). Those two early postwar manifestos would not have received the overwhelming governmental support they each enjoyed had they not been expressing the newly burgeoning cultural norms (ethical values) they were codifying.

Neither of these two instruments recognized environmental concerns. In fact, widely shared environmental norms did not begin to surface for another two decades or so, and gained momentum only over a period of some further years. Thus, expressions of emerging, widely shared core environmental values did not surface until adoption of the 1972 Stockholm Declaration on the Human Environment (UN document No. A/conf.48/14/rev.1), to be followed a decade later by the almost universal adoption of the 1982 World Charter for Nature (UN resolution No. 37/7), and that in turn by the 1992

Rio Declaration on Environment and Development (UN document No. A/conf.151/5/rev.1). Unsurprisingly, all three of these instruments were based essentially on anthropocentric concerns. But interestingly, all three variously proclaimed the need to avoid wartime damage to the environment.

Ethical concerns related to war—aimed not at its abolition but rather at civilizing its conduct—began to be seriously expressed as early as 1899 and 1907 via the then almost universal adoption of the core international treaties comprising what came to be known as the law of war, although later often referred to as international humanitarian law, together with the related and overlapping body of international arms control law. Largely through the tireless efforts of the International Committee of the Red Cross, the law of war was updated and enlarged at various times since, especially in 1929, 1949, and 1977. Most of the law of war concerns international war, and again not surprisingly, it derives almost entirely from anthropocentric concerns.

Three major bodies of international law have the potential for expressing (revealing) widely held cultural norms or ethical values relating to the environmental impact of war. Two of these—international environmental law and international human rights law—fail to do so. The third, the law of war, does contain a number of provisions that incidentally offer environmental benefit, among them the clearly expressed nearly universal anathema against the use of chemical and biological weapons and the expanding revulsion against the use of antipersonnel land mines. (Curiously, as of 2008, there had not clearly surfaced a similar sentiment that would renounce the use of nuclear weapons, doubtlessly the most socially and environmentally destructive weapon of war.) Of comparable environmental benefit, substantial support based on social concerns has been demonstrated for constraining attacks upon certain targets, including agricultural areas, dams, and nuclear electrical generating facilities, the latter two because they would release the dangerous forces noted earlier. Similarly, it has long been widely accepted that an occupying power is enjoined from the nonusufructuary exploitation of forests and agricultural works in enemy territory.

The most interesting expression of a cultural norm concerning war and the environment was the addition to the law of war of the 1977 Protocol on International Armed Conflicts (UN Treaty Series No. 17512, articles 35.3 and 55.1), prohibiting means of warfare that may be expected to cause widespread, long-term, and severe damage to the natural environment. The sentiment expressed there was an unveiled international rebuke of U.S. actions during the Vietnam War and seemed to derive in part from ecocentric concerns.

Religious norms have had hardly any influence on societies' cultural norms, whether military or environmental. Indeed, the influence seems to flow largely in the other direction. By way of example, the Christian religion of Western Civilization and the Buddhist religion of Central and East Asian Civilizations are strongly pacifist in their origins and essence. Indeed, one of the central tenets of Christianity is, "Blessed are the peacemakers; for they shall be called the sons of God" (Matthew 5:9). And the very first of the five precepts of Buddhism is the rule to abstain from taking life, including animal life. Nonetheless, the associated societies have long records of military activity unsurpassed in magnitude and ferocity. And secular proenvironmental norms are now being ever more widely embraced despite the antienvironmental tenets found in both Eastern and Western (Genesis 1:28) teachings to be fruitful and fill the earth, to subdue it, and to have dominion over all other living things on earth.

WARREN, KAREN J.
1947–

Karen J. Warren was born on Long Island, New York, on September 10, 1947. She received a bachelor of arts degree from the University of Minnesota in 1970. The University of Massachusetts at Amherst awarded her a master's degree in 1974 and a doctorate in 1978 for one of the earliest dissertations on environmental ethics. She was the second Ecofeminist Scholar-in-Residence at Murdoch University, Australia, in 1995; held the Women's Chair in Humanistic Studies at Marquette University in 2004; and as of 2008 is a professor of philosophy at Macalester College in St. Paul, Minnesota, where she has taught since 1985. An international expert in environmental ethics, feminism, and peace studies, she is known for her work in connecting those fields. Committed to philosophy as democratic practice, she has taught prison inmates and developed award-winning environmental curricula for schoolchildren.

Warren's publications and philosophical practices demonstrate the potential of ecofeminism to restructure human relationships with other humans and with nonhuman others; create life-affirming, intentional interspecies communities; and rethink philosophy as a forum for public thinking and action. Her editorial work in introducing ecofeminism to North American audiences has influenced feminist scholars worldwide. She shares the social ecologist's insight that environmental issues are connected with social justice, in contrast to approaches, such as wilderness-oriented ethics, that tend to overlook the relationship between environmental degradation and human suffering. Warren edited the section "Ecofeminism and Social Justice" in *Environmental Philosophy: From Animal Rights to Radical Ecology* (2005). That collection, widely used as a university text, appeared in a fourth edition. Her *Gendering the History of Western Philosophy* (2008), a more directly feminist project, is a fifteen-chapter book that pairs male and female philosophers through the centuries, with introductions by Warren and commentaries by other feminists.

Warren's best-known work as of 2008 is "The Power and Promise of Ecological Feminism," first printed in *Environmental Ethics* in 1990, widely reprinted, translated into five languages, and revised in 2005. She argues that there are important connections between the domination of women and the exploitation of nature; that is, women and nature are objects of the same oppressive patriarchal conceptual framework. She defines key features of an oppressive conceptual framework: oppositional value dualisms, hierarchical thinking, and a logic of domination that assumes that alleged superiority justifies the subordination of alleged inferiors. Patriarchy structures a man-woman dualism hierarchically to establish male privilege and uses that privilege to validate women's oppression.

Man-nature dualism is inseparable historically from gender oppression, and so feminism and environmental ethics are linked. However, ecofeminism unifies through solidarity, not sameness, and so it can celebrate difference and oppose all forms of domination. Warren articulates the boundary conditions of ecofeminism: It (1) does not promote social domination but is (2) contextualist, (3) pluralistic, and (4) inclusive; (5) it is theory in process that (6) takes objectivity as a false promise and opts instead for critical analysis of which biases are better than others, (7) makes a place for traditionally neglected values (e.g., care and friendship), moral emotions, and emotional intelligence, and (8) reconceives ethics and the meaning of being human.

A distinctive feature of ecofeminism is attitude. Using her experience in mountain climbing, Warren advocates caring over conquering to show the limitations of the conquering and the potential for success, growth, and development of caring. She defends first-person narration as ecofeminist methodology: It gives voice to felt sensitivity and experience, expresses values overlooked in mainstream ethics, develops a stance not imposed but emergent from diverse individual voices, and suggests what might count as an ethical solution in a particular situation.

Warren's first single-authored book is *Ecofeminist Philosophy: A Western Perspective on What It Is and Why It Matters* (2000), a philosophical work for nonspecialists that integrates previous research with original material to define ecofeminism, explore its potential, and defend it against typical criticisms. Key metaphors are a quilt and a fruit bowl. A quilt's borders define its limits, but different quilters can contribute to its design. Similarly, theory has necessary conditions, but diverse thinkers can add specifics. Ecofeminism is thus inclusive theory in process and always is revisable, like a quilt whose individual patches can be replaced or repaired without abandoning the larger design. The fruit bowl is used to explain

ecofeminist ethics. Fruit is selected from the bowl to fit specific situations, for example, bananas when one is making banana bread, but none is inherently better. Similarly, no ethical principle has intrinsic superiority, though monist exclusionary principles that disallow emotional intelligence are prohibited. Methodologically, Warren revisits her arguments for taking empirical data seriously in a significant and original challenge to the traditional pursuit of universal truth through abstract, detached philosophical reasoning.

Warren's feminism has been criticized for political naiveté. She has claimed, for instance, that feminism can be defined as "the movement to end all forms of oppression," though a completely non-oppressive context is impossible. Nonetheless, Warren draws attention to women's lived experience of disproportionate harm in consequence of environmental degradation and shows that ecofeminism neither favors a privileged class of white Western women nor reinscribes essentialism. Rather, ecofeminism is a conceptually mature possibility of novel ethical relations between humans and between humans and nonhuman others.

WASTE MANAGEMENT

Waste can be defined as unwanted material, or as material that the holder discards or intends to discard. The distinction between wastes and resources depends on one's willingness and technical ability to reuse artifacts and materials. One person's waste can be another person's resources.

Industrial mass manufacture and modern packaging have led to a dramatic and still ongoing increase in the volume and variety of the waste produced by households, industrial concerns, and other workplaces. Such waste includes various categories of hazardous waste, such as anthropotoxic, ecotoxic, infectious, and radioactive waste.

Waste management is often discussed in terms of a *waste hierarchy* that lists the major treatment methods in order of decreasing priority. One common variant of the hierarchy has six steps:

1. *Prevent* the creation of future waste.
2. *Minimize* the volumes and the harmful properties of future waste.
3. *Reuse* the artifact.
4. *Recycle* the material in the artifact.
5. Incinerate the waste, and use the heat to *recover energy*.
6. *Dispose* of the waste.

The waste hierarchy is not always applicable to hazardous waste. In the Third World, recycling often takes the form of scavenging. The waste pickers are poor, marginalized people, including children, with no or inadequate protection against toxic or infectious waste. When recycling involves serious occupational risks, it may be wrong to prefer recycling to final disposal.

WASTE DISASTERS

Public discussions on waste disposal have largely focused on a few major environmental disasters and scandals, among them the following: In 1978 a local resident in Love Canal, close to Niagara Falls, New York, suspected that her children's health problems were related to leakage of chemical waste in the neighborhood. It emerged that the entire settlement was built on top of an old landfill containing more than 20,000 tons of chemical waste. Leakage of several toxic chemicals was confirmed, a federal emergency was declared, and eventually more than 800 families were evacuated and relocated. The Love Canal events stimulated the creation of the Superfund Act, adopted by the U.S. Congress in 1980, which provides funds for cleanup of contaminated areas.

In 1982 the U.S. Environmental Protection Agency closed down Times Beach, a town in Missouri. More than

Computer Waste, Guiyu, China. *A worker with a hammer smashes a junk computer to pieces to obtain the usable parts. Environmental groups have contacted Guiyu, a cluster of five villages southwest of Shanghai, with a cautionary tale for poor countries that accept high-tech waste, drawing attention to the toxic chemicals released when the locals melt the computer parts to extract precious metals such as gold and platinum.* **AP IMAGES.**

2,000 inhabitants were relocated, and all buildings were demolished. The agency had discovered potentially dangerous levels of dioxin, originating in waste oil that had been sprayed on streets and parking lots to control dust. In hindsight, it has been questioned whether the actual risks were severe enough to justify the drastic measures taken by the Environmental Protection Agency at Times Beach. However, it should be remembered that these decisions were based on more uncertain information about the health effects of dioxins than what was later available.

In 1986 the cargo ship *Khian Sea* sailed with around 14,000 tons of toxic incinerator ash from Philadelphia to the Bahamas. After being denied permission to unload there, the ship sailed around the world for sixteen months, changing its name twice, in a vain search for a country where it could get rid of its freight. Eventually, most of the waste was dumped into the ocean.

In the early 2000s the exportation of e-waste, waste from electronic appliances, from industrial to developing countries became a major issue. One of the best-known examples is the Guiyu area in China's Guangdong Province, which receives large quantities of electronic waste, in particular from the United States. Here and in numerous places in the Third World, unprotected workers disassemble computers by hand and sort the material for recycling.

GEOGRAPHICAL JUSTICE

A large part of the ethical discussion of waste management has focused on questions of geographical justice. Empirical evidence shows that the disadvantages associated with waste treatment and disposal fall mostly on underprivileged persons, who benefit little or none from the products that gave rise to the waste. Internationally, rich countries figure as the major exporters of waste, and poor countries and regions as the major importers. Internally in the United States, studies have shown that communities receiving hazardous wastes from other communities are economically underprivileged and have high proportions of ethnic minorities. This phenomenon has been called *environmental racism.*

Companies and public authorities searching for places to site waste-treatment plants and dumps have often found it difficult to convince local populations and their elected representatives. Local resistance to waste facilities has been named the NIMBY phenomenon (not in my backyard). The allegation is that locals obstruct the creation of a facility that would contribute to the common good. The NIMBY phenomenon has sometimes been interpreted as an expression of irrational risk aversion of an uneducated public.

The NIMBY attitude is not necessarily irrational or unethical. Individuals need not be wrong in refusing to accept disadvantages for themselves (waste dumps in their neighborhood) to achieve advantages for others (removal of waste from other areas). In other contexts, taking a risk to help others is often considered supererogatory, virtuous beyond the call of duty. When members of a local community are required to accept a risk exposure not imposed on others, they may legitimately ask why they and not others are selected for this sacrifice.

Attempts are sometimes made to solve siting problems by compensation, for example, by offering monetary or other advantages to homeowners in exchange for accepting a waste facility in the vicinity. Such compensation is often controversial. On the one hand, it may be claimed that those who (have to) accept a disadvantage of this kind should not do it for free. On the other hand, the practice can be interpreted as buying people off to make them accept dangers that they would not otherwise accept. The line between fair compensation and corruptive practices is not easy to draw. One important factor in this demarcation is the magnitude of the dangers compensated for. It is much more controversial to buy acceptance of a large risk than to buy acceptance of a small risk.

The exportation of waste has often been criticized. In particular, protests have been waged against the transportation of waste from industrialized to developing countries. The Basel Convention, which entered into

force in 1992, prohibits such exportation for final disposal, but allows it for recycling. A 1995 amendment, the Basel Ban Amendment, prohibits all exports of hazardous waste from industrialized to developing countries. This amendment was as of 2008 not in force (because of too few ratifications). The European Union has nevertheless adopted it and made it binding on all its member states. Other industrial nations, including the United States, oppose it and do not implement it.

INTERGENERATIONAL JUSTICE

Leakage from toxic waste can make neighborhoods uninhabitable and waters unpotable for many generations. Therefore, waste management involves issues of intergenerational justice.

Discussions of intergenerational justice in waste management have focused mostly on spent nuclear fuel. This deadly material remains lethal for tens of thousands of years. (Owing to radioactive decay, some dangerous isotopes disappear in relatively short periods, but isotopes with long half-lives remain for tens of thousands of years or longer.) The waste-management solution preferred by governments and the nuclear industry is deep geological disposal, which involves placing the waste in final, sealed repositories in stable geological formations usually around 500 to 1,000 meters below ground. Then humans and the environment are protected by a combination of highly durable containers and a geological environment so selected that any leakage will move very slowly. Critics claim that there is nevertheless insufficient guarantee against future groundwater contamination, which would threaten the health of coming generations.

The planned Yucca Mountain Repository in Nevada was as of 2008 projected to receive spent fuel from American nuclear plants from 2017. However, crucial regulatory, legal, and political decisions remained to be made. The project is based on extensive scientific and engineering studies showing that the risks associated with the repository are very small. However, some of these studies have been subject to controversy. The repository has also met with strong local opposition, and Native Americans have claimed that it infringes on their holy lands.

A major alternative solution to sealed repositories is monitored retrievable storage. Such storage would give future generations control over the waste. They would have to monitor it, unless they chose at some stage to transfer it to permanent storage. This solution has the comparative advantage of not binding future generations to possible imperfections in our current technology, the disadvantage of leaving a problem for them to solve, and also the disadvantage of keeping nuclear material easily retrievable for conversion into weapons-grade material for nuclear warheads. Hence, the choice of principles for managing nuclear waste involves complex ethical issues concerning what risks and what responsibilities we can and should hand over to coming generations.

PRODUCER RESPONSIBILITY

According to the polluter-pays principle, the polluting party should pay for the damage done to the environment. According to the principle of extended producer responsibility, the manufacturer's responsibility covers the entire life cycle of the product and the waste it gives rise to. This means that the producer has to plan and pay for recycling or other measures needed for responsible waste management. Deposit systems for bottles exemplify application of extended producer responsibility.

Extended producer responsibility, combined with the principles for waste management enshrined in the waste hierarchy, lead to far-reaching demands on producers. The highest levels of the waste hierarchy, prevention and minimization, are often in conflict with producers' interests in expanding business and maximizing sales of their products. Waste management is an area with many potential conflicts between business interests and the environment. Hence, it is also an area in great need of ethical discussion.

WATER

Earth is the blue planet, the water planet. Nearly three-quarters of the earth's surface is covered by water, mostly in oceans. Water gives rhythm and pulse to life. Moving through all living entities—our bodies, the land, the atmosphere, and our cultures—water connects, transports, and transforms.

That water is life has become a truism. But the fact is, the earth has a biosphere because it has a hydrosphere. Owing to its vital place in life, water has turned into a culture and language unto itself. There are countless sayings, imageries, and references to water. Many fluid phenomena—the fluidity of globalization, liquid capital, and streams of consciousness—have been tied to a water metaphor as flexible and mysterious as the molecule itself.

Ubiquitous as water may be, freshwater is a finite resource. Most water is saline; only 2.5 percent is fresh. More than two-thirds of all freshwater is locked in ice at the polar regions or in glaciers in distant mountainous areas, a little less than one-third is groundwater, and only 0.3 percent is surface water (rivers, lakes, and reservoirs).

Water is in constant motion all around us: in the atmosphere, on the earth's surface, and in its depths. It constantly alternates among three physical states: gas, liquid, and solid. Evaporated or transpired by plants, it rises up into the sky and falls to the earth again as rain or snow, where it finds its way back underground or into lakes, rivers, and oceans. The hydrological cycle then repeats itself. The amount of water on the earth is basically the same as it was 4 billion years ago, and it has been recycled ever since.

Water has the rare characteristic of being less dense as a solid than as a liquid. Consequently, ice floats. Without this crucial property, rivers and lakes in the higher latitudes would freeze from the bottom up, with only a melted puddle on top during the warm season. Water freezing and thawing is capable of breaking granite. Water seeps into cracks, expands and contracts, and with a slow steady force turns even the hardest stone into soil. Water also has a great capacity to absorb heat. Ocean currents play a large role in the earth's climate patterns, tempering climates in many coastal regions.

Water has a pervasive presence in every aspect of our daily lives. We drink it, bathe in it, and cook with it. Our food consists in considerable part of water. Spinach equals milk in being approximately 90 percent water; tomatoes 95 percent; and beef, seemingly so solid, 60 percent. We ourselves are composed mainly of water (two-thirds of our body weight), and we need about 2 to 3 liters a day to live. We can survive for a month without food, but only 5 to 7 days without water.

CULTURAL, RELIGIOUS, AND PHILOSOPHICAL LEGACIES OF WATER

Because of its vital role, water has always been intrinsically linked with culture. Virtually all civilizations developed around water: Tribes settled on the shores or banks of water bodies, and cities originated at the confluence of rivers. The first complex societies—societies as diverse as ancient China, India, Mesopotamia, Mexico, and Peru—were irrigation-based cultures with ingenious water-management structures, a centralized government, and extensive division of labor. The Romans were also skilled water engineers, building innumerable aqueducts for public water supply using various techniques of hydraulic architecture. Karl A. Wittfogel called them "hydraulic civilizations."

Through the ages, poetry, music, and religion have found a deep well of meaning in water and crosscurrents of meaning in a vast pool of reflections and emotions about water. Narcissus epitomized the rise of self-consciousness in his self-reflection on the surface of a pond. The cosmogonic power of water has been a major theme in many ancient accounts of origin. These poetic sources are precursors of the later scientifically developed theory of evolution, which confirmed that all life forms emerged phylogenetically and ontogenetically out of water.

In the *Enuma Elish*, the Mesopotamian-Babylonian creation epic of the third millennium B.C.E., the primordial waters are Apsu (meaning sweet-water "ocean," "deep abyss," or "outermost limit") and Tiamat (meaning "primeval waters," the one who "is too deep to fathom," the salt sea). Apsu and Tiamat are brought under control by gods (their offspring) to create the topography of earth and sky.

We see a similar structure in Genesis (compiled between approximately 1400 and 400 B.C.E.), the first book of the Old Testament. Clearly influenced by the *Enuma Elish*, its opening lines read, "In the beginning . . . darkness was upon the face of the deep; and the Spirit of God was moving over the face of the waters." The Hebrew word *Tehom*, meaning "deep [waters]," is etymologically related to *Tiamat*.

The Greek philosopher Thales of Miletus (c. 624–545 B.C.E.) considered water an originating and guiding principle (*archē*). There were similarities between Thales' philosophy and the ancient legends and myths, specifically the ones about Oceanus and his consort Tethys, who was both sister and wife of Oceanus and whose name has etymological ties to *Tiamat* and *Tehom*. Thales, however, broke with the traditional belief that the gods organized, shaped, and controlled the cosmos. Hence, for Aristotle, Thales was no longer a theologian, like the old poets, but the founder of natural philosophy, investigating the basic

principles of matter and theoretically moving toward a scientific treatment of natural phenomena.

Nearly a century later Heraclitus of Ephesus (c. 535–475 B.C.E.) found in the *movement* of water a guiding principle: "All things flow" (*Panta rhei*), and "One cannot step in the same river twice." Heraclitus, less concerned with finding unity in a material substrate, was a protophenomenologist, interested in the everyday experience of change: "Cold things warm up, the hot cools off, wet becomes dry, dry becomes wet." Heraclitus emphasized that opposites are equally capable of transforming and are permanently changing into one another—a constant flux governed by Logos, the first proposed law of nature in Western natural philosophy.

Similarly, the ancient Chinese text *Tao Te Ching* of Lao Tzu (sixth century B.C.E.) masterfully invokes the paradoxical powers of water: "Nothing in the world is as soft and yielding as water. Yet for dissolving the hard and inflexible, nothing can surpass it" (chap. 78). Water is powerful yet unassuming. Thus, "The supreme good is like water, which nourishes all things without trying to. It is content with the low places that people disdain. Thus it is like the Tao" (chap. 8). Water is exemplary for leadership in that as the highest power, it accepts the lowest place: "All streams flow to the sea because it is lower than they are. Humility gives it its power. . . . If you want to govern the people, you must place yourself below them. If you want to lead the people, you must learn how to follow them" (chap. 66).

Humility is also an important value in the Bible, often thematically combined with God's punishment of human hubris. The Flood is the most famous biblical water story, the ultimate expression of God's wrath. In the deluge, only Noah, his family, and the pairs of animals on his arc are saved. At that point the imagery moves from water as an agent of punishment to water as a cleansing agent, and there appears a rainbow, the symbol of God's covenant with his people, in which humans have the first right to the goods of his creation, but in return have to take care of the earth.

In Islam there is a similar ethic of stewardship: The blessings of water come with human responsibility for its proper use. All life forms, including plants and animals, should be supported according to their needs. The Koran explicitly states that the supply of water is fixed and should not be wasted. Water is architecturally revered most majestically and aesthetically in Alhambra, the fourteenth-century Muslim palace in southern Spain. From every room can be heard fountains with running water, which have a cooling effect. A stately pool, a symbol of power, reflects the building at its entrance.

The revered place of water appears in a wide variety of religious rituals and cultural practices, such as baptism and pilgrimages to sacred wells. The spring in the Grotto of Lourdes (in southern France), where Mary is said to have appeared to fourteen-year-old Saint Bernadette in 1858, soon became the world's leading pilgrimage site even though the holy water was "not exactly inviting," in the words of Emile Zola. The healing powers attributed to the water that wells up from the grotto attracts 5 million pilgrims a year from all over the world. People drink it, bathe in it, and buy plastic Mary figures filled with it. It is probably no coincidence that the Virgin Mary is portrayed as dressed in blue and white, water's colors, which contributes to Mary's image as the life-giving mother of Christ.

Water is a recurrent theme in literature. The French philosopher of science Gaston Bachelard (1884–1962), in *Water and Dreams*, saw water as a prime source for the imagination. He connected water's symbolic power to purify to its material power to clean and rinse and ultimately rejuvenate, as expressed metaphorically in the notion of the Fountain of Youth. According to the philosopher of technology Ivan Illich (1926–2002), this symbolic force of water has been compromised in modern life. For him, water in its engineered form reduced to H_2O hardly speaks to the imagination. Chemically purified and piped, water as a living element has been separated from our daily consciousness.

Water has always played an important role in the arts. Famous Dutch seventeenth-century landscape painting was born out of seascapes (a fact that resonates with the trajectories of early myths of origin). In sculpture, architecture, multimedia, and landscape art, contemporary artists such as Tadao Ando, William Pye, Roni Horn, Basia Irland, and Herbert Dreiseitl—to name just a few—all explore innovative ways with water, implicitly articulating the larger cultural interest in the element. William Shakespeare in *King Henry VIII* invokes water to convey the fleeting nature of virtue: "Men's evil manners live in brass; their virtues we write in water." Virtues are seen as ephemeral, as fluid, like water, while vices are like brass—here to last.

LEGACIES OF MODERNITY

The late nineteenth century and entire twentieth century saw a massive harnessing of water through extensive damming, draining, and diverting. Progress was measured, in part, in terms of the control, mainly through large-scale water-engineering projects. The leading water-development paradigm was one of economic growth driven by a utilitarian ethic. Any drop reaching the ocean instead of being used for agriculture, industry, or hydropower was considered a waste. From the late nineteenth century, an unprecedented boom of large-scale water projects ensued, followed a century later by a rising tide

Delivering Water under the Hot Desert Sun. *A group of Kenyan Oromos (an ethnic division of Ethiopia) travel through the desert to deliver water to Oromo Liberation Front (OLF) troops in 2006. The walk takes a full day, and they each carry at least 30 kilos of water on their back. Although three-quarters of the earth is covered with water, freshwater for drinking is a finite resource, and in many places such as Africa this scarcity is already displaying its effects. In addition, the quality of water too is declining, as toxins and other industrial waste pollute the supply.* **GETTY IMAGES.**

of problems varying from silting reservoirs to oxygen-depleted dead zones and heightened coastal vulnerability because the massive destruction of wetlands has taken away a buffer zone of natural barriers against hurricanes and cyclones.

In this whole process, water consumption has skyrocketed. A growing world population has led to greater needs for food and industrial production and an explosive rate of urbanization. Consequentially, the amount of water available for humans and other species keeps declining. About 70 percent of global water use goes to agriculture, and 22 percent to industry, while domestic and municipal use accounts for a mere 8 percent. The high percentage of water for agriculture is partially due to low water-use efficiency, further aggravated by archaic water laws and irrigation subsidies, which take away incentives to use water more efficiently. Moreover, meeting the Millennium Development Goal on hunger entails doubling food production by 2050, which means more irrigation.

An important closeted use of water has been exposed through John Anthony Allan's notion of *virtual water*, also referred to as embedded water, embodied water, hidden water, or water footprint. It is the water used in the production of a good or service. Allan called it "virtual" because once, for example, an irrigated crop of wheat is grown, the water used to grow it is no longer actually contained, molecule for molecule, in the wheat. It thus takes 2,000 liters of water to make a cotton T-shirt, 2,400 liters for a hamburger, and 400,000 liters for a car.

Also declining is the quality of water, polluted by heavy metals and other industrial toxic wastes, by microbial pathogens and excessive nutrients from untreated sewage and intensive use of agricultural fertilizers. Whereas once dilution was the solution to pollution, such practice has reached its saturation point. According to Jeremy Jackson, a leading oceanographer, the oceans are at a tipping point; that is, environmental damage any moment now could pass an unknown point of no return, at which the ocean's

resilience, its capacity to bounce back into a healthy state, is exhausted. With the bulk of the human population (60% of people worldwide) already living along or near coasts, and with ongoing growth (by 2025 coastal populations are expected to reach 6 billion people), coastal and ocean ecosystems are on a fast track to devastation. Worldwide fish stocks are already in steep decline. Sea-level rise caused by climate warming will have tremendous consequences for millions of people.

Some foresee that, owing to population growth, increasing environmental degradation, and global climate change, by the end of the twenty-first century water will be the single dominant factor in world natural-resource politics. Freshwater is a crucial limiting factor for health, food security, economic growth, biodiversity, and environmental sustainability. The total volume of water on the earth may be sufficient to accommodate our needs on a sustainable basis, but, as has been argued by various U.N. agencies, nongovernmental organizations, and other water organizations, creating sustainable conditions requires a serious political commitment. Much water is wasted, polluted, drained, or misallocated.

Uneven distribution of water is one of the most poignant problems. People in developing countries use on average 10 liters of water per person each day, while in Europe the average is 135 liters, and in the United States, 570 liters. Roughly 1.2 billion people, one-fifth of the world's population in 2008, lack access to potable water. And approximately 2.4 billion people, two-fifths of the population, do not have adequate sanitation services. Water-related diseases cause 80 percent of all illnesses and deaths in the developing world. In addition, many African and Asian women and girls spend hours a day walking to get water, an activity that severely reduces their participation in other productive activities, including education.

Increasingly, water scarcity is seen in terms of a crisis of management. Moreover, the water crisis is linked to a development crisis and an energy crisis. Its solution is a matter not only of engineering know-how, which we have in abundance, but also of political will. To build a secure and sustainable future for a huge and still growing world population, considerations of equity may become more crucial than concerns of economic efficiency and invisible-hand allocation of water by the free market. Emerging is a paradigm shift from large-scale, utilitarian, supply-side management of water to an environmentally sound and equitably just allocation of water.

TOWARD AN INTEGRATED SENSE OF WATER

Since the early 1990s an approach known as integrated water-resource management has gained ground. Integrated management explicitly advocates a holistic approach, managing water at the basin or watershed level and integrating land and water; upstream and downstream; surface water, groundwater, and coastal water. A more transparent and participatory style of management replaces sector-by-sector and top-down management. In multiple-stakeholder processes, hydrological and engineering expertise is complemented with ecological concerns, while also tending to urban, agricultural, industrial, and recreational interests. Water connects them all and calls for a water ethics that integrates local problems of water quality and quantity in transregional and global political contexts.

Peter Gleick, a leading water-policy expert and director of the Pacific Institute, speaks of a "soft path" that complements the twentieth-century large-scale centralized infrastructure with "lower cost community-scale systems, decentralized and open decision-making, water markets and equitable pricing, application of efficient technology, and environmental protection." Conservation is one of the main strategies to keep more water in the system. Sandra Postel, another well-known water expert and director of the Global Water Policy Project, calls conservation our "last oasis."

A variety of changes in technology and legal structures have been explored, and these, together with an increased awareness of the need for water conservation and proper economic incentives, have resulted in more efficient water use. There has been a resurgence of traditional technologies, such as rainwater harvesting (the systematic capturing of rainfall or floodwater) and small-scale run-of-river irrigation systems. Such technologies are often more cost-effective and less disruptive to the social and environmental functioning of local communities. Various new water-conservation techniques have been implemented, such as highly efficient time-released drip irrigation systems. Two commonly mentioned contemporary technologies to increase available freshwater are desalination and water reuse. Desalination, however, is energy- and capital-intensive and generates vast amounts of wastewater, twice as saline as seawater. Oil-rich and water-poor countries like Saudi Arabia get most of their water through desalination and account for almost one-fourth of the world's desalinized water. Reuse is more widespread. Countries as different as Japan and Dubai make extensive use of grey water (nonsewage wash water used in the home) for landscape irrigation. Water gets polluted, but it can be cleaned, one of the great assets of water. More and more municipalities consider treated sewage water as an option for providing water.

New laws also have beneficial effects. Two excellent examples of such legal change are the implementation in the United States in the 1970s of the Clean Water Act and the Safe Drinking Water Act, which require industries to

clean up their wastewater. These laws made many industries more water-efficient, because it turned out to be cheaper not to produce the waste than to clean it up. As of 2008 it takes 5 to 6 tons of water to make a ton of steel, for example, whereas it used to take 200 tons.

Water privatization may be seen as another tool of efficiency. While most water-provision and sanitation systems are publicly owned and operated (globally, 90%), there is a tendency toward private-sector participation in these very basic municipal services. The proponents of privatization argue that it will improve the quality of service, reduce costs, and mobilize more financial investment and technical expertise. Opponents counter that privatization leads to poorer service and higher costs because competitive water markets are hard to arrange (owing to the nature of the service) and profits are valued over service. There have been intense political campaigns against privatization in Ghana (2003), Uruguay (2004), and, most famously, Bolivia, the site of the Cochabamba Water Riots of 2000. Some countries (e.g., the Netherlands, 2004) have enacted laws banning the privatization of public water supply.

Progressive water pricing is often mentioned as a regulative approach to conservation that encourages more responsible water use by means of an incentive. In such a system, a daily minimum amount of water is sold at an affordable price. As a customer's use increases, the price per unit also increases in a stepwise manner. This is the reverse of the usual approach of markets, in which high-use customers are charged less per unit than low-use customers. From a progressive-water-pricing perspective, agricultural water stands out as seriously underpriced.

In reaction to conventional antiprogressive water pricing and water privatization, a growing movement has emerged for implementing a U.N.-mandated human right to water, which would entitle all people to sufficient, safe, accessible, and affordable water. This right would trump contractual rights to water and property rights in water.

There are awareness campaigns about the value of water, water-education programs in schools and municipalities, venues to involve various stakeholders in water management and in citizen-based projects of wetland, riparian, and coastal restoration. Environmental restoration requires amending our relation to the land as much as restoring the land itself. Watershed restoration involves a broad spectrum of human-water-land relations spanning ethics, aesthetics, politics, and participatory activities and encompasses modes of knowledge as diverse as science, engineering, elders' experiences, storytelling, and children's imagination. Celebrations such as World Water Day and local river festivals provide playful ways to reconnect with water and to enhance motivation to learn about water quality and quantity.

Almost 2,500 years later, we are relearning the old Daoist and Heraclitean aquatic wisdom: In water's humility lies its power; in its constant flow lies its stability. All living entities—including the earth's biosphere—depend on the ongoing cycling of water. On a planetary level, we are all downstream. Our future and the future of the planet are written in water.

WATERSHEDS

Watersheds are land areas in which all the ground and surface water flows to the same place, creating a systemic link among land, water, and everything that lives on the land. Shaped by biological and geological forces, watersheds give rise to a variety of ethical issues involving political boundaries, population growth, urbanization, externalities, income inequality, changing knowledge, and future generations.

Shaped by nature rather than by political forces, watersheds often cross political boundaries. For instance, rivers often have been perceived as convenient boundary markers. Consequently, because watersheds are situated on both sides of rivers, there is often no single political entity to provide oversight of watershed matters. Rivers that provide water to more than one nation-state include the Danube, Jordan, Ganges, Indus, Nile, and Colorado rivers. Within nations watersheds cross a multitude of provincial, prefectural, and state and local boundaries. Effective management requires the cooperation of diverse political entities. Because the power of a jurisdiction does not always correspond to its demand for water, there is a need for cooperation and ethical behavior in caring for and distributing water.

ALLOCATION

The press of population growth on the resources of some watersheds has been so great that ethical issues have been created that involve not only allocation of water among humans but also the fulfillment of the water needs of a watershed's land, plants, and animals. Although water allocation has been a topic of global conferences since the 1970s, the conferences have been slow to recognize the ethical issues implied in allocation decisions within watersheds. Before the 1990s some conferences treated water solely as a marketable commodity without any discussion of ethical issues. However, subsequently the ethical issues of providing a basic amount of water as a human right and meeting the needs of the entire ecosystem of a watershed were acknowledged. In 2002 the United Nations Committee on Economic, Social, and Cultural Rights called for the combined basic physical and cultural and social needs for water to be met without regard to costs. The Earth and Johannesburg summits of 1992 and 2002 gave explicit recognition to the need of the entire ecosystem for water.

URBANIZATION AND EXTERNALITIES

The growing urbanization of human populations creates an ethical challenge when cities draw on water from outside their boundaries, often from rural watersheds. In essence cities are drawing on nature's services in distant watersheds. This raises two ethical issues. The first is the ethical obligation to leave enough water to meet the water needs of the supplying watershed. The second is compensation of rural areas for the use of the natural services. For instance, New York, Beijing, and Los Angeles draw on water far from their boundaries. Los Angeles and Beijing have caused depletion of distant water supplies, and New York used eminent domain to flood villages to create space for its reservoirs. The procedure used in New York, though it created conflict, was fairly open and included compensation for the actions taken by the city; in contrast, the Los Angeles story is famous for deception and chicanery.

The interconnected and open nature of watersheds has created a class of ethical issues through what economists call *externalities*: the impact of decisions on third parties not responsible for those decisions. One example stems from the generally open access to watershed waters and land. Because watercourses are ubiquitous and impossible to patrol, the decisions of individuals and corporations to refrain from polluting them depend on an ethical determination rather than fear of a legal penalty. There is even more open access to the air that affects watersheds. Fuels selected by power companies can create acid rain in distant watersheds.

Private ownership of property provides another example. For instance, much U.S. forest land is privately owned, but little is under a management plan to maintain diversity in the types and ages of trees needed for watershed protection. Economic incentives favor cutting down the biggest trees, which often offer the most protection. Although state governments may be able to make legal arguments in favor of taking over the privately held forest land in a watershed by eminent domain to protect the water supply, the local communities would be likely to consider this approach unethical. Because of such community pressures, New York City signed an agreement with communities in its distant rural watershed not to take land by eminent domain and instead seek land through voluntary sales and has created incentives to induce private forest land owners to put their land under conservation management.

Inequality of income among watershed residents and users creates two types of ethical questions. The first

concerns the way society provides and finances watershed services; the second concerns the way wealthy persons and companies observe laws. Often high-cost water protection and distribution infrastructure systems, even if built by governments, bring water to the middle and upper classes, leaving lower-income persons with relatively more expensive water sources or without safe water. Even when water is provided universally within a watershed, the taxes used to finance the infrastructure are often regressive, resulting in lower-income persons paying a higher percent on their incomes than higher-income persons. Also, although taxes and fines may be set to encourage conservation and prevent pollution, persons with a high income and wealthy companies can afford to pay them. Additionally, companies can pass the cost of fines to the public in the form of higher prices, which can also, depending on the consumption pattern of the product, affect lower-income groups more than upper-income groups.

Because knowledge, weather, and technology are always changing, there is an ongoing ethical need to devise new laws as the situation demands and redress the harms that have been done. For instance, the water in most river basin watersheds is insufficient to meet current needs, and global climate change is exacerbating the problem. Existing water agreements may be unrealistic. For instance, the Colorado River Basin agreement was based on atypical, historically high water flows. Around the world many others rivers face demands that exceed their potential supply, including the Yangtze in China, the Nile in Egypt, and the Litani and Jordan rivers in the Levant. However, many international water treaties do not address allocation issues. Further, serious pollution of water supplies may have occurred as a result of the use of technologies whose toxicity was not well understood. An example is the polluting of the Hudson River in New York with cancer-inducing polychlorinated biphenyls (PCBs) by the General Electric Corporation. The responsibility to remediate situations such as these faces companies and governments around the world.

Future generations depend on the ethical choices made by the contemporary generation to provide them with adequate water supplies. Many contend that free markets cannot ensure such protection because people tend to value near-term benefits and market criteria cannot capture the holistic nature and needs of watersheds. They argue that preserving watershed services for future generations requires decision making that honors the need for safety and precaution, based on an understanding of how the web of relationships in a watershed works.

POSSIBLE SOLUTIONS

Political boundaries and urbanization problems can be addressed in watershed treaties and collaborations. Treaties on the sharing of water across boundaries, although hammered out over time, can represent a set of rules rather than an ongoing process. Collaboration, however, is a process in which the diverse stakeholders in a watershed make a commitment to work with one another to evolve workable compromises to protect and share the water in a watershed. Collaborations that involve distant partners or technological complexities are likely to require regulations to protect water.

Collaboration Collaboration tools are being developed to help stakeholders understand the implications of choices before they make them. For instance, a model system for water allocation that was developed for Middle Eastern countries not only allows consideration of diverse options but allows variation in the input of social values as well as financial costs. Both treaties and collaborations can address inequalities of need through compensation programs that are in essence payments for the ecosystem services of a watershed. There has been growing recognition that residents of rural areas should be compensated for the provision of nature's services from their land to cities.

Water as a Human Right The need to prioritize watershed services has generated a variety of approaches to providing basic water allocation as a human right. It is argued that this right should become embodied in international law to help build protection of basic water rights into water treaties and collaborations. Within single watersheds with poor communities ladders of use have been recommended. The ladder gives first priority to enhancing open sources, then public taps, then communal sources, and finally individual taps. Another technique is the use of virtual water: the importation of water-intensive crops such as wheat from water-rich to water-poor watersheds to allow the water-poor areas to retain their water for basic needs. For example, Egypt saves water by importing wheat. However, the dependence on virtual water would create an ethical demand for the continued provision of those crops. The impact of the financing of the imported crop on the distribution of income is also an ethical issue.

Education Education and access to information are vital tools for addressing the externality problem created by open access to watersheds. For instance, many governments fund education about the value of and ways to use a watershed for both children and adults through schools and other community facilities. An example of an information tool is the U.S. toxic-release inventory law, which requires companies to publish releases of certain toxic substances into the environment. It was discovered that the companies reduced their emissions to avoid adverse publicity. Also, the information has been used for legal suits by citizens against polluters.

Financial, Taxation, and Subsidy Policies Ethical issues created by inequality of income distribution and private ownership of land within watersheds can be addressed through progressive financial, taxation, and subsidy policies. For instance, rising unit prices can be charged for escalating use of water for inessential purposes such as private swimming pools. The United States provides an example of subsidies helping to reduce inequality. Because U.S. national taxes tend to be progressive and local taxes tend to be regressive, national water infrastructure grants were especially beneficial to poorer members of watersheds. In the United States tax deductions for privately owned land put under conservation easements address environmental and economic needs simultaneously.

Restoration and financial compensation by polluters will not prevent the loss of many lives (human, animal, and plant) and enduring harm to landscapes and habitat. This is why many people recommend the use of the precautionary principle and advocate cradle-to-grave clean technologies so that people can keep track of what they bring to and create in watersheds, honoring the privilege of using those resources by leaving a watershed and its inhabitants and constituent parts at least as well off as they originally were.

WETLANDS

Wetlands are found on every continent except Antarctica, and at every latitude from the tropics to the tundra. About 6 percent of the land surface of the Earth is wetlands, and in the boreal regions this is 11 percent. Wetland ecosystems on global scales cover more than 1,280 million hectares, an area 33 percent larger than the United States.

Individual wetlands are often relatively transient features of a landscape. They may have differing water levels depending on seasonal changes and climate. They may fill with debris. Water-loving plants invade the margins of a lake; as detritus collects, marsh-loving plants replace them; afterward the bog fills and shrubs and trees can enter. Meanwhile wetlands will be generated elsewhere on the landscape.

Though sometimes transient, wetlands considered as a biological phenomenon are often long-lived and constantly present throughout Earth's evolutionary past, and there is no cause for wetlands not to persist indefinitely in the future. Like the forest and the sea, mountains and rivers, lakes and islands, wetlands are a form of landscape that Earth has regularly been producing over the epochs of natural history.

Wetlands vary in size from small soggy areas and pools to vast tracts covering many thousands of hectares, both freshwater and brackish. Wetlands are dominated by water, but there is a wide water gradient from drier uplands to deep water, and this often differs depending on rainfall from season to season and year to year. As a result, what is recognized as wetlands varies, depending somewhat on whether the focus is plants adapted to flooding and saturated soil or wildlife so adapted, or the water table relative to ground surface, or the wet/dry season of the year.

Wetlands may be the most threatened of all landscape types. The world has lost half its wetlands since 1900. The United States has lost over half its wetlands. Most wetlands in Europe have been drained or filled for development. Africa, South America, and Asia are continually developing vast wetland areas for food and fiber. The Millennium Ecosystem Assessment, sponsored by the United Nations, has an assessment: *Ecosystems and Human Well-Being: Wetlands and Water*. The authors express concern: ''The degradation and loss of wetlands is more rapid than that of other ecosystems. Similarly, the status of both freshwater and coastal wetland species is deteriorating faster than those of other ecosystems'' (Millennium Ecosystem Assessment 2000, p. ii).

Since 1989, the U.S. Environmental Protection Agency has had a policy of ''no net loss'' of wetlands, resulting in a quagmire of controversies about what counts as wetlands (a golf course lake with swampy shoreline?), wetland remediation, loss (of acres or function?) and gain (when does ''wet land'' become ''wetland''?). With wetland legislation, this has resulted in legal quarrels about what is a jurisdictional wetland, what permits may be required to dredge or fill them, or when a mitigation is successful—often destroying a wetland in one place and creating a substitute one elsewhere. A frequent judgment is that recreated wetlands are no match for the originals (Kaiser 2001). A National Research Council report was quite blunt: ''The goal of no net loss of wetlands is not being met for wetland functions by the mitigation process, despite progress in the last 20 years'' (National Research Council 2001, p. 2).

On international scales, the Convention on Wetlands of International Importance (commonly called the Ramsar Convention, from its first adoption at Ramsar, Iran, in 1971) has become increasingly important, with, since 1987, a permanent secretariat headquartered at the International Union for the Conservation of Nature and Natural Resources in Switzerland. By the turn of the twenty-first century, 117 nations had joined the convention and there were over a thousand wetland sites (Frazier 1999).

The wide varieties of wetlands and the varieties of peoples experiencing them over many centuries have generated a rich terminology: bogs; marshes; mires; muskegs; aapa peatlands, palsa bogs; fens; swamps; wetland moors; wetland prairies; tidal salt marshes; mangrove wetlands; river floodplains, deltas; wetland alluvial fans. Scientists have attempted more precision in classifying schemes (Cowardin et al. 1979; Gore 1983; National Research Council 1995; Mitsch and Gosselink 2000). The National Research Council report cautioned that certain types of wetlands (fens and bogs) are much more difficult to restore than others; some may be impossible to restore.

Human encounters with wetlands have distinctive dimensions (Vileisis 1997). Wetlands have been much misunderstood environments, perhaps the most misunderstood (Miller 1989). The contemporary term *wetlands* has been chosen partly to avoid classical terms such as *swamp, bog, mire*, which have negative connotations. A ''pleasant mire'' is almost a contradiction in terms. Swamps are damp, marshy, overgrown, rank, dismal, gloomy. They are uninviting places where one has to contend with insects while trying to keep from falling into the treacherous mud. Wetlands are often believed to be wastelands, best to be filled, drained, and converted into a useful resource.

Traditionally, there was an element of truth in such dislike. *Miasma,* from a Greek word for pollution, was poisonous air rising from the rotting bogs. *Malaria* means ''bad air,'' and the disease was more often caught by those who lived near wetlands, breathing this bad air. That the disease was carried by a protist in mosquitoes, breeding in stagnant or slow moving waters, was unknown until the 1890s.

Wetlands have economic uses and provide ecological services (Maltby 1986; Gore 1983; Richardson 1994; Mitsch and Gosselink 2000, Chapter 16). They provide habitats for fishing and for hunting waterfowl; they may contain timber that can be harvested. Rice, a staple grain for over half the world, is grown on managed agricultural wetlands. Peatlands provide fuel and energy. Coastal marshes are critical to the marine fishing, shellfish, and shrimp industries. Eighty percent of the commercial catch off the southeast U.S. coast is linked to salt marshes. There may be important biogeochemical transformations involving phosphates, nitrogen

Wetland Habitat in Wisconsin. *The term "wetland" refers to various transient features of a landscape, but essentially includes any area dominated by water. Wetlands may be one of the most threatened ecosystems, and because of their important economic and biological uses, recent efforts have been made in an attempt to preserve these landscapes. However, as in the United States, legal measures to retain a net amount of wetlands produces additional problems and controversy.* **PHOTO BY RYAN HAGERTY/U.S. FISH AND WILDLIFE SERVICE.**

compounds, sulfur compounds, and carbon. Wetlands serve for water storage and as filters for wastewater treatment. Wetlands provide flood control. In one notable example, damage in New Orleans from hurricane Katrina (2005) was much worse than it might have been, as a result of wetland losses. The four decades of wetlands loss before the turn of the twenty-first century increased storm surges about three feet (Stokstad 2005). The Millennium Ecosystem Assessment analysis also laments: "Many water resource developments undertaken to increase access to water have not given adequate consideration to harmful trade-offs with other services provided by wetlands" (Millennium Ecosystem Assessment 2000, p. ii).

Scientific understanding of wetlands has led to their better appreciation. The first misperception to be set aside is that wetlands are wastelands biologically. Wetlands can be high in biodiversity and biomass productivity, especially if open to hydrologic and nutrient fluxes. "Wetlands . . . are among the most fertile and productive ecosystems in the world" (Maltby 1986, p. 9). There is often less diversity in northern wetlands than in those in warmer regimes, but the fewer species there may be present in enormous numbers. In wetlands, obtaining nutrients and oxygen can be problematic, sometimes resulting in ingenious solutions to these stresses.

Wetlands offer unusual experiences of natural history (Rolston 2000). The slowed processes of decay underwater keep the evidences of former life close to the surface. The black ooze is a mixture of silt and partly decayed plants and animals that have gradually piled up on the bottom. The waterlogged remains are oxygen-starved, compared to terrestrial sites, and decay slowly: waterlogged logs, a soggy thatch of dead plants, or peat. The retreat of the glaciers left a Finnish landscape of lakes, scoured hollows, kettles, bogs, and mires. Many Finnish mires are thought to have existed continuously for 8,000 years (Ruuhijärvi 1983, p. 48). Studies of the pollen preserved therein record life in these wetlands, ongoing with vigor for eight millennia.

Wetland plants can tolerate extremes of moisture, nutrients, and oxygen in the soil. Insectivorous plants have adapted to the nitrogen-deficient soils of bogs by reversing the usual trophic pyramids, in which insects typically eat plants. Here plants eat insects, as with the sundews, pitcher plants, Venus flytraps, or bladderworts. Marshes and mires are remarkable places for adapted fit, complex networks connected in biotic community, as we learn when we try to recreate them.

Bird life in wetlands can be abundant, with distinctive adaptations to life in the wetlands. The ducks include mallards, pintails, shovelers, buffleheads, teal. There are also the blackbirds, coots, grebes, cormorants, pelicans, mergansers, gallinules, jacanas, herons, marsh hawks, cranes (Burt 2007). Perhaps the most celebrated of the northland waterbirds are the loons, ancient, deep-diving birds with their striking call.

In sum, wetlands are "biological supermarkets" for the diversity of life (Mitsch and Gosselink 2000, p. 4). Wetlands are especially demanding environments to understand and to conserve. Wetlands are challenging scientifically, economically, politically, socially, philosophically, ethically. Conserving them, we respect life; and, as the Millennium Ecosystem Report insists, the integrity of wetlands is closely linked to human well-being.

WHITE, LYNN, JR.
1907–1987

A leading historian of medieval technology, Lynn White Jr. was born on April 29, 1907, in San Francisco and died March 30, 1987. In his seminal paper "The Historical Roots of Our Ecologic Crisis" (1967), he argued that the Judeo-Christian worldview underlies the distinctively Western tendency to exploit nature through technology, and only a revision of that worldview can resolve our ecological problems. White's view that ecological problems are caused by Judeo-Christian values has been much debated by environmental philosophers, theologians, and others.

White maintains that while nineteenth- and twentieth-century attempts to dominate nature arose from the coalescence of science and technology in the industrial revolution, the attitudes underlying these practices are a millennium older, deriving from the conversion of Western Europe to Christianity. (Orthodox Christianity is exempted from these charges, although White's interpretations of Judeo-Christian scriptures make it implicitly subject to them as well.) Christianity, according to White, is the most anthropocentric religion of the world, because Christianity teaches that God desires humanity to exploit nature in its own interest, with indifference to other

creatures. In the early middle ages, these exploitative attitudes were apparent in the new technology of deep plowing (''Formerly man had been part of nature; now he was the exploiter of nature'' [White 1967, p. 1205]) and in new calendars representing man modifying nature (''Man and nature are two things, and man is master'' [White 1967, p. 1205]). Environmental problems cannot be solved unless the West changes religious values by turning to Zen Buddhism or, failing that, to Saint Francis's belief in the equality of all creatures.

Curiously, White elsewhere expressed admiration for Western medieval technology as a humane and liberating force (see 1962), besides stressing the long-term significance of such technology. Indeed, his staccato remarks about the changed relation of man and nature seem disproportionate to the alterations he actually describes. Did previous civilizations, including the Romans, really behave as ''part of nature''? Did deep plowing really betoken universal exploitation of nature or signify an end in the West to love and respect for land? Did symbols of farming in Frankish calendars exhibit a significantly greater sense of mastery than the works of (say) Hesiod or Vitruvius (fl. first century BCE)? Historical debates about White's thesis have also concerned methodology; Elspeth Whitney (1993), for example, questions the assumption that religious beliefs could drive technological change, rather than expressing changes driven by economic and social forces.

White's article also generated debates among biblical scholars, historians of ideas, and ecologically concerned theologians on the interpretation of the Old and New Testaments and the attitudes of Judaism and Christianity toward nature. John Passmore, for instance, rejects an anthropocentric interpretation of the Hebrew Bible and Judaism. Certainly passages such as Psalm 104 express God's concern for nonhuman creatures, while books such as Leviticus and Deuteronomy convey the idea that the land is not human property but God's, and is held subject to a range of ethical conditions, including concern for other creatures. Clarence Glacken interprets humanity's role in the Bible as that of steward of the natural kingdom, as do many ecologically concerned theologians (such as Paul Santmire) when expounding the teachings of Christianity.

Certainly, Old Testament passages affirming ''man's dominion'' (Genesis 1, Psalm 8) raise theological problems. But the Hebrew term *rada* may convey nothing more than governorship of a kind answerable to God (as James Barr and Michael Northcott argue). *Dominion*, with its Latin-derived overtones of mastery, is misleading enough; reinterpreting *rada* as meaning domination (disproportionate power) or domineering (oppressive exercise of power) is a distortion. Interpretations stressing responsible stewardship are thus preferable to White's reading of these texts as conveying monarchical and unconditional mastery. Not even the ''in the image of God'' teaching of Genesis (1:26–27) warrants such an interpretation.

Jesus's teaching about sparrows and lilies (Matthew 6) embodies a nonanthropocentric view of nature, and other New Testament passages suggest that the whole of nature has a place in God's plan of salvation (Romans 8, Colossians 1). Christianity has sometimes been interpreted as legitimizing human domination of nature yet has just as often offered prayers for beasts and encouraged humanity to adorn the world so as to complete God's creation. As for the widespread medieval use of Christian language to endorse technology, perhaps this just reflects,

EXCERPT FROM LYNN WHITE'S ''THE HISTORICAL ROOTS OF OUR ECOLOGIC CRISIS''

SOURCE: (from White, Lynn, Jr. 1967. ''The Historical Roots of Our Ecologic Crisis.'' *Science* 155: 1203–1207.)

as Whitney has suggested, "an age in which a religious perspective permeated every dimension of human life" (2005, p. 1736).

As Santmire shows, Christian writers' stances on the environment have been ambivalent. Some—such as Origen (185?–254?), Thomas Aquinas (1224/5–1274), and John Calvin (1509–1564)—adopted metaphysical forms of anthropocentrism, while others, such as Augustine (354–430) and René Descartes (1596–1650), without embracing the kind of anthropocentrism depicted by White, endorsed despotic interpretations. Yet many others—such as Irenaeus (c. 120/40–c. 200/3), Basil (c. 329–379), Ambrose (339–397), Cuthbert (635?–687), and Saint Francis (1181/2–1226)—adopted much gentler stances. Matthew Hale (1609–1676) explicitly viewed humanity as the steward of nature, and has had many modern successors.

The main historical significance of White's provocative paper has consisted not in his arguments but in the challenge it presented to theologians and philosophers worldwide to reappraise their attitudes toward the environment and the links of their thought with religion and culture. White expressly declares that reforming human behavior toward nature must be preceded by a reformed conception of the relationship between humanity and nature. Yet White's influence may unduly ascribe our environmental problems to culturally shared attitudes and values (Whitney 1993, pp. 168–169) and make their solution turn on a reform of worldview. Effectively solving such problems may require greater focus on reforming institutions, such as economic and political structures, rather than on reforming worldviews.

WILDERNESS

Throughout history wilderness has had many definitions and connotations. In the Book of Joel in the Bible the wilderness is characterized as a "desolate" place to put behind one and set in contrast to the "Garden of Eden" before one. For American transcendentalists such as John Muir wilderness was to be preserved because it was viewed as the handiwork of God. For Muir's father, Daniel, in contrast, wilderness was to be destroyed because it was the foothold of the Devil. Dictionary definitions range from the Middle English denotation of "a place of wild beasts," to a place "uncultivated," to a place "undisturbed" or "uninhabited" by human beings. Aldo Leopold referred to wilderness as "the raw material out of which man has hammered the artifact called civilization" and therefore considered it "a resource which can shrink but cannot grow" (1949, pp. 188, 199). For the historian Frederick Jackson Turner experience with the wilderness frontier shaped and has continued to influence the American character.

ORIGINS OF WILDERNESS PRESERVATION

Though wilderness is a variously defined and ancient concept, many environmentalists consider the preservation of wilderness one of the most important goals of environmentalism. The focus on wilderness preservation is perhaps

Hiking in the Arctic National Wildlife Refuge, Alaska. *The Arctic National Wildlife Refuge encompasses 19.2 million acres of Arctic and subartic habitat, 8 million acres of which are designated wilderness. Established in 1960, the refuge became a place of debate in the 1980s and onward because of the presence of (projectedly) billions of barrels of crude oil underneath its surface.* **U.S. FISH AND WILDLIFE SERVICE.**

the most characteristic component and contribution of North American environmentalism. The movement to preserve areas of wilderness in the United States, for instance, goes back to the early 1900s and can be seen as a reaction against a certain level of civilizing transformation and the despoliation of a presumably pristine landscape, whether the battle to save Hetch Hetchy Valley in the Yosemite from damming in the early 1900s or the early twenty-first-century battle over oil drilling in the Arctic National Wildlife Refuge.

Wilderness preservation has been the cause célèbre of a number of environmental groups. In late 1934 and early 1935 a group of American environmental leaders that included Benton MacKaye, Robert Marshall, Aldo Leopold, and Robert Sterling Yard founded the Wilderness Society, whose purpose is "to save from invasion … that extremely minor fraction of outdoor America which yet remains free from mechanical sights and sounds and smell." Other environmental groups, including the Wildlands Project and the Rewilding Institute, also focus their efforts on the preservation of wilderness, and groups such as the Sierra Club (founded by John Muir in 1892) see wilderness preservation as a significant dimension of their work. The uniqueness of North American ideas about wilderness is pointed out by the fact that although the preservation of "protected areas" has become a component of conservation efforts in other parts of the world, the term *wilderness* seldom is evoked in those places; when it is used, American ideas about the meaning of wilderness almost always are cited.

In the late 1980s and early 1990s a number of environmental historians and philosophers introduced a series of criticisms of the concept of wilderness. Those criticisms prompted defensive responses from other environmental scholars and activists. This "great new wilderness debate" continues to rage. The concept is "alleged" by its critics "to be ethnocentric, androcentic, phallogocentric, unscientific, unphilosophic, impolitic, outmoded, even genocidal" (Callicott and Nelson 1998, p. 2).

THE RECEIVED WILDERNESS IDEA

The legitimacy of such charges depends on the existence of a "received wilderness idea," or a conception of wilderness that is socially crafted and that infiltrates the collective consciousness of a specific community in an essentially uniform fashion. Thus, those who offer a critique of the concept of wilderness do so with the assumption that wilderness is a social construction and that even from an environmental standpoint it is flawed, counterproductive, and even dangerous. Many of those who consider themselves defenders of wilderness deny that there is a received wilderness idea, asserting instead a wilderness realism or the idea that wilderness has a reality beyond that which people socially construct for it. Others defend the concept of wilderness by agreeing that it is a social construction but argue that it is not the social construction that critics believe it to be.

Wilderness constructivists point out that the concept of wilderness has been defined variously and incommensurably over millennia, that the word *wilderness* does not appear in all languages, and that current ideas and laws about wilderness preservation reflect previous definitions of and justifications for wilderness preservation while ignoring others. Hence, when the most important piece of wilderness legislation, the Wilderness Act of 1964, was enacted in the United States, a wilderness area was defined in a way that reflected—and now codified as law—the dominant received wilderness idea: "in contrast with those areas where man and his own works dominate the landscape … an area where earth and its community of life are untrammeled by man, where man is a visitor who does not remain."

CRITICISMS BY WILDERNESS CONSTRUCTIVISTS

Constructivist critics suggest that even though variations in definition occur in characterizations of wilderness, all the definitions set wilderness in opposition to humans and human civilization (''visitors who do not remain''), make the presumed lack of human influence the measure of ''untrammeled,'' and generally consider wilderness areas to be places ''in contrast'' to human works. Further, critics argue that this characterization has a series of significant shortcomings.

First, the received wilderness idea is said to be ethnocentric to the point of being genocidal when transported outside North America. Wilderness critics suggest that the concept as constructed in its North American context is so specific to that context that it has negative human implications when exported to other countries. They point out that if one considers long-term human habitation as anathema to wilderness, if a country desires to create a wilderness area and there are aboriginal people living in that area, those people must be deported. To the degree that the identity of a people is embedded in its landscape, the forced removal of that people from that landscape may constitute a form of cultural genocide. Wilderness defenders sometimes deny this implication and sometimes admit it and openly opt for the preservation of the nonhuman over the preservation of specific human communities. Some historical work (Spence 1999, Burnham 2000) suggests that evicting native peoples from their homelands to establish national parks and other ''protected areas'' occurred in the United States in a number of instances.

Second, the received wilderness idea is said to be inappropriately andro- or phallogocentric. Former U.S. president Theodore Roosevelt touted the importance of wilderness experience because it ''promoted that lacking vigorous manliness,'' and the nature writer Sigurd Olson championed wilderness travel because it provided ''that virile, masculine type of experience men need today'' (quoted in Callicott and Nelson 1998). This hypermasculine image of wilderness is thought by some to be offensive and exclusionary.

Third, constructivists argue that wilderness (set in opposition to humanity) is viewed as the highest manifestation of nature. In light of the fact that the received wilderness idea evolved parallel to and was influenced directly by the development of the science of ecology and the fact that people often look to ecology to deliver the clearest images of the ontology of nature, ideas about wilderness and the preservation of wilderness reflect those early ecological paradigms. Whether portrayed as a collection of superorganisms by Frederick Clements or likened to a functioning economy by Charles Elton, the background reality of nature—and therefore wilderness—was thought to be harmonious and balanced, static and unchanging unless spoiled by human impact. Since the 1980s and drawing on ecological thought going back to the 1920s, however, the reigning ecological image of nature has been one of disturbance, flux, change, and discord. This background image of an ever-changing nature contrasts sharply and incommensurably with received ideas of wilderness as primeval, a place frozen in time, land as it was before human conquest. This rethought image of nature and wilderness affects people's corresponding assumptions about how they should interact with wilderness or what constitutes harm to wilderness. If wilderness is protected properly only when it remains static, any impact that alters wilderness also harms wilderness. However, if nature and wilderness are inherently dynamic, the idea of an untouched and unchanged wilderness as a properly treated wilderness has to be revised.

Fourth, critics of the received idea suggest that this view is unphilosophical and impolitic. The image of wilderness as land at the far end of the spectrum between the natural and the unnatural perpetuates a metaphysical bifurcation between humans and nature. Such an image also creates and enforces a value dualism in light of the positive value that wilderness advocates assign to wilderness and the corresponding and consistent negative value they are obligated to assign to humans and human activities. Wilderness critics point out that these dualisms are malignant. For instance, from them flows the inevitable condemnation of human interactions with nature, including not only oil spills and species eradication but also acts of ecological restoration. Moreover, because of the logic of these dualisms, wilderness advocacy has been criticized for being elitist and exclusionary in that nonwilderness areas are treated as places of lesser value, and the people who love them are by implication environmentalists of lesser worth.

Fifth, wilderness critics suggest that the received wilderness idea interferes with the acquisition of an inclusive environmental ethic, especially the land ethic of Aldo Leopold. That is seemingly the environmental ethic of many environmental activists, natural resource managers, and the environmentally literate public, and it promises to deliver direct moral standing to the nonhuman world. If Leopold is correct and an appropriate moral relationship between humans and land depends on people viewing themselves as fully and properly part of an inclusive biotic community, anything that conceptually separates people from land, even people's images of wilderness, stands in the way of an inclusive environmental ethic. According to this line of thought, to the degree that people's ideas about wilderness conceptually separate

humans from nature, wilderness destroys the ability to extend direct moral consideration to nature.

RESPONSES TO THE CRITICS

In response to these criticisms, wilderness defenders deny that wilderness is a received concept and attempt to refute these criticisms one by one or admit that wilderness is a received idea but suggest that wilderness critics have portrayed it in the wrong light or that it can and should be reconceived. Some wilderness critics agree that the concept of wilderness should be and can be reworked, whereas others have suggested that the idea is too burdened with past associations and should be jettisoned in favor of some other term and corresponding "protected area" strategy. J. Baird Callicott (Callicott and Nelson 1998, Nelson and Callicott 2008), for example, suggests that *biodiversity reserve* is a preferable label in that it clearly indicates that such set-asides are protected first and foremost for the good of biodiversity, not for the good of human recreational, scientific, or aesthetic interests.

Ideas about the nature of wilderness and prehuman conditions can affect ecological sciences in different ways. The effect of a prehuman or nonhuman landscape is not apparent in "pure" ecology or in ecological descriptions and modeling aimed at understanding how a specific system works; examples of this would be the answers to questions such as: Why are there so many species in an ecosystem? and Why do predator-prey systems seem more stable than theory suggests they should be? However, that effect is present in more normative "applied" ecology, in which the goal is to predict the future with an eye toward guiding people's actions. Various forms of applied ecology—from restoration to wildlife management—seem to evoke a kind of naturalism (equating the good with the natural) in which a wilderness or pre- or nonhuman condition is seen as good or desirable and constitutes the proper target of conservation efforts, whereas the humanized is thought of as a bad or undesirable state of affairs. The alternative interpretation in this context appears to be uncritically anthropocentric.

WILDERNESS ACT OF 1964

The Wilderness Act of 1964 was signed into law by President Lyndon Johnson on September 3 of that year. It is one of the most significant pieces of environmental legislation because of its continental scope and the idea of wilderness it contains. It was sent to President Johnson after eight years of rewriting and negotiations in Congress.

PURPOSE OF THE ACT AND DEFINITION OF WILDERNESS

The overall purpose of the act is to establish a National Wilderness Preservation System that identifies, protects, and administers areas designated as wilderness for the future recreational use of the American people. Proponents of the act believed that in its absence expanding population and development would leave no lands in their natural condition.

Some portions of the lands that came to be designated as wilderness under the act already were protected by various overlapping designations. Some of the lands were controlled by the federal agencies with jurisdiction, including the Forest Service, the National Parks Service, and the Bureau of Land Management. This was the source of an important controversy regarding the act. Conservationists and other protectors of wilderness believed that those agencies were open to manipulation by business interests and political groups. Proponents of the act cited cases of logging, mining, and dam building within lands already under some form of federal protection. They feared that wilderness areas might disappear through administrative neglect. Federal agencies, with the exception of U.S. Fish and Wildlife Service, saw the act as a challenge to their authority and expertise. Further, the Forest Service and other agencies were committed to a multiple-use doctrine by which all lands under their control should be used for more than wilderness recreation, whether logging or mining or hydroelectric power.

This set of issues is reflected in the concessions to existing federal agencies in the act: They would be allowed to continue to manage and have jurisdiction over the newly designated wilderness areas and further, the secretary of agriculture would have ten years after the act is signed to review and submit primitive areas as wilderness. Once areas are designated as wilderness by the act, their uses are limited with some exceptions. Deciding whether a specific primitive or roadless area is wilderness is still an agency decision, to be confirmed by the president, who then advises Congress.

OBJECTIONS

In addition to the initial opposition by some federal agencies, logging, mining, hydropower, motorized recreation, and tourist lodging interests opposed the passage of the act, arguing that it was not necessary, would impede economic development, was designed to benefit only an elite group, and undermined the wisdom of the multiple-use doctrine.

Those objections resulted in some important qualifications in the act. For instance, mining and prospecting as allowed by U.S. mining law were to continue with some restriction until 1983. Also, grazing and the use of motorboats and planes were allowed in areas where they already had been established. Those concessions did not eliminate opposition to the act but made it sufficiently palatable for senators and representatives in western states and congressional districts to vote for it.

Several people and groups played key roles in passing the act. Howard Zahniser became the leader of the Wilderness Society and the editor of its magazine in 1945. In the years from 1956 to 1964 Zahniser produced several dozen drafts of the act, continuously lobbied, and wrote and spoke for its passage. Although that eight-year battle culminated in the act becoming law, Zahniser did not live to see it; he died of a heart attack shortly before the signing.

Many other conservationists were involved in drafting and lobbying for the act. The Minnesota native Sigurd Olson, an acquaintance of Zahniser, advised Senator Hubert H. Humphrey to support the act after Zahniser solicited Humphrey's help. Largely on the basis of Olson's recommendation, Humphrey introduced the act in the Senate in 1956. Humphrey proved to be a crucial proponent of the act through the years of hearings, compromises, and rewriting. Besides Olson, David Brower worked on editing early versions of the act.

EFFECTS ON ENVIRONMENTAL ETHICS

The act has figured into environmental and philosophical thinking in several ways insofar as it provides a definition of wilderness that continues to draw sharp criticism. That definition says in part that wilderness is primeval and uninhabited and untrammeled by humans and also that it should provide opportunities for solitude and primitive recreation. One kind of criticism focuses on the relative vagueness of the terms used and the possibility of misunderstanding that may result. Other criticisms revolve around the inherent conflict involved in trying to satisfy both of those conditions for wilderness. For instance, it seems as if increases in the numbers of people wanting primitive recreation will have an adverse effect on the natural, primitive, and untrammeled character of wilderness areas, to say nothing of solitude. A final conceptual difficulty is that the definition of wilderness endorsed by the act insists on a sharp division between wilderness and humans that is subject to serious challenge because, for example, it seems to ignore the historical presence of aboriginal peoples in many of those areas and, when imitated in other countries, can result in the eviction and dispossession of indigenous peoples.

The act set aside some 9 million acres of land as wilderness, a number that has grown to over 100 million acres. Controversy was expected to continue and even intensify in light of increasing demands for resources.

WILSON, EDWARD O.
1929–

Born on June 10, 1929, in Birmingham, Alabama, Edward Osborne Wilson, one of the twentieth century's exemplary individuals, started out as an ecological scientist and transitioned to applied conservationist and environmental ethicist. Early in his life, Wilson began to observe some of the smallest and most diverse organisms: insects, especially ants. "In 1942, when I was 13 years old," he remembers, "I was studying ants for a Boy Scout project. . ., and so I discovered a nest of red fire ants" (2006, p. 71), which was the first known colony of the invasive exotic species *Solenopsis invicta* in the United States. In his autobiography *Naturalist* (1994), Wilson recalls how his childhood years in the U.S. South imbued him with a curiosity for all aspects of natural history and provided the foundation of his scientific career. This boyhood fascination with ants eventually led to a Ph.D. and faculty career at Harvard University where he explored diverse topics and scales, ranging from chemical ecology to biogeography, from taxonomy to the evolution of social interactions. For *The Ants* (coauthored with Bert Hölldobler), he was awarded a Pulitzer Prize for nonfiction in 1990.

In the 1960s, ant-collecting expeditions to Pacific islands and the New World Tropics grounded Wilson's scientific work in basic natural history, which emphasized descriptions of species and their interactions. Then, however, he used firsthand experiences in observing small organisms as illustrations for addressing major ecological and evolutionary questions, in the process positing the taxon cycle (Wilson 1959, 1961) and island biogeography theory (MacArthur and Wilson 1967). Both hypotheses were major conceptual advances in explaining patterns of species richness from biogeographic and demographic principles. This body of work, resting on theoretical principles, was also rigorously shown in the field with whole island experiments in the Florida Keys. It has since proved to be not only a powerful current of thought in general ecological theory, but also in conservation, as the idea of island patches of suitable habitats for particular species can be used to manage vulnerable populations across the landscape matrix.

Wilson's investigation of ants also led to insights regarding their communication and colony organization. His seminal research in chemical ecology showed that ants use pheromone cues to coordinate their complex group superstructure. Such results eventually led to a path of inquiry regarding the biological basis of social interactions in general. With *Sociobiology: The New Synthesis* (1975), Wilson sought to explain behavioral traits within strictly biological confines—an idea that proved controversial, but also founded a new discipline and earned him his first Pulitzer Prize for nonfiction in 1978 for *On Human Nature*.

As a writer, Edward O. Wilson was able to transcend his academic discipline and link it with society by effectively communicating scientific understanding to a wider audience, often employing ground-breaking neologisms. For example, the term *biophilia* (humans' innate attraction to living systems) was coined by Erich Fromm in *The Heart of Man* (1964), but Wilson's homonymous book generated dynamic discussion about the concept in 1984. Likewise, in an academic symposium moderated by Wilson, Walter G. Rosen coined the term *biodiversity* in 1985, but Wilson's 1988 book of the same name introduced the term into our collective vocabulary and imagination and from there helped to coalesce the environmental movement and governmental policy around concern over the modern crisis of mass extinctions of species. In 2006 Wilson himself invented the term *Eremozoic Era* as a provocative depiction of the "Age of Loneliness" that will succeed the sixth mass extinction if humanity does not undertake immediate actions to protect the planet's biodiversity.

To perpetuate his legacy, the Edward O. Wilson Biodiversity Foundation was launched in 2007 to "preserve biological diversity in the living environment by inventing and implementing business and education strategies in the science of conservation." Its approach parallels Wilson's own development. The foundation attempts to maintain Wilson's traditional emphasis on the need to understand all biodiversity with a natural history-oriented program consisting of hands-on education and citizen science. Yet the organization also uses the experience of its cofounders and capital derived from the biotechnology industry to put forward a technology-based, capitalistic model for future research and conservation. This market-based approach to conservation and development—involving, for example, tapping genetic resources and creating win-win cooperative agreements with industry—coincides with Wilson's own strong belief in the power of science and technology to solve problems. This approach is ironic to some, as many conservation problems are in fact the result of science and technology.

As a scientist, Wilson has earned the highest professional recognition (e.g., the National Medal of Science, the Craaford Prize, and the Tyler Award), but unlike most academics he has also attained great social relevance. In both arenas, his popular and scientific work has significantly contributed to shedding light on the beauty and value of the diversity of insects and other inconspicuous organisms found in the living systems around us. Prestige, however, does not confer immunity from disapproval. By placing such a high value on technological and scientific solutions, Wilson has also been

the focus of criticism. In particular, his defense of sociobiology created a storm of rancorous debate, leading to a confrontation in which activists dumped a pitcher of water on Wilson's head at a conference. The current orientation of his foundation may also prove problematic for some conservationists. Nonetheless, Edward O. Wilson established himself as one of the most influential thinkers of his day precisely by working in the natural sciences and simultaneously at the interface of science and society.

WORDSWORTH, WILLIAM
1770–1850

William Wordsworth was born on April 7, 1770, in Cockermouth in Cumberland's Lake District and is considered one of England's finest nature poets. His poetry and critical works manifest a complex understanding of the relationship among the natural environment, language, and human passions. That complexity is apparent in his best-known critical essay, the Preface to *Lyrical Ballads* (Wordsworth and Coleridge 1969 [1800, 1802]), which was written to justify the experimental style of those poems. The Preface indicts the artificial diction of earlier poets and calls for a new way of describing and relating to the natural world that will honor the qualities most fundamental to human life: imagination and emotion. Wordsworth did not advocate a simple return to nature. Instead, he reminded his readers that the source of what is best in human manners, feelings, language, and community resides in a positive relationship to the natural world. Wordsworth died on April 23 in Rydal Mount, Westmorland, England.

POETRY AND THE BOND WITH NATURE

The bond of humanity with nature, Wordsworth suggested—though as indestructible as the deep, universal emotions that structure people's inner lives and influence their actions and relationships—was being attenuated in an increasingly urban Great Britain. The radical industrialization of English life and the tumultuous events connected with the French Revolution of 1789, he suggested, were "acting with a combined force to blunt the discriminating powers of the mind" (Wordsworth and Coleridge 1969, p. 160). That situation can be considered the predecessor of the contemporary information age, with its taste for news, novelty, and speed. The more city people's cravings for "extraordinary incident" (Wordsworth and Coleridge 1969, p. 160) are satisfied by tabloid-style accounts and the more their desire for racy or mawkish entertainment is satisfied by pandering artists, the more they tend toward a paradoxical, narcotized state of "savage torpor" (Wordsworth and Coleridge 1969, p. 160). Essentially, Wordsworth's complaint is about the hollowing out of emotion and experience until no feeling, event, or utterance seems authentic: Cheap spectacle replaces genuinely artistic representation, and quantity replaces quality in all areas of life.

In response to a development destructive to individual identity and genuine community, Wordsworth outlined a redemptive poetics. Because the corruption of language and sentiment lay at the heart of the problem, he considered it vital to have recourse to devise a better model in both areas: life in the English countryside. The Preface states that the main object of *Lyrical Ballads* was "to chuse incidents and situations from common life, and to relate or describe them, throughout, as far as was possible, in a selection of language really used by men" (Wordsworth and Coleridge 1969, p. 156). Readers are told, "Low and rustic life was generally chosen, because in that condition, the essential passions of the heart find a better soil in which they can attain their maturity, are less under restraint, and speak a plainer and more emphatic language ..." (Wordsworth and Coleridge 1969, p. 156). Country people are less distanced from their vital passions than are urban dwellers; they

express what they feel more readily to other members of the community and have not lost the emotional connection to nature that has been forfeited by the average Londoner. They also have not lost the ability to see what is in front of them in a meadow or a wood, in all its particularity as well as in its universal dimension among "the beautiful and permanent forms of nature" (Wordsworth and Coleridge 1969, p. 156).

What the pastoral citizen has achieved over a lifetime, the poet can accomplish by an initially more self-conscious effort involving careful selection from the chosen language model and by methods of composition best characterized as meditative. The latter quality underlies Wordsworth's famous definition: "Poetry is the spontaneous overflow of powerful feelings: it takes its origin from emotion recollected in tranquillity: the emotion is contemplated till by a species of reaction the tranquillity gradually disappears, and an emotion, kindred to that which was before the subject of contemplation, is gradually produced . . ." (Wordsworth and Coleridge 1969, p. 173). By this process, the lyricist will compose poems that help ordinary people recover the passion and sense of community from which city life bars them. The poet who can do this, Wordsworth declared, will have attained the status of a priest or prophet and will be "the rock of defence of human nature; an upholder and preserver, carrying every where with him relationship and love" (Wordsworth and Coleridge 1969, p. 168).

NATURE AND HUMANITY

In keeping with that ideal and in terms of descriptive quality and aesthetic appeal, Wordsworth's poetry is not timid about suffusing nature with human reference and spiritual significance. His reference in "I Wandered Lonely as a Cloud" to common meadow flowers transfigured into an almost biblical "host of golden daffodils" suggests this, as does his attention to what he calls in Book 11 of the 1805 *Prelude* "spots of time": moments in the presence of nature that form highly charged "renovating" memories to which people may repair in times of trouble. (The ode "Tintern Abbey" involves strong memories connected to a beautiful natural scene.) Many of Wordsworth's poems are not simply about nature; they are about the joys and travails of human beings in the presence of or in painful separation from nature. The *Prelude* traces the development of his own artistic and spiritual qualities even if those qualities owe almost everything to the natural environment in which he grew up and with which he sought to keep communion.

Wordsworth was the British poet laureate from 1843 to 1850, and his poetry and poetic theory are central to British romanticism. They also figure in the work of later authors, among them John Ruskin. Wordsworth's close attention to nature's particularities, insistence that the language of poetry should be the language of ordinary uncorrupted humanity, and impassioned argument that literary art can help people achieve both individual happiness and community have been used as points of departure by authors from his own time through the present.

WORLD TRADE ORGANIZATION

The product of a decades-long global movement to ease trade barriers among nations, the World Trade Organization (WTO) was founded on January 1, 1995, to provide an international negotiating forum, enforcement agency, and dispute-resolution mechanism for countries seeking to benefit from liberalized trade policies. As of June 2008, 152 nations were members of the WTO.

The underlying principle of all WTO regulations is the most-favored-nation policy: Each member nation is obliged to grant to all members the most favorable trade terms that it grants to any other member, and members are required to give equal treatment to overseas and domestic suppliers of goods and services. Although the WTO has achieved substantial reductions in tariffs and other trade barriers since its founding, it has also generated storms of controversy and protest among various constituencies—chiefly trade unions, student groups, and environmental organizations—that contend that the WTO's basic orientation favors the commercial interests of transnational corporations at the expense of labor and environmental standards and that its rules and governance procedures constitute a threat to the institutions of civil society. Many environmental organizations share the basic view expressed by Greenpeace International: "The World Trade

Organisation (WTO) promotes free trade for the gain of private interests, over and above our health and the environment" (Greenpeace International 2008).

ORIGINS AND STRUCTURE

The WTO is the successor to the General Agreement on Tariffs and Trade (GATT). GATT was founded in 1947 to foster a worldwide reduction in tariffs, mainly on manufactured goods. The final Uruguay round of negotiations under GATT resulted in a pact that aimed to achieve an eventual one-third reduction in global tariffs and a gradual elimination of other hurdles to open trade among nations, especially in agricultural goods. This agreement also took unprecedented steps toward liberalizing international commerce in investments and services and bolstering international intellectual-property rights. These initiatives were carried over into the WTO, which was created to provide stronger enforcement and dispute-resolution capabilities for the agreements forged by GATT and to further lower hurdles to global trade.

The WTO is headquartered in Geneva, Switzerland. Its highest governing body is the Ministerial Conference, which is composed of all the members of the organization. A General Council carries out the decisions of the conference and is responsible for daily administrative tasks. The director-general, appointed by the Ministerial Conference, is the group's chief executive officer. Substantive trade negotiations take place in various rounds launched by the Ministerial Conference. The Doha Round was launched in 2001 in Doha, Qatar but stalled over disagreements between the industrialized countries and the nations of the third world, largely over agricultural subsidies in the European Union and the United States that many third-world governments believe force their countries to import cheaper agribusiness foodstuffs that were once grown locally, thereby placing their farmers at a competitive disadvantage and threatening the livelihoods of millions of farm families.

CONFLICTS AND CONTROVERSIES

The free-trade agenda of the WTO began to generate gales of protest and controversy in the late 1990s. The watershed event in this wave of anti-WTO sentiment was the series of mass demonstrations and street disruptions that greeted the WTO Ministerial Conference in Seattle, which began on November 30, 1999. These protests arose as part of a worldwide surge of "antiglobalization" sentiment in the opening decade of the twenty-first century. Many of the leaders of this movement deny that its intent is antiglobalist. They insist, rather, that they are opposed to what they term "corporate globalization"—the erosion of the sovereign powers of nation-states and the institutions of civil society in the face of institutions like the WTO that, they believe, reflect the interests of private transnational corporations rather than the public interests of the poor, the labor movement, and the environment.

Although some of this antiglobalist ire has been directed against other instruments of international commerce, such as the World Bank and the International Monetary Fund, the WTO has borne the brunt of the protests because of its aggressive agenda of dismantling barriers to transnational corporate investment. There are three main areas of controversy: governance and dispute-resolution procedures, labor standards, and environmental policies.

Governance and Dispute-Resolution Procedures The WTO prides itself on its democratic practice of according one vote to each country, regardless of its size or wealth. Yet, purportedly in the interests of avoiding conflict, the WTO has never taken a formal vote on trade proposals, preferring instead to rely on negotiation and consensus decision making to minimize conflicts and polarization. Critics have noted, however, that much of the real agenda setting and substantive negotiation in the WTO takes place among informal groups, the so-called miniministerials, consisting mostly of the most powerful members, so the interests of developing countries tend to be underrepresented in the final agreements. Even the WTO acknowledges, "It would be wrong to suggest that every country has the same bargaining power" (WTO 2008a).

The WTO's dispute-resolution procedures have also aroused considerable controversy. The member nations agree to avoid unilateral action and to rely instead on the WTO's multilateral system. If the contending parties cannot resolve their issues through mediation and negotiation, the complainant can request the convening of a special panel, the decisions of which are binding on all parties. These panels consist of three officials appointed by the WTO secretariat. Critics have raised a number of objections to these tribunals: The panelists are unelected and are under no obligation to disclose conflicts of interest; only the official national trade representatives of the contending parties can attend the proceedings—all other government officials are prohibited from attending; all proceedings, documents, and transcripts are secret; and the press is barred from the tribunals. Whether the closed, secretive nature of these panels vitiates the WTO's claims to be democratic and open to public concerns remains a topic of vigorous debate.

A matter of broader concern is the WTO's requirement that member nations' future laws conform to WTO rules, which some critics assert is bound to have a chilling effect on the law making of sovereign states. In

this view, transnational corporations looking for overseas investment opportunities will seek out the countries with the fewest impediments to low-cost production, including labor and environmental regulations, thus setting off an economic race to the bottom in workers' rights and environmental protection.

Labor and Workers' Rights On the labor front the WTO asserts that "all WTO member governments are committed to a narrower set of internationally recognized 'core standards' for labor," but it also acknowledges that there is "no work on this subject in the WTO's Councils and Committees," that "it is not easy for [member nations] to agree" on labor standards, that "the question of international enforcement is a minefield," and that "WTO agreements do not deal with labor standards as such" (WTO 2008b).

The pressure to minimize labor standards in WTO rules comes chiefly from two sources: the transnational corporations seeking low-wage production opportunities abroad and third-world governments desiring such investments. Both parties have characterized the quest for rigorous labor standards in trade agreements as a form of protectionism. In the words of the WTO's 1996 Singapore ministerial declaration on core labor standards, "We reject the use of labour standards for protectionist purposes, and agree that the comparative advantage of countries, particularly low-wage developing countries, must in no way be put into question" (WTO 2008b). Despite the WTO's pledge to work with the International Labor Organization on this issue, there was little progress as of 2008. Labor groups throughout the world regard this charge of "protectionism" as a guise for promoting flagrant exploitation in the interests of large corporations. Labor-movement representatives still decry the shift in investments from the highly unionized, high-wage countries of the developed world to third-world export-processing zones, areas specially designated for export-oriented manufacturing that are often exempt from national labor codes (Jauch 2002).

The WTO and the Environment The WTO states, "Sustainable development and protection and preservation of the environment are fundamental goals of the WTO." It further asserts, "The Doha Agenda includes specific negotiations on trade and environment and some tasks assigned to the regular Trade and Environment Committee" (WTO 2008c).

Critics claim that the reality belies this reassuring rhetoric. They note, for example, that WTO panels have consistently ruled that trade regulations cannot discriminate among products on the basis of their method of production or harvesting, so that, for example, preferring sustainably harvested wood to clear-cut timber from tropical forests would be considered a restraint of trade. Likewise, sustainably caught fish or products resulting from humane labor conditions or humane treatment of animals cannot be accorded preferential treatment under WTO rules. Critics further charge that the WTO's tariff policies on raw materials encourage the depletion of dwindling natural resources and put pressure on third-world countries to focus on extracting and exporting raw materials, often in partnership with giant transnational mining companies, rather than on sustainable industrial development.

The record of WTO rulings in environment-related disputes has not reassured critics or lent credibility to the WTO's claims of environmental sensitivity. The original General Agreement on Tariffs and Trade contained a provision, Article XX, that claimed to allow exceptions to trade rules based on domestic concerns about health, safety, and the environment. Nevertheless, nearly all the decisions of the WTO panel have ruled in favor of challenges to environmental protections. Of the nine cases that bear on the environment, three have aroused the most controversy:

- In 1997 Venezuela and Brazil challenged a U.S. policy that limited gasoline imports based on the chemical makeup of the product. The WTO's ruling in favor of the plaintiffs led the United States to comply with the ruling by weakening provisions of the Clean Air Act, downgrading cleanliness rules to allow imports that would result in a 5- to 7-percent increase in nitrous oxide emissions.
- The United States once banned shrimp imports from countries whose boats did not use turtle-excluder devices. In 1998 India, Malaysia, Pakistan, and Thailand challenged this U.S. ban on their shrimp as a restraint of trade. The WTO found in favor of the plaintiffs, obliging the United States to weaken that provision of the Endangered Species Act. It still restricts imports of shrimp to those brought in by ships with turtle-excluder nets, but with no requirement that those ships be verified as the ones that actually caught the fish.
- After years of Mexican threats of a trade challenge to a U.S. policy requiring that domestically sold tuna have a "dolphin-safe" label, the Bush administration in 2002 softened U.S. regulations to permit "dolphin-safe" labeling for tuna harvested with techniques that had previously been deemed dangerous to dolphins.

Another major area of environmental concern is the WTO's posture on trade in genetically modified organisms. In response to a formal complaint from three major growers of genetically modified crops—the United States, Canada, and Argentina—the WTO ruled in

May 2006 that the European Union's delays in coming up with a systematic regulatory policy regarding genetically modified organisms were a violation of WTO rules. The European Union policy in place in 2008 does require that genetically modified products be labeled, segregated, and traceable. The WTO has ruled, however, that outright national bans on specific genetically modified crops are illegal restraints of trade if the country's regulations are based on criteria stricter than those contained in the WTO's Sanitary and Phytosanitary Measures, which many environmental groups consider to be inadequate.

THE WTO AND POLITICAL AND SOCIAL PHILOSOPHY

The opponents in the controversies that swirl around the WTO fall broadly into two camps. The WTO's champions are, for the most part, proponents of a free-market liberalism—often dubbed neoliberalism in contemporary discourse—that regards the unfettered operation of free markets as the most efficient way to create wealth and to address social and economic ills. The WTO's critics—a disparate coalition that includes labor unions, antiglobalist student activists, displaced third-world farmers, and environmental organizations—typically regard the unregulated free market as a recipe for increasing inequality and exploitation of the environment and other humans. The WTO's supporters tend to be suspicious of the public sphere and the state, which they view as a brake on individual initiative and creativity. WTO opponents regard the public sphere as the domain of democracy, where citizens can deliberate about which policies best serve their interests as a cooperative community, not merely as an array of discrete, self-interested individuals. These WTO critics point to the irony that the antistatist free-traders seem all too ready to accept the dictates of a secretive, powerful, privately run de facto world government that enforces the interests of corporations while these same "neoliberals" resent and resist the incursions of governmental bodies that represent a broader public interest. This clash of the social and the individual, the public and the private, has been a long-standing theme in world politics and social theory. The WTO has become the latest, and in some respects the most prominent, lightning rod for these clashing views of how humans should relate to one another and their environment.

WORLD WIDE FUND FOR NATURE

Environmental and ecological degradation occurs worldwide, and international organizations have become major players in nature and environmental conservation. One of the leading organizations in this area is the World Wide Fund for Nature (WWF), whose founding was brought about by, among others, Sir Julian Huxley, then director-general of the United Nations Educational, Scientific and Cultural Organization (UNESCO). After visiting eastern Africa in 1960, he was shocked by the destruction of wildlife habitats and the rate of hunting and published his findings in the British newspaper *The Observer*. One of his readers, the businessman Victor Stolan, suggested establishing an international organization for fund-raising. Huxley interested conservationists and naturalists such as Max Nicholson, director of Britain's Nature Conservancy,

and Peter Scott, vice president of the International Union for the Conservation of Nature (IUCN), in the idea of establishing a fund-raising organization to support scientifically sound conservation projects of existing nongovernmental organizations (NGOs).

ESTABLISHMENT AND ACTIVITIES OF THE WWF

In September 1961 the new organization was established as the World Wildlife Fund with headquarters in Switzerland, later to be known as WWF International. Within six weeks independent WWF offices were set up in a number of other countries. According to the Deed of Foundation, the organization was created to ensure the "conservation of world fauna, flora, forests, landscape, water, soils and other natural resources by the acquisition and management of land, research and investigation, education at all levels, information and publicity, coordination of efforts, cooperation with other interested parties and all other appropriate means."

Although the Deed of Foundation expressed a broad agenda, the first twenty years of the WWF were characterized by the establishment of wildlife reserves and the protection of impressive animal species, often in developing countries. For example, whales, elephants, rhinoceroses, and tigers played an important role in public campaigns. Through contacts in higher social circles and appeals to the public, WWF raised large amounts of money in the subsequent years.

However, by the end of the 1970s WWF realized that it was not addressing the fact that entire ecosystems were under threat from socioeconomic and political developments. In collaboration with the IUCN and the United Nations Environment Programme (UNEP), the *World Conservation Strategy* was published in 1980, stressing the interrelationship between conservation and socioeconomic development. That document introduced the concept of sustainable development, which was elaborated further in 1987 in *Our Common Future* by the World Commission on Environment and Development. In line with those documents, IUCN, UNEP, and WWF published *Caring for the Earth: A Strategy for Sustainable Living* in 1991, a document that explored strategic perspectives on sustainable development.

Because of its broadening scope, in 1985 WWF decided to change its name to the World Wide Fund for Nature, although the U.S. and Canadian offices retained the old name. Beginning in the early 1990s, a new WWF mission statement expressed the changing perspectives: "To stop the degradation of the planet's natural environment and to build a future in which humans live in harmony with nature." Preserving biodiversity, ensuring the use of renewable natural resources, and reducing pollution and wasteful consumption became the main aim. Because it was recognized that many threatened ecosystems had been the homes of indigenous peoples for thousands of years, traditional knowledge and a respect for indigenous traditions became part of the conservation goals of WWF. That led to alliances with NGOs for indigenous people and to conservation guidelines announced by the IUCN, WPCA (World Commission on Protected Areas), and WWF in 1999.

To keep track of the state of the natural habitat and human pressure on the planet, in 1998 the WWF began to publish the biennial *Living Planet Report,* in which the living planet index, covering population trends in over 1,300 species, and the ecological footprint, measuring the area of the planet needed for sustainable use, were explored. Those reports showed that the planet was in an alarming state. The ecological footprint had tripled since 1960, and the living planet index had decreased by about one-third since 1970.

According to WWF, recognition of this worldwide environmental crisis called for larger geographical scales of conservation. To that end, the term *ecoregion* was coined. David M. Olson and Eric Dinerstein defined an ecoregion as "a large unit of land or water containing a geographically distinct assemblage of species, natural communities, and environmental conditions" (Olson and Dinerstein 1998, p. 502). Recognizing that resources had to be used effectively and efficiently, WWF announced the Global 200, a set of over 200 ecoregions prioritized for conservation (Olson and Dinerstein 1998).

In the same period WWF intensified its focus on economic issues. The organization took part in the establishment of the Forest Steward Council, an independent agency that certifies sustainable timber production. WWF also established the Marine Steward Council (MSC) in cooperation with Unilever, one of the world's largest producers of seafood. This alliance points to another development within WWF: cooperation with multinational companies to develop standards and practices for corporate responsibility in regard to social and conservation issues.

CRITICISMS AND RESPONSES

This globalizing aspect of the work of WWF has led to criticism. In 2004 the anthropologist Mac Chapin criticized WWF and other large international nature protection organizations for their domination of the conservation agenda, neglect of indigenous people in spite of agreements and documents, and increasing financial dependency on multinationals and governmental agencies. In their response in 2005 the WWF representatives

Carter S. Roberts and Chris Hails pointed out that they shared Chapin's broader concerns "in spite of exaggerations and inaccuracies" (Roberts and Hails 2005, p. 7).

Chapin's article and the many responses to it made clear that the relationship between the rights and interests of indigenous people and conservation in a globalizing world is complex, implying often painstaking decisions. In the first decade of the twenty-first century WWF had offices in over fifty countries and was active in more than a hundred, with nearly five million individual members and an annual budget of around $500 million. Established as an organization that primarily focused on animal species with great public appeal, it gradually came to include ecological, environmental, developmental, and economic issues in its mission. WWF became a powerful player in international civil society, bringing states, companies, and NGOs together. Balancing those different forces has been one of its main challenges.

WRIGHT, FRANK LLOYD
1867–1959

Frank Lloyd Wright, who was born in Richland Center, Wisconsin, on June 8, 1867, is recognized as one of the most influential modern architects, the preeminent American architect of the late nineteenth and early twentieth centuries, and, along with Louis Sullivan, the inspiration for the Prairie School of architecture. After studying engineering at the University of Wisconsin, Wright spent his formative years as an architect under the tutelage of Joseph Lyman Silsbee and Sullivan. Sullivan's architectural maxim "form follows function" prompted Wright to develop a distinct approach called *organic architecture* that was driven by the maxim "form and function are one." That maxim was expressed in Wright's written works, especially "The Art and Craft of the Machine" (1992 [1901]), *An Organic Architecture* (1970 [1939]), *The Future of Architecture* (1953), *The Natural House* (1954), and *The Living City* (1963 [1958]), and in many of his over 500 completed designs, especially at Taliesin in Wisconsin, Falling Water in Pennsylvania, and Taliesin West in Arizona. Wright's significance for environmental ethics and philosophy lies in the commitment of his architectural ethos to organicism and openness through the use of the horizontal line.

Wright believed that architectural principles should be modeled after forms found in nature. Because forms have a quality of life that is the same as their function, they are formal declarations of function. The continuity Wright saw between architectural and natural forms drove his organic architecture, at the heart of which was the building that declares its purpose (function) without pretense and is enmeshed in and indeed is one with its urban or rural site.

Wright's organic architecture centered on projects that exemplified harmony with nature. To realize that harmony, architecture had to break down the nature-culture dualism that informed the creation of conceptually and architecturally situating human-made objects that stand in opposition to nature. Wright's strategy for breaking down that dualism included a focus on the horizontal over the vertical. When preference is given to the horizontal, more specifically the horizontal line (for

Fallingwater, Bear Run, Pennsylvania. *One of Frank Lloyd Wright's most recognizable works of architecture, Fallingwater was designed in 1936 as a summer home for Pittsburgh department store owner Edgar Kaufmann. The home is toured by over 70 thousand people each year.* **AP IMAGES.**

example, in Robie House in Illinois), buildings stand a better chance of expressing the openness and freedom of nature because deference to the horizontal leads to structures close to and guided by the forms and lines of the earth, starting with the horizon.

If one evaluates Wright's architectural ethos in terms of specific buildings or projects, one is likely to focus on Wright's success in developing a set of principles useful for guiding green architects as they work to bring about unity within buildings and in the way buildings fit into their sites in an unobtrusive and ecologically sensitive manner (Rogers 2004). On this level, a question can be asked about Wright's ethos that looks similar to a question that often comes up in relation to ecological design generally and biomimicry more specifically, namely is it justified to base norms and principles that are to guide human conduct on the perceived norms in and of nonhuman nature?

However, troubling philosophical issues arise with respect to the use of Wright's approach as an ecologically informed guide for planning and sustainability. Wright's commitment to openness through the horizontal line led him to develop a response to what he saw as the failures of urbanism. According to Wright, the artificial, constricted, and centralized industrial city demanded a response. In what can be seen as a precursor to the type of antiurbanism found in the work of later environmental ethicists, most notably Murray Bookchin (1974), Wright called for a decentralized and horizontal approach to human settlement. In his effort to make human settlements look more like natural organisms, Wright arrived at his "Broadacre City" concept, a precursor to later suburban development. Insofar as basic elements of the concept can be viewed as being related to environmental problems faced in the twenty-first century, Broadacre City delimits what is considered part of the ecological equation. For example, Wright's allowance of one acre per person attempts to honor a commitment to openness and freedom but ends up encouraging populations to spread out over vast distances and as a result contribute to a need for massive transportation infrastructure. Site and immediate surroundings are chosen over and at the expense of the ecological region, as well as wider ecological cycles and processes. It is paradoxical that Wright's ethos, which accomplishes so much in terms of ecological insight on the micro level, ultimately stands opposed to an ecological approach to architecture that recognizes the vital role of human-made structures in ecosystem operations on the macro level.

Glossary

Acoustic ecology: The interdisciplinary field that studies the auditory relationship between living organisms and their environments. In urban and suburban settings acoustic ecologists investigate the sonic effects of constant sound and noise pollution. In oceans, national parks, and wilderness areas there is heated debate over the presence of jet skis, airplane overflights, off-road vehicles, and military monitoring systems that rely on high-intensity underwater sonar blasts. Acoustic ecologists generally advocate the value of listening, the quality of the soundscape, and more consciously choosing the sounds humans create.

Androcentrism: Literally "male-centered," the conscious or unconscious practice of emphasizing the male viewpoint and male interests over the female viewpoint and female interests. Feminist theory commonly criticizes androcentrism on the grounds that it assumes a universal human nature corresponding to male attitudes while female attitudes are considered deviant.

Animal law: The branch of law concerning all interactions with animals from the perspective of traditional statutory and case law. The subjects of animal law include wildlife, animals kept in captivity, companion animals, and animals used for various entertainment, research, and food purposes. In the United States animal laws exist at local, state, and national levels.

Anthropocentrism: Literally "man-centered," the conscious or unconscious practice of emphasizing the human viewpoint and human interests over nonhuman viewpoints and interests. Anthropocentrism is frequently justified on the grounds that, because humans are the most significant fact of the universe, they are the most important. See also *chauvinism, human*.

Anthropocosmism: An alternative to the dichotomy between anthropocentrism and nonanthropocentrism that seeks to encapsulate both humanity and the natural world without placing greater value on a particular center—anthropocentric, biocentric, ecocentric—and thereby excluding or marginalizing something of peripheral value. From the anthropocosmic perspective, the values of humans ("anthropoi") and the world ("cosmos") are not in opposition, but are intimately interwoven.

Autecology: The study of the relationship between an individual organism or an individual species and its physical environment. Contrast to *synecology*.

Behaviorism: A psychological theory and method of investigation that seeks to explain behavior solely in terms of observable and quantifiable responses to environmental stimuli. Behaviorism ignores conscious experience and subjective phenomena like desires, motives, and emotions.

Biocentric egalitarianism: See *egalitarianism*.

Biocide: Any chemical agent capable of destroying living organisms. Although biocides are commonly associated with pesticides (herbicides, fungicides, insecticides), antimicrobials (antibacterials, antivirals, antiparasites) are biocides as well. See also *persistent organic pollutant (POP)*.

Bioethics: The branch of ethics that investigates issues surrounding health care and the biological sciences. These include access to the allocation of limited resources (organs, treatment); the authority of the patient, the physician, and others; and the scope and limits of confidentiality. While bioethics has traditionally focused on abortion, euthanasia, surrogacy, in vitro fertilization, and

organ transplants, it is increasingly concerned with drug research, embryonic stem cell research, genetic engineering (cloning, screening, gene therapy), recent work in synthetic biology (biotechnology), and a wide spectrum of environmental concerns.

Biome: The largest, most comprehensive ecological community adapted to a climatic type. While biomes are often thought of in terms of vegetative communities, animals, fungi, and microbes also constitute biomes. The terrestrial biomes are tundra, desert, chaparral, coniferous (boreal) forest, temperate forest, temperate grassland, tropical rainforest, and tropical savanna and scrub. The two basic aquatic biomes, freshwater and marine, include reefs, marshes, swamps, estuaries, shoreline, flowing waters, the continental shelf, lakes and ponds, and the open ocean.

Biomimicry (bionics): Literally ''life imitation,'' a design strategy that takes nonhuman natural process as models to solve human problems. Velcro was inspired by burrs; glue-free tape by the Gecko lizard's sticky feet; and, to achieve passive air conditioning, Eastgate Center in Harare, Zimbabwe, was designed after the termite mound. Some of the underlying assumptions of the biomimetic approach are that ''nature knows best;'' natural things and processes work because they have been ''field-tested'' by evolution; and engineering projects based upon biomimetic principles will be conducive to life, or at least not be detrimental to it.

Biopiracy (bioprospecting): The unauthorized and uncompensated appropriation of biological material (plants, animals, genetic cell lines) or indigenous knowledge for the purposes of commercial development. Insofar as it promises to provide just compensation to aggrieved parties, the concept of biopiracy is attractive to indigenous rights advocates. Yet the concept has been criticized on the grounds that laws against biopiracy cannot provide adequate protection for all indigenous people—not every indigenous territory contains useful biological material—and it is unclear whether biological materials can and should be owned as a matter of natural right.

Bioregion: A territory defined in ecological units (watershed or ecosystem) with similar flora, fauna, and environmental conditions as opposed to a territory defined in political or administrative terms.

Bioregionalism: A loose-knit movement formed in the late 1970s, in response to the modern environmental crisis, which advocates transforming human societies to mirror naturally occurring bioregions. The hope is that if people live in accordance with and in awareness of these ecological units, they will live in a sustainable fashion.

Carbon sequestration: The process of removing and storing atmospheric carbon in forests, oceans, or fossil fuel reservoirs. Efforts are underway to develop technologies that can capture CO_2 emissions and sequester them under pressure underground where they cannot be reemitted into the atmosphere.

Carrying capacity: The maximum population size that a given environment can sustain without degradation.

Charismatic megafauna: See *flagship species*.

Chauvinism, human: The exaggerated belief in and devotion to the supremacy of the human species over all other species. See also *anthropocentrism*.

Coevolution: The biological process, sometimes called an evolutionary arms race, whereby two or more species evolve in response to one another. Such a process includes predator-prey relationships (robins and earthworms) and various mutualistic and parasitic relationships (legumes and nitrogen-fixing bacteria, wasps and caterpillars).

Communalism: An umbrella term centered on notions of the community, shared living, public ownership, and so on.

Consequentialism: Any ethical approach that understands the moral rightness of an action as determined solely by its results. Roughly, if the consequences of an act are good, the act is right; if they are bad, the act is wrong. For the consequentialist, the character and motives of an actor, as well as any formal characteristics of an act itself, are irrelevant to its moral status. The two chief consequentialist theories are ethical egoism and utilitarianism.

Constructivism, ethical: In metaethics, the antirealist view that moral facts exist insofar as they are the result of an actual or hypothetical constructive process. Hence, prior to the constructive process, there are no moral standards or moral facts.

Contractarianism (contractualism): Any theory that justifies moral principles or political arrangements by appealing to a voluntarily accepted social contract that is committed to under ideal conditions—no ignorance of relevant facts and no personal biases, power inequalities, or malicious ambitions.

Cornucopianism: The pro-technology view that material resources are less important than resources of the mind. Necessity, the mother of invention, will see to it that once a problem becomes sufficiently acute—be it pollution, resource depletion, or global climate change—creative minds, motivated by the promise of wealth, will find appropriate solutions. Such an approach implies that there is little reason to conserve resources as they will be replaced by alternatives, that toxic waste is an opportunity to develop waste disposal technologies, and so forth.

Cradle-to-cradle design: A burgeoning design and production approach that seeks not only to reduce but to eliminate all waste from the manufacturing process. Much like a food chain, the goal is for all products and byproducts to feed into production systems thereby wasting nothing. The cradle-to-cradle approach is generally pro-technology and pro-consumerist: sustainability is not about consuming less, but about consuming differently.

Cybernetics: The study of the control and communication processes in living organisms and artificial systems, especially the comparison between the two. A key feature of cybernetics is a system's use of feedback to steer it toward a goal: when the feedback causes changes in the system itself, it appears to be self-organizing.

Cyborg: Short for "cybernetic organism," a self-regulating organism, part-human and part-machine. The proportion of human qualities to machine qualities in cyborgs ranges from humans with synthetic implants (artificial hearts and pacemakers) to futuristic visions of sentient computers that can think thoughts and feel emotions.

Deconstruction: The view that language is a closed system of meanings with little direct reference to actual objects or relations among objects and thus that "reality" is "socially constructed"; deconstruction is the critical process of revealing and undermining the contingent way that the world is organized conceptually, including such binary categories as male/female, mind/body, and nature/culture.

Deontology: Literally the "science of duty," a general approach in ethics that sees the morality of an action in terms of motives for acting as well as the rightness and wrongness of the act itself regardless of consequences.

Distributive justice: Principles about the proper distribution of benefits (power, wealth, privilege) and burdens (taxes, environmental harms) among members of a society. Common bases for distribution are desert, needs, and entitlement.

Divine Command Theory: The theory that morality is grounded in God's will and that ethical principles are simply commandments of God. For many, God is required to make morality strong and firm. The fear is that without an ultimate guarantor of right and wrong, there will be only moral nihilism. The character Ivan Karamazov in Dostoevsky's *The Brothers Karamazov* famously sums up this fear: "If God doesn't exist, everything is permissible?"

Dualism, human/nature: The conscious or unconscious view that humanity and nature are fundamentally distinct, independent, and mutually exclusive. Some interpret the emphasis on the separation of humanity and nature as encouraging the belief that nature is to be controlled or dominated, or else simply a domain of facts to be studied—all hallmark attitudes of Renaissance humanism and contemporary Western science.

Dualism, substance: The view that the mind and the body are fundamentally different substances each with an independent existence and having a unique set of properties. Substance dualism is often used to support the view that, despite changes to the body, up to the point of death, the mental or spiritual substance abides unaffected.

Ecocentrism: In contrast to an *anthropocentrism*, an emphasis on the ecological point of view, frequently crediting ecological units of nature (rivers, species, communities, populations, ecosystems) with rights. Through metaphors like "the web of life," the ecocentric approach tends to view ecological interactions holistically.

Ecofascism: Primarily an inflammatory criticism of ecocentrism asserting that granting rights to ecological units of nature leads to the inappropriate sacrifice of the rights of the individual. As the term is an insult, the connection between ecocentrism and fascist societies—Nazi Germany in particular—is rarely explored. Rather, because supporters of German fascism exalted nature and the "Land" and the Nazi party tapped into this sentiment, or because Hitler was allegedly a vegetarian and animal lover who supported organic farming, any environmental cause or ecocentric approach is bound to be fascist.

Ecological anthropology: The study of how human culture mediates human-environment interactions. Not only does culture influence the character of human interactions with the environment (land, climate, species), but the environment shapes culture (beliefs, traditions, organizations). The principal subdisciplines of contemporary ecological anthropology include cultural ecology, historical ecology, political ecology, spiritual ecology, and environmental anthropology.

Ecological footprint: A spatial metaphor to communicate the total amount of resources required to produce and dispose of the goods and services of a particular lifestyle. An ecological footprint's size is determined by calculating the amount of land needed for food production, housing, transportation, consumer goods, services, and so forth.

Egalitarianism: The doctrine or belief in the equality of humankind—morally, politically, economically, and socially. *Biocentric egalitarianism* extends this notion to confer intrinsic value on all living entities, human and nonhuman, sentient and non-sentient.

Embodied knowledge: Knowledge derived from the subjective experience of one's own body as opposed to knowledge derived from objective, scientific understanding.

Emissions trading: A market-based response to pollution that allows polluters to select cost-effective solutions to achieve specific emissions goals. The open-market trading system allows a polluter to earn emission rights by reducing its emissions to levels below an established standard. In a cap-and-trade system, the government determines an acceptable level of pollution (the "cap") and then issues permits to pollute. Companies producing fewer emissions than allowed can sell or trade their excess capacity to others who might otherwise exceed the cap and incur a penalty.

Endangered species: Any species at risk of extinction throughout all or a significant portion of its range if existing pressures persist. Such pressures include pollution, habitat destruction, invasive species, and unsustainable exploitation. A related term, "threatened species," refers to any species liable to become endangered in the near future.

Enlightenment: Also known as the "Age of Reason," a European intellectual movement of the seventeenth and eighteenth centuries that emphasized the use of reason to critically inspect longstanding doctrines, traditions, and authorities of previous generations.

Environmental determinism: The largely discredited view that the physical environment, as opposed to social circumstances, wholly determines cultural characteristics. Environmental determinism has been associated with outdated racist theories that identify persons from tropical climates as inferior to those from northern climates: tropical climates purportedly cause laziness and promiscuity while variability of weather in northern latitudes purportedly determines a strong work ethic.

Environmental literature: A diffuse, quickly evolving literary genre that includes *nature writing*, oral storytelling, and ecological fiction, drama, and poetry. It is not necessarily concerned with conservationist causes nor is it simply trying to solve environmental problems. Rather, environmental literature is about fundamental human attitudes about the nonhuman natural world and our experience of it. While such explorations may be critical, they may also be celebratory, inquisitive, or downright humorous.

Environmental racism: Deliberate or unintentional racial discrimination in environmental policy making, enforcement of environmental regulations, the targeting of communities for the disposal of toxic wastes and siting of polluting industries, and the distribution of environmental amenities (parks, vistas, open spaces). *Environmental justice* is the movement to end environmental racism.

Ethnobotany: The study of the relationship between people and plants including plant lore, agricultural customs, and the use of plants in medicines and artifacts (houses, storage, modes of transportation).

Ethnocentrism: The conscious or unconscious practice of emphasizing the viewpoint of one's ethnic group and interests over the viewpoint of other cultures. Such bias can lead to the evaluation of other cultures in terms of one's own and perhaps even the belief that one's culture is superior to others.

Eutrophication: The process of nutrient enrichment (nitrogen and phosphorus), increased production of organic matter, and succeeding ecosystem degradation in a water body. In the United States nutrient enrichment is often the result of excess synthetic fertilizers on commercial farmland that gets into riverine systems and eventually into the ocean.

Existentialism: A broad philosophical movement emphasizing subjective choice over objective description, lived experience over abstract reasoning, individuality over mass culture, freedom over determinism, and authenticity over inauthenticity. Insofar as humans create value and meaning in an otherwise meaningless universe, existentialism may also stress one's emotional reaction to such a realization: sadness, dread, or feelings of absurdity about life.

Extinct in the wild: A species whose only living members are in captivity or live as a naturalized population outside of their traditional range. Examples of species extinct in the wild include the Barbary Lion, Spix's Macaw, the Hawaiian Crow, and the Wyoming Toad.

Extirpation: See *local extinction.*

Fact/value distinction: The assumption that facts and values are mutually exclusive. Facts represent what is while values describe what ought to be. The fact/value distinction has been criticized on the grounds that it is impossible to precisely distinguish facts from values as the two necessarily interpermeate.

Flagship species: Any species having broad public appeal and that can be used to promote conservation efforts. The hope is that, in protecting flagship species, entire biological communities and their associated ecosystems will also be protected. *Charismatic megafauna* are large animals belonging to flagship species including lions and tigers, bison and elephants, gorillas and orangutans, pandas and polar bears, and whales and sea turtles.

Fluorocarbon: See *perfluorinated compounds (PFCs).*

Fossil fuels: Any hydrocarbon deposit such as petroleum, coal, or natural gas that, when burned with air directly, produces heat or indirectly produces energy. All fossil fuels are the result of geologic processes acting on the fossilized remains of plants and animals that lived millions of years ago.

Gene bank: A facility that preserves genetic material for the ex situ conservation of individuals (seeds), tissues, and reproductive cells of plants or animals.

Genome, human: The complete set of genetic information or hereditary material in the chromosomes of each cell of a human being.

Green architecture: See *sustainable architecture*.

Green revolution: The intensification of industrial agriculture in the 1960s in the developing world. The green revolution led to a dramatic increase of crop yields per unit area of farmland. Practices supporting such an increase include turning large tracts of land over to monocultures of high-yield cereal crops (rice and wheat); the heavy use of irrigation, pesticides, and synthetic fertilizers; and sowing and harvesting on a single piece of land multiple times per season or per year. The green revolution has been criticized for its long-term deleterious ecological and social effects.

Green space: Open, undeveloped space frequently containing forests, gardens, or grass within or adjacent to a built-up area. Green spaces are often designated for parks, trails, gardens, preserves, playgrounds, or habitat restoration.

Greenhouse gas: Any gas contributing to the greenhouse effect by absorbing some of the outgoing terrestrial infrared radiation and re-emitting it back to the earth's surface. The most important greenhouse gases, in order of relative abundance, are water vapor, carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), and the halocarbon gases.

Human ecology: The study of the interactions between humans, their communities, and the environment including responses to and effects on the environment.

Humanism: A nineteenth-century term for the values and ideals of the European Renaissance. Broadly speaking humanism centers on and assigns a positive role to the human individual as the ultimate source of value, and as capable of developing the moral, physical, spiritual, and rational faculties. The movement was originally sparked by the rediscovery of Greek and Roman literature in the twelfth century.

Hydrography: The study, measurement, and description of large bodies of water. The central goal of hydrography is to provide for safe navigation and protection of the marine environment through the creation of accurate nautical charts and related publications.

Idealism: The metaphysical theory that the external world is not physical but is in fact mental or psychical. The epistemological claim that reality is best explained in terms of psychic phenomena like minds, spirits, or ideas instead of in terms of matter. The ethical device of positing an action, person, political organization, or state of being that is free of all the imperfections that characterize actual actions, persons, political organizations, and states of being.

Individualism/holism debate: The debate over whether the individual or the whole is primary: ethically, semantically, ontologically, or epistemologically. For instance, the ontological individualist claims that individual elements are independent and self-existent whereas for the holist they are interdependent and constituted by the qualities of others. The ontological individualist claims, and the holist denies, that all complex phenomena are reducible; for the holist some qualities only emerge at the level of the whole.

Island biogeography: The study of the geographical distribution of plants and animals on islands or in isolated locales ("habitat islands"). According to the equilibrium theory of island biogeography, species richness on an island stems from a balance between the number of species added by immigration and the number lost to extirpation. First proposed by Edward O. Wilson and Robert H. MacArthur in 1963, the theory is increasingly important to conservation efforts—the creation of habitat islands represents one of the chief threats to biodiversity.

Kantianism: Any philosophical approach or theory that follows the work of Immanuel Kant and, perhaps, shares his interest in elevating philosophy to the level of science. In ethics, Kantianism refers to an emphasis on moral duty, the universalizability of moral commands, and the idea that humans, as rational beings, are ends unto themselves, never simply a means to an end.

Kyoto protocol: First drafted in 1997, the international agreement on global climate change to reduce the emissions by signatory nations of six greenhouse gases to levels below those in 1990. While the United States. has staunchly refused to ratify the protocol, it nevertheless came into effect in 2005 with Russia's ratification of it. By 2004 only the United Kingdom (closely followed by Germany) had met its reduction target while the United States, Canada, Italy, and Japan had all increased their greenhouse gas emissions.

Local extinction: The disappearance or elimination of a population or species in a particular locale but not from its entire range (global extinction). Also known as *extirpation*.

Materialism: The belief that only matter exists. Mind or consciousness is (somehow) reducible to matter, its properties, or interactions.

Mechanism: The view that all phenomena can be explained using the principles by which machines are explained: classical physics and chemistry, and mechanical science.

The seventeenth-century mechanists—Galileo, Boyle, Descartes, Hobbes, and Newton, among others—advanced the theory of mechanism to eliminate all non-observable and mathematically untreatable explanations, in particular vitalistic and teleological explanations. While mechanism has been extremely successful in terms of epistemological clarity and technical application, it has been criticized for unduly reducing the richness and complexity of life to a few basic entities and forces. Opposite of *organicism*.

Mendelian inheritance: As opposed to extrachromosomal inheritance, the pattern of gene inheritance, first described by Gregor Johann Mendel, in which one copy of a gene (allele) is inherited from each parent by an offspring.

Metaphysics: The philosophical study of the most general or abstract characteristics of reality: identity, existence, substance; permanence and change, time and space, cause and effect, difference and sameness, unity and variety, mind and matter, and so forth.

Microcosm/macrocosm: Literally "small-order"/"large-order," the very old and very common belief, found in both Western and Eastern cultures, that parts of the human body correspond to aspects of the universe, that every part mirrors the whole, or that the microcosm corresponds to the macrocosm. Variations on this theme include the analogies between the human being and society, and between society and the universe. Since the Renaissance, the microcosm/macrocosm analogy has largely been displaced by a mechanistic, ontologically materialistic model of the universe.

Naturalism: A broad concept including the notions that (a) the universe is wholly natural, not derived from or constituted by any nonnatural component (supernatural or transcendental); (b) empirical science in principle can explain all phenomena; (c) humans are no different in kind from the rest of the universe; and (d) values do not have a supernatural origin or sanction, but are either humanly constructed or grounded in natural phenomena.

Naturalistic fallacy: First identified by G. E. Moore, the practice of identifying goodness with a natural quality like pleasantness or beauty. For Moore moral goodness is a primitive, unanalyzable, and nonnatural concept that cannot be equated with or explained in terms of natural properties.

Nature writing: Literary nonfiction that intertwines careful, often scientifically oriented, personal observation of the natural world with spiritual, philosophical, and perhaps even political reflections. Nature writers are especially concerned with exploring epistemologies of place, encouraging an appreciation of sensual experience, and tracing the relationship between humans and the "more-than-human world." If nature writing can be said to have an overarching goal, it is to nudge Western culture toward a more sustainable relationship with the world. Nature writing is a subset of *environmental literature*.

Neo-colonialism: The control and management of a weaker nation by a stronger one through economic and cultural measures like trade agreements, the operations of transnational corporations, and particular business models.

Neo-Darwinism: The synthesis of Darwin's theory of evolution by natural selection with Gregor Mendel's theory of genetic inheritance by chance mutation and recombination. Also called the "modern synthesis" and "neo-Darwinianism."

North/South divide: A geographic division thought to reflect the socioeconomic and political divisions between the developed wealthy "northern" countries (Japan, Europe, United States) and the developing or least developed "southern" countries (southern Asia, Africa, Central and South America). As more and more countries in the South industrialize (Mexico and South Korea, for instance), the usefulness of the term will further diminish.

Old growth forest: The North American term for a late successional forest that has not been significantly altered by human activity and that contains numerous mature, dying, and fallen trees.

Organicism: In philosophy, any theory describing the universe as the analog of a living organism, especially in terms of development and organization. Opposite of *mechanism*.

Perennial polyculture: A biomimetic (see *biomimicry*) approach to agriculture in which numerous plantings are intercropped for three or more seasons in rows or mixed arrangements. Perennial polyculture is one response to the degradation and loss of topsoil in industrial monocultural farming with its heavy emphasis on annual crops, frequent plowing, and inputs of synthetic fertilizer and pesticides. Perennial polyculture emphasizes renewable natural resources and the self-regeneration of local ecosystems.

Perfluorinated compounds (PFCs): Also known as "fluorocarbons," human-made chemicals composed of only carbon and fluorine. PFCs are widely used in manufacturing, particularly in food packaging and Teflon products like nonstick cookware. They are a *persistent organic pollutant* and are found in the vast majority of people living in the industrialized world today. While PFCs do not harm the ozone layer, in a gaseous state they are a powerful greenhouse gas.

Persistent Organic Pollutant (POP): A toxic chemical substance persisting in the environment for an unreasonable amount of time, usually decades or more. POPs

also bioaccumulate in food chains and can travel long distances. DDT, PCBs, PFCs, Heptachlor, and Furans are examples of POPs.

Population viability analysis (PVA): Analysis predicting the likelihood that a population or species will persist or go extinct in an environment over a certain period of time. Such analysis includes estimating the minimum size required for a population to persist and the effects on endangered species of habitat loss, fragmentation, and deterioration.

Positivism: Developed by Auguste Comte, the philosophy that there exist three stages of thought—the theological, the metaphysical, and the positive—each having an economic and cultural correlate. The last and highest stage is "positive" insofar as human thought is limited only to facts, to what is positively given, while scrupulously avoiding any *a priori* speculation. Positivism is sanguine about science's ability to explain all phenomena as well as the advantages of a thoroughly scientific society.

Post-materialism: A cultural shift of focus from material affluence and physical security to quality-of-life concerns, including civil liberties, minority rights, and environmental protection. It is uncertain whether the United States has ever fully experienced a post-material revolution.

Postmodernism: In philosophy, the view that universal statements about value, progress, or historical causation are impossible because all knowledge is shaped by the conceptual framework of the knower. Everything we perceive and interpret is necessarily influenced by specific circumstances, including, for instance, sex, gender, class, culture, biology, and historical era. Thus, knowledge can never be universal, but must always be partial, situated, and embodied. Postmodernism has led to a proliferation of philosophical theories critical of grand narratives, most notably post-structuralism. See also *relativism, ethical.*

Precautionary principle: The principle that an action should not be undertaken until its effects are adequately understood and deemed safe. The precautionary principle requires that new technology be considered guilty until proven innocent.

Preservationism: Any movement that seeks to protect natural areas, historical sites, or endangered species from loss or danger due to human intervention.

Primatology: The interdisciplinary study of nonhuman primates. Today many primatologists work with conservation groups to preserve the habitats and populations of the species they study.

Progressivism: A period of economic and social reform in the United States that occurred roughly between 1900 and 1920. Progressives were composed of Democrats, Republicans, and nonpartisans, all of whom were distressed by the concentration of political and economic power, which they believed was contrary to equality and democracy. Progressives called for the government to be more active in reform and to eliminate inequities created by the rapid industrialization of America. Much of the Progressive agenda passed into law during the presidencies of Theodore Roosevelt, William Howard Taft, and Woodrow Wilson.

Reductionism (reductivism): Either the explanation of all fields of knowledge in terms of a single, simpler science (physics) or the metaphysical belief that all things, regardless of outward appearance, are really just one kind of thing. While reductionism was popular in the early days of analytic philosophy, the failure of philosophers to come up with satisfactory inter-theoretic reductions along with the recognition of emergent or supervenient properties has undermined enthusiasm about reductionism as a philosophical program. Nonetheless, as a general methodological tendency, reductionism still holds sway in most academic disciplines today.

Relativism, ethical: The doctrine that moral values are relative to particular persons or cultures and cannot be assessed apart from these criteria. If values are relative, no overarching standards exist according to which individuals and cultures can be judged—what is right in one place may be wrong in another simply because the only criteria for distinguishing right from wrong are the moral values of the society or individual. See also *postmodernism.*

Relativity theory: First proposed by Albert Einstein, the theory that time, space, and mass, rather than being absolutes, are relative to the observer and the observed.

Rights: A certain type of relationship between two parties, the rights holder and the rights observer. For the holder, a right is a permission to act; for the observer, it is an obligation to respect that permission. While rights of noninterference (negative rights) are widely accepted in the United States, rights that obligate others to take positive steps in helping a person exercise his or her right (positive rights)—such as Affirmative Action or basic health care—are controversial insofar as they may allow for an endless expansion of rights. Perhaps due to the ascendancy of individualism in Western society, rights talk is the commonest form of moral discourse today.

Scholasticism: The methods and teachings of academic philosophers and theologians of the Middle Ages beginning with St. Augustine in the fifth century and lasting up to the mid-seventeenth century with the birth of Renaissance humanism. A primary goal of scholasticism was to reconcile faith with reason, Christian theology

with the Greek philosophy of Aristotle (and to a lesser extent Plato). With the coming of the Renaissance, scholasticism's methods of deductive logic and dialectical reasoning were fiercely criticized and replaced by the methods of modern science as first articulated by Galileo Galilei, Francis Bacon, René Descartes, and Thomas Hobbes, among others.

Speciation: The biological process by which new species arise from pre-existing species. The main type of species development is allopatric speciation or development owing to the physical separation of populations over a geographic distance. A new species emerges when it can no longer interbreed with the population from which it was isolated. At this point each species embarks upon an independent evolutionary trajectory.

Supernaturalism: Belief in a domain of existence over and above the natural or material domain. Belief in ultimate forces or agencies that transcend the universe but somehow influence natural events in it.

Superorganism: A collection of individual yet interdependent organisms that behave as if they were a single organism. Examples of superorganisms include coral, insect colonies, and the Portuguese man-of-war. Frederick Clements argued that what later came to be called ecosystems were also superorganisms.

Synecology: The study of entire communities of organisms and interactions within them. Contrast to *autecology*.

Theocentrism: Literally "God-centered." In contrast to anthropocentrism, the belief that God's values, including the God-ordained goodness of creation, trump human values, including the way humans value nature.

Transcendentalism: A literary and philosophical movement of nineteenth-century American philosophers and writers who postulated the existence of a nonphysical, spiritual reality knowable only through intuition, the highest form of knowledge. They also emphasized humanity's essential goodness, God's immanence in nature, and the essential unity of creation; along with the values of individualism, self-reliance, and the rejection of authority. The central Transcendentalists were Ralph Waldo Emerson, Henry David Thoreau, Margaret Fuller, and Amos Bronson Alcott. The movement has influenced scores of American writers including Nathaniel Hawthorne, Herman Melville, and Walt Whitman.

List of Primary Sources

THE LAND ETHIC

SOURCE Leopold, Aldo. 1968 (1949). In *A Sand County Almanac and Sketches Here and There.* Oxford, U.K.: Oxford University Press.

INTRODUCTION *Aldo Leopold (1887–1948) worked for nineteen years in the U.S. Forest Service beginning in 1909. His writings have been extremely influential in conservation and in the development of the field of environmental ethics. Leopold begins the essay "The Land Ethic" by discussing the development of ethics, which historically has steadily extended outward to encompass more and more subjects. Ethics evolved as a means of social cohesion and developed correlatively to the development of societies or communities—from small bands of hunter-gatherers to the global village. Leopold argues for the necessity of taking the next step in the sequence of social-ethical evolution—an ethic dealing with our relationship to the land and nonhuman life. Ethics acknowledges the membership of an individual in a community, and Leopold urges ecologically broadening our understanding of community to include the land itself. A shift is required from humanity's role of conqueror over nature to "plain member and citizen of it." Embracing this shift would prevent approaching land-use issues purely out of self-interest. Bringing about such an ethic would require a change in conscience, leading individuals to feel a sense of personal obligation to the land. To explain this, Leopold characterizes the land pyramid to show that the land is something toward which we can and must act ethically, rather than basing our actions on what is economically expedient.*

A FABLE FOR TOMORROW

SOURCE Carson, Rachel. 1962. *Silent Spring.* Boston: Houghton Mifflin. Copyright renewed 1990 by Roger Christie. Reproduced by permission of Houghton Mifflin.

INTRODUCTION *Rachel Carson (1907–1964) was a marine biologist for the U.S. Bureau of Fisheries who later devoted herself full time to nature writing. Her concern about pesticides, in relation to conservation and environmental issues, led to the writing of* Silent Spring*, which is often cited as the book that launched the modern environmental movement. In "A Fable for Tomorrow," the book's first chapter, Carson traces the effects of the pesticide DDT on an imaginary town. She evokes a town once full of life, color, and voices, where human and nonhuman life mysteriously becomes sick and dies. An uncharacteristic stillness descends upon this town, the cause of which can be traced back to a "white granular powder." Who or what is responsible? It is the people of this town who have brought this unnatural stillness and death upon themselves. Carson closes with the claim that, while this is an imaginary town, these events were happening in real places around the country. Her book is an attempt to explain how and why.*

There was once a town in the heart of America where all life seemed to live in harmony with its surroundings. The town lay in the midst of a checkerboard of prosperous farms, with fields of grain and hillsides of orchards where, in spring, white clouds of bloom drifted above the green fields. In autumn, oak and maple and birch set up a blaze of color that flamed and flickered across a backdrop of pines. Then foxes barked in the hills and deer silently crossed the fields, half hidden in the mists of the fall mornings.

Along the roads, laurel, viburnum and alder, great ferns and wildflowers delighted the traveler's eye through much of the year. Even in winter the roadsides were places of beauty, where countless birds came to feed on the berries and on the seed heads of the dried weeds rising above the snow. The countryside was, in fact, famous for the abundance and variety of its bird life, and when the flood of migrants was pouring through in spring and fall people traveled from great distances to observe them. Others came to fish the streams, fish flowed clear and cold out of the hills and contained shady pools where trout lay. So it had been from the days many years ago when the first settlers raised their houses, sank their wells, and built their barns.

Then a strange blight crept over the area and everything began to change. Some evil spell had settled on the community: mysterious maladies swept the flocks of chickens; the cattle and sheep sickened and died. Everywhere was a shadow of death. The farmers spoke of much illness among their families. In the town the doctors had become more and more puzzled by new kinds of sickness appearing among their patients. There had been several sudden and unexplained deaths, not only among adults but even among children, who would be stricken suddenly while at play and die within a few hours.

There was a strange stillness. The birds, for example—where had they gone? Many people spoke of them, puzzled and disturbed. The feeding stations in the backyards were deserted. The few birds seen anywhere were moribund; they trembled violently and could not fly. It was spring without voices. On the mornings that had once throbbed with the dawn chorus of robins, catbirds, doves, jays, wrens, and scores of other bird voices there was now no sound; only silence lay over the fields and woods and marsh.

On the farms the hens brooded, but no chicks hatched. The farmers complained that they were unable to raise any pigs—the litters were small and the young survived only a few days. The apple trees were coming into bloom but no bees droned among the blossoms, so there was no pollination and there would be no fruit.

The roadsides, once so attractive, were now lined with browned and withered vegetation as though swept by fire. These, too, were silent, deserted by all living things. Even the streams were now lifeless. Anglers no longer visited them, for all the fish had died.

In the gutters under the eaves and between the shingles of the roofs, a white granular powder still showed a few patches; some weeks before it had fallen like snow upon the roofs and the lawns, the fields and streams.

No witchcraft, no enemy action had silenced the rebirth of new life in this stricken world. The people had done it themselves.

This town does not actually exist, but it might easily have a thousand counterparts in America or elsewhere in the world. I know of no community that has experienced all the misfortunes I describe. Yet every one of these disasters has actually happened somewhere, and many real communities have already suffered a substantial number of them. A grim specter has crept upon us almost unnoticed, and this imagined tragedy may easily become a stark reality we all shall know.

What has already silenced the voices of spring in countless towns in America? This book is an attempt to explain.

THE HISTORICAL ROOTS OF OUR ECOLOGIC CRISIS

SOURCE White Jr., Lynn. 1967. *Science.* 155 (March 10): 1203–1207. Reproduced by permission of AAAS.

INTRODUCTION *Lynn White Jr. (1907–1987) was professor of medieval history at the University of California, Los Angeles; he also taught at Princeton and Stanford and served as president of Mills College in Oakland, California, for fifteen years. "The Historical Roots of Our Ecologic Crisis" is a seminal piece in environmental ethics that often serves as the starting point for addressing environmental issues as they relate to philosophy. White argues that while all living things modify their environments, the ability of humanity to transform our environment radically changed when we married science to technology, which is the proximate cause of the current ecological crisis. White argues that science and technology are distinctively Western in provenance, born when Europe was dominated by the Christian worldview. He characterizes Christianity as anthropocentric and argues that it desanctifies nature, leaving it vulnerable to exploitation. Christianity thus bears significant blame for the ecological crisis. White does allow for an alternative Christian tradition that focuses on St. Francis of Assisi. Science and technology cannot solve our environmental problems, and indeed will only exacerbate them unless we address the fact that the crisis is largely conceptual in nature. Ultimately, White famously claims, we must either "find a new religion or rethink our old one." More generally, he claims that what we do in regard to the natural environment depends on what we think about it and about ourselves in relationship to it.*

A conversation with Aldous Huxley not infrequently put one at the receiving end of an unforgettable monologue. About a year before his lamented death he was discoursing on a favorite topic: Man's unnatural treatment of nature and its sad results. To illustrate his point he told how, during the previous summer, he had returned to a little valley in England where he had spent many happy months as a child. Once it had been composed of delightful grassy glades; now it was becoming overgrown with unsightly brush because the rabbits that formerly kept such growth under control had largely succumbed to a disease, myxomatosis, that was deliberately introduced by the local farmers to reduce the rabbits' destruction of crops. Being something of a Philistine, I could be silent no longer, even in the interests of great rhetoric. I interrupted to point out that the rabbit itself had been brought as a domestic animal to England in 1176, presumably to improve the protein diet of the peasantry.

All forms of life modify their contexts. The most spectacular and benign instance is doubtless the coral polyp. By serving its own ends, it has created a vast undersea world favorable to thousands of other kinds of animals and plants. Ever since man became a numerous species he has affected his environment notably. The hypothesis that his fire-drive method of hunting created the world's great grasslands and helped to exterminate the monster mammals of the Pleistocene from much of the globe is plausible, if not proved. For 6 millennia at least, the banks of the lower Nile have been a human artifact rather than the swampy African jungle which nature, apart from man, would have made it. The Aswan Dam, flooding 5000 square miles, is only the latest stage in a long process. In many regions terracing or irrigation, overgrazing, the cutting of forests by Romans to build ships to fight Carthaginians or by Crusaders to solve the logistics problems of their expeditions, have profoundly changed some ecologies. Observation that the French landscape falls into two basic types, the open fields of the north and the bocage of the south and west, inspired Marc Bloch to undertake his classic study of medieval agricultural methods. Quite unintentionally, changes in human ways often affect nonhuman nature. It has been noted, for example, that the advent of the automobile eliminated huge flocks of sparrows that once fed on the horse manure littering every street.

The history of ecologic change is still so rudimentary that we know little about what really happened, or what the results were. The extinction of the European aurochs as late as 1627 would seem to have been a simple case of overenthusiastic hunting. On more intricate matters it often is impossible to find solid information. For a thousand years or more the Frisians and Hollanders have been pushing back the North Sea, and the process is culminating in our own time in the reclamation of the Zuider Zee. What, if any, species of animals, birds, fish, shore life, or plants have died out in the process? In their epic combat with Neptune have the Netherlanders overlooked ecological values in such a way that the quality of human life in the Netherlands has suffered? I cannot discover that the questions have ever been asked, much less answered.

People, then, have often been a dynamic element in their own environment, but in the present state of historical scholarship we usually do not know exactly when, where, or with what effects man-induced changes came. As we enter the last third of the 20th century, however, concern for the problem of ecologic backlash is mounting feverishly. Natural science, conceived as the effort to understand the nature of things, had flourished in several eras and among several peoples. Similarly there had been an age-old accumulation of technological skills, sometimes growing rapidly, sometimes slowly. But it was not

until about four generations ago that Western Europe and North America arranged a marriage between science and technology, a union of the theoretical and the empirical approaches to our natural environment. The emergence in widespread practice of the Baconian creed that scientific knowledge means technological power over nature can scarcely be dated before about 1850, save in the chemical industries, where it is anticipated in the 18th century. Its acceptance as a normal pattern of action may mark the greatest event in human history since the invention of agriculture, and perhaps in nonhuman terrestrial history as well.

Almost at once the new situation forced the crystallization of the novel concept of ecology; indeed, the word ecology first appeared in the English language in 1873. Today, less than a century later, the impact of our race upon the environment has so increased in force that it has changed in essence. When the first cannons were fired, in the early 14th century, they affected ecology by sending workers scrambling to the forests and mountains for more potash, sulphur, iron ore, and charcoal, with some resulting erosion and deforestation. Hydrogen bombs are of a different order: a war fought with them might alter the genetics of all life on this planet. By 1285 London had a smog problem arising from the burning of soft coal, but our present combustion of fossil fuels threatens to change the chemistry of the globe's atmosphere as a whole, with consequences which we are only beginning to guess. With the population explosion, the carcinoma of planless urbanism, the now geological deposits of sewage and garbage, surely no creature other than man has ever managed to foul its nest in such short order.

There are many calls to action, but specific proposals, however worthy as individual items, seem too partial, palliative, negative: ban the bomb, tear down the billboards, give the Hindus contraceptives and tell them to eat their sacred cows. The simplest solution to any suspect change is, of course, to stop it, or better yet, to revert to a romanticized past: make those ugly gasoline stations look like Anne Hathaway's cottage or (in the Far West) like ghost-town saloons. The "wilderness area" mentality invariably advocates deep-freezing an ecology, whether San Gimignano or the High Sierra, as it was before the first Kleenex was dropped. But neither atavism nor prettification will cope with the ecologic crisis of our time.

What shall we do? No one yet knows. Unless we think about fundamentals, our specific measures may produce new backlashes more serious than those they are designed to remedy.

As a beginning we should try to clarify our thinking by looking, in some historical depth, at the presuppositions that underlie modern technology and science. Science was traditionally aristocratic, speculative, intellectual in intent; technology was lower-class, empirical, action-oriented. The quite sudden fusion of these two, towards the middle of the 19th century, is surely related to the slightly prior and contemporary democratic revolutions which, by reducing social barriers, tended to assert a functional unity of brain and hand. Our ecologic crisis is the product of an emerging, entirely novel, democratic culture. The issue is whether a democratized world can survive its own implications. Presumably we cannot unless we rethink our axioms.

THE WESTERN TRADITIONS OF TECHNOLOGY AND SCIENCE

One thing is so certain that it seems stupid to verbalize it: both modern technology and modern science are distinctively Occidental. Our technology has absorbed elements from all over the world, notably from China; yet everywhere today, whether in Japan or in Nigeria, successful technology is Western. Our science is the heir to all the sciences of the past, perhaps to the work of the great Islamic scientists of the Middle Ages, who so often outdid the ancient Greeks in skill and perspicacity: al-Razi in medicine, for example; or ibn-al-Haytham in optics; or Omar Khayyam in mathematics. Indeed, not a few works of such geniuses seem to have vanished in the original Arabic and to survive only in medieval Latin translations that helped to lay the foundations for later Western developments. Today, around the globe, all significant science is Western in style and method, whatever the pigmentation or language of the scientists.

A second pair of facts is less well recognized because they result from quite recent historical scholarship. The leadership of the West, both in technology and in science, is far older than the so-called Scientific Revolution of the 17th century or the so-called Industrial Revolution of the 18th century. These terms are in fact outmoded and obscure the true nature of what they try to describe—significant stages in two long and separate developments. By A.D. 1000 at the latest—and perhaps, feebly, as much as 200 years earlier—the West began to apply water power to industrial processes other than milling grain. This was followed in the late 12th century by the harnessing of wind power. From simple beginnings, but with remarkable consistency of style, the West rapidly expanded its skills in the development of power machinery, labor-saving devices, and automation. Those who doubt should contemplate that most monumental achievement in the history of automation: the weight-driven mechanical clock, which appeared in two forms in the early 14th century. Not in craftsmanship but in basic technological capacity, the Latin West of the later Middle Ages far outstripped its elaborate, sophisticated, and esthetically magnificent sister cultures, Byzantium and Islam. In 1444 a great Greek ecclesiastic, Bessarion,

who had gone to Italy, wrote a letter to a prince in Greece. He is amazed by the superiority of Western ships, arms, textiles, glass. But above all he is astonished by the spectacle of waterwheels sawing timbers and pumping the bellows of blast furnaces. Clearly, he had seen nothing of the sort in the Near East.

By the end of the 15th century the technological superiority of Europe was such that its small, mutually hostile nations could spill out over all the rest of the world, conquering, looting, and colonizing. The symbol of this technological superiority is the fact that Portugal, one of the weakest states of the Occident, was able to become, and to remain for a century, mistress of the East Indies. And we must remember that the technology of Vasco da Gama and Albuquerque was built by pure empiricism, drawing remarkably little support or inspiration from science.

In the present-day vernacular understanding, modern science is supposed to have begun in 1543, when both Copernicus and Vesalius published their great works. It is no derogation of their accomplishments, however, to point out that such structures as the Fabrica and the De revolutionibus do not appear overnight. The distinctive Western tradition of science, in fact, began in the late 11th century with a massive movement of translation of Arabic and Greek scientific works into Latin. A few notable books—Theophrastus, for example—escaped the West's avid new appetite for science, but within less than 200 years effectively the entire corpus of Greek and Muslim science was available in Latin, and was being eagerly read and criticized in the new European universities. Out of criticism arose new observation, speculation, and increasing distrust of ancient authorities. By the late 13th century Europe had seized global scientific leadership from the faltering hands of Islam. It would be as absurd to deny the profound originality of Newton, Galileo, or Copernicus as to deny that of the 14th century scholastic scientists like Buridan or Oresme on whose work they built. Before the 11th century, science scarcely existed in the Latin West, even in Roman times. From the 11th century onward, the scientific sector of Occidental culture has increased in a steady crescendo.

Since both our technological and our scientific movements got their start, acquired their character, and achieved world dominance in the Middle Ages, it would seem that we cannot understand their nature or their present impact upon ecology without examining fundamental medieval assumptions and developments.

MEDIEVAL VIEW OF MAN AND NATURE

Until recently, agriculture has been the chief occupation even in "advanced" societies; hence, any change in methods of tillage has much importance. Early plows, drawn by two oxen, did not normally turn the sod but merely scratched it. Thus, cross-plowing was needed and fields tended to be squarish. In the fairly light soils and semiarid climates of the Near East and Mediterranean, this worked well. But such a plow was inappropriate to the wet climate and often sticky soils of northern Europe. By the latter part of the 7th century after Christ, however, following obscure beginnings, certain northern peasants were using an entirely new kind of plow, equipped with a vertical knife to cut the line of the furrow, a horizontal share to slice under the sod, and a moldboard to turn it over. The friction of this plow with the soil was so great that it normally required not two but eight oxen. It attacked the land with such violence that cross-plowing was not needed, and fields tended to be shaped in long strips.

In the days of the scratch-plow, fields were distributed generally in units capable of supporting a single family. Subsistence farming was the presupposition. But no peasant owned eight oxen: to use the new and more efficient plow, peasants pooled their oxen to form large plow-teams, originally receiving (it would appear) plowed strips in proportion to their contribution. Thus, distribution of land was based no longer on the needs of a family but, rather, on the capacity of a power machine to till the earth. Man's relation to the soil was profoundly changed. Formerly man had been part of nature; now he was the exploiter of nature. Nowhere else in the world did farmers develop any analogous agricultural implement. Is it coincidence that modern technology, with its ruthlessness toward nature, has so largely been produced by descendants of these peasants of northern Europe?

This same exploitive attitude appears slightly before A.D. 830 in Western illustrated calendars. In older calendars the months were shown as passive personifications. The new Frankish calendars, which set the style for the Middle Ages, are very different: they show men coercing the world around them—plowing, harvesting, chopping trees, butchering pigs. Man and nature are two things, and man is master.

These novelties seem to be in harmony with larger intellectual patterns. What people do about their ecology depends on what they think about themselves in relation to things around them. Human ecology is deeply conditioned by beliefs about our nature and destiny—that is, by religion. To Western eyes this is very evident in, say, India or Ceylon. It is equally true of ourselves and of our medieval ancestors.

The victory of Christianity over paganism was the greatest psychic revolution in the history of our culture. It has become fashionable today to say that, for better or worse, we live in the "post-Christian age." Certainly the

forms of our thinking and language have largely ceased to be Christian, but to my eye the substance often remains amazingly akin to that of the past. Our daily habits of action, for example, are dominated by an implicit faith in perpetual progress which was unknown either to Greco-Roman antiquity or to the Orient. It is rooted in, and is indefensible apart from, Judeo-Christian theology. The fact that Communists share it merely helps to show what can be demonstrated on many other grounds: that Marxism, like Islam, is a Judeo-Christian heresy. We continue today to live, as we have lived for about 1700 years, very largely in a context of Christian axioms.

What did Christianity tell people about their relations with the environment? While many of the world's mythologies provide stories of creation, Greco-Roman mythology was singularly incoherent in this respect. Like Aristotle, the intellectuals of the ancient West denied that the visible world had a beginning. Indeed, the idea of a beginning was impossible in the framework of their cyclical notion of time. In sharp contrast, Christianity inherited from Judaism not only a concept of time as nonrepetitive and linear but also a striking story of creation. By gradual stages a loving and all-powerful God had created light and darkness, the heavenly bodies, the earth and all its plants, animals, birds, and fishes. Finally, God had created Adam and, as an afterthought, Eve to keep man from being lonely. Man named all the animals, thus establishing his dominance over them. God planned all of this explicitly for man's benefit and rule: no item in the physical creation had any purpose save to serve man's purposes. And, although man's body is made of clay, he is not simply part of nature: he is made in God's image.

Especially in its Western form, Christianity is the most anthropocentric religion the world has seen. As early as the 2nd century both Tertullian and Saint Irenaeus of Lyons were insisting that when God shaped Adam he was foreshadowing the image of the incarnate Christ, the Second Adam. Man shares, in great measure, God's transcendence of nature. Christianity, in absolute contrast to ancient paganism and Asia's religions (except, perhaps, Zorastrianism), not only established a dualism of man and nature but also insisted that it is God's will that man exploit nature for his proper ends.

At the level of the common people this worked out in an interesting way. In Antiquity every tree, every spring, every stream, every hill had its own genius loci, its guardian spirit. These spirits were accessible to men, but were very unlike men; centaurs, fauns, and mermaids show their ambivalence. Before one cut a tree, mined a mountain, or dammed a brook, it was important to placate the spirit in charge of that particular situation, and to keep it placated. By destroying pagan animism, Christianity made it possible to exploit nature in a mood of indifference to the feelings of natural objects.

It is often said that for animism the Church substituted the cult of saints. True; but the cult of saints is functionally quite different from animism. The saint is not in natural objects; he may have special shrines, but his citizenship is in heaven. Moreover, a saint is entirely a man; he can be approached in human terms. In addition to saints, Christianity of course also had angels and demons inherited from Judaism and perhaps, at one remove, from Zorastrianism. But these were all as mobile as the saints themselves. The spirits in natural objects, which formerly had protected nature from man, evaporated. Man's effective monopoly on spirit in this world was confirmed, and the old inhibitions to the exploitation of nature crumbled.

When one speaks in such sweeping terms, a note of caution is in order. Christianity is a complex faith, and its consequences differ in differing contexts. What I have said may well apply to the medieval West, where in fact technology made spectacular advances. But the Greek East, a highly civilized realm of equal Christian devotion, seems to have produced no marked technological innovation after the late 7th century, when Greek fire was invented. The key to the contrast may perhaps be found in a difference in the tonality of piety and thought which students of comparative theology find between the Greek and the Latin Churches. The Greeks believed that sin was intellectual blindness, and that salvation was found in illumination, orthodoxy—that is, clear thinking. The Latins, on the other hand, felt that sin was moral evil, and that salvation was to be found in right conduct. Eastern theology has been intellectualist. Western theology has been voluntarist. The Greek saint contemplates; the Western saint acts. The implications of Christianity for the conquest of nature would emerge more easily in the Western atmosphere.

The Christian dogma of creation, which is found in the first clause of all the Creeds, has another meaning for our comprehension of today's ecologic crisis. By revelation, God had given man the Bible, the Book of Scripture. But since God had made nature, nature also must reveal the divine mentality. The religious study of nature for the better understanding of God was known as natural theology. In the early Church, and always in the Greek East, nature was conceived primarily as a symbolic system through which God speaks to men: the ant is a sermon to sluggards; rising flames are the symbol of the soul's aspiration. The view of nature was essentially artistic rather than scientific. While Byzantium preserved and copied great numbers of ancient Greek scientific texts, science as we conceive it could scarcely flourish in such an ambience.

However, in the Latin West by the early 13th century natural theology was following a very different bent. It was ceasing to be the decoding of the physical symbols of

God's communication with man and was becoming the effort to understand God's mind by discovering how his creation operates. The rainbow was no longer simply a symbol of hope first sent to Noah after the Deluge: Robert Grosseteste, Friar Roger Bacon, and Theodoric of Freiberg produced startlingly sophisticated work on the optics of the rainbow, but they did it as a venture in religious understanding. From the 13th century onward, up to and including Leitnitz and Newton, every major scientist, in effect, explained his motivations in religious terms. Indeed, if Galileo had not been so expert an amateur theologian he would have got into far less trouble: the professionals resented his intrusion. And Newton seems to have regarded himself more as a theologian than as a scientist. It was not until the late 18th century that the hypothesis of God became unnecessary to many scientists.

It is often hard for the historian to judge, when men explain why they are doing what they want to do, whether they are offering real reasons or merely culturally acceptable reasons. The consistency with which scientists during the long formative centuries of Western science said that the task and the reward of the scientist was "to think God's thoughts after him" leads one to believe that this was their real motivation. If so, then modern Western science was cast in a matrix of Christian theology. The dynamism of religious devotion shaped by the Judeo-Christian dogma of creation, gave it impetus.

AN ALTERNATIVE CHRISTIAN VIEW

We would seem to be headed toward conclusions unpalatable to many Christians. Since both science and technology are blessed words in our contemporary vocabulary, some may be happy at the notions, first, that viewed historically, modern science is an extrapolation of natural theology and, second, that modern technology is at least partly to be explained as an Occidental, voluntarist realization of the Christian dogma of man's transcendence of, and rightful master over, nature. But, as we now recognize, somewhat over a century ago science and technology—hitherto quite separate activities—joined to give mankind powers which, to judge by many of the ecologic effects, are out of control. If so, Christianity bears a huge burden of guilt.

I personally doubt that disastrous ecologic backlash can be avoided simply by applying to our problems more science and more technology. Our science and technology have grown out of Christian attitudes toward man's relation to nature which are almost universally held not only by Christians and neo-Christians but also by those who fondly regard themselves as post-Christians. Despite Copernicus, all the cosmos rotates around our little globe. Despite Darwin, we are not, in our hearts, part of the natural process. We are superior to nature, contemptuous of it, willing to use it for our slightest whim. The newly elected Governor of California, like myself a churchman but less troubled than I, spoke for the Christian tradition when he said (as is alleged), "when you've seen one redwood tree, you've seen them all." To a Christian a tree can be no more than a physical fact. The whole concept of the sacred grove is alien to Christianity and to the ethos of the West. For nearly 2 millennia Christian missionaries have been chopping down sacred groves, which are idolatrous because they assume spirit in nature.

What we do about ecology depends on our ideas of the man-nature relationship. More science and more technology are not going to get us out of the present ecologic crisis until we find a new religion, or rethink our old one. The beatniks, who are the basic revolutionaries of our time, show a sound instinct in their affinity for Zen Buddhism, which conceives of the man-nature relationship as very nearly the mirror image of the Christian view. Zen, however, is as deeply conditioned by Asian history as Christianity is by the experience of the West, and I am dubious of its viability among us.

Possibly we should ponder the greatest radical in Christian history since Christ: Saint Francis of Assisi. The prime miracle of Saint Francis is the fact that he did not end at the stake, as many of his left-wing followers did. He was so clearly heretical that a General of the Franciscan Order, Saint Bonavlentura, a great and perceptive Christian, tried to suppress the early accounts of Franciscanism. The key to an understanding of Francis is his belief in the virtue of humility—not merely for the individual but for man as a species. Francis tried to depose man from his monarchy over creation and set up a democracy of all God's creatures. With him the ant is no longer simply a homily for the lazy, flames a sign of the thrust of the soul toward union with God; now they are Brother Ant and Sister Fire, praising the Creator in their own ways as Brother Man does in his.

Later commentators have said that Francis preached to the birds as a rebuke to men who would not listen. The records do not read so: he urged the little birds to praise God, and in spiritual ecstasy they flapped their wings and chirped rejoicing. Legends of saints, especially the Irish saints, had long told of their dealings with animals but always, I believe, to show their human dominance over creatures. With Francis it is different. The land around Gubbio in the Apennines was ravaged by a fierce wolf. Saint Francis, says the legend, talked to the wolf and persuaded him of the error of his ways. The wolf repented, died in the odor of sanctity, and was buried in consecrated ground.

What Sir Steven Ruciman calls "the Franciscan doctrine of the animal soul" was quickly stamped out. Quite possibly it was in part inspired, consciously or unconsciously, by the belief in reincarnation held by the Cathar heretics who at that time teemed in Italy and southern

France, and who presumably had got it originally from India. It is significant that at just the same moment, about 1200, traces of metempsychosis are found also in western Judaism, in the Provencal Cabbala. But Francis held neither to transmigration of souls nor to pantheism. His view of nature and of man rested on a unique sort of panpsychism of all things animate and inaminate, designed for the glorification of their transcendent Creator, who, in the ultimate gesture of cosmic humility, assumed flesh, lay helpless in a manger, and hung dying on a scaffold.

I am not suggesting that many contemporary Americans who are concerned about our ecologic crisis will be either able or willing to counsel with wolves or exhort birds. However, the present increasing disruption of the global environment is the product of a dynamic technology and science which were originating in the Western medieval world against which Saint Francis was rebelling in so original a way. Their growth cannot be understood historically apart from distinctive attitudes toward nature which are deeply grounded in Christian dogma. The fact that most people do not think of these attitudes as Christian is irrelevant. No new set of basic values has been accepted in our society to displace those of Christianity. Hence we shall continue to have a worsening ecologic crisis until we reject the Christian axiom that nature has no reason for existence save to serve man.

The greatest spiritual revolutionary in Western history, Saint Francis, proposed what he thought was an alternative Christian view of nature and man's relation to it; he tried to substitute the idea of the equality of all creatures, including man, for the idea of man's limitless rule of creation. He failed. Both our present science and our present technology are so tinctured with orthodox Christian arrogance toward nature that no solution for our ecologic crisis can be expected from them alone. Since the roots of our trouble are so largely religious, the remedy must also be essentially religious, whether we call it that or not. We must rethink and refeel our nature and destiny. The profoundly religious, but heretical, sense of the primitive Franciscans for the spiritual autonomy of all parts of nature may point a direction. I propose Francis as a patron saint for ecologists.

THE TRAGEDY OF THE COMMONS

SOURCE Hardin, Garrett. 1968. *Science* 162 (December 13): 1243–1248. Reproduced by permission of AAAS.

INTRODUCTION *Garrett Hardin (1915–2003) was for fifteen years professor of human ecology at the University of California, Santa Barbara. He begins his hugely influential "The Tragedy of the Commons" by drawing attention to the fact that there are some problems for which a technical solution does not exist. The "population problem" falls into this class of problems; failure to acknowledge this fact will lead to increased human suffering in a world of finite resources. Hardin argues that to adequately address the urgent population problem, we must reject Adam Smith's notion of the "invisible hand." He provides the now-famous example of herdsmen adding cattle to a pasture open to all, to disprove the operative assumption in Smith that an individual, pursuing his own good, will produce a collective good. In this imagined commons, a rational agent is compelled to seek his own benefit at the expense of the collective good, thus bringing ruin to all. Hardin argues that population growth (as well as a host of other problems) is a problem of the commons, and that we must abandon the idea of the unregulated freedom to breed if we wish to preserve other freedoms.*

ECOLOGY AND MAN—A VIEWPOINT

SOURCE Shepard, Paul. 1969. "Ecology and Man—a Viewpoint." *The Subversive Science.* Paul Shepard and Daniel McKinley, eds. Boston: Houghton Mifflin.

INTRODUCTION *Paul Shepard (1925–1996) was Avery Professor of natural philosophy and human ecology at Pitzer College and Claremont Graduate School, where he taught for twenty-one years. In the introduction to his influential collection of essays,* The Subversive Science: Essays Toward an Ecology of Man *(co-edited with Daniel McKinley), Shepard begins by criticizing the "web of life" metaphor in ecology for failing to accurately reflect the complexity of the natural world. Shepard urges that we revive a more ancient way of perceiving humanity in the world. To do so entails redefining the self as something not distinct from nature, but extended into nature, where we overcome the dualism that has dominated much recent human history. For Shepard, humanity and the environment are interdependent; the complexity of humanity is directly linked to the complexity of natural systems.*

Shepard insists that this fact be highlighted in a time where the diversity and complexity of systems are diminishing. Part of the role of ecology, as Shepard describes it, is to realize that the "ecological crisis" is partly a matter of shifting values, and ecology must strive to communicate our interconnectedness with, and likeness to, nonhuman nature.

Ecology is sometimes characterized as the study of a natural "web of life." It would follow that man is somewhere in the web or that he in fact manipulates its strands, exemplifying what Thomas Huxley called "man's place in nature." But the image of a web is too meager and simple for the reality. A web is flat and finished and has the mortal frailty of the individual spider. Although elastic, it has insufficient depth. However solid to the touch of the spider, for us it fails to denote the *eikos*—the habitation—and to suggest the enduring integration of the primitive Greek domicile with its sacred hearth, bonding the earth to all aspects of society.

Ecology deals with organisms in an environment and with the processes that link organism and place. But ecology as such cannot be studied, only organisms, earth, air, and sea can be studied. It is not a discipline: there is no body of thought and technique which frames an ecology of man.[1] It must be therefore a scope or a way of seeing. Such a *perspective* on the human situation is very old and has been part of philosophy and art for thousands of years. It badly needs attention and revival.

Man is in the world and his ecology is the nature of that *inness*. He is in the world as in a room, and in transience, as in the belly of a tiger or in love. What does he do there in nature? What does nature do there *in him*? What is the nature of the transaction? Biology tells us that the transaction is always circular, always a mutual feedback. Human ecology cannot be limited strictly to biological concepts, but it cannot ignore them. It cannot even transcend them. It emerges from biological reality and grows from the fact of interconnection as a general principle of life. It must take a long view of human life and nature as they form a mesh or pattern going beyond historical time and beyond the conceptual bounds of other humane studies. As a natural history of what it means to be human, ecology might proceed the same way one would define a stomach, for example, by attention to its nervous and circulatory connections as well as its entrance, exit, and muscular walls.

Many educated people today believe that only what is unique to the individual is important or creative, and turn away from talk of populations and species as they would from talk of the masses. I once knew a director of a wealthy conservation foundation who had misgivings about the approach of ecology to urgent environmental problems in America because its concepts of communities and systems seemed to discount the individual. Communities to him suggested only followers, gray masses without the tradition of the individual. He looked instead—or in reaction—to the profit motive and capitalistic formulas, in terms of efficiency, investment, and production. It seemed to me that he had missed a singular opportunity. He had shied from the very aspect of the world now beginning to interest industry, business, and technology as the biological basis of their—and our—affluence, and which his foundation could have shown to be the ultimate basis of all economics.

Individual man *has* his particular integrity, to be sure. Oak trees, even mountains, have selves or integrities too (a poor word for my meaning, but it will have to do). To our knowledge, those other forms are not troubled by seeing themselves in more than one way, as man is. In one aspect the self is an arrangement of organs, feelings, and thoughts—a "me"—surrounded by a hard body boundary: skin, clothes, and insular habits. This idea needs no defense. It is conferred on us by the whole history of our civilization. Its virtue is verified by our affluence. The alternative is a self as a center of organization, constantly drawing on and influencing the surroundings, whose skin and behavior are soft zones contacting the world instead of excluding it. Both views are real and their reciprocity significant. We need them both to have a healthy social and human maturity.

The second view—that of relatedness of the self—has been given short shrift. Attitudes toward ourselves do not change easily. The conventional image of a man, like that of the heraldic lion, is iconographic; its outlines are stylized to fit the fixed curves of our vision. We are hidden from ourselves by habits of perception. Because we learn to talk at the same time we learn to think, our language, for example, encourages us to see ourselves—or a plant or animal—as an isolated sack, a thing, a contained self. Ecological thinking, on the other hand, requires a kind of vision across boundaries. The epidermis of the skin is ecologically like a pond surface or a forest soil, not a shell so much as a delicate interpenetration. It reveals the self enobled and extended rather than threatened as part of the landscape and the ecosystem, because the beauty and complexity of nature are continuous with ourselves.

And so ecology as applied to man faces the task of renewing a balanced view where now there is man-centeredness, even pathology of isolation and fear. It implies that we must find room in "our" world for all plants and animals, even for their otherness and their opposition. It further implies exploration and openness across an inner boundary—an ego boundary—and appreciative understanding of the animal in ourselves which our heritage

of Platonism, Christian morbidity, duality, and mechanism have long held repellant and degrading. The older counter-currents—relics of pagan myth, the universal application of Christian compassion, philosophical naturalism, nature romanticism and pantheism—have been swept away, leaving only odd bits of wreckage. Now we find ourselves in a deteriorating environment which breeds aggressiveness and hostility toward ourselves and our world.

How simple our relationship to nature would be if we only had to choose between protecting our natural home and destroying it. Most of our efforts to provide for the natural in our philosophy have failed—run aground on their own determination to work out a peace at arm's length. Our harsh reaction against the peaceable kingdom of sentimental romanticism was evoked partly by the tone of its dulcet facade but also by the disillusion to which it led. Natural dependence and contingency suggest togetherness and emotional surrender to mass behavior and other lowest common denominators. The environmentalists matching culture and geography provoke outrage for their over-simple theories of cause and effect, against the sciences which sponsor them and even against a natural world in which the theories may or may not be true. Our historical disappointment in the nature of nature has created a cold climate for ecologists who assert once again that we are limited and obligated. Somehow they must manage in spite of the chill to reach the centers of humanism and technology, to convey there a sense of our place in a universal vascular system without depriving us of our self-esteem and confidence.

Their message is not, after all, all bad news. Our natural affiliations define and illumine freedom instead of denying it. They demonstrate it better than any dialectic. Being more enduring than we individuals, ecological patterns—spatial distributions, symbioses, the streams of energy and matter and communication—create among individuals the tensions and polarities so different from dichotomy and separateness. The responses, or what theologians call "the sensibilities" of creatures (including ourselves) to such arrangements grow in part from a healthy union of the two kinds of self already mentioned, one emphasizing integrity, the other relatedness. But it goes beyond that to something better known to 12th century Europeans or Paleolithic hunters than to ourselves. If nature is not a prison and earth a shoddy way-station, we must find the faith and force to affirm its metabolism as our own—or rather, our own as part of it. To do so means nothing less than a shift in our whole frame of reference and our attitude towards life itself, a wider perception of the landscape as a creative, harmonious being where relationships of things are as real as the things. Without losing our sense of a great human destiny and without intellectual surrender, we must affirm that the world is a being, a part of our own body.[2]

Such a being may be called an ecosystem or simply a forest or landscape. Its members are engaged in a kind of choreography of materials and energy and information, the creation of order and organization. (Analogy to corporate organization here is misleading, for the distinction between social (one species) and ecological (many species) is fundamental). The pond is an example. Its ecology includes all events: the conversion of sunlight to food and the food-chains within and around it, man drinking, bathing, fishing, plowing the slopes of the watershed, drawing a picture of it, and formulating theories about the world based on what he sees in the pond. He and all the other organisms at and in the pond act upon one another, engage the earth and atmosphere, and are linked to other ponds by a network of connections like the threads of protoplasm connecting cells in living tissues.

The elegance of such systems and delicacy of equilibrium are the outcome of a long evolution of interdependence. Even society, mind and culture are parts of that evolution. There is an essential relationship between them and the natural habitat: that is, between the emergence of higher primates and flowering plants, pollinating insects, seeds, humus, and arboreal life. It is unlikely that a manlike creature could arise by any other means than a long arboreal sojourn following and followed by a time of terrestriality. The fruit's complex construction and the mammalian brain are twin offspring of the maturing earth, impossible, even meaningless, without the deepening soil and the mutual development of savannas and their faunas in the last geological epoch. Internal complexity, as the mind of a primate, is an extension of natural complexity, measured by the variety of plants and animals and the variety of nerve cells—organic extensions of each other.

The exuberance of kinds as the setting in which a good mind could evolve (to deal with a complex world) was not only a past condition. Man did not arrive in the world as though disembarking from a train in the city. He continues to arrive, somewhat like the birth of art, a train in Roger Fry's definition, passing through many stations, none of which is wholly left behind. This idea of natural complexity as a counterpart to human intricacy is central to an ecology of man. The creation of order, of which man is an example, is realized also in the number of species and habitats, an abundance of landscapes lush and poor. Even deserts and tundras increase the planetary opulence. Curiously, only man and possibly a few birds can appreciate this opulence, being the world's travelers. Reduction of this variegation would, by extension then, be an amputation of man. To convert all "wastes"—all

deserts, estuaries, tundras, ice-fields, marshes, steppes and moors—into cultivated fields and cities would impoverish rather than enrich life esthetically as well as ecologically. By esthetically, I do not mean that weasel term connoting the pleasure of baubles. We have diverted ourselves with litterbug campaigns and greenbelts in the name of esthetics while the fabric of our very environment is unravelling. In the name of conservation, too, such things are done, so that conservation becomes ambiguous. Nature is a fundamental "resource" to be sustained for our own well-being. But it loses in the translation into usable energy and commodities. Ecology may testify as often against our uses of the world, even against conservation techniques of control and management for sustained yield, as it does for them. Although ecology may be treated as a science, its greater and overriding wisdom is universal.

That wisdom can be approached mathematically, chemically, or it can be danced or told as a myth. It has been embodied in widely scattered economically different cultures. It is manifest, for example, among pre-Classical Greeks, in Navajo religion and social orientation, in Romantic poetry of the 18th and 19th centuries, in Chinese landscape painting of the 11th century, in current Whiteheadian philosophy, in Zen Buddhism, in the world view of the cult of the Cretan Great Mother, in the ceremonials of Bushman hunters, and in the medieval Christian metaphysics of light. What is common among all of them is a deep sense of engagement with the landscape, with profound connections to surroundings and to natural processes central to all life.

It is difficult in our language even to describe that sense. English becomes imprecise or mystical—and therefore suspicious—as it struggles with "process" thought. Its noun and verb organization shapes a divided world of static doers separate from the doing. It belongs to an idiom of social hierarchy in which all nature is made to mimic man. The living world is perceived in that idiom as an upright ladder, a "great chain of being," an image which seems at first ecological but is basically rigid, linear, condescending, lacking humility and love of otherness.

We are all familiar from childhood with its classifications of everything on a scale from the lowest to the highest: inanimate matter/vegetative life/lower animals/higher animals/men/angels/gods. It ranks animals themselves in categories of increasing good: the vicious and lowly parasites, pathogens and predators/the filthy decay and scavenging organisms/indifferent wild or merely useless forms/good tame creatures/and virtuous beasts domesticated for human service. It shadows the great man-centered political scheme upon the world, derived from the ordered ascendency from parishioners to clerics to bishops to cardinals to popes, or in a secular form from criminals to proletarians to aldermen to mayors to senators to presidents.

And so is nature pigeonholed. The sardonic phrase, "the place of nature in man's world," offers, tongue-in-cheek, a clever footing for confronting a world made in man's image and conforming to words. It satirizes the prevailing philosophy of anti-nature and human omniscience. It is possible because of an attitude which—like ecology—has ancient roots, but whose modern form was shaped when Aquinas reconciled Aristotelian homocentrism with Judeo-Christian dogma. In a later setting of machine technology, puritanical capitalism, and an urban ethos it carves its own version of reality into the landscape like a schoolboy initialing a tree. For such a philosophy nothing in nature has inherent merit. As one professor recently put it, "The only reason anything is done on this earth is for people. Did the rivers, winds, animals, rocks, or dust ever consider my wishes or needs? Surely, we do all our acts in an earthly environment, but I have never had a tree, valley, mountain, or flower thank me for preserving it."[3] This view carries great force, epitomized in history by Bacon, Descartes, Hegel, Hobbes, and Marx.

Some other post-Renaissance thinkers are wrongly accused of undermining our assurance of natural order. The theories of the heliocentric solar system, of biological evolution, and of the unconscious mind are held to have deprived the universe of the beneficence and purpose to which man was a special heir and to have evoked feelings of separation, of antipathy towards a meaningless existence in a neutral cosmos. Modern despair, the arts of anxiety, the politics of pathological individualism and predatory socialism were not, however, the results of Copernicus, Darwin and Freud. If man was not the center of the universe, was not created by a single stroke of Providence, and is not ruled solely by rational intelligence, it does not follow therefore that nature is defective where we thought it perfect. The astronomer, biologist and psychiatrist each achieved for mankind corrections in sensibility. Each showed the interpenetration of human life and the universe to be richer and more mysterious than had been thought.

Darwin's theory of evolution has been crucial to ecology. Indeed, it might have helped rather than aggravated the growing sense of human alienation had its interpreters emphasized predation and competition less (and, for this reason, one is tempted to add, had Thomas Huxley, Herbert Spencer, Samuel Butler and G. B. Shaw had less to say about it). Its bases of universal kinship and common bonds of function, experience and value among organisms were obscured by pre-existing ideas of animal depravity. Evolutionary theory was exploited to justify

the worst in men and was misused in defense of social and economic injustice. Nor was it better used by humanitarians. They opposed the degradation of men in the service of industrial progress, the slaughter of American Indians, and child labor, because each treated men "like animals." That is to say, men were not animals, and the temper of social reform was to find good only in attributes separating men from animals. Kindness both towards and among animals was still a rare idea in the 19th century, so that using men as animals could mean only cruelty.

Since Thomas Huxley's day the non-animal forces have developed a more subtle dictum to the effect that, "Man may be an animal, but he is more than an animal, too!" The *more* is really what is important. This appealing aphorism is a kind of anesthetic. The truth is that we are ignorant of what it is like or what it means to be any other kind of creature than we are. If we are unable to truly define the animal's experience of life or "being an animal" how can we isolate our animal part?

The rejection of animality is a rejection of nature as a whole. As a teacher, I see students develop in their humanities studies a proper distrust of science and technology. What concerns me is that the stigma spreads to the natural world itself. C. P. Snow's "Two Cultures," setting the sciences against the humanities, can be misunderstood as placing nature against art. The idea that the current destruction of people and environment is scientific and would be corrected by more communication with the arts neglects the hatred for this world carried by our whole culture. Yet science as it is now taught does not promote a respect for nature. Western civilization breeds no more ecology in Western science than in Western philosophy. Snow's two cultures cannot explain the antithesis that splits the world, nor is the division ideological, economic or political in the strict sense. The antidote he proposes is roughly equivalent to a liberal education, the traditional prescription for making broad and well-rounded men. Unfortunately, there is little even in the liberal education of ecology-and-man. Nature is usually synonymous with either natural resources or scenery, the great stereotypes in the minds of middle class, college-educated Americans.

One might suppose that the study of biology would mitigate the humanistic—largely literary—confusion between materialism and a concern for nature. But biology made the mistake at the end of the 17th century of adopting a *modus operandi* or life style from physics, in which the question why was not to be asked, only the question how. Biology succumbed to its own image as an esoteric prologue to technics and encouraged the whole society to mistrust naturalists. When scholars realized what the sciences were about it is not surprising that they threw out the babies with the bathwater: the information content and naturalistic lore with the rest of it. This is the setting in which academia and intellectual America undertook the single-minded pursuit of human uniqueness, and uncovered a great mass of pseudo distinctions such as language, tradition, culture, love, consciousness, history and awe of the supernatural. Only men were found to be capable of escape from predictability, determinism, environmental control, instincts and other mechanisms which "imprison" other life. Even biologists, such as Julian Huxley, announced that the purpose of the world was to produce man, whose social evolution excused him forever from biological evolution. Such a view incorporated three important presumptions: that nature is a power structure shaped after human political hierarchies; that man has a monopoly of immortal souls; and omnipotence will come through technology. It seems to me that all of these foster a failure of responsible behavior in what Paul Sears calls "the living landscape" except within the limits of immediate self-interest.

What ecology must communicate to the humanities—indeed, as a humanity—is that such an image of the world and the society so conceived are incomplete. There is overwhelming evidence of likeness, from molecular to mental, between men and animals. But the dispersal of this information is not necessarily a solution. The Two Culture idea that the problem is an information bottleneck is only partly true; advances in biochemistry, genetics, ethology, paleoanthropology, comparative physiology and psychobiology are not self-evidently unifying. They need a unifying principle not found in any of them, a wisdom in the sense that Walter B. Cannon used the word in his book *Wisdom of the Body*,[4] about the community of self-regulating systems within the organism. If the ecological extension of that perspective is correct, societies and ecosystems as well as cells have a physiology, and insight into it is built into organisms, including man. What was intuitively apparent last year—whether aesthetically or romantically—is a find of this year's inductive analysis. It seems apparent to me that there is an ecological instinct which probes deeper and more comprehensively than science, and which anticipates every scientific confirmation of the natural history of man.

It is not surprising, therefore, to find substantial ecological insight in art. Of course there is nothing wrong with a poem or dance which is ecologically neutral; its merit may have nothing to do with the transaction of man and nature. It is my impression, however, that students of the arts no longer feel that the subject of a work of art—what it "represents"—is without importance, as was said about 40 years ago. But there are poems and dances as there are prayers and laws attending to ecology. Some are more than mere comments on it. Such creations become part of all life. Essays on nature are an element of a functional or feedback system influencing men's reactions to their environment, messages

projected by men to themselves through some act of design, the manipulation of paints or written words. They are natural objects, like bird nests. The essay is as real a part of the community—in both the one-species sociological and many-species ecological senses—as are the songs of choirs or crickets. An essay is an Orphic sound, words that make knowing possible, for it was Orpheus as Adam who named and thus made intelligible all creatures.

What is the conflict of Two Cultures if it is not between science and art or between national ideologies? The distinction rather divides science and art within themselves. An example within science was the controversy over the atmospheric testing of nuclear bombs and the effect of radioactive fallout from the explosions. Opposing views were widely published and personified when Linus Pauling, a biochemist, and Edward Teller, a physicist, disagreed. Teller, one of the ''fathers'' of the bomb, pictured the fallout as a small factor in a world-wide struggle, the possible damage to life in tiny fractions of a percent, and even noted that evolutionary progress comes from mutations. Pauling, an expert on the hereditary material, knowing that most mutations are detrimental, argued that a large absolute number of people might be injured, as well as other life in the world's biosphere.

The humanness of ecology is that the dilemma of our emerging world ecological crises (over-population, environmental pollution, etc.) is at least in part a matter of values and ideas. It does not divide men as much by their trades as by the complex of personality and experience shaping their feelings towards other people and the world at large. I have mentioned the disillusion generated by the collapse of unsound nature philosophies. The anti-nature position today is often associated with the focusing of general fears and hostilities on the natural world. It can be seen in the behavior of control-obsessed engineers, corporation people selling consumption itself, academic superhumanists and media professionals fixated on political and economic crisis; neurotics working out psychic problems in the realm of power over men or nature, artistic symbol-manipulators disgusted by anything organic. It includes many normal, earnest people who are unconsciously defending themselves or their families against a vaguely threatening universe. The dangerous eruption of humanity in a deteriorating environment does not show itself as such in the daily experience of most people, but is felt as general tension and anxiety. We feel the pressure of events not as direct causes but more like omens. A kind of madness arises from the prevailing nature-conquering, nature-hating and self- and world-denial. Although in many ways most Americans live comfortable, satiated lives, there is a nameless frustration born of an increasing nullity. The aseptic home and society are progressively cut off from direct organic sources of health and increasingly isolated from the means of altering the course of events. Success, where its price is the misuse of landscapes, the deterioration of air and water and the loss of wild things, becomes a pointless glut, experience one-sided, time on our hands an unlocalized ache.

The unrest can be exploited to perpetuate itself. One familiar prescription for our sick society and its loss of environmental equilibrium is an increase in the intangible Good Things: more Culture, more Security and more Escape from pressures and tempo. The ''search for identity'' is not only a social but an ecological problem having to do with a sense of place and time in the context of all life. The pain of that search can be cleverly manipulated to keep the *status quo* by urging that what we need is only improved forms and more energetic expressions of what now occupy us: engrossment with ideological struggle and military power, with productivity and consumption as public and private goals, with commerce and urban growth, with amusements, with fixation on one's navel, with those tokens of escape or success already belabored by so many idealists and social critics so ineffectually.

To come back to those Good Things: the need for culture, security and escape are just near enough to the truth to take us in. But the real cultural deficiency is the absence of a true *cultus* with its significant ceremony, relevant mythical cosmos, and artifacts. The real failure in security is the disappearance from our personal lives of the small human group as the functional unit of society and the web of other creatures, domestic and wild, which are part of our humanity. As for escape, the idea of simple remission and avoidance fails to provide for the value of solitude, to integrate leisure and natural encounter. Instead of these, what are foisted on the puzzled and troubled soul as Culture, Security and Escape are more art museums, more psychiatry, and more automobiles.

The ideological status of ecology is that of a resistance movement. Its Rachel Carsons and Aldo Leopolds are subversive (as Sears recently called ecology itself[5]). They challenge the public or private right to pollute the environment, to systematically destroy predatory animals, to spread chemical pesticides indiscriminately, to meddle chemically with food and water, to appropriate without hindrance space and surface for technological and military ends; they oppose the uninhibited growth of human populations, some forms of ''aid'' to ''underdeveloped'' peoples, the needless addition of radioactivity to the landscape, the extinction of species of plants and animals, the domestication of all wild places, large-scale manipulation of the atmosphere or the sea, and most other purely engineering solutions to problems of and intrusions into the organic world.

If naturalists seem always to be *against* something it is because they feel a responsibility to share their

understanding, and their opposition constitutes a defense of the natural systems to which man is committed as an organic being. Sometimes naturalists propose projects too, but the project approach is itself partly the fault, the need for projects a consequence of linear, compartmental thinking, of machine-like units to be controlled and manipulated. If the ecological crisis were merely a matter of alternative techniques, the issue would belong among the technicians and developers (where most schools and departments of conservation have put it).

Truly ecological thinking need not be incompatible with our place and time. It does have an element of humility which is foreign to our thought, which moves us to silent wonder and glad affirmation. But it offers an essential factor, like a necessary vitamin, to all our engineering and social planning, to our poetry and our understanding. There is only one ecology, not a human ecology on one hand and another for the subhuman. No one school or theory or project or agency controls it. For us it means seeing the world mosaic from the human vantage without being man-fanatic. We must use it to confront the great philosophical problems of man—transience, meaning, and limitation—without fear. Affirmation of its own organic essence will be the ultimate test of the human mind.

SHOULD TREES HAVE STANDING?—TOWARD LEGAL RIGHTS FOR NATURAL OBJECTS

SOURCE *Stone, Christopher D. 1972. *Southern California Law Review* 45: 450–457. Reproduced by permission.

INTRODUCTION *In 2008 Christopher D. Stone (1937–) was J. Thomas McCarthy Trustee Chair in law at the University of Southern California. "Should Trees Have Standing?" is a highly influential essay that weaves together environmental philosophy and law. Stone begins by stating that a parallel phenomenon to moral extensionism is observable in the history of the law—the class of rights bearers has grown through history. Once unthinkable, inanimate things such as trusts and corporations are now possessors of rights. Stone argues for giving legal rights to natural objects, and the natural environment as a whole. He qualifies what it might mean for the environment to be a holder of rights, advocating a "guardianship approach" whereby an appointed guardian represents the interests of natural objects themselves, not as their degradation impacts human interests, and where monetary remedies would run to the benefit of the natural objects directly. Stone also argues that a change in our "environmental consciousness" is necessary, but may not be sufficient to address environmental problems. Nonetheless, he proposes that the law may be instrumental in creating a "new theory or myth" for humanity's relationship to nature, and that the courts, by conferring rights on nature, might help bring about a necessary shift in popular consciousness.*

INTRODUCTION: THE UNTHINKABLE

In *Descent of Man*, Darwin observes that the history of man's moral development has been a continual extension in the objects of his ''social instincts and sympathies.'' Originally each man had regard only for himself and those of a very narrow circle about him; later, he came to regard more and more ''not only the welfare, but the happiness of all his fellowmen''; then ''his sympathies became more tender and widely diffused, extending to men of all races, to the imbecile, maimed, and other useless members of society, and finally to the lower animals. . . .''[1]

The history of the law suggests a parallel development. Perhaps there never was a pure Hobbesian state of nature, in which no ''rights'' existed except in the vacant sense of each man's ''right to self-defense.'' But it is not unlikely that so far as the earliest ''families'' (including extended kinship groups and clans) were concerned, everyone outside the family was suspect, alien, rightless.[2] And even within the family, persons we presently regard as the natural holders of at least some rights had none. Take, for example, children. We know something of the early rights-status of children from the widespread practice of infanticide—especially of the deformed and female.[3] (Senicide,[4] as among the North American Indians, was the corresponding rightlessness of the aged).[5] Maine tells us that as late as the Patria Potestas of the Romans, the father had *jus vitae necisque*—the power of life and death—over his children. A fortiori, Maine writes, he had power of ''uncontrolled corporal chastisement; he can modify their personal condition at pleasure; he can give a wife to his son; he can give his daughter in marriage; he can divorce his children of either sex; he can transfer them to another family by

adoption; and he can sell them.'' The child was less than a person: an object, a thing.[6]

The legal rights of children have long since been recognized in principle, and are still expanding in practice. Witness, just within recent time, *In re Gault*,[7] guaranteeing basic constitutional protections to juvenile defendants, and the Voting Rights Act of 1970.[8] We have been making persons of children although they were not, in law, always so. And we have done the same, albeit imperfectly some would say, with prisoners,[9] aliens, women (especially of the married variety), the insane,[10] Blacks, foetuses,[11] and Indians.

Nor is it only matter in human form that has come to be recognized as the possessor of rights. The world of the lawyer is peopled with inanimate right-holders: trusts, corporations, joint ventures, municipalities, Subchapter R partnerships,[12] and nation-states, to mention just a few. Ships, still referred to by courts in the feminine gender, have long had an independent jural life, often with striking consequences.[13] We have become so accustomed to the idea of a corporation having ''its'' own rights, and being a ''person'' and ''citizen'' for so many statutory and constitutional purposes, that we forget how jarring the notion was to early jurists. ''That invisible, intangible and artificial being, that mere legal entity'' Chief Justice Marshall wrote of the corporation in *Bank of the United States v. Deveaux*[14]—could a suit be brought in its name? Ten years later, in the *Dartmouth College* case,[15] he was still refusing to let pass unnoticed the wonder of an entity ''existing only in contemplation of law.''[16] Yet, long before Marshall worried over the personifying of the modern corporation, the best medieval legal scholars had spent hundreds of years struggling with the notion of the legal nature of those great public ''corporate bodies,'' the Church and the State. How could they exist in law, as entities transcending the living Pope and King? It was clear how a king could bind *himself*—on his honor—by a treaty. But when the king died, what was it that was burdened with the obligations of, and claimed the rights under, the treaty *his* tangible hand had signed? The medieval mind saw (what we have lost our capacity to see)[17] how *unthinkable* it was, and worked out the most elaborate conceits and fallacies to serve as anthropomorphic flesh for the Universal Church and the Universal Empire.[18]

It is this note of the *unthinkable* that I want to dwell upon for a moment. Throughout legal history, each successive extension of rights to some new entity has been, theretofore, a bit unthinkable. We are inclined to suppose the rightlessness of rightless ''things'' to be a decree of Nature, not a legal convention acting in support of some status quo. It is thus that we defer considering the choices involved in all their moral, social, and economic dimensions. And so the United States Supreme Court could straight-facedly tell us in *Dred Scott* that Blacks had been denied the rights of citizenship ''as a subordinate and inferior class of beings, who had been subjugated by the dominant race. . . .''[19] In the nineteenth century, the highest court in California explained that Chinese had not the right to testify against white men in criminal matters because they were ''a race of people whom nature has marked as inferior, and who are incapable of progress or intellectual development beyond a certain point . . . between whom and ourselves nature has placed an impassable difference.[20] The popular conception of the Jew in the 13th Century contributed to a law which treated them as ''men *ferae naturae*, protected by a quasi-forest law. Like the roe and the deer, they form an order apart.''[21] Recall, too, that it was not so long ago that the foetus was ''like the roe and the deer.'' In an early suit attempting to establish a wrongful death action on behalf of a negligently killed foetus (now widely accepted practice), Holmes, then on the Massachusetts Supreme Court, seems to have thought it simply inconceivable ''that a man might owe a civil duty and incur a conditional prospective liability in tort to one not yet in being.''[22] The first woman in Wisconsin who thought she might have a right to practice law was told that she did not, in the following terms:

> The law of nature destines and qualifies the female sex for the bearing and nurture of the children of our race and for the custody of the homes of the world . . . . [A]ll life-long callings of women, inconsistent with these radical and sacred duties of their sex, as is the profession of the law, are departures from the order of nature; and when voluntary, treason against it . . . . The peculiar qualities of womanhood, its gentle graces, its quick sensibility, its tender susceptibility, its purity, its delicacy, its emotional impulses, its subordination of hard reason to sympathetic feeling, are surely not qualifications for forensic strife. Nature has tempered woman as little for the juridical conflicts of the court room, as for the physical conflicts of the battle field . . . .[23]

The fact is, that each time there is a movement to confer rights onto some new ''entity,'' the proposal is bound to sound odd or frightening or laughable.[23a] This is partly because until the rightless thing receives its rights, we cannot see it as anything but a *thing* for the use of ''us''—those who are holding rights at the time.[24] In this vein, what is striking about the Wisconsin case above is that the court, for all its talk about women, so clearly was never able to see women as they are (and might become). All it could see was the popular ''idealized'' version of *an object it needed*. Such is the way the slave South looked upon the Black.[25] There is something of a seamless web involved: there will be resistance to giving the thing ''rights'' until it can be seen and valued for itself; yet, it is hard to see it and

value it for itself until we can bring ourselves to give it "rights"—which is almost inevitably going to sound inconceivable to a large group of people.

The reason for this little discourse on the unthinkable, the reader must know by now, if only from the title of the paper. I am quite seriously proposing that we give legal rights to forests, oceans, rivers and other so-called "natural objects" in the environment—indeed, to the natural environment as a whole.[26]

As strange as such a notion may sound, it is neither fanciful nor devoid of operational content. In fact, I do not think it would be a misdescription of recent developments in the law to say that we are already on the verge of assigning some such rights, although we have not faced up to what we are doing in those particular terms.[27] We should do so now, and begin to explore the implications such a notion would hold.

TOWARD RIGHTS FOR THE ENVIRONMENT

Now, to say that the natural environment should have rights is not to say anything as silly as that no one should be allowed to cut down a tree. We say human beings have rights, but—at least as of the time of this writing—they can be executed.[28] Corporations have rights, but they cannot plead the fifth amendment[29]; *In re Gault* gave 15-year-olds certain rights in juvenile proceedings, but it did not give them the right to vote. Thus, to say that the environment should have rights is not to say that it should have every right we can imagine, or even the same body of rights as human beings have. Nor is it to say that everything in the environment should have the same rights as every other thing in the environment.

What the granting of rights does involve has two sides to it. The first involves what might be called the legal-operational aspects; the second, the psychic and socio-psychic aspects. I shall deal with these aspects in turn.

THE LEGAL-OPERATIONAL ASPECTS

What it Means to be a Holder of Legal Rights

There is, so far as I know, no generally accepted standard for how one ought to use the term "legal rights." Let me indicate how I shall be using it in this piece.

First and most obviously, if the term is to have any content at all, an entity cannot be said to hold a legal right unless and until *some public authoritative body* is prepared to give *some amount of review* to actions that are colorably inconsistent with that "right." For example, if a student can be expelled from a university and cannot get any public official, even a judge or administrative agent at the lowest level, either (i) to require the university to justify its actions (if only to the extent of filling out an affidavit alleging that the expulsion "was not wholly arbitrary and capricious") or (ii) to compel the university to accord the student some procedural safeguards (a hearing, right to counsel, right to have notice of charges), then the minimum requirements for saying that the student has a legal right to his education do not exist.[30]

But for a thing to be *a holder of legal rights*, something more is needed than that some authoritative body will review the actions and processes of those who threaten it. As I shall use the term, "holder of legal rights," each of three additional criteria must be satisfied. All three, one will observe, go towards making a thing *count* jurally—to have a legally recognized worth and dignity in its own right, and not merely to serve as a means to benefit "us" (whoever the contemporary group of rights-holders may be). They are, first, that the thing can institute legal actions *at its behest*; second, that in determining the granting of legal relief, the court must take *injury to it* into account; and, third, that relief must run to the *benefit* of it.

To illustrate, even as between two societies that condone slavery there is a fundamental difference between S_1, in which a master can (if he chooses), go to court and collect reduced chattel value damages from someone who has beaten his slave, and S_2, in which the slave can institute the proceedings *himself*, for *his* own recovery, damages being measured by, say, *his* pain and suffering. Notice that neither society is so structured as to leave wholly unprotected the slave's interests in not being beaten. But in S_2 as opposed to S_1 there are three operationally significant advantages that the slave has, and these make the slave in S_2, albeit a slave, a holder of rights. Or, again, compare two societies, S_1, in which pre-natal injury to a live-born child gives a right of action against the tortfeasor at the mother's instance, for the mother's benefit, on the basis of the mother's mental anguish, and S_2, which gives the child a suit in its own name (through a guardian *ad litem*) for its own recovery, for damages to it.

When I say, then, that at common law "natural objects" are not holders of legal rights, I am not simply remarking what we would all accept as obvious. I mean to emphasize three specific legal-operational advantages that the environment lacks, leaving it in the position of the slave and the foetus in S_1, rather than the slave and foetus of S_2.

The Rightlessness of Natural Objects at Common Law

Consider, for example, the common law's posture toward the pollution of a stream. True, courts have always been able, in some circumstances, to issue orders that will stop the pollution—just as the legal system in S_1 is so structured as incidentally to discourage beating slaves and being reckless around pregnant women. But the stream itself is fundamentally rightless, with implications that deserve careful reconsideration.

The first sense in which the stream is not a rights-holder has to do with standing. The stream itself has none. So far as the common law is concerned, there is in general no way to challenge the polluter's actions save at the behest of a lower riparian—another human being—able to show an invasion of *his* rights. This conception of the riparian as the holder of the right to bring suit has more than theoretical interest. The lower riparians may simply not care about the pollution. They themselves may be polluting, and not wish to stir up legal waters. They may be economically dependent on their polluting neighbor.[31] And, of course, when they discount the value of winning by the costs of bringing suit and the chances of success, the action may not seem worth undertaking. Consider, for example, that while the polluter might be injuring 100 downstream riparians $10,000 a year *in the aggregate*, each riparian separately might be suffering injury only to the extent of $100—possibly not enough for any one of them to want to press suit by himself, or even to go to the trouble and cost of securing co-plaintiffs to make it worth everyone's while. This hesitance will be especially likely when the potential plaintiffs consider the burdens the law puts in their way:[32] proving, *e.g.*, specific damages, the "unreasonableness" of defendant's use of the water, the fact that practicable means of abatement exist, and overcoming difficulties raised by issues such as joint causality, right to pollute by prescription, and so forth. Even in states which, like California, sought to overcome these difficulties by empowering the attorney-general to sue for abatement of pollution in limited instances, the power has been sparingly invoked and, when invoked, narrowly construed by the courts.[33]

The second sense in which the common law denies "rights" to natural objects has to do with the way in which the merits are decided in those cases in which someone is competent and willing to establish standing. At its more primitive levels, the system protected the "rights" of the property owning human with minimal weighing of any values: "*Cujus est solum, ejus est usque ad coelum et ad infernos.*"[34] Today we have come more and more to make balances—but only such as will adjust the economic best interests of identifiable humans. For example, continuing with the case of streams, there are commentators who speak of a "general rule" that "a riparian owner is legally entitled to have the stream flow by his land with its quality unimpaired" and observe that "an upper owner has, prima facie, no right to pollute the water."[35] Such a doctrine, if strictly invoked, would protect the stream absolutely whenever a suit was brought; but obviously, to look around us, the law does not work that way. Almost everywhere there are doctrinal qualifications on riparian "rights" to an unpolluted stream.[36] Although these rules vary from jurisdiction to jurisdiction, and upon whether one is suing for an equitable injunction or for damages, what they all have in common is some sort of balancing. Whether under language of "reasonable use," "reasonable methods of use," "balance of convenience" or "the public interest doctrine,"[37] what the courts are balancing, with varying degrees of directness, are the economic hardships on the upper riparian (or dependent community) of abating the pollution vis-à-vis the economic hardships of continued pollution on the lower riparians. What does not weigh in the balance is the damage to the stream, its fish and turtles and "lower" life. So long as the natural environment itself is rightless, these are not matters for judicial cognizance. Thus, we find the highest court of Pennsylvania refusing to stop a coal company from discharging polluted mine water into a tributary of the Lackawana River because a plaintiff's "grievance is for a mere personal inconvenience; and ... mere private personal inconveniences ... must yield to the necessities of a great public industry, which although in the hands of a private corporation, subserves a great public interest."[38] The stream itself is lost sight of in "a quantitative compromise between *two* conflicting interests."[39]

The third way in which the common law makes natural objects rightless has to do with who is regarded as the beneficiary of a favorable judgment. Here, too, it makes a considerable difference that it is not the natural object that counts in its own right. To illustrate this point, let me begin by observing that it makes perfectly good sense to speak of, and ascertain, the legal damage to a natural object, if only in the sense of "making it whole" with respect to the most obvious factors.[40] The costs of making a forest whole, for example, would include the costs of reseeding, repairing watersheds, restocking wildlife—the sorts of costs the Forest Service undergoes after a fire. Making a polluted stream whole would include the costs of restocking with fish, water-fowl, and other animal and vegetable life, dredging, washing out impurities, establishing natural and/or artificial aerating agents, and so forth. Now, what is important to note is that, under our present system, even if a plaintiff riparian wins a water pollution suit for damages, no money goes to the benefit of the stream itself to repair *its* damages.[41] This omission has the further effect that, at most, the law confronts a polluter with what it takes to make the plaintiff riparians whole; this may be far less than the damages to the stream,[42] but not so much as to force the polluter to desist. For example, it is easy to imagine a polluter whose activities damage a stream to the extent of $10,000 annually, although the aggregate damage to all the riparian plaintiffs who come into the suit is only $3000. If $3000 is less than the cost to the polluter of shutting down, or making the requisite technological changes, he might prefer to pay off the damages (*i.e.*,

the legally cognizable damages) and continue to pollute the stream. Similarly, even if the jurisdiction issues an injunction at the plaintiffs' behest (rather than to order payment of damages), there is nothing to stop the plaintiffs from "selling out" the stream, *i.e.*, agreeing to dissolve or not enforce the injunction at some price (in the example above, somewhere between plaintiffs' damages—$3000—and defendant's next best economic alternative). Indeed, I take it this is exactly what Learned Hand had in mind in an opinion in which, after issuing an anti-pollution injunction, he suggests that the defendant "make its peace with the plaintiff as best it can."[43] What is meant is a peace between *them*, and not amongst them and the river.

I ought to make clear at this point that the common law as it affects streams and rivers, which I have been using as an example so far, is not exactly the same as the law affecting other environmental objects. Indeed, one would be hard pressed to say that there was a "typical" environmental object, so far as its treatment at the hands of the law is concerned. There are some differences in the law applicable to all the various resources that are held in common: rivers, lakes, oceans, dunes, air, streams (surface and subterranean), beaches, and so forth.[44] And there is an even greater difference as between these traditional communal resources on the one hand, and natural objects on traditionally private land, *e.g.*, the pond on the farmer's field, or the stand of trees on the suburbanite's lawn.

On the other hand, although there be these differences which would make it fatuous to generalize about a law of the natural environment, most of these differences simply underscore the points made in the instance of rivers and streams. None of the natural objects, whether held in common or situated on private land, has any of the three criteria of a rights-holder. They have no standing in their own right; their unique damages do not count in determining outcome; and they are not the beneficiaries of awards. In such fashion, these objects have traditionally been regarded by the common law, and even by all but the most recent legislation, as objects for man to conquer and master and use—in such a way as the law once looked upon "man's" relationships to African Negroes. Even where special measures have been taken to conserve them, as by seasons on game and limits on timber cutting, the dominant motive has been to conserve them *for us*—for the greatest good of the greatest number of human beings. Conservationists, so far as I am aware, are generally reluctant to maintain otherwise.[45] As the name implies, they want to conserve and guarantee *our* consumption and *our* enjoyment of these other living things. In their own right, natural objects have counted for little, in law as in popular movements.

As I mentioned at the outset, however, the rightlessness of the natural environment can and should change; it already shows some signs of doing so.

Toward Having Standing in its Own Right

It is not inevitable, nor is it wise, that natural objects should have no rights to seek redress in their own behalf. It is no answer to say that streams and forests cannot have standing because streams and forests cannot speak. Corporations cannot speak either; nor can states, estates, infants, incompetents, muncipalities or universities. Lawyers speak for them, as they customarily do for the ordinary citizen with legal problems. One ought, I think, to handle the legal problems of natural objects as one does the problems of legal incompetents—human beings who have become vegetable. If a human being shows signs of becoming senile and has affairs that he is de jure incompetent to manage, those concerned with his well being make such a showing to the court, and someone is designated by the court with the authority to manage the incompetent's affairs. The guardian[46] (or "conservator"[47] or "committee"[48]—the terminology varies) then represents the incompetent in his legal affairs. Courts make similar appointments when a corporation has become "incompetent"—they appoint a trustee in bankruptcy or reorganization to oversee its affairs and speak for it in court when that becomes necessary.

On a parity of reasoning, we should have a system in which, when a friend of a natural object perceives it to be endangered, he can apply to a court for the creation of a guardianship.[49] Perhaps we already have the machinery to do so. California law, for example, defines an incompetent as "any person, whether insane or not, who by reason of old age, disease, weakness of mind, or other cause, is unable, unassisted, properly to manage and take care of himself or his property, and by reason thereof is likely to be deceived or imposed upon by artful or designing persons."[50] Of course, to urge a court that an endangered river is "a person" under this provision will call for lawyers as bold and imaginative as those who convinced the Supreme Court that a railroad corporation was a "person" under the fourteenth amendment, a constitutional provision theretofore generally thought of as designed to secure the rights of freedmen.[51] (As this article was going to press, Professor Byrn of Fordham petitioned the New York Supreme Court to appoint him legal guardian for an unrelated foetus scheduled for abortion so as to enable him to bring a class action on behalf of all foetuses similarly situated in New York City's 18 municipal hospitals. Judge Holtzman granted the petition of guardianship.[52]) If such an argument based on present statutes should fail, special environmental legislation could be enacted along traditional guardianship lines. Such provisions could provide for guardianship

both in the instance of public natural objects and also, perhaps with slightly different standards, in the instance of natural objects on "private" land.[53]

The potential "friends" that such a statutory scheme would require will hardly be lacking. The Sierra Club, Environmental Defense Fund, Friends of the Earth, Natural Resources Defense Counsel, and the Izaak Walton League are just some of the many groups which have manifested unflagging dedication to the environment and which are becoming increasingly capable of marshalling the requisite technical experts and lawyers. If, for example, the Environmental Defense Fund should have reason to believe that some company's strip mining operations might be irreparably destroying the ecological balance of large tracts of land, it could, under this procedure, apply to the court in which the lands were situated to be appointed guardian.[54] As guardian, it might be given rights of inspection (or visitation) to determine and bring to the court's attention a fuller finding on the land's condition. If there were indications that under the substantive law some redress might be available on the land's behalf, then the guardian would be entitled to raise the land's rights in the land's name, *i.e.*, without having to make the roundabout and often unavailing demonstration, discussed below, that the "rights" of the club's members were being invaded. Guardians would also be looked to for a host of other protective tasks, *e.g.*, monitoring effluents (and/or monitoring the monitors), and representing their "wards" at legislative and administrative hearings on such matters as the setting of state water quality standards. Procedures exist, and can be strengthened, to move a court for the removal and substitution of guardians, for conflicts of interest or for other reasons,[55] as well as for the termination of the guardianship.[56]

In point of fact, there is a movement in the law toward giving the environment the benefits of standing, although not in a manner as satisfactory as the guardianship approach. What I am referring to is the marked liberalization of traditional standing requirements in recent cases in which environmental action groups have challenged federal government action. *Scenic Hudson Preservation Conference v. FPC*[57] is a good example of this development. There, the Federal Power Commission had granted New York's Consolidated Edison a license to construct a hydroelectric project on the Hudson River at Storm King Mountain. The grant of license had been opposed by conservation interests on the grounds that the transmission lines would be unsightly, fish would be destroyed, and nature trails would be inundated. Two of these conservation groups, united under the name Scenic Hudson Preservation Conference, petitioned the Second Circuit to set aside the grant. Despite the claim that Scenic Hudson had no standing because it had not made the traditional claim "of any personal economic injury resulting from the Commission's actions,"[58] the petitions were heard, and the case sent back to the Commission. On the standing point, the court noted that Section 313(b) of the Federal Power Act gave a right of instituting review to any party "aggrieved by an order issued by the Commission"[59]; it thereupon read "aggrieved by" as not limited to those alleging the traditional personal economic injury, but as broad enough to include "those who by their activities and conduct have exhibited a special interest" in "the aesthetic, conservational, and recreational aspects of power development. . . ."[60] A similar reasoning has swayed other circuits to allow proposed actions by the Federal Power Commission, the Department of Interior, and the Department of Health, Education and Welfare to be challenged by environmental action groups on the basis of, *e.g.*, recreational and esthetic interests of members, in lieu of direct economic injury.[61] Only the Ninth Circuit has balked, and one of these cases, involving the Sierra Club's attempt to challenge a Walt Disney development in the Sequoia National Forest, is at the time of this writing awaiting decision by the United States Supreme Court.[62]

Even if the Supreme Court should reverse the Ninth Circuit in the Walt Disney-Sequoia National Forest matter, thereby encouraging the circuits to continue their trend toward liberalized standing in this area, there are significant reasons to press for the guardianship approach notwithstanding. For one thing, the cases of this sort have extended standing on the basis of interpretations of specific federal statutes—the Federal Power Commission Act,[63] the Administrative Procedure Act,[64] the Federal Insecticide, Fungicide and Rodenticide Act,[65] and others. Such a basis supports environmental suits only where acts of federal agencies are involved; and even there, perhaps, only when there is some special statutory language, such as "aggrieved by" in the Federal Power Act, on which the action groups can rely. Witness, for example, *Bass Angler Sportsman Society v. United States Steel Corp.*[66] There, plaintiffs sued 175 corporate defendants located throughout Alabama, relying on 33 U.S.C. § 407 (1970), which provides:

> It shall not be lawful to throw, discharge, or deposit . . . any refuse matter . . . into any navigable water of the United States, or into any tributary of any navigable water from which the same shall float or be washed into such navigable water. . . .[67]

Another section of the Act provides that one-half the fines shall be paid to the person or persons giving information which shall lead to a conviction.[68] Relying on this latter provision, the plaintiff designated his action a *qui tam* action[69] and sought to enforce the Act by injunction and fine. The District Court ruled that, in the absence of

express language to the contrary, no one outside the Department of Justice had standing to sue under a criminal act and refused to reach the question of whether violations were occurring.[70]

Unlike the liberalized standing approach, the guardianship approach would secure an effective voice for the environment even where federal administrative action and public-lands and waters were not involved. It would also allay one of the fears courts—such as the Ninth Circuit—have about the extended standing concept: if any ad hoc group can spring up overnight, invoke some "right" as universally claimable as the esthetic and recreational interests of its members and thereby get into court, how can a flood of litigation be prevented?[71] If an ad hoc committee loses a suit brought *sub nom.* Committee to Preserve our Trees, what happens when its very same members reorganize two years later and sue *sub nom.* the Massapequa Sylvan Protection League? Is the new group bound by res judicata? Class action law may be capable of ameliorating some of the more obvious problems. But even so, court economy might be better served by simply designating the guardian de jure representative of the natural object, with rights of discretionary intervention by others, but with the understanding that the natural object is "bound" by an adverse judgment.[72] The guardian concept, too, would provide the endangered natural object with what the trustee in bankruptcy provides the endangered corporation: a continuous supervision over a period of time, with a consequent deeper understanding of a broad range of the ward's problems, not just the problems present in one particular piece of litigation. It would thus assure the courts that the plaintiff has the expertise and genuine adversity in pressing a claim which are the prerequisites of a true "case or controversy."

The guardianship approach, however, is apt to raise two objections, neither of which seems to me to have much force. The first is that a committee or guardian could not judge the needs of the river or forest in its charge; indeed, the very concept of "needs," it might be said, could be used here only in the most metaphorical way. The second objection is that such a system would not be much different from what we now have: is not the Department of Interior already such a guardian for public lands, and do not most states have legislation empowering their attorneys general to seek relief—in a sort of *parens patriae* way—for such injuries as a guardian might concern himself with?

As for the first objection, natural objects *can* communicate their wants (needs) to us, and in ways that are not terribly ambiguous. I am sure I can judge with more certainty and meaningfulness whether and when my lawn wants (needs) water, than the Attorney General can judge whether and when the United States wants (needs) to take an appeal from an adverse judgment by a lower court. The lawn tells me that it wants water by a certain dryness of the blades and soil—immediately obvious to the touch—the appearance of bald spots, yellowing, and a lack of springiness after being walked on; how does "the United States" communicate to the Attorney General? For similar reasons, the guardian-attorney for a smog-endangered stand of pines could venture with more confidence that his client wants the smog stopped, than the directors of a corporation can assert that "the corporation" wants dividends declared. We make decisions on behalf of, and in the purported interests of, others every day; these "others" are often creatures whose wants are far less verifiable, and even far more metaphysical in conception, than the wants of rivers, trees, and land.[73]

As for the second objection, one can indeed find evidence that the Department of Interior was conceived as a sort of guardian of the public lands.[74] But there are two points to keep in mind. First, insofar as the Department already is an adequate guardian it is only with respect to the federal public lands as per Article IV, section 3 of the Constitution.[75] Its guardianship includes neither local public lands nor private lands. Second, to judge from the environmentalist literature and from the cases environmental action groups have been bringing, the Department is itself one of the bogeys of the environmental movement. (One thinks of the uneasy peace between the Indians and the Bureau of Indian Affairs.) Whether the various charges be right or wrong, one cannot help but observe that the Department has been charged with several institutional goals (never an easy burden), and is currently looked to for action by quite a variety of interest groups, only one of which is the environmentalists. In this context, a guardian outside the institution becomes especially valuable. Besides, what a person wants, fully to secure his rights, is the ability to retain independent counsel even when, and perhaps especially when, the government is acting "for him" in a beneficent way. I have no reason to doubt, for example, that the Social Security System is being managed "for me"; but I would not want to abdicate my right to challenge its actions as they affect me, should the need arise.[76] I would not ask more trust of national forests, vis-à-vis the Department of Interior. The same considerations apply in the instance of local agencies, such as regional water pollution boards, whose members' expertise in pollution matters is often all too credible.[77]

The objection regarding the availability of attorneys-general as protectors of the environment within the existing structure is somewhat the same. Their statutory powers are limited and sometimes unclear. As political creatures, they must exercise the discretion they have with an eye toward advancing and reconciling a broad variety

of important social goals, from preserving morality to increasing their jurisdiction's tax base. The present state of our environment, and the history of cautious application and development of environmental protection laws long on the books,[78] testifies that the burdens of an attorney-general's broad responsibility have apparently not left much manpower for the protection of nature. (*Cf. Bass Anglers*, above.) No doubt, strengthening interest in the environment will increase the zest of public attorneys even where, as will often be the case, well-represented corporate pollutors are the quarry. Indeed, the United States Attorney General has stepped up anti-pollution activity, and ought to be further encouraged in this direction.[79] The statutory powers of the attorneys-general should be enlarged, and they should be armed with criminal penalties made at least commensurate with the likely economic benefits of violating the law.[80] On the other hand, one cannot ignore the fact that there is increased pressure on public law-enforcement offices to give more attention to a host of other problems, from crime "on the streets" (why don't we say "in the rivers"?) to consumerism and school bussing. If the environment is not to get lost in the shuffle, we would do well, I think, to adopt the guardianship approach as an additional safeguard, conceptualizing major natural objects as holders of their own rights, raisable by the court-appointed guardian.

Toward Recognition of its Own Injuries

As far as adjudicating the merits of a controversy is concerned, there is also a good case to be made for taking into account harm to the environment—in its own right. As indicated above, the traditional way of deciding whether to issue injunctions in law suits affecting the environment, at least where communal property is involved, has been to strike some sort of balance regarding the economic hardships *on human beings*. Even recently, Mr. Justice Douglas, our jurist most closely associated with conservation sympathies in his private life, was deciding the propriety of a new dam on the basis of, among other things, anticipated lost profits from fish catches, some $12,000,000 annually.[81] Although he decided to delay the project pending further findings, the reasoning seems unnecessarily incomplete and compromising. Why should the environment be of importance only indirectly, as lost profits to someone else? Why not throw into the balance the cost *to the environment*?

The argument for "personifying" the environment, from the point of damage calculations, can best be demonstrated from the welfare economics position. Every well-working legal-economic system should be so structured as to confront each of us with the full costs that our activities are imposing on society.[82] Ideally, a paper-mill, in deciding what to produce—and where, and by what methods—ought to be forced to take into account not only the lumber, acid and labor that its production "takes" from other uses in the society, but also what costs alternative production plans will impose on society through pollution. The legal system, through the law of contracts and the criminal law, for example, makes the mill confront the costs of the first group of demands. When, for example, the company's purchasing agent orders 1000 drums of acid from the *Z* Company, the *Z* Company can bind the mill to pay for them, and thereby reimburse the society for what the mill is removing from alternative uses.

Unfortunately, so far as the pollution costs are concerned, the allocative ideal begins to break down, because the traditional legal institutions have a more difficult time "catching" and confronting us with the full social costs of our activities. In the lakeside mill example, major riparian interests might bring an action, forcing a court to weigh *their* aggregate losses against the costs to the mill of installing the anti-pollution device. But many other interests—and I am speaking for the moment of recognized homocentric interests—are too fragmented and perhaps "too remote" causally to warrant securing representation and pressing for recovery: the people who own summer homes and motels, the man who sells fishing tackle and bait, the man who rents rowboats. There is no reason not to allow the lake to prove damages to them as the prima facie measure of damages to it. *By doing so, we in effect make the natural object, through its guardian, a jural entity competent to gather up these fragmented and otherwise unrepresented damage claims, and press them before the court even where, for legal or practical reasons, they are not going to be pressed by traditional class action plaintiffs.*[83] Indeed, one way—the homocentric way—to view what I am proposing so far, is to view the guardian of the natural object as the guardian of unborn generations, as well as of the otherwise unrepresented, but distantly injured, contemporary humans.[84] By making the lake itself the focus of these damages, and "incorporating" it so to speak, the legal system can effectively take proof upon, and confront the mill with, a larger and more representative measure of the damages its pollution causes.

So far, I do not suppose that my economist friends (unremittent human chauvanists, every one of them!) will have any large quarrel in principle with the concept. Many will view it as a *trompe l'oeil* that comes down, at best, to effectuate the goals of the paragon class action, or the paragon water pollution control district. Where we are apt to part company is here—I propose going beyond gathering up the loose ends of what most people would presently recognize as economically valid damages. The guardian would urge before the court injuries not presently cognizable—the death of eagles and inedible crabs, the suffering of sea lions, the loss from the face of the

earth of species of commercially valueless birds, the disappearance of a wilderness area. One might, of course, speak of the damages involved as "damages" to us humans, and indeed, the widespread growth of environmental groups shows that human beings do feel these losses. But they are not, at present, economically measurable losses: how can they have a monetary value for the guardian to prove in court?

The answer for me is simple. Wherever it carves out "property" rights, the legal system is engaged in the process of *creating* monetary worth. One's literary works would have minimal monetary value if anyone could copy them at will. Their economic value to the author is a product of the law of copyright; the person who copies a copyrighted book has to bear a cost to the copyright-holder because the law says he must. Similarly, it is through the law of torts that we have made a "right" of—and guaranteed an economically meaningful value to—privacy. (The value we place on gold—a yellow inanimate dirt—is not simply a function of supply and demand—wilderness areas are scarce and pretty too—, but results from the actions of the legal systems of the world, which have institutionalized that value; they have even done a remarkable job of stabilizing the price). I am proposing we do the same with eagles and wilderness areas as we do with copyrighted works, patented inventions, and privacy: *make* the violation of rights in them to be a cost by declaring the "pirating" of them to be the invasion of a property interest.[85] If we do so, the net social costs the polluter would be confronted with would include not only the extended homocentric costs of his pollution (explained above) but also costs to the environment *per se*.

How, though, would these costs be calculated? When we protect an invention, we can at least speak of a fair market value for it, by reference to which damages can be computed. But the lost environmental "values" of which we are now speaking are by definition over and above those that the market is prepared to bid for: they are priceless.

One possible measure of damages, suggested earlier, would be the cost of making the environment whole, just as, when a man is injured in an automobile accident, we impose upon the responsible party the injured man's medical expenses. Comparable expenses to a polluted river would be the costs of dredging, restocking with fish, and so forth. It is on the basis of such costs as these, I assume, that we get the figure of $1 billion as the cost of saving Lake Erie.[86] As an ideal, I think this is a good guide applicable in many environmental situations. It is by no means free from difficulties, however.

One problem with computing damages on the basis of making the environment whole is that, if understood most literally, it is tantamount to asking for a "freeze" on environmental quality, even at the costs (and there will be costs) of preserving "useless" objects.[87] Such a "freeze" is not inconceivable to me as a general goal, especially considering that, even by the most immediately discernible homocentric interests, in so many areas we ought to be cleaning up and not merely preserving the environmental status quo. In fact, there is presently strong sentiment in the Congress for a total elimination of all river pollutants by 1985,[88] notwithstanding that such a decision would impose quite large direct and indirect costs on us all. Here one is inclined to recall the instructions of Judge Hays, in remanding Consolidated Edison's Storm King application to the Federal Power Commission in *Scenic Hudson*:

> The Commission's renewed proceedings must include as a basic concern the preservation of natural beauty and of natural historic shrines, keeping in mind that, in our affluent society, the cost of a project is only one of several factors to be considered.[89]

Nevertheless, whatever the merits of such a goal in principle, there are many cases in which the social price tag of putting it into effect are going to seem too high to accept. Consider, for example, an oceanside nuclear generator that could produce low cost electricity for a million homes at a savings of $1 a year per home, spare us the air pollution that comes of burning fossil fuels, but which through a slight heating effect threatened to kill off a rare species of temperature-sensitive sea urchins; suppose further that technological improvements adequate to reduce the temperature to present environmental quality would expend the entire one million dollars in anticipated fuel savings. Are we prepared to tax ourselves $1,000,000 a year on behalf of the sea urchins? In comparable problems under the present law of damages, we work out practicable compromises by abandoning restoration costs and calling upon fair market value. For example, if an automobile is so severely damaged that the cost of bringing the car to its original state by repair is greater than the fair market value, we would allow the responsible tortfeasor to pay the fair market value only. Or if a human being suffers the loss of an arm (as we might conceive of the ocean having irreparably lost the sea urchins), we can fall back on the capitalization of reduced earning power (and pain and suffering) to measure the damages. But what is the fair market value of sea urchins? How can we capitalize their loss to the ocean, independent of any commercial value they may have to someone else?

One answer is that the problem can sometimes be sidestepped quite satisfactorily. In the sea urchin example, one compromise solution would be to impose on the nuclear generator the costs of making the ocean whole somewhere else, in some other way, *e.g.*, reestablishing a

sea urchin colony elsewhere, or making a somehow comparable contribution.[90] In the debate over the laying of the trans-Alaskan pipeline, the builders are apparently prepared to meet conservationists' objections half-way by re-establishing wildlife away from the pipeline, so far as is feasible.[91]

But even if damage calculations have to be made, one ought to recognize that the measurement of damages is rarely a simple report of economic facts about "the market," whether we are valuing the loss of a foot, a foetus, or a work of fine art. Decisions of this sort are always hard, but not impossible. We have increasingly taken (human) pain and suffering into account in reckoning damages, not because we think we can ascertain them as objective "facts" about the universe, but because, even in view of all the room for disagreement, we come up with a better society by making rude estimates of them than by ignoring them.[92] We can make such estimates in regard to environmental losses fully aware that what we are really doing is making implicit normative judgments (as with pain and suffering)—laying down rules as to what the society is going to "value" rather than reporting market evaluations. In making such normative estimates decision-makers would not go wrong if they estimated on the "high side," putting the burden of trimming the figure down on the immediate human interests present. All burdens of proof should reflect common experience; our experience in environmental matters has been a continual discovery that our acts have caused more long-range damage than we were able to appreciate at the outset.

To what extent the decision-maker should factor in costs such as the pain and suffering of animals and other sentient natural objects, I cannot say; although I am prepared to do so in principle.[93] Given the conjectural nature of the "estimates" in all events, and the roughness of the "balance of conveniences" procedure where that is involved, the practice would be of more interest from the socio-psychic point of view, discussed below, than from the legal-operational.

Toward Being a Beneficiary in its Own Right

As suggested above, one reason for making the environment itself the beneficiary of a judgment is to prevent it from being "sold out" in a negotiation among private litigants who agree not to enforce rights that have been established among themselves.[94] Protection from this will be advanced by making the natural object a party to an injunctive settlement. Even more importantly, we should make it a beneficiary of money awards. If, in making the balance requisite to issuing an injunction, a court decides *not* to enjoin a lake polluter who is causing injury to the extent of $50,000 annually, then the owners and the lake ought both to be awarded damages. The natural object's portion could be put into a trust fund to be administered by the object's guardian, as per the guardianship recommendation set forth above. So far as the damages are proved, as suggested in the previous section, by allowing the natural object to cumulate damages to others as prima facie evidence of damages to it, there will, of course, be problems of distribution. But even if the object is simply construed as representing a class of plaintiffs under the applicable civil rules,[95] there is often likely to be a sizeable amount of recovery attributable to members of the class who will not put in a claim for distribution (because their pro rata share would be so small, or because of their interest in the environment). Not only should damages go into these funds, but where criminal fines are applied (as against water polluters) it seems to me that the monies (less prosecutorial expenses, perhaps) ought sensibly to go to the fund rather than to the general treasuries. Guardians fees, including legal fees, would then come out of this fund. More importantly, the fund would be available to preserve the natural object as close as possible to its condition at the time the environment was made a rights-holder.[96]

The idea of assessing damages as best we can and placing them in a trust fund is far more realistic than a hope that a total "freeze" can be put on the environmental status quo. Nature is a continuous theatre in which things and species (eventually man) are destined to enter and exit.[97] In the meantime, co-existence of man and his environment means that *each* is going to have to compromise for the better of both. Some pollution of streams, for example, will probably be inevitable for some time. Instead of setting an unrealizable goal of enjoining absolutely the discharge of all such pollutants, the trust fund concept would (a) help assure that pollution would occur only in those instances where the social need for the pollutant's product (via his present method of production) was so high as to enable the polluter to cover *all* homocentric costs, plus some estimated costs to the environment *per se*, and (b) would be a corpus for preserving monies, if necessary, while the technology developed to a point where repairing the damaged portion of the environment was feasible. Such a fund might even finance the requisite research and development.

(Incidentally, if "rights" are to be granted to the environment, then for many of the same reasons it might bear "liabilities" as well—as inanimate objects did anciently.[98] Rivers drown people, and flood over and destroy crops; forests burn, setting fire to contiguous communities. Where trust funds had been established, they could be available for the satisfaction of judgments against the environment, making it bear the costs of some of the harms it imposes on other right holders. In effect, we would be narrowing the claim of Acts of God. The ontological problem would be troublesome here, however; when the Nile

overflows, is it the ''responsibility'' of the river? the mountains? the snow? the hydrologic cycle?[99])

Toward Rights in Substance

So far we have been looking at the characteristics of being a *holder of rights*, and exploring some of the implications that making the environment a holder of rights would entail. Natural objects would have standing in their own right, through a guardian; damage to and through them would be ascertained and considered as an independent factor; and they would be the beneficiaries of legal awards. But these considerations only give us the skeleton of what a meaningful rights-holding would involve. To flesh out the ''rights'' of the environment demands that we provide it with a significant body of rights for it to invoke when it gets to court.

In this regard, the lawyer is constantly aware that a right is not, as the layman may think, some strange substance that one either has or has not. One's life, one's right to vote, one's property, can all be taken away. But those who would infringe on them must go through certain procedures to do so; these procedures are a measure of what we value as a society. Some of the most important questions of ''right'' thus turn into questions of degree: how much review, and of which sort, will which agencies of state accord us when we claim our ''right'' is being infringed?

We do not have an absolute right either to our lives or to our driver's licenses. But we have a greater right to our lives because, if even the state wants to deprive us of that ''right,'' there are authoritative bodies that will demand that the state make a very strong showing before it does so, and it will have to justify its actions before a grand jury, petit jury (convincing them ''beyond a reasonable doubt''), sentencing jury, and, most likely, levels of appellate courts. The carving out of students ''rights'' to their education is being made up of this sort of procedural fabric. No one, I think, is maintaining that in no circumstances ought a student to be expelled from school. The battle for student ''rights'' involves shifting the answers to questions like: before a student is expelled, does he have to be given a hearing; does he have to have prior notice of the hearing, and notice of charges; may he bring counsel, (need the state provide counsel if he cannot?); need there be a transcript; need the school carry the burden of proving the charges; may he confront witnesses; if he is expelled, can he get review by a civil court; if he can get such review, need the school show its actions were ''reasonable,'' or merely ''not unreasonable,'' and so forth?[100]

In this vein, to bring the environment into the society as a rights-holder would not stand it on a better footing than the rest of us mere mortals, who every day suffer injuries that are *damnum absque injuria*. What the environment must look for is that its interests be taken into account in subtler, more procedural ways.

The National Environmental Policy Act is a splendid example of this sort of rights-making through the elaboration of procedural safeguards. Among its many provisions, it establishes that every federal agency must:

> (C) include in every recommendation or report on proposals for legislation and other major Federal actions significantly affecting the quality of the human environment, a detailed statement by the responsible official on—
>
> (i) the environmental impact of the proposed action,
>
> (ii) any adverse environmental effects which cannot be avoided should the proposal be implemented,
>
> (iii) alternatives to the proposed action,
>
> (iv) the relationship between local short-term uses of man's environment and the maintenance and enhancement of long-term productivity, and
>
> (v) any irreversible and irretrievable commitments of resources which would be involved in the proposed action should it be implemented.

Prior to making any detailed statement, the responsible Federal official shall consult with and obtain the comments of any Federal agency which has jurisdiction by law or special expertise with respect to any environmental impact involved. Copies of such statement and the comments and views of the appropriate Federal, State, and local agencies, which are authorized to develop and enforce environmental standards, shall be made available to the President, the Council on Environmental Quality and to the public as provided by section 552 of title 5, United States Code, and shall accompany the proposal through the existing agency review processes;

> (D) study, develop, and describe appropriate alternatives to recommended courses of action in any proposal which involves unresolved conflicts concerning alternative uses of available resources;
>
> (E) recognize the worldwide and long-range character of environmental problems and, where consistent with the foreign policy of the United States, lend appropriate support to initiatives, resolutions, and programs designed to maximize international cooperation in anticipating and preventing a decline in the quality of mankind's environment;
>
> (F) make available to States, counties, municipalities, institutions, and individuals, advice and information useful in restoring, maintaining, and enhancing the quality of the environment ….[101]

These procedural protections have already begun paying off in the courts. For example, it was on the basis of the Federal Power Commission's failure to make adequate inquiry into "alternatives" (as per subsection (iii)) in *Scenic Hudson*, and the Atomic Energy Commission's failure to make adequate findings, apparently as per subsections (i) and (ii), in connection with the Amchitka Island underground test explosion,[102] that Federal Courts delayed the implementation of environment-threatening schemes.

Although this sort of control (remanding a cause to an agency for further findings) may seem to the layman ineffectual, or only a stalling of the inevitable, the lawyer and the systems analyst know that these demands for further findings can make a difference. It may encourage the institution whose actions threaten the environment to really *think about* what it is doing, and that is neither an ineffectual nor a small feat. Indeed, I would extend the principle beyond federal agencies. Much of the environment is threatened not by them, but by private corporations. Surely the constitutional power would not be lacking to mandate that all private corporations whose actions may have significant adverse affect on the environment make findings of the sort now mandated for federal agencies. Further, there should be requirements that these findings and reports be channeled to the Board of Directors; if the directors are not charged with the knowledge of what their corporation is doing to the environment, it will be all too easy for lower level management to prevent such reports from getting to a policy-making level. We might make it grounds for a guardian to enjoin a private corporation's actions if such procedures had not been carried out.

The rights of the environment could be enlarged by borrowing yet another page from the Environmental Protection Act and mandating comparable provisions for "private governments." The Act sets up within the Executive Office of the President a Council on Environmental Quality "to be conscious of and responsive to the scientific, economic, social, esthetic, and cultural needs of the Nation; and to formulate and recommend national policies to promote the improvement of the quality of the environment."[103] The Council is to become a focal point, within our biggest "corporation"—the State—to gather and evaluate environmental information which it is to pass on to our chief executive officer, the President. Rather than being ineffectual, this may be a highly sophisticated way of steering organizational behavior. Corporations—especially recidivist polluters and land despoilers—should have to establish comparable internal reorganization, *e.g.*, to set up a Vice-President for Ecological Affairs. The author is not offering this suggestion as a cure-all, by any means, but I do not doubt that this sort of control over internal corporate organization would be an effective supplement to the traditional mechanisms of civil suits, licensing, administrative agencies, and fines.[104]

Similarly, courts, in making rulings that may affect the environment, should be compelled to make findings with respect to environmental harm—showing how they calculated it and how heavily it was weighed—even in matters outside the present Environmental Protection Act. This would have at least two important consequences. First, it would shift somewhat the focus of court-room testimony and concern; second, the appellate courts, through their review and reversals for "insufficient findings," would give content to, and build up a body of, environmental rights, much as content and body has been given, over the years, to terms like "Due Process of Law."

Beyond these procedural safeguards, would there be any rights of the environment that might be deemed "absolute," at least to the extent of, say, Free Speech? Here, the doctrine of irreparable injury comes to mind. There has long been equitable support for an attorney-general's enjoining injury to communal property if he can prove it to be "irreparable." In other words, while repairable damage to the environment might be balanced and weighed, irreparable damage could be enjoined absolutely. There are several reasons why this doctrine has not been used effectively (witness Lake Erie).[105] Undoubtedly, political pressures (in the broadest sense) have had an influence. So, too, has the failure of all of us to understand just how delicate the environmental balance is; this failure has made us unaware of how early "irreparable" injury might be occurring, and, if aware, unable to prove it in court. But most important I think, is that the doctrine simply is not practical as a rule of universal application. For one thing, there are too many cases like the sea urchin example above, where the marginal costs of abating the damage seem too clearly to exceed the marginal benefits, even if the damage to the environment itself is liberally estimated. For another, there is a large problem in how one defines "irreparable." Certainly the great bulk of the environment in civilized parts of the world has been injured "irreparably" in the sense of "irreversably"; we are not likely to return it to its medieval quality. Despite the scientific ring to the term, judgments concerning "irreparable injury" are going to have to subsume questions both of degree of damage and of value—to all of "us" including the environment, *i.e.*, to "spaceship earth"—of the damaged object. Thus, if we are going to revitalize the "irreparable damages" doctrine, and expect it to be taken seriously, we have to recognize that what will be said to constitute "irreparable damage" to the ionosphere, because of its importance to all life, or to the Grand Canyon, because of its uniqueness, is going to rest upon normative judgments that ought to be made explicit.

This suggests that some (relatively) absolute rights be defined for the environment by setting up a constitutional list of "preferred objects," just as some of our Justices feel there are "preferred rights" where humans are concerned.[106] Any threatened injury to these most jealously-to-be-protected objects should be reviewed with the highest level of scrutiny at all levels of government, including our "counter-majoritarian" branch, the court system. Their "Constitutional rights" should be implemented, legislatively and administratively, by, *e.g.*, the setting of environmental quality standards.

I do not doubt that other senses in which the environment might have rights will come to mind, and, as I explain more fully below, would be more apt to come to mind if only we should speak in terms of their having rights, albeit vaguely at first. "Rights" might well lie in unanticipated areas. It would seem, for example, that Chief Justice Warren was only stating the obvious when he observed in *Reynolds v. Sims* that "legislators represent people, not trees or acres." Yet, could not a case be made for a system of apportionment which *did* take into account the wildlife of an area?[107] It strikes me as a poor idea that Alaska should have no more congressmen than Rhode Island primarily *because there are in Alaska all those trees and acres, those waterfalls and forests*.[108] I am not saying anything as silly as that we ought to overrule *Baker v. Carr* and retreat from one man-one vote to a system of one man-or-tree one vote. Nor am I even taking the position that we ought to count each acre, as we once counted each slave, as three-fifths of a man. But I am suggesting that there is nothing unthinkable about, and there might on balance even be a prevailing case to be made for, an electoral apportionment that made some systematic effort to allow for the representative "rights" of non-human life. And if a case can be made for that, which I offer here mainly for purpose of illustration, I suspect that a society that grew concerned enough about the environment to make it a holder of rights would be able to find quite a number of "rights" to have waiting for it when it got to court.

Do We Really Have to Put it that Way?

At this point, one might well ask whether much of what has been written could not have been expressed without introducing the notion of trees, rivers, and so forth "having rights." One could simply and straightforwardly say, for example, that (R_1) "the class of persons competent to challenge the pollution of rivers ought to be extended beyond that of persons who can show an immediate adverse economic impact on themselves," and that (R_2), "judges, in weighing competing claims to a wilderness area, ought to think beyond the economic and even esthetic impact on man, and put into the balance a concern for the threatened environment as such." And it is true, indeed, that to say trees and rivers have "rights" is not in itself a stroke of any operational significance—no more than to say "people have rights." To solve any concrete case, one is always forced to more precise and particularized statements, in which the word "right" might just as well be dropped from the elocution.

But this is not the same as to suggest that introducing the notion of the "rights" of trees and rivers would accomplish nothing beyond the introduction of a set of particular rules like (R_1) and (R_2), above. I think it is quite misleading to say that "*A* has a right to . . ." can be fully explicated in terms of a certain set of specific legal rules, and the manner in which conclusions are drawn from them in a legal system. That is only part of the truth. Introducing the notion of something having a "right" (simply *speaking* that way), brings into the legal system a flexibility and open-endedness that no series of specifically stated legal rules like R_1, R_2, R_3, . . . R_n can capture. Part of the reason is that "right" (and other so-called "legal terms" like "infant," "corporation," "reasonable time") have meaning—vague but forceful—in the ordinary language, and the force of these meanings, inevitably infused with our thought, becomes part of the context against which the "legal language" of our contemporary "legal rules" is interpreted.[109] Consider, for example, the "rules" that govern the question, on whom, and at what stages of litigation, is the burden of proof going to lie? Professor Krier has demonstrated how terribly significant these decisions are in the trial of environmental cases, and yet, also, how much discretion judges have under them.[110] In the case of such vague rules, it is *context*—senses of direction, of value and purpose—that determines how the rules will be understood, every bit as much as their supposed "plain meaning." In a system which spoke of the environment "having legal rights," judges would, I suspect, be inclined to interpret rules such as those of burden of proof far more liberally from the point of the environment. There is, too, the fact that the vocabulary and expressions that are available to us influence and even steer our thought. Consider the effect that was had by introducing into the law terms like "motive," "intent," and "due process." These terms work a subtle shift into the rhetoric of explanation available to judges; with them, new ways of thinking and new insights come to be explored and developed.[111] In such fashion, judges who could unabashedly refer to the "legal rights of the environment" would be encouraged to develop a viable body of law—in part simply through the availability and force of the expression. Besides, such a manner of speaking by courts would contribute to popular notions, and a society that spoke of the "legal rights of the environment" would be inclined to legislate more environment-protecting rules by formal enactment.

If my sense of these influences is correct, then a society in which it is stated, however vaguely, that "rivers have legal rights" would evolve a different legal system than one which did not employ that expression, even if the two of them had, at the start, the very same "legal rules" in other respects.

THE PSYCHIC AND SOCIO-PSYCHIC ASPECTS

There are, as we have seen, a number of developments in the law that may reflect a shift from the view that nature exists *for men*. These range from increasingly favorable procedural rulings for environmental action groups—as regards standing and burden of proof requirements, for example—to the enactment of comprehensive legislation such as the National Environmental Policy Act and the thoughtful Michigan Environmental Protection Act of 1970. Of such developments one may say, however, that it is not the environment *per se* that we are prepared to take into account, but that man's increased awareness of possible long range effects on himself militate in the direction of stopping environmental harm in its incipiency. And this is part of the truth, of course. Even the far-reaching National Environmental Policy Act, in its preambulatory "Declaration of National Environmental Policy," comes out both for "restoring and maintaining environmental quality *to the overall welfare and development of man*" as well as for creating and maintaining "conditions under which *man and nature can exist in productive harmony*."[112] Because the health and well-being of mankind depend upon the health of the environment, these goals will often be so mutually supportive that one can avoid deciding whether our rationale is to advance "us" or a new "us" that includes the environment. For example, consider the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) which insists that, *e.g.*, pesticides, include a warning "adequate to prevent injury to living man and other vertebrate animals, vegetation, and useful invertebrate animals."[113] Such a provision undoubtedly reflects the sensible notion that the protection of humans is best accomplished by preventing dangerous accumulations in the food chain. Its enactment does not necessarily augur far-reaching changes in, nor even call into question, fundamental matters of consciousness.

But the time is already upon us when we may have to consider subordinating some human claims to those of the environment *per se*. Consider, for example, the disputes over protecting wilderness areas from development that would make them accessible to greater numbers of people. I myself feel disingenuous rationalizing the environmental protectionist's position in terms of a utilitarian calculus, even one that takes future generations into account, and plays fast and loose with its definition of "good." Those who favor development have the stronger argument—they at least hold the protectionist to a standstill—from the point of advancing the greatest good of the greatest number of people. And the same is true regarding arguments to preserve useless species of animals, as in the sea urchin hypothetical. One *can* say that we never know what is going to prove useful at some future time. In order to protect ourselves, therefore, we ought to be conservative now in our treatment of nature. I agree. But when conservationists argue this way to the exclusion of other arguments, or find themselves speaking in terms of "recreational interests" so continuously as to play up to, and reinforce, homocentrist perspectives, there is something sad about the spectacle. One feels that the arguments lack even their proponent's convictions. I expect they want to say something less egotistic and more emphatic but the prevailing and sanctioned modes of explanation in our society are not quite ready for it. In this vein, there must have been abolitonists who put their case in terms of getting more work out of the Blacks. Holdsworth says of the early English Jew that while he was "regarded as a species of res nullius ... [H]e was valuable for his acquisitive capacity; and for that reason the crown took him under its protection."[114] (Even today, businessmen are put in the position of insisting that their decent but probably profitless acts will "help our company's reputation and be good for profits."[115])

For my part, I would prefer a frank avowal that even making adjustments for esthetic improvemens, what I am proposing is going to cost "us," *i.e.*, reduce our standard of living as measured in terms of our present values.

Yet, this frankness breeds a frank response—one which I hear from my colleagues and which must occur to many a reader. Insofar as the proposal is not just an elaborate legal fiction, but really comes down in the last analysis to a compromise of *our* interests for *theirs*, why should we adopt it? "What is in it for 'us'?"

This is a question I am prepared to answer, but only after permitting myself some observations about how *odd* the question is. It asks for me to justify my position in the very anthropocentric hedonist terms that I am proposing we modify. One is inclined to respond by a counter: "couldn't you (as a white) raise the same questions about compromising your preferred rights-status with Blacks?"; or "couldn't you (as a man) raise the same question about compromising your preferred rights-status with women?" Such counters, unfortunately, seem no more responsive than the question itself. (They have a nagging ring of "yours too" about them.) What the exchange actually points up is a fundamental problem regarding the nature of philosophical argument. Recall that Socrates, whom we remember as an opponent of hedonistic thought, confutes Thrasymachus by arguing

that immorality makes one miserably unhappy! Kant, whose moral philosophy was based upon the categorical imperative ("Woe to him who creeps through the serpent windings of Utilitarianism"[116]) finds himself justifying, *e.g.*, promise keeping and truth telling, on the most prudential—one might almost say, commercial—grounds.[117] This "philosophic irony" (as Professor Engel calls it) may owe to there being something unique about ethical argument.[118] "Ethics cannot be put into words", Wittgenstein puts it; such matters "make themselves "manifest."[119] On the other hand, perhaps the truth is that in any argument which aims at persuading a human being to action (on ethical or any other bases), "logic" is only an instrument for illuminating positions, at best, and in the last analysis it is psycho-logical appeals to the listener's self-interest that hold sway, however "principled" the rhetoric may be.

With this reservation as to the peculiar task of the argument that follows, let me stress that the strongest case can be made from the perspective of human advantage for conferring rights on the environment. Scientists have been warning of the crises the earth and all humans on it face if we do not change our ways—radically—and these crises make the lost "recreational use" of rivers seem absolutely trivial. The earth's very atmosphere is threatened with frightening possibilities: absorption of sunlight, upon which the entire life cycle depends, may be diminished; the oceans may warm (increasing the "greenhouse effect" of the atmosphere), melting the polar ice caps, and destroying our great coastal cities; the portion of the atmosphere that shields us from dangerous radiation may be destroyed. Testifying before Congress, sea explorer Jacques Cousteau predicted that the oceans (to which we dreamily look to feed our booming populations) are headed toward their own death: "The cycle of life is intricately tied up with the cycle of water ... the water system has to remain alive if we are to remain alive on earth."[120] We are depleting our energy and our food sources at a rate that takes little account of the needs even of humans now living.

These problems will not be solved easily; they very likely can be solved, if at all, only through a willingness to suspend the rate of increase in the standard of living (by present values) of the earth's "advanced" nations, and by stabilizing the total human population. For some of us this will involve forfeiting material comforts; for others it will involve abandoning the hope someday to obtain comforts long envied. For all of us it will involve giving up the right to have as many offspring as we might wish. Such a program is not impossible of realization, however. Many of our so-called "material comforts" are not only in excess of, but are probably in opposition to, basic biological needs. Further, the "costs" to the advanced nations is not as large as would appear from Gross National Product figures. G.N.P. reflects social gain (of a sort) without discounting for the social *cost* of that gain, *e.g.*, the losses through depletion of resources, pollution, and so forth. As has well been shown, as societies become more and more "advanced," their real marginal gains become less and less for each additional dollar of G.N.P.[121] Thus, to give up "human progress" would not be as costly as might appear on first blush.

Nonetheless, such far-reaching social changes are going to involve us in a serious reconsideration of our consciousness towards the environment. I say this knowing full well that there is something more than a trifle obscure in the claim: is popular consciousness a meaningful notion, to begin with? If so, what is our present consciousness regarding the environment? Has it been causally responsible for our material state of affairs? Ought we to shift our consciousness (and if so, to what exactly, and on what grounds)? How, if at all, would a shift in consciousness be translated into tangible institutional reform? Not one of these questions can be answered to everyone's satisfactions, certainly not to the author's.

It is commonly being said today, for example, that our present state of affairs—at least in the West—can be traced to the view that Nature is the dominion of Man, and that this attitude, in turn, derives from our religious traditions.

> Whatever the origins, the text is quite clear in Judaism, was absorbed all but unchanged into Christianity, and was inflated in Humanism to become the implicit attitude of Western man to Nature and the environment. Man is exclusively divine, all other creatures and things occupy lower and generally inconsequential stature; man is given dominion over all creatures and things; he is enjoined to subdue the earth.... This environment was created by the man who believes that the cosmos is a pyramid erected to support man on its pinnacle, that reality exists only because man can perceive it, that God is made in the image of man, and that the world consists solely of a dialogue between men. Surely this is an infantalism which is unendurable. It is a residue from a past of inconsequence when a few puny men cried of their supremacy to an unhearing and uncaring world. One longs for a psychiatrist who can assure man that his deep seated cultural inferiority is no longer necessary or appropriate.... It is not really necessary to destroy nature in order to gain God's favor or even his undivided attention.[122]

Surely this is forcibly put, but it is not entirely convincing as an explanation for how we got to where we are. For one thing, so far as intellectual influences are to be held responsible for our present state of affairs, one might as fairly turn on Darwin as the Bible. It was, after all,

Darwin's views—in part through the prism of Spencer—that gave moral approbation to struggle, conquest, and domination; indeed, by emphasizing man's development as a product of chance happenings, Darwin also had the effect—intended or not—of reducing our awareness of the mutual interdependency of everything in Nature. And besides, as Professor Murphy points out, the spiritual beliefs of the Chinese and Indians "in the unity between man and nature had no greater effect than the contrary beliefs in Europe in producing a balance between man and his environment"; he claims that in China, *tao* notwithstanding, "ruthless deforestation has been continuous.[123] I am under the impression, too, that notwithstanding the vaunted "harmony" between the American Plains Indians and Nature, once they had equipped themselves with rifles their pursuit of the buffalo expanded to fill the technological potential.[124] The fact is, that "consciousness" explanations pass too quickly over the less negative but simpler view of the situation: there are an increasing number of humans, with increasing wants, and there has been an increasing technology to satisfy them at "cost" to the rest of nature. Thus, we ought not to place too much hope that a changed environmental consciousness will in and of itself reverse present trends. Furthermore, societies have long since passed the point where a change in human consciousness on any matter will rescue us from our problems. More then ever before we are in the hands of institutions. These institutions are not "mere legal fictions" moreover—they have wills, minds, purposes, and inertias that are in very important ways their own, *i.e.*, that can transcend and survive changes in the consciousnesses of the individual humans who supposedly comprise them, and whom they supposedly serve. (It is more and more the individual human being, with his consciousness, that is the legal fiction.[125])

For these reasons, it is far too pat to suppose that a western "environmental consciousness" is solely or even primarily responsible for our environmental crisis. On the other hand, it is not so extravagant to claim that it has dulled our resentment and our determination to respond. For this reason, whether we will be able to bring about the requisite institutional and population growth changes depends in part upon effecting a radical shift in our feelings about "our" place in the rest of Nature.

A radical new conception of man's relationship to the rest of nature would not only be a step towards solving the material planetary problems; there are strong reasons for such a changed consciousness from the point of making us far better humans. If we only stop for a moment and look at the underlying human qualities that our present attitudes toward property and nature draw upon and reinforce, we have to be struck by how stultifying of our own personal growth and satisfaction they can become when they take rein of us. Hegel, in "justifying" private property, unwittingly reflects the tone and quality of some of the needs that are played upon:

> A person has as his substantive end the right of putting his will into any and every thing and thereby making it his, because it has no such end in itself and derives its destiny and soul from his will. This is the absolute right of appropriation which man has over all "things."[126]

What is it within us that gives us this need not just to satisfy basic biological wants, but to extend our wills over things, to object-ify them, to make them ours, to manipulate them, to keep them at a psychic distance? Can it all be explained on "rational" bases? Should we not be suspect of such needs within us, cautious as to why we wish to gratify them? When I first read that passage of Hegel, I immediately thought not only of the emotional contrast with Spinoza, but of the passage in Carson McCullers' *A Tree, A Rock, A Cloud*, in which an old derelict has collared a twelve year old boy in a streetcar cafe. The old man asks whether the boy knows "how love should be begun?"

> The old man leaned closer and whispered:
>
> "A tree. A rock. A cloud."
>
> . . .
>
> "The weather was like this in Portland," he said. "At the time my science was begun. I meditated and I started very cautious. I would pick up something from the street and take it home with me. I bought a goldfish and I concentrated on the goldfish and I loved it. I graduated from one thing to another. Day by day I was getting this technique.. . .
>
> . . .
>
> . . . "For six years now I have gone around by myself and built up my science. And now I am a master. Son. I can love anything. No longer do I have to think about it even. I see a street full of people and a beautiful light comes in me. I watch a bird in the sky. Or I meet a traveler on the road. Everything, Son. And anybody. All stranger and all loved! Do you realize what a science like mine can mean?"[127]

To be able to get away from the view that Nature is a collection of useful senseless objects is, as McCullers' "madman" suggests, deeply involved in the development of our abilities to love—or, if that is putting it too strongly, to be able to reach a heightened awareness of our own, and others' capacities in their mutual interplay. To do so, we have to give up some psychic investment in our sense of separateness and specialness in the universe. And this, in turn, is hard giving indeed, because it involves us in a flight backwards, into earlier stages of civilization and childhood in which we had to trust (and perhaps fear) our environment, for we had not then the power to master it. Yet, in doing so, we—as

persons—gradually free ourselves of needs for supportive illusions. Is not this one of the triumphs for "us" of our giving legal rights to (or acknowledging the legal rights of) the Blacks and women?[128]

Changes in this sort of consciousness are already developing, for the betterment of the planet and us. There is now federal legislation which "establishes by law"[129]

> the humane ethic that animals should be accorded the basic creature comforts of adequate housing, ample food and water, reasonable handling, decent sanitation, sufficient ventilation, shelter from extremes of weather and temperature, and adequate veterinary care including the appropriate use of pain-killing drugs.. . .[130]

The Vietnam war has contributed to this movement, as it has to others. Five years ago a Los Angeles mother turned out a poster which read "War is not Healthy for children and other living things."[131] It caught on tremendously—at first, I suspect, because it sounded like another clever protest against the war, *i.e.*, another angle. But as people say such things, and think about them, the possibilities of what they have stumbled upon become manifest—in its suit against the Secretary of Agriculture to cancel the registration of D.D.T., Environmental Defense Fund alleged "biological injury to man and other living things."[132] A few years ago the pollution of streams was thought of only as a problem of smelly, unsightly, unpotable water *i.e.*, to us. Now we are beginning to discover that pollution is a process that destroys wondrously subtle balances of life within the water, and as between the water and its banks. This heightened awareness enlarges our sense of the dangers to us. But it also enlarges our empathy. We are not only developing the scientific capacity, but we are cultivating the personal capacities *within us* to recognize more and more the ways in which nature—like the woman, the Black, the Indian and the Alien—is like us (and we will also become more able realistically to define, confront, live with and admire the ways in which we are all different).[133]

The time may be on hand when these sentiments, and the early stirrings of the law, can be coalesced into a radical new theory or myth—felt as well as intellectualized—of man's relationships to the rest of nature. I do not mean "myth" in a demeaning sense of the term, but in the sense in which, at different times in history, our social "facts" and relationships have been comprehended and integrated by reference to the "myths" that we are co-signers of a social contract, that the Pope is God's agent, and that all men are created equal. Pantheism, Shinto and Tao all have myths to offer. But they are all, each in its own fashion, quaint, primitive and archaic. What is needed is a myth that can fit our growing body of knowledge of geophysics, biology and the cosmos. In this vein, I do not think it too remote that we may come to regard the Earth, as some have suggested, as one organism, of which Mankind is a functional part—the mind, perhaps: different from the rest of nature, but different as a man's brain is from his lungs.

> Ever since the first Geophysical Year, international scientific studies have shown irrefutably that the Earth as a whole is an organized system of most closely interrelated and indeed interdependent activities. It is, in the broadest sense of the term, an "organism." The so-called life-kingdoms and the many vegetable and animal species are dependent upon each other for survival in a balanced condition of planet-wide existence; and they depend on their environment, conditioned by oceanic and atmospheric currents, and even more by the protective action of the ionosphere and many other factors which have definite rhythms of operation. Mankind is part of this organic planetary whole; and there can be no truly new global society, and perhaps in the present state of affairs no society at all, as long as man will not recognize, accept and enjoy the fact that mankind has a definite function to perform within this planetary organism of which it is an active part.
>
> In order to give a constructive meaning to the activities of human societies all over the globe, these activities—physical and mental—should be understood and given basic value with reference to the wholesome functioning of the entire Earth, and we may add of the entire solar system. This cannot be done (1) if man insists on considering himself an alien Soul compelled to incarnate on this sorrowful planet, and (2) if we can see in the planet, Earth, nothing but a mass of material substances moved by mechanical laws, and in "life" nothing but a chance combination of molecular aggregations.
>
> . . . As I see it, the Earth is only one organized "field" of activities—and so is the *human person*—but these activities take place at various levels, in different "spheres" of being and realms of consciousness. The lithosphere is not the biosphere, and the latter not the . . . ionosphere. The Earth is not *only* a material mass. Consciousness is not only "human"; it exists at animal and vegetable levels, and most likely must be latent, or operating in some form, in the molecule and the atom; and all these diverse and in a sense hierarchical modes of activity and consciousness should be seen integrated in and perhaps transcended by an all-encompassing and "eonic" planetary Consciousness.
>
> . . . .
>
> Mankind's function within the Earth-organism is to extract from the activities of all other operative systems within this organism the type of consciousness which we call "reflective" or "self"-consciousness—or, we may also say to *mentalize*

> and give meaning, value, and "name" to all that takes place anywhere within the Earth-field. . . .
>
> This "mentalization" process operates through what we call culture. To each region of, and living condition in the total field of the Earth-organism a definite type of culture inherently corresponds. Each region is the "womb" out of which a specific type of human mentality and culture can and sooner or later will emerge. All these cultures—past, present and future—and their complex interrelationships and interactions are the collective builders of the Mind of humanity; and this means of the *conscious Mind of the Earth*.[134]

As radical as such a consciousness may sound today, all the dominant changes we see about us point in its direction. Consider just the impact of space travel, of world-wide mass media, of increasing scientific discoveries about the interrelatedness of all life processes. Is it any wonder that the term "spaceship earth" has so captured the popular imagination? The problems we have to confront are increasingly the world-wide crises of a global organism: not pollution of a stream, but pollution of the atmosphere and of the ocean. Increasingly, the death that occupies each human's imagination is not his own, but that of the entire life cycle of the planet earth, to which each of us is as but a cell to a body.

To shift from such a lofty fancy as the planetarization of consciousness to the operation of our municipal legal system is to come down to earth hard. Before the forces that are at work, our highest court is but a frail and feeble—a distinctly human—institution. Yet, the Court may be at its best not in its work of handing down decrees, but at the very task that is called for: of summoning up from the human spirit the kindest and most generous and worthy ideas that abound there, giving them shape and reality and legitimacy.[135] Witness the School Desegregation Cases which, more importantly than to integrate the schools (assuming they did), awakened us to moral needs which, when made visible, could not be denied. And so here, too, in the case of the environment, the Supreme Court may find itself in a position to award "rights" in a way that will contribute to a change in popular consciousness. It would be a modest move, to be sure, but one in furtherance of a large goal: the future of the planet as we know it.

How far we are from such a state of affairs, where the law treats "environmental objects" as holders of legal rights, I cannot say. But there is certainly intriguing language in one of Justice Black's last dissents, regarding the Texas Highway Department's plan to run a six-lane expressway through a San Antonio Park. [136] Complaining of the Court's refusal to stay the plan, Black observed that "after today's decision, the people of San Antonio and the birds and animals that make their home in the park will share their quiet retreat with an ugly, smelly stream of traffic. . . . Trees, shrubs, and flowers will be mown down."[137] Elsewhere he speaks of the "burial of public parks," of segments of a highway which "devour parkland," and of the park's heartland.[138] Was he, at the end of his great career, on the verge of saying—just saying—that "nature has 'rights' on its own account"? Would it be so hard to do?

2. *See* DARWIN, *supra* note 1, at 113–14:

> . . . No tribe could hold together if murder, robbery, treachery, etc., were common; consequently such crimes within the limits of the same tribe "are branded with everlasting infamy"; but excite no such sentiment beyond these limits. A North-American Indian is well pleased with himself, and is honored by others, when he scalps a man of another tribe; and a Dyak cuts off the head of an unoffending person, and dries it as a trophy . . . It has been recorded that an Indian Thug conscientiously regretted that he had not robbed and strangled as many travelers as did his father before him. In a rude state of civilization the robbery of strangers is, indeed, generally considered as honorable.

See also Service, *Forms of Kinship* in MAN IN ADAPTATION 112 (Y. Cohen ed. 1968).

3. *See* DARWIN, *supra* note 1, at 113. *See also* E. WESTERMARCK, 1 THE ORIGIN AND DEVELOPMENT OF THE MORAL IDEAS 406–12 (1912).

The practice of allowing sickly children to die has not been entirely abandoned, apparently, even at our most distinguished hospitals. *See Hospital Let Retarded Baby Die, Film Shows*, L. A. Times, Oct. 17, 1971, § A, at 9, col. 1.

4. There does not appear to be a word "gericide" or "geronticide" to designate the killing of the aged. "Senicide" is as close as the Oxford English Dictionary comes, although, as it indicates, the word is rare. 9 OXFORD ENGLISH DICTIONARY 454 (1933).

5. *See* DARWIN, *supra* note 1, at 386–93. WESTERMARCK, *supra* note 3, at 387–89, observes that where the killing of the aged and infirm is practiced, it is often supported by humanitarian justification; this, however, is a far cry from saying that the killing is *requested* by the victim as his right.

6. H. MAINE, ANCIENT LAW 153 (Pollock ed. 1930). Maine claimed that these powers of the father extended to all regions of private law, although not to the Jus Publicum, under which a son, notwithstanding his subjection in private life, might vote alongside his father *Id.* at 152. WESTERMARCK, *supra* note 3, at 393–94, was skeptical that the arbitrary power of the father over the children extended as late as into early Roman law.

7. 387 U.S. 1 (1967).

8. 42 U.S.C. §§ 1973 *et seq.* (1970).

9. *See* Landman v. Royster, 40 U.S.L.W. 2256 (E.D. Va., Oct. 30, 1971) (eighth amendment and due process clause of the fourteenth amendment require federal injunctive relief, including compelling the drafting of new prison rules, for Virginia prisoners against prison conduct prohibited by vague rules or no rules, without disciplinary proceedings embodying rudiments of procedural due process, and by various penalties that constitute cruel and unusual punishment). *See* Note, *Courts, Corrections and the Eighth Amendment: Encouraging Prison Reform by Releasing Inmates*, 44 S. CAL. L. REV. 1060 (1971).

10. *But see* T. SZASZ, LAW, LIBERTY AND PSYCHIATRY (1963).

11. *See* notes 22, 52 and accompanying text *infra.* The trend toward liberalized abortion can be seen either as a legislative tendency back in the direction of rightlessness for the foetus—or toward increasing rights of women. This inconsistency is not unique in the law of course; it is simply support for Hohfeld's scheme that the "jural opposite" of someone's right is someone else's "no-right." W. HOHFELD, FUNDAMENTAL LEGAL CONCEPTIONS (1923).

Consider in this regard a New York case in which a settlor *S* established a trust on behalf of a number of named beneficiaries and "lives in being." Desiring to amend the deed of trust, the grantor took steps pursuant to statute to obtain "the written consent of all persons beneficially interested in [the] trust." At the time the grantor was pregnant and the trustee Chase Bank advised it would not recognize the proposed amendment because the child *en ventre sa mere* might be deemed a person beneficially interested in the trust. The court allowed the amendment to stand, holding that birth rather than conception is the controlling factor in ascertaining whether a person is beneficially interested in the trust which the grantor seeks to amend. *In re* Peabody, 5 N.Y.2d 541, 158 N.E.2d 841 (1959).

The California Supreme Court has recently refused to allow the deliberate killing of a foetus (in a non-abortion situation) to support a murder prosecution. The court ruled foetuses not to be denoted by the words "human being" within the statute defining murder. Keeler v. Superior Court, 2 Cal. 3d 619, 87 Cal. Rptr. 481, 470 P.2d 617 (1970). But see note 52 and accompanying text *infra.*

Some jurisdictions have statutes defining a crime of "feticide"—deliberately causing the death of an unborn child. The absence of such a specific feticide provision in the California case was one basis for the ruling in *Keeler*. *See* 2 Cal. 3d at 633 n.16, 87 Cal. Rptr. at 489 n.16, 470 P.2d at 625 n.16.

12. INT. REV. CODE of 1954, § 1361 (repealed by Pub. L. No. 89-389, effective Jan. 1, 1969).

13. For example, *see* United States v. Cargo of the Brig Malek Adhel, 43 U.S. (2 How.) 210 (1844). There, a ship had been seized and used by pirates. All this was done without the knowledge or consent of the owners of the ship. After the ship had been captured, the United States condemned and sold the "offending vessel." The owners objected. In denying release to the owners, Justice Story cited Chief Justice Marshall from an earlier case: "This is not a proceeding against the owner; it is a proceeding against the vessel for an offense committed by the vessel; which is not the less an offense . . . because it was committed without the authority and against the will of the owner." 43 U.S. at 234, quoting from United States v. Schooner Little Charles, 26 F. Cas. 979 (No. 15,612) (C.C.D. Va. 1818).

14. 9 U.S. (5 Cranch) 61, 86 (1809).

15. Trustees of Darmouth College v. Woodward, 17 U.S. (4 Wheat.) 518 (1819).

16. *Id.* at 636.

17. Consider, for example, that the claim of the United States to the naval station at Guantanamo Bay, at $2000-a-year rental, is based upon a treaty signed in 1903 by José Montes for the President of Cuba and a minister representing Theodore Roosevelt; it was subsequently ratified by two-thirds of a Senate no member of which is living today. Lease [from Cuba] of Certain Areas for Naval or Coaling Stations, July 2, 1903, T.S. No. 426; C. BEVANS, 6 TREATIES AND OTHER INTERNATIONAL AGREEMENTS OF THE UNITED STATES 1776–1949, at 1120 (U.S. Dep't of State Pub. 8549, 1971).

18. O. GIERKE, POLITICAL THEORIES OF THE MIDDLE AGE (Maitland transl. 1927), especially at 22–30. The reader may be tempted to suggest that the "corporate" examples in the text are distinguishable from environmental objects in that the former are comprised by and serve humans. On the contrary, I think that the more we learn about the sociology of the firm—and the realpolitik of our society—the more we discover the ultimate reality of these institutions, and the increasingly legal fictiveness of the individual human being. *See* note 125 and accompanying text *infra.*

19. Dred Scott v. Sandford, 60 U.S. (19 How.) 396, 404–05 (1856). In Bailey v. Poindexter's Ex'r, 56 Va. (14 Gratt.) 132, 142–43 (1858) a provision in a will that testator's slaves could choose between emancipation and public sale was held void on the ground that slaves have no legal capacity to choose:

> These decisions are legal conclusions flowing naturally and necessarily from the one clear, simple, fundamental idea of chattel slavery. That fundamental idea is, that, in the eye of the law, so far certainly as civil rights and relations are concerned, the slave is not a person, but a thing. The investiture of a chattel with civil rights or legal capacity is indeed a legal solecism and absurdity. The attribution of legal personality to a chattel slave,—legal conscience, legal intellect, legal freedom, or liberty and power of free choice and action, and corresponding legal obligations growing out of such qualities, faculties and action—implies a palpable contradiction in terms.

20. People v. Hall, 4 Cal. 399, 405 (1854). The statute there under interpretation provided that "no Black or Mulatto person, or Indian shall be allowed to give evidence in favor of, or against a white man," but was silent as to Chinese. The "policy" analysis by which the court brings Chinese under "Black . . . or Indian" is a fascinating illustration of the relationship between a "policy" decision and a "just" decision, especially in light of the exchange between Hart, *Positivism and the Separation of Law and Morals*, 71 HARV. L. REV. 593 (1958) and Fuller, *Positivism and Fidelity to Law—A Reply to Professor Hart, id.* at 630.

21. Schechter, *The Rightlessness of Mediaeval English Jewry*, 45 JEWISH Q. REV. 121, 135 (1954) quoting from M. BATESON, MEDIEVAL ENGLAND 139 (1904). Schechter also quotes Henry de

Bracton to the effect that "a Jew cannot have anything of his own, because whatever he acquires he acquires not for himself but for the king...." *Id.* at 128.

22. Dietrich v. Inhabitants of Northampton, 138 Mass. 14, 16 (1884).

23. *In re* Goddell, 39 Wisc. 232, 245 (1875). The court continued with the following "clincher":

> And when counsel was arguing for this lady that the word, person, in sec. 32. ch. 119 [respecting those qualified to practice law], necessarily includes females, her presence made it impossible to suggest to him as *reductio ad absurdum* of his position, that the same construction of the same word ... would subject woman to prosecution for the paternity of a bastard, and ... prosecution for rape.

Id. at 246.

The relationship between our attitudes toward woman, on the one hand, and, on the other, the more central concern of this article—land—is captured in an unguarded aside of our colleague, Curt Berger. "... after all, land, like woman, was meant to be possessed...." LAND OWNERSHIP AND USE 139 (1968).

23a. Recently, a group of prison inmates in Suffolk County tamed a mouse that they discovered, giving him the name Morris. Discovering Morris, a jailer flushed him down the toilet. The prisoners brought a proceeding against the Warden complaining, *inter alia*, that Morris was subjected to discriminatory discharge and was otherwise unequally treated. The action was unsuccessful, on grounds that the inmates themselves were "guilty of imprisoning Morris without a charge, without a trial, and without bail," and that other mice at the prison were not treated more favorably. "As to the true victim the Court can only offer again the sympathy first proffered to his ancestors by Robert Burns...." The Judge proceeded to quote from Burns' "To a Mouse." Morabito v. Cyrta, 9 CRIM. L. REP. 2472 (N.Y. Sup. Ct. Suffolk Co. Aug. 26, 1971).

The whole matter seems humorous, of course. But what we need to know more of is the function of humor in the unfolding of a culture, and the ways in which it is involved with the social growing pains to which it is testimony. Why do people make jokes about the Women's Liberation Movement? Is it not on account of—rather than in spite of—the underlying validity of the protests, and the uneasy awareness that a recognition of them is inevitable? A. Koestler rightly begins his study of the human mind, ACT OF CREATION (1964), with an analysis of humor, entitled "The Logic of Laughter." And *cf.* Freud, *Jokes and the Unconscious*, 8 STANDARD EDITION OF THE COMPLETE PSYCHOLOGICAL WORKS OF SIGMUND FREUD (J. Strachey transl. 1905). (Query too: what is the relationship between the conferring of proper *names, e.g.*, Morris, and the conferring of social and legal *rights?*)

24. Thus it was that the Founding Fathers could speak of the inalienable rights of all men, and yet maintain a society that was, by modern standards, without the most basic rights for Blacks, Indians, children and women. There was no hypocrisy; emotionally, no one *felt* that these other things were men.

25. The second thought streaming from ... the older South [is] the sincere and passionate belief that somewhere between men and cattle, God created a *tertium quid*, and called it a Negro—a clownish, simple creature, at times even lovable within its limitations, but straitly foreordained to walk within the Veil.

W. E. B. DUBOIS, THE SOULS OF BLACK FOLK 89 (1924).

26. In this article I essentially limit myself to a discussion of non-animal but natural objects. I trust that the reader will be able to discern where the analysis is appropriate to advancing our understanding of what would be involved in giving "rights" to other objects not presently endowed with rights—for example, not only animals (some of which already have rights in some senses) but also humanoids, computers, and so forth. *Cf.* the National Register for Historic Places, 16 U.S.C. § 470 (1970), discussed in Ely v. Velde, 321 F. Supp. 1088 (E.D. Va. 1971).

As the reader will discover, there are large problems involved in defining the boundaries of the "natural object." For example, from time to time one will wish to speak of that portion of a river that runs through a recognized jurisdiction; at other times, one may be concerned with the entire river, or the hydrologic cycle—or the whole of nature. One's ontological choices will have a strong influence on the shape of the legal system, and the choices involved are not easy. *See* notes 49, 73 and accompanying text *infra*.

On the other hand, the problems of selecting an appropriate ontology are problems of all language—not merely of the language of legal concepts, but of ordinary language as well. Consider, for example, the concept of a "person" in legal *or* in everyday speech. Is each *person* a fixed bundle of relationships, persisting unaltered through time? Do our molecules and cells not change at every moment? Our hypostatizations always have a pragmatic quality to them. *See* D. HUME, *Of Personal Identity*, in TREATISE OF HUMAN NATURE bk. 1, pt. IV, § VI, in THE PHILOSOPHICAL WORKS OF DAVID HUME 310–18, 324 (1854); T. MURTI, THE CENTRAL PHILOSOPHY OF BUDDHISM 70–73 (1955). In LOVES BODY 146–47 (1966) Norman O. Brown observes:

> The existence of the "let's pretend" boundary does not prevent the continuance of the real traffic across it. Projection and introjection, the process whereby the self as distinct from the other is constituted, is not past history, an event in childhood, but a present process of continuous creation. The dualism of self and external world is built up by a constant process of reciprocal exchange between the two. The self as a stable substance enduring through time, an identity, is maintained by constantly absorbing good parts (or people) from the outside world and expelling bad parts from the inner world. "There is a continual 'unconscious' wandering of other personalities into ourselves."
>
> Every person, then, is many persons; a multitude made into one person; a corporate body; incorporated, a corporation. A "corporation sole"; every man a parson-person. The unity of the person is as real, or unreal, as the unity of the corporation.

See generally, W. BISHIN & C. STONE, LAW, LANGUAGE AND ETHICS Ch. 5 (1972).

In different legal systems at different times, there have been many shifts in the entity deemed "responsible" for harmful acts: an entire clan was held responsible for a crime before the notion

of individual responsibility emerged; in some societies the offending hand, rather than an entire body, may be "responsible." Even today, we treat father and son as separate jural entities for some purposes, but as a single jural entity for others. I do not see why, in principle, the task of working out a legal ontology of natural objects (and "qualities." *e.g.*, climatic warmth) should be any more unmanageable. Perhaps someday all mankind shall be, for some purposes, one jurally recognized "natural object."

27. The statement in text is not quite true; *cf.* Murphy, *Has Nature Any Right to Life?*, 22 HAST. L.J. 467 (1971). An Irish court, passing upon the validity of a testamentary trust to the benefit of someone's dogs, observed in dictum that "'lives' means lives of human beings, not of animals or trees in California." Kelly v. Dillon, 1932 Ir. R. 255, 261. (The intended gift over on the death of the last surviving dog was held void for remoteness, the court refusing "to enter into the question of a dog's expectation of life," although prepared to observe that "in point of fact neighbor's [sic] dogs and cats are unpleasantly long-lived...." *Id.* at 260–61).

28. Four cases dealing with the Constitutionality of the death penalty under the eighth and fourteenth amendments are pending before the United States Supreme Court. Branch v. Texas, 447 S.W.2d 932 (Tex. 1969), *cert. granted*, 91 S. Ct. 2287 (1970); Aikens v. California, 70 Cal. 2d 369, 74 Cal. Rptr. 882, 450 P.2d 258 (1969). *cert. granted*, 91 S. Ct. 2280 (1970); Furman v. Georgia, 225 Ga. 253, 167 S.E.2d 628 (1969), *cert. granted*, 91 S. Ct. 2282 (1970); Jackson v. Georgia, 225 Ga. 790, 171 S.E.2d 501 (1969), *cert. granted*, 91 S. Ct. 2287 (1970).

29. *See* George Campbell Painting Corp. v. Reid, 392 U.S. 286 (1968); Oklahoma Press Pub. Co. v. Walling, 327 U.S. 186 (1946); Baltimore & O.R.R. v. ICC, 221 U.S. 612 (1911); Wilson v. United States, 221 U.S. 361 (1911); Hale v. Henkel, 201 U.S. 43 (1906).

30. *See* Dixon v. Alabama State Bd. of Educ., 294 F.2d 150 (5th Cir.), *cert. denied*, 368 U.S. 930 (1961).

31. For example, *see* People *ex rel.* Ricks Water Co. v. Elk River Mill & Lumber Co., 107 Cal. 221, 40 Pac. 531 (1895) (refusing to enjoin pollution by a upper riparian at the instance of the Attorney General on the grounds that the lower riparian owners, most of whom were dependent on the lumbering business of the polluting mill, did not complain).

32. The law in a suit for injunctive relief is commonly easier on the plaintiff than in a suit for damages. *See* J. GOULD, LAW OF WATERS § 206 (1883).

33. However, in 1970 California amended its Water Quality Act to make it easier for the Attorney General to obtain relief, *e.g.*, one must no longer allege irreparable injury in a suit for an injunction. CAL. WATER CODE § 13350(b) (West 1971).

34. To whomsoever the soil belongs, he owns also to the sky and to the depths. *See* W. BLACKSTONE, 2 COMMENTARIES *18.

At early common law, the owner of land could use all that was found under his land "at his free will and pleasure" without regard to any "inconvenience to his neighbour." Acton v. Blundell, 12 Meeson & Welsburg 324, 354, 152 Eng. Rep. 1223, 1235 (1843). "He [the landowner] may waste or despoil the land as he pleases...." R. MECARRY & H. WADE, THE LAW OF REAL PROPERTY 70 (3d ed. 1966). *See* R. POWELL, 5 THE LAW OF REAL PROPERTY 725 (1971).

35. *See* Note, *Statutory Treatment of Industrial Stream Pollution*, 24 GEO. WASH. L. REV. 302, 306 (1955); H. FARNHAM, 2 LAW OF WATERS AND WATER RIGHTS § 461 (1904); GOULD, *supra* note 32, at § 204.

36. For example, courts have upheld a right to pollute by prescription. Mississippi Mills Co. v. Smith, 69 Miss. 299, 11 So. 26 (1882), and by easement, Luama v. Bunker Hill & Sullivan Mining & Concentrating Co., 41 F.2d 358 (9th Cir. 1930).

37. *See* Red River Roller Mills v. Wright, 30 Minn. 249, 15 N.W. 167 (1883) (enjoyment of stream by riparian may be modified or abrogated by reasonable use of stream by others); Townsend v. Bell, 167 N.Y. 462, 60 N.E. 757 (1901) (riparian owner not entitled to maintain action for pollution of stream by factory where he could not show use of water was unreasonable); Smith v. Staso Milling Co., 18 F.2d 736 (2d Cir. 1927) (in suit for injunction, right on which injured lower riparian stands is a quantitative compromise between two conflicting interests); Clifton Iron Co. v. Dye, 87 Ala. 468, 6 So. 192 (1889) (in determining whether to grant injunction to lower riparian, court must weigh interest of public as against injury to one or the other party). *See also* Montgomery Limestone Co. v. Bearder, 256 Ala. 269, 54 So. 2d 571 (1951).

38. Pennsylvania Coal Co. v. Sanderson, 113 Pa. 126, 149, 6 A. 453, 459 (1886).

39. Hand, J. in Smith v. Staso Milling Co., 18 F.2d 736, 738 (2d Cir. 1927) (emphasis added). *See also* Harrisonville v. Dickey Clay Co., 289 U.S. 334 (1933) (Brandeis, J.).

40. Measuring plantiff's damages by "making him whole" has several limitations; these and the matter of measuring damages in this area generally are discussed more fully at notes 83–93 and accompanying text *infra.*

41. Here, again, an analogy to corporation law might be profitable. Suppose that in the instance of negligent corporate management by the directors, there were no institution of the stockholder derivative suit to force the directors to make *the corporation* whole, and the only actions provided for were direct actions by stockholders to collect for damages *to themselves qua* stockholders. Theoretically and practically, the damages might come out differently in the two cases, and not merely because the creditors' looses are not aggregated in the stockholders' direct actions.

42. And even far less than the damages to all human economic interests derivately through the stream; *see* text accompanying notes 83–84, 120 *infra.*

43. Smith v. Staso, 18 F.2d, 736, 738 (2d Cir. 1927).

44. Some of these public properties are subject to the "public trust doctrine," which, while ill-defined, might be developed in such fashion as to achieve fairly broad-ranging environmental protection. *See* Gould v. Greylock Reservation Comm'n, 350 Mass. 410, 215 N.E.2d 114 (1966), discussed in Sax, *The Public Trust Doctrine in Natural Resource Law: Effective Judicial Intervention*, 68 MICH. L. REV. 471, 492–509 (1970).

45. By contrast, for example, with humane societies.

46. *See, e.g.*, Cal. Prob. Code §§ 1460–62 (West Supp. 1971).

47. CAL PROB. CODE § 1751 (West Supp. 1971) provides for the appointment of a "conservator."

48. In New York the Supreme Court and county courts outside New York City have jurisdiction to appoint a committee of the person and/or a committee of the property for a person "incompetent to manage himself or his affairs." N.Y. MENTAL HYGIENE LAW § 100 (McKinney 1971).

49. This is a situation in which the ontological problems discussed in note 26 *supra* become acute. One can conceive a situation in which a guardian would be appointed by a county court with respect to a stream, bring a suit against alleged polluters, and lose. Suppose now that a federal court were to appoint a guardian with respect to the larger river system of which the stream were a part, and that the federally appointed guardian subsequently were to bring suit against the same defendants in state court, now on behalf of the river, rather than the stream. (Is it possible to bring a still subsequent suit, if the one above fails, on behalf of the entire hydrologic cycle, by a guardian appointed by an international court?)

While such problems are difficult, they are not impossible to solve. For one thing, pre-trial hearings and rights of intervention can go far toward their amelioration. Further, courts have been dealing with the matter of potentially inconsistent judgments for years, as when one state appears on the verge of handing down a divorce decree inconsistent with the judgment of another state's courts. Kempson v. Kempson, 58 N.J. Eg. 94, 43 A. 97 (Ch. Ct. 1899). Courts could, and of course would, retain some natural objects in the res nullius classification to help stave off the problem. Then, too, where (as is always the case) several "objects" are interrelated, several guardians could all be involved, with procedures for removal to the appropriate court—probably that of the guadian of the most encompassing "ward" to be acutely threatened. And in some cases subsequent suit by the guardian of more encompassing ward, not guilty of laches, might be appropriate. The problems are at least no more complex than the corresponding problems that the law has dealt with for years in the class action area.

50. CAL. PROB. CODE § 1460 (West Supp. 1971). The N.Y. MENTAL HYGIENE LAW (McKinney 1971) provides for jurisdiction "over the custody of a person and his property if he is incompetent to manage himself or his affairs by reason of age, drunkenness, mental illness or other cause. . . ."

51. Santa Clara County v. Southern Pac. R.R., 118 U.S. 394 (1886). Justice Black would have denied corporations the rights of "persons" under the fourteenth amendment. *See* Connecticut Gen. Life Ins. Co. v. Johnson, 303 U.S. 77, 87 (1938) (Black, J. dissenting): "Corporations have neither race nor color."

52. *In re* Byrn, L. A. Times, Dec. 5, 1971, § 1, at 16, col. 1. A preliminary injunction was subsequently granted, and defendant's cross-motion to vacate the guardianship was denied. Civ. 13113/71 (Sup. Ct. Queens Co., Jan. 4, 1972) (Smith, J.). Appeals are pending. Granting a guardianship in these circumstances would seem to be a more radical advance in the law than granting a guardianship over communal natural objects like lakes. In the former case there is a traditionally recognized guardian for the object—the mother—and her decision has been in favor of aborting the foetus.

53. The laws regarding the various communal resources had to develop along their own lines, not only because so many different persons' "rights" to consumption and usage were continually and contemporaneously involved, but also because no one had to bear the costs of his consumption of public resources in the way in which the owner of resources on private land has to bear the costs of what he does. For example, if the landowner strips his land of trees, and puts nothing in their stead, he confronts the costs of what he has done in the form of reduced value of his land: but the river polluter's actions are costless, so far as he is concerned—except insofar as the legal system can somehow force him to internalize them. The result has been that the private landowner's power over natural objects on his land is far less restrained by law (as opposed to economics) than his power over the public resources that he can get his hands on. If this state of affairs is to be changed, the standard for interceding in the interests of natural objects on traditionally recognized "private" land might well parallel the rules that guide courts in the matter of people's children whose upbringing (or lack thereof) poses social threat. The courts can, for example, make a child "dependent of the court" where the child's "home is an unfit place for him by reason of neglect, cruelty, or depravity of either of his parents. . . ." CAL. WELF. & INST. CODE § 600(b) (West 1966). *See also id* at § 601: any child "who from any cause is in danger of leading an idle, dissolute, lewd, or immoral life [may be adjudged] a ward of the court."

54. *See* note 53 *supra.* The present way of handling such problems on "private" property is to try to enact legislation of general application under the police power, *see* Pennsylvania Coal Co. v. Mahon, 260 U.S. 393 (1922), rather than to institute civil litigation which, though a piecemeal process, can be tailored to individual situations.

55. CAL. PROB. CODE § 1580 (West Supp. 1971) lists specific causes for which a guardian may, after notice and a hearing, be removed.

Despite these protections, the problem of overseeing the guardian is particularly acute where, as here, there are no immediately identifiable human beneficiaries whose self-interests will encourage them to keep a close watch on the guardian. To ameliorate this problem, a page might well be borrowed from the law of ordinary charitable trusts, which are commonly placed under the supervision of the Attorney General. *See* CAL. PROB. CODE §§ 9505, 10207 (West 1955).

56. *See* CAL. PROB. CODE § 1472, 1590 (West 1956 and Supp. 1971).

57. 354 F.2d 608 (2d Cir. 1965), *cert. denied*, Consolidated Edison Co. v. Scenic Hudson Preservation Conf., 384 U.S. 941 (1966).

58. 354 F.2d 608, 615 (2d Cir. 1965).

59. Act of Aug. 26, 1935, ch. 687, Title II, § 213, 49 Stat. 860 (*codified in* 16 U.S.C. § 8251(b) (1970).

60. 354 F.2d 608, 616 (2d Cir. 1965). The court might have felt that because the New York-New Jersey Trial Conference, one of the two conservation groups that organized Scenic Hudson, had some 17 miles of trailways in the area of Storm King Mountain, it therefore had sufficient economic interest to establish standing; Judge Hays' opinion does not seem to so rely, however.

61. Road Review League v. Boyd, 270 F. Supp. 650 (S.D.N.Y. 1967). Plaintiffs who included the Town of Bedford and the Road Review League, a non-profit association concerned with community problems, brought an action to review and set

aside a determination of the Federal Highway Administrator concerning the alignment of an interstate highway. Plaintiffs claimed that the proposed road would have an adverse effect upon local wildlife sanctuaries, pollute a local lake, and be inconsistent with local needs and planning. Plaintiffs relied upon the section of the Administrative Procedure Act, 5 U.S.C. § 702 (1970), which entitles persons "aggrieved by agency action within the meaning of a relevant statute" to obtain judicial review. The court held that plaintiffs had standing to obtain judicial review of proposed alignment of the road:

> I see no reason why the word "aggrieved" should have different meaning in the Administrative Procedure Act from the meaning given it under the Federal Power Act.... The "relevant statute," i.e., the Federal Highways Act, contains language which seems even stronger than that of the Federal Power Act, as far as local and conservation interests are concerned.

Id. at 661.

In Citizens Comm. for the Hudson Valley v. Volpe, 425 F.2d 97 (2d Cir. 1970), plaintiffs were held to have standing to challenge the construction of a dike and causeway adjacent to the Hudson Valley. The Sierra Club and the Village of Tarrytown based their challenge upon the provisions of the Rivers and Harbors Act of 1899. While the Rivers and Harbors Act does not provide for judicial review as does the Federal Power Act, the court stated that the plaintiffs were "aggrieved" under the Department of Transportation Act, the Hudson River Basin Compact Act, and a regulation under which the Corps of Engineers issued a permit, all of which contain broad provisions mentioning recreational and environmental resources and the need to preserve the same. Citing the *Road Review League* decision, the court held that as "aggrieved" parties under the Administrative Procedure Act, plaintiffs similarly had standing. Other decisions in which the court's grant of standing was based upon the Administrative Procedure Act include: West Virginia Highlands Conservancy v. Island Creek Coal Co., 441 F.2d 231 (4th Cir. 1971); Environmental Defense Fund, Inc. v. Hardin, 428 F.2d 1093 (D.C. Cir. 1970); Allen v. Hickel, 424 F.2d 944 (D.C. Cir. 1970); Brooks v. Volpe, 329 F. Supp. 118 (W.D. Wash. 1971); Delaware v. Pennsylvania N.Y. Cent. Transp. Co., 323 F. Supp. 487 (D. Del. 1971); Izaak Walton League of America v. St. Clair, 313 F. Supp. 1312 (D. Minn. 1970); Pennsylvania Environmental Council, Inc. v. Bartlett, 315 F. Supp. 238 (M.D. Pa. 1970).

62. Sierra Club v. Hickel, 433 F.2d 24 (9th Cir. 1970), *cert. granted sub nom*. Sierra Club v. Morton, 401 U.S. 907 (1971) (No. 70-34). The Sierra Club, a non-profit California corporation concerned with environmental protection, claimed that its interest in the conservation and sound management of natural parks would be adversely affected by an Interior permit allowing Walt Disney to construct the Mineral King Resort in Sequoia National Forest. The court held that because of the Sierra Club's failure to assert a direct legal interest, that organization lacked standing to sue. The court stated that the Sierra Club had claimed an interest only in the sense that the proposed course of action was displeasing to its members. The court purported to distinguish *Scenic Hudson* on the grounds that the plaintiff's claim of standing there was aided by the "aggrieved party" language of the Federal Power Act.

63. 16 U.S.C. §§ 791(a) *et seq.* (1970). *See* note 59 and accompanying text *supra.*

64. 5 U.S.C. §§ 551 *et seq.* (1970). Decisions relying upon 5 U.S.C. § 702 are listed in note 56 *supra.*

65. 7 U.S.C. §§ 135 *et seq.* (1970). Section 135b(d) affords a right of judicial review to anyone "adversely affected" by an order under the Act. *See* Environmental Defense Fund, Inc. v. Hardin, 428 F.2d 1093, 1096 (D.C. Cir. 1970).

66. 324 F. Supp. 412 (N.D., M.D. & S.D. Ala. 1970), *aff'd mem., sub nom.* Bass Anglers Sportsman Soc'y of America, Inc. v. Koppers Co., 447 F.2d 1304 (5th Cir. 1971).

67. Section 13 of Rivers and Harbors Appropriation Act of 1899.

68. 33 U.S.C. § 411 (1970) reads:

> Every person and every corporation that shall violate, or that shall knowingly aid, abet, authorize, or instigate a violation of the provisions of sections 407, 408, and 409 of the title shall ... be punished by a fine ... or by imprisonment ... in the discretion of the court, one-half of said fine to be paid to the person or persons giving information which shall lead to conviction.

69. This is from the latin, "who brings the action as well for the King as for himself," referring to an action brought by a citizen for the state as well as for himself.

70. These sections create a criminal liability. No civil action lies to enforce it; criminal statutes can only be enforced by the government. A qui tam action lies only when expressly or impliedly authorized by statute to enforce a penalty by civil action, not a criminal fine.

324 F. Supp. 412, 415–16 (ND., M.D. & S.D. Ala. 1970). Other *qui tam* actions brought by the Bass Angler Sportsman Society have been similarly unsuccessful. *See* Bass Anglers Sportsman Soc'y of America v. Scholze Tannery, 329 F. Supp. 339 (E.D. Tenn. 1971); Bass Anglers Sportsman's Soc'y of America v. United States Plywood-Champion Papers, Inc., 324 F. Supp. 302 (S.D. Tex. 1971).

71. Concern over an anticipated flood of litigation initiated by environmental organizations is evident in Judge Trask's opinion in Alameda Conservation Ass'n v. California, 437 F.2d 1087 (9th Cir.), *cert. denied*, Leslie Salt Co. v. Alameda Conservation Ass'n, 402 U.S. 908 (1971), where a non-profit corporation having as a primary purpose protection of the public's interest in San Francisco Bay was denied standing to seek an injunction prohibiting a land exchange that would allegedly destroy wildlife, fisheries and the Bay's unique flushing characteristics:

> Standing is not established by suit initiated by this association simply because it has as one of its purposes the protection of the "public interest" in the waters of the San Francisco Bay. However well intentioned the members may be, they may not by uniting create for themselves a super-administrative agency or a *parens patriae* official status with the capability of over-seeing and of challenging the action of the appointed and elected officials of the

> state government. Although recent decisions have considerably broadened the concept of standing, we do not find that they go this far. [Citation.]
>
> Were it otherwise the various clubs, political, economic and social now or yet to be organized, could wreak havoc with the administration of government, both federal and state. There are other forums where their voices and their views may be effectively presented, but to have standing to submit a "case or controversy" to a federal court, something more must be shown.

437 F.2d at 1090.

72. *See* note 49 *supra.*

73. Here, too, we are dogged by the ontological problem discussed in note 26 *supra.* It is easier to say that the smog-endangered stand of pines "wants" the smog stopped (assuming that to be a jurally significant entity) then it is to venture that the mountain, or the planet earth, or the cosmos, is concerned about whether the pines stand or fall. The more encompassing the entity of concern, the less certain we can be in venturing judgments as to the "wants" of any particular substance, quality, or species within the universe. Does the cosmos care if we humans persist or not? "Heaven and earth . . . regard all things as insignificant, as though they were playthings made of straw." LAO-TZU, TAO TEH KING 13 (D. Goddard transl. 1919).

74. *See* Knight v. United States Land Ass'n, 142 U.S. 161, 181 (1891).

75. Clause 2 gives Congress the power "to dispose of and make all needful Rules and Regulations respecting the Territory or other Property belonging to the United States."

76. *See* Flemming v. Nestor, 363 U.S. 603 (1960).

77. *See* the L. A. Times editorial *Water: Public vs. Polluters* criticizing:

> . . . the ridiculous built-in conflict of interests on Regional Water Quality Control Board. By law, five of the seven seats are given to spokesmen for industrial, governmental, agricultural or utility users. Only one representative of the public at large is authorized, along with a delegate from fish and game interests.

Feb. 12, 1969, Part II, at 8, cols. 1–2.

78. The Federal Refuse Act is over 70 years old. Refuse Act of 1899, 33 U.S.C. § 407 (1970).

79. *See* Hall, *Refuse Act of 1899 and the Permit Program*, 1 NAT'L RES. DEFENSE COUNCIL NEWSLETTER 1 (1971).

80. To be effective as a deterrent, the sanction ought to be high enough to bring about an internal reorganization of the corporate structure which minimizes the chances of future violations. Because the corporation is not necessarily a profit-maximizing "rationally economic man," there is no reason to believe that setting the fine as high as—but no higher than—anticipated profits from the violation of the law, will bring the illegal behavior to an end.

81. Udall v. FPC, 387 U.S. 428, 437 n.6 (1967). *See also* Holmes, J. in New Jersey v. New York, 283 U.S. 336, 342 (1931): "A river is more than an amenity, it is a treasure. It offers a necessity of life that must be rationed among those who have power over it."

82. To simplify the description, I am using here an ordinary language sense of causality, *i.e.*, assuming that the pollution causes harm to the river. As Professor Coase has pointed out in *The Problem of Social Cost*, 3 J. LAW & ECON. 1 (1960), harm-causing can be viewed as a reciprocal problem, *i.e.*, in the terms of the text, the mill wants to harm the river, and the river—if we assume it "wants" to maintain its present environmental quality—"wants" to harm the mill. Coase rightly points out that at least in theory (if we had the data) we ought to be comparing the alternative social product of different social arrangements, and not simply imposing full costs on the party who would popularly be identified as the harm-causer.

83. I am assuming that one of the considerations that goes into a judgment of "remoteness" is a desire to discourage burdensome amounts of petty litigation. This is one of the reasons why a court would be inclined to say—to use the example in the text—that the man who sells fishing tackle and bait has not been "proximately" injured by the polluter. Using proximate cause in this manner, the courts can protect themselves from a flood of litigation. But once the guardian were in court anyway, this consideration would not obtain as strongly, and courts might be more inclined to allow proof on the damages to remotely injured humans (although the proof itself is an added burden of sorts).

84. *Cf.* Golding, *Ethical Issues in Biological Engineering*, 15 U.C.L.A.L. REV. 443, 451–63 (1968).

85. Of course, in the instance of copyright and patent protection, the creation of the "property right" can be more directly justified on homocentric grounds.

86. *See* Schrag, *Life on a Dying Lake*, in THE POLITICS OF NEGLECT 167, at 173 (R. Meek & J. Straayer eds. 1971).

87. One ought to observe, too, that in terms of real effect on marginal welfare, the poor quite possibly will bear the brunt of the compromises. They may lack the wherewithal to get out to the countryside—and probably want an increase in material goods more acutely than those who now have riches.

88. On November 2, 1971, the Senate, by a vote of 86–0, passed and sent to the House the proposed Federal Water Pollution Control Act Amendments of 1971, 117 CONG. REC. S17464 (daily ed. Nov. 2, 1971). Sections 101(a) and (a)(1) of the bill declare it to be "national policy that, consistent with the provisions of this Act—(1) the discharge of pollutants into the navigable waters be eliminated by 1985." S.2770, 92d Cong., 1st Sess., 117 CONG. REC. S17464 (daily ed. Nov. 2, 1971).

89. 354 F.2d 608, 624 (2d Cir. 1965).

90. Again, there is a problem involving what we conceive to be the injured entity. *See* notes 26, 73 *supra.*

91. N.Y. Times, Jan. 14, 1971, § 1, col. 2, and at 74, col. 7.

92. Courts have not been reluctant to award damages for the destruction of heirlooms, literary manuscripts or other property having no ascertainable market value. In Willard v. Valley Gas Fuel Co., 171 Cal. 9, 151 Pac. 286 (1915), it was held that the measure of damages for the negligent destruction of a rare old book written by one of plaintiff's ancestors was the amount which would compensate the owner for all detriment including

sentimental loss proximately caused by such destruction. The court, at 171 Cal. 15, 151 Pac. 289, quoted approvingly from Southern Express Co. v. Owens, 146 Ala. 412, 426, 41 S. 752, 755 (1906):

> Ordinarily, where property has a market value that can be shown, such value is the criterion by which actual damages for its destruction or loss may be fixed. But it may be that property destroyed or lost has no market value. In such state of the case, while it may be that no rule which will be absolutely certain to do justice between the parties can be laid down, it does not follow from this, nor is it the law, that the plaintiff must be turned out of court with nominal damages merely. Where the article or thing is so unusual in its character that market value cannot be predicated of it, its value, or plaintiff's damages, must be ascertained in some other rational way and from such elements as are attainable.

Similarly, courts award damages in wrongful death actions despite the impossibility of precisely appraising the damages in such cases. In affirming a judgment in favor of the administrator of the estate of a child killed by defendant's automobile, the Oregon Supreme Court, in Lane v. Hatfield, 173 Or. 79, 88–89, 143 P.2d 230, 234 (1943), acknowledged the speculative nature of the measure of damages:

> No one knows or can know when, if at all, a seven year old girl will attain her majority, for her marriage may take place before she has become twenty-one years of age.... Moreover, there is much uncertainty with respect to the length of time anyone may live. A similar uncertainty veils the future of a minor's earning capacity or habit of saving. Illness or a non-fatal accident may reduce an otherwise valuable and lucrative life to a burden and liability.
>
> The rule, that the measure of recovery by a personal representative for the wrongful death of his decedent is the value of the life of such decedent, if he had not come to such an untimely end, has been termed vague, uncertain and speculative if not, conjectural. It is, however, the best that judicial wisdom has been able to formulate.

93. It is not easy to dismiss the idea of "lower" life having consciousness and feeling pain, especially since it is so difficult to know what these terms mean even as applied to humans. *See* Austin, *Other Minds*, in *Logic and Language* 342 (S. Flew ed. 1965); Schopenhauer, *On the Will in Nature*, in TWO ESSAYS BY ARTHUR SCHOPENHAUER 193, 281–304 (1889). Some experiments on plant sensitivity—of varying degrees of extravagance in their claims—include Lawrence, *Plants Have Feelings, Too* . . ., ORGANIC GARDENING & FARMING 64 (April 1971); Woodlief, Royster & Huang, *Effect of Random Noise on Plant Growth*, 46 J. ACOUSTICAL SOC. AM. 481 (1969); Backster, *Evidence of a Primary Perception in Plant Life*, 10 INT'L J. PARAPSYCHOLOGY 250 (1968).

94. *See* note 39 *supra*, and Coase, note 82 *supra*.

95. *See* FED. R. CIV. P. 23 and note 49 *supra.*

96. This is an ideal, of course—like the ideal that no human being ought to interfere with any other human being. *See* Dyke, *Freedom, Consent and the Costs of Interaction*, and Stone, *Comment*, in IS LAW DEAD? 134–67 (E. Rostow ed. 1971). Some damages would inevitably be *damnum absque injuria. See* note 93 *supra.*

97. The inevitability of some form of evolution is not inconsistent with the establishment of a legal system that attempts to interfere with or ameliorate the process: is the same not true of the human law we now have, *e.g.*, the laws against murder?

98. Holmes, *Early Forms of Liability*, in THE COMMON LAW (1881), discusses the liability of animals and inanimate objects in early Greek, early Roman and some later law. Alfred's Laws (A.D. 871–901) provided, for example, that a tree by which a man was killed should "be given to the kindred, and let them have it off the land within 30 nights." *Id.* at 19. In Edward I's time, if a man fell from a tree the tree was deodand. *Id.* at 24. Perhaps the liability of non-human matter is, in the history of things, part of a paranoid, defensive phase in man's development; as humans become more abundant, both from the point of material wealth and iternally, they may be willing to allow an advance to the stage where non-human matter has rights.

99. *See* note 26 *supra*. In the event that a person built his house near the edge of a river that flooded, would "assumption of the risk" be available on the river's behalf?

100. *See* Dixon v. Alabama State Bd. of Educ., 294 F.2d 150 (5th Cir.), *cert. denied*, 368 U.S. 930 (1961); Comment, *Private Government on the Campus—Judicial Review of University Expulsions*, 72 YALE L.J. 1362 (1963).

101. National Environmental Policy Act. 92 U.S.C. § 4332 (1970).

102. *See* Committee for Nuclear Responsibility Inc. v. Schlesinger, 40 U.S.L.W. 3214 (Nov. 5, 1971) (Douglas, J. dissent to denial of application for injunction in aid of jurisdiction).

103. 42 U.S.C. § 4342 (1970).

104. As an indication of what lower-level management is apt to do, *see* Ehrenreich & Ehrenreich, *Conscience of a Steel Worker*, 213 THE NATION 268 (1971). One steel company's "major concession [toward obedience to the 1899 Refuse Act, note 78 *supra*] was to order the workers to confine oil dumping to the night shift. 'During the day the Coast Guard patrols. But at night, the water's black, the oil's black; no one can tell.'" An effective corporation law would assure that the internal information channels within a corporation were capable of forcing such matters to the attention of high-level officials. Even then, there is no guarantee that the law will be obeyed—but we may have improved the odds.

105. In the case of Lake Erie, in addition to the considerations that follow in the text, there were possibly additional factors such as that no one polluter's acts could be characterized as inflicting irreparable injury.

106. *See* for example Justice Reed's opinion for the Court in Kovacs v. Cooper, 336 U.S. 77 (1949) (*but see* Mr. Justice Frankfurter's concurring opinion, 336 U.S. at 89–96), and United States v. Carolene Products, 304 U.S. 144, 152 n.4 (1938).

107. Note that in the discussion that follows I am referring to legislative apportionment, not voting proper.

108. In point of fact, there is no reason to suppose that an increase of Congressmen for Alaska would be a benefit to the environment; the reality of the political situation might just as likely result in the election of additional Congressmen with closer ties to oil companies and other developers.

109. *See* Simpson, *The Analysis of Legal Concepts*, 80 LAW Q. REV. 535 (1964).

110. Krier, *Environmental Litigation and the Burden of Proof*, in LAW AND THE ENVIRONMENT 105 (M. Baldwin & J. Page eds. 1970). *See* Texas East Trans. Corp. v. Wildlife Preserves, 48 N.J. 261, 225 A.2d 130 (1966). There, where a corporation set up to maintain a wildlife preserve resisted condemnation for the construction of plaintiff's pipe line, the court ruled that "... the *quantum* of proof required of this defendant to show arbitrariness against it would not be as substantial as that to be assumed by the ordinary property owner who devotes his land to conventional uses." 225 A.2d at 137.

111. See Stone, *Existential Humanism and the Law*, in EXISTENTIAL HUMANISTIC PSYCHOLOGY 151 (T. Greening ed. 1971).

112. National Environmental Policy Act, 42 U.S.C. §§ 4321–47 (1970).

113. *See* note 65 *supra.*

114. W. HOLDSWORTH, HISTORY OF ENGLISH LAW 45 (5th ed. 1931).

115. Note that it is in no small way the law that imposes this manner of speech on businessmen. *See* Dodge v. Ford Motor Co., 204 Mich. 459, 499–505, 170 N.W. 668, 682–83 (1919) (holding that Henry Ford, as dominant stockholder in Ford Motor Co., could not withhold dividends in the interests of operating the company "as a semi-elecmosynary institution and not as a business institution").

116. I. KANT, PHILOSOPHY OF LAW 195 (Hastle Transl. 1887).

122. McHarg, *Values, Process and Form*, in THE FITNESS OF MAN'S ENVIRONMENT 213–14 (1968).

123. Murphy, *supra* note 27, at 477.

124. On the other hand, the statement in text, and the previous one of Professor Murphy, may be a bit severe. One could as easily claim that Christianity has had no influence on overt human behavior in light of the killings that have been carried out by professed Christians, often in its name. *Feng shui* has, on all accounts I am familiar with, influenced the development of land in China *See* Freedman, *Geomancy*, 1968 PROCEEDINGS OF THE ROYAL ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND 5; March, *An Appreciation of Chinese Geomancy*, 27 J. ASIAN STUDIES 253 (1968).

125. The legal system does the best it can to maintain the illusion of the reality of the individual human being. Consider, for example, how many constitutional cases, brought in the name of some handy individual, represent a power struggle between institutions—the NAACP and a school board, the Catholic Church and a school board, the ACLU and the Army, and so forth. Are the individual human plaintiffs the real moving causes of these cases—or an afterthought?

When we recognize that our problems are increasingly institutional, we would see that the solution, if there is one, must involve coming to grips with how the "corporate" (in the broadest sense) entity is directed, and we must alter our views of "property" in the fashion that is needed to regulate organizations successfully. For example, instead of ineffectual, after-the-fact criminal fines we should have more preventive in-plant inspections, notwithstanding the protests of "invasion of [corporate] privacy."

In-plant inspection of production facilities and records is presently allowed only in a narrow range of areas, *e.g.*, in federal law, under the Federal Food, Drug, and Cosmetic Act, 21 U.S.C. § 374 *et seq.* (1970), and provisions for meat inspection, 21 U.S.C. § 608 (1970). Similarly, under local building codes we do not wait for a building to collapse before authoritative sources inquire into the materials and procedures that are being used in the construction; inspectors typically come on site to check the progress at every critical stage. A sensible preventive legal system calls for extending the ambit of industries covered by comparable "privacy invading" systems of inspection.

126. G. HEGEL, HEGEL'S PHILOSOPHY OF RIGHT 41 (T. Knox transl. 1945).

127. C. MCCULLERS, THE BALLAD OF THE SAD CAFE AND OTHER STORIES 150–51 (1958).

128. Consider what Schopenhauer was writing "Of Women," about the time the Wisconsin Supreme Court was explaining why women were unfit to practice law, note 23 *supra:*

> You need only look at the way in which she is formed, to see that woman is not meant to undergo great labour, whether of the mind or of the body. She pays the debt of life not by what she does, but by what she suffers; by the pains of childbearing and care for the child, and by submission to her husband, to whom she should be a patient and cheering companion. The keenest sorrows and joys are not for her, nor is she called upon to display a great deal of strength. The current of her life should be more gentle, peaceful and trivial than man's, without being essentially happier or unhappier.
>
> Women are directly fitted for acting as the nurses and teachers of our early childhood by the fact that they are themselves childish, frivolous and short-sighted; in a word, they are big children all their life long—a kind of intermediate stage between the child and the full-grown man, who is man in the strict sense of the word. . . .
>
> However many disadvantages all this may involve, there is at least this to be said in its favour: that the woman lives more in the present than the man, and that, if the present is at all tolerable, she enjoys it more eagerly. This is the source of that cheerfulness

> which is peculiar to woman, fitting her to amuse man in his hours of recreation, and, in case of need, to console him when he is borne down by the weight of his cares.
>
> ...
>
> ... [I]t will be found that the fundamental fault of the female character is that it has *no sense of justice.* This is mainly due to the fact, already mentioned, that women are defective in the powers of reasoning and deliberation; but it is also traceable to the position which Nature has assigned to them as the weaker sex. They are dependent, not upon strength, but upon craft; and hence their instinctive capacity for cunning, and their ineradicable tendency to say what is not true. ***For as lions are provided with claws and teeth, and elephants and boars with tusks, bulls with horns, and the cuttle fish with its cloud of inky fluid, so Nature has equipped woman, for her defense and protection, with the arts of dissimulation; and all the power which Nature has conferred upon man in the shape of physical strength and reason, has been bestowed upon women in this form. Hence, dissimulation is innate in woman, and almost as much a quality of the stupid as of the clever.. . .

A. SCHOPENHAUER, *On Women*, in STUDIES IN PESSIMISM 105–10 (T. B. Saunders transl. 1893).

If a man should write such insensitive drivel today, we would suspect him of being morally and emotionally blind. Will the future judge us otherwise, for venting rather than examining the needs that impel us to treat the environment as a senseless object—to blast to pieces some small atoll to find out whether an atomic weapon works?

129. Of course, the phase one looks toward is a time in which such sentiments need not be prescribed *by law.*

130. The "Purpose of the Legislation" in H.R. Rep. No. 91-1651, 91st Cong., 2d Sess. to the "[Animal] Welfare Act of 1970," 3 U.S. CODE CONG. & ADMIN. NEWS 5103, 5104 (1970). Some of the West Publishing Co. typesetters may not be quite ready for this yet; they printed out the title as "Annual Welfare Act of 1970."

131. *See* MCCALL'S May, 1971, at 44.

132. Environmental Defense Fund, Inc. v. Hardin, 428 F.2d 1093, 1096 (D.C. Cir. 1970). Plaintiffs would thus seem to have urged a broader than literal reading of the statute, 7 U.S.C. § 135(z) (2) (d) (1970), which refers to "... living man and other vertebrate animals, vegetation, and useful invertebrate animals."

E.D.F. was joined as petitioners by the National Audubon Society, the Sierra Club, and the West Michigan Environmental Action Council, 428 F.2d at 1094–95 n.5.

133. In the case of the bestowal of rights on other humans, the action also helps the recipient to discover new personal depths and possibilities—new dignity—within himself. I do not want to make much of the possibility that this effect would be relevant in the case of bestowing rights on the environment. But I would not dismiss it out of hand, either. How, after all, do we judge that a man is, say, "flourishing with a new sense of pride and dignity?" What we mean by such statements, and the nature of the evidence upon which we rely in support of them, is quite complex. *See* Austin, note 93 *supra.* A tree treated in a "rightful" manner would respond in a manner that, when described, would sound much like the response of a person accorded "new dignity." *See also* note 93 *supra.*

IS THERE A NEED FOR A NEW, AN ENVIRONMENTAL, ETHIC?

SOURCE Sylvan (Routley), Richard. 2001 (1973). In *Environmental Philosophy,* 2nd edition, 17–25. Michael E. Zimmerman, J. Baird Callicott, et al. Saddle River, NJ: Prentice-Hall. Reprinted with permission of the author.

INTRODUCTION *Richard Sylvan (formerly Routley) (1935–1996) taught at the University of Sydney, University of New England, and Monash University. For twenty-five years he was a fellow in the Research School of Social Sciences at the Australian National University. "Is There a Need for a New, an Environmental, Ethic?" was originally published in the 1973* Proceedings of the XV World Congress of Philosophy. *Sylvan begins by questioning whether we need a new ethic regulating human interaction with the natural environment. The dominant ethical systems do address environmental concerns, but only in an unsatisfactory, anthropocentric manner. The question is, do we need to extend or modify our ethics to include the natural world, or create a new one? Sylvan identifies three approaches to the environment in prevailing Western ethics—dominance, stewardship, and cooperation. He argues that all three are inconsistent with an adequate environmental ethic, and thus that we need a new—a distinctly environmental—ethic. Sylvan demonstrates his point by identifying a core principle of Western ethical systems*—basic (human) chauvinism—*and shows how it is inconsistent with a true environmental ethic. He then provides a series of counter-examples to this principle, such as the famous* last man *example, which supposes a sole survivor of a major collapse who would be free, according to the dominant Western ethical paradigm, to exterminate all life around him. Sylvan argues that our intuition is that he would still be acting unethically to do so—thus pointing up the need for a new, an environmental ethic.*

1

It is increasingly said that civilization, Western civilization at least, stands in need of a new ethic (and derivatively of a new economics) setting out people's relations to the natural environment, in Leopold's words "an ethic dealing with man's relation to land and to the animals and plants which grow upon it."[1] It is not of course that old and prevailing ethics do not deal with man's relation to nature; they do, and on the prevailing view man is free to deal with nature as he pleases, i.e., his relations with nature, insofar at least as they do not affect others, are not subject to moral censure. Thus assertions such as "Crusoe ought not to be mutilating those trees" are significant and morally determinate but, inasmuch at least as Crusoe's actions do not interfere with others, they are false or do not hold—and trees are not, in a good sense, moral objects.[2] It is to this, to the values and evaluations of the prevailing ethics, that Leopold and others in fact take exception. Leopold regards as subject to moral criticism, as wrong, behaviour that on prevailing views is morally permissible. But it is not, as Leopold seems to think, that such behavior is beyond the scope of the prevailing ethics and that an extension of traditional morality is required to cover such cases, to fill a moral void. If Leopold is right in his criticism of prevailing conduct what is required is a change in the ethics, in attitudes, values and evaluations. For as matters stand, as he himself explains, men do not feel morally ashamed if they interfere with a wilderness, if they maltreat the land, extract from it whatever it will yield, and then move on; and such conduct is not taken to interfere with and does not rouse the moral indignation of others. "A farmer who clears the woods off a 75% slope, turns his cows into the clearing, and dumps its rainfall, rocks, and soil into the community creek, is still (if otherwise decent) a respected member of society."[3] Under what we shall call an *environmental ethic* such traditionally permissible conduct would be accounted morally wrong, and the farmer subject to proper moral criticism.

Let us grant such evaluations for the purpose of the argument. What is not so clear is that a new ethic is required even for such radical judgments. For one thing it is none too clear what is going to count as a new ethic, much as it is often unclear whether a new development in physics counts as a new physics or just as a modification or extension of the old. For, notoriously, ethics are not clearly articulated or at all well worked out, so that the application of identity criteria for ethics may remain obscure.[4] Furthermore we tend to cluster a family of ethical systems which do not differ on core or fundamental principles together as one ethic; e.g. the Christian ethic, which is an umbrella notion covering a cluster of differing and even competing systems. In fact then there are two other possibilities, apart from a new environmental ethic, which might cater for the evaluations, namely that of an extension or modification of the prevailing ethics or that of the development of principles that are already encompassed or latent within the prevailing ethic. The second possibility, that environmental evaluations can be incorporated within (and ecological problems solved within) the framework of prevailing Western ethics, is open because there isn't a single ethical system uniquely assumed in Western civilization: on many issues, and especially on controversial issues such as infanticide, women's rights, and drugs, there are competing sets of principles. Talk of a new ethic and prevailing ethics tends to suggest a sort of monolithic structure, a uniformity, that prevailing ethics, and even a single ethic, need not have.

Indeed Passmore has mapped out three important traditions in Western ethical views concerning man's relation to nature; a dominant tradition, the despotic position, with man as despot (or tyrant), and two lesser traditions, the stewardship position, with man as custodian, and the co-operative position with man as perfecter.[5] Nor are these the only traditions; primitivism is another, and both romanticism and mysticism have influenced Western views.

The dominant Western view is simply inconsistent with an environmental ethic; for according to it nature is the dominion of man and he is free to deal with it as he pleases (since—at least on the mainstream Stoic-Augustine view—it exists only for his sake), whereas on an environmental ethic man is not so free to do as he pleases. But it is not quite so obvious that an environmental ethic cannot be coupled with one of the lesser traditions. Part of the problem is that the lesser traditions are by no means adequately characterized anywhere, especially when the religious backdrop is removed, e.g. *who* is man steward for and responsible to? However both traditions are inconsistent with an environmental ethic because they imply policies of complete interference, whereas on an environmental ethic some worthwhile parts of the earth's surface should be preserved from substantial human interference, whether of the "improving" sort or not. Both traditions would in fact prefer to see the earth's land surfaces reshaped along the lines of the tame and comfortable north-European small farm and village landscape. According to the co-operative position man's proper role is to develop, cultivate and perfect nature—all nature eventually—by bringing out its potentialities, the test of perfection being primarily usefulness for human purposes; while on the stewardship view man's role, like that of a farm manager, is to make nature productive by his efforts though not by means that will deliberately degrade its resources. Although these positions both depart from the dominant position in a way which enables the incorporation of some evaluations of an environmental ethic, e.g. some of those concerning the

irresponsible farmer, they do not go far enough: for in the present situation of expanding populations confined to finite natural areas, they will lead to, and enjoin, the perfecting, farming and utilizing of all natural areas. Indeed these lesser traditions lead to, what a thoroughgoing environmental ethic would reject, a principle of total use, implying that every natural area should be cultivated or otherwise used for human ends, ''humanized.''[6]

As the important Western traditions exclude an environmental ethic, it would appear that such an ethic, not primitive, mystical or romantic, would be new all right. The matter is not so straightforward; for the dominant ethic has been substantially qualified by the rider that one is not always entitled to do as one pleases where this physically interferes with others. Maybe some such proviso was implicit all along (despite evidence to the contrary), and it was simply assumed that doing what one pleased with natural items would not affect others (the non-interference assumption). Be this as it may, the *modified* dominant position appears, at least for many thinkers, to have supplanted the dominant position; and the modified position can undoubtedly go much further towards an environmental ethic. For example, the farmer's polluting of a community stream may be ruled immoral on the grounds that it physically interferes with others who use or would use the streams. Likewise business enterprises which destroy the natural environment for no satisfactory returns or which cause pollution deleterious to the health of future humans, can be criticized on the sort of welfare basis (e.g. that of Barkley and Seckler) that blends with the modified position; and so on.[7] The position may even serve to restrict the sort of family size one is entitled to have since in a finite situation excessive population levels will interfere with future people. Nonetheless neither the modified dominant position nor its Western variants, obtained by combining it with the lesser traditions, is adequate as an environmental ethic, as I shall try to show. A new ethic is wanted.

2

As we noticed (an) *ethic* is ambiguous, as between a specific ethical system, a *specific* ethic, and a more generic notion, a super ethic, under which specific ethics cluster.[8] An ethical system S is, near enough, a propositional system (i.e. a structured set of propositions) or theory which includes (like individuals of a theory) a set of values and (like postulates of a theory) a set of general evaluative judgments concerning conduct, typically of what is obligatory, permissible and wrong, of what are rights, what is valued, and so forth. A general or lawlike proposition of a system is a principle; and certainly if systems S_1 and S_2 contain different principles, then they are different systems. It follows that any environmental ethic differs from the important traditional ethics outlined. Moreover if environmental ethics differ from Western ethical systems on some core principle embedded in Western systems, then these systems differ from the Western super ethic (assuming, what seems to be so, that it can be uniquely characterized)—in which case if an environmental ethic is needed then a new ethic is wanted. It suffices then to locate a core principle and to provide environmental counter examples to it.

It is commonly assumed that there are what amount to core principles of Western ethical systems, principles that will accordingly belong to the super ethic. The fairness principle inscribed in the Golden Rule provides one example. Directly relevant here, as a good stab at a core principle, is the commonly formulated liberal principle of the modified dominance position. A recent formulation runs as follows:

> ''The liberal philosophy of the Western world holds that one should be able to do what lie wishes, providing (1) that he does not harm others and (2) that he is not likely to harm himself irreparably.''[9]

Let us call this principle *basic (human) chauvinism*—because under it humans, or people, come first and everything else a bad last—though sometimes the principle is hailed as a *freedom* principle because it gives permission to perform a wide range of actions (including actions which mess up the environment and natural things) providing they do not harm others. In fact it tends to cunningly shift the onus of proof to others. It is worth remarking that *harming others* in the restriction is narrower than a restriction to the (usual) interests of others; it is not enough that it is in my interests, because I detest you, that you stop breathing; you are free to breathe, for the time being anyway, because it does not harm me. There remains a problem however as to exactly what counts as harm or interference. Moreover the width of the principle is so far obscure because ''other'' may be filled out in significantly different ways: it makes a difference to the extent, and privilege, of the chauvinism whether ''other'' expands to ''other human''—which is too restrictive—or to ''other person'' or to ''other sentient being''; and it makes a difference to the adequacy of the principle, and inversely to its economic applicability, to which class of others it is intended to apply, whether to future as well as to present others, whether to remote future others or only to non-discountable future others and whether to possible others. The latter would make the principle completely unworkable, and it is generally assumed that it applies at most to present and future others.

It is taken for granted in designing counter examples to basic chauvinist principles, that a semantic analysis of

permissibility and obligation statements stretches out over ideal situations (which may be incomplete or even inconsistent), so that what is permissible holds in some ideal situation, what is obligatory in every ideal situation, and what is wrong is excluded in every ideal situation. But the main point to grasp for the counter examples that follow, is that ethical principles if correct are universal and are assessed over the class of ideal situations.

> (i) The *last man* example. The last man (or person) surviving the collapse of the world system lays about him, eliminating, as far as he can, every living thing, animal or plant (but painlessly if you like, as at the best abattoirs). What he does is quite permissible according to basic chauvinism, but on environmental grounds what he does is wrong. Moreover one does not have to be committed to esoteric values to regard Mr. Last Man as behaving badly (the reason being perhaps that radical thinking and values have shifted in an environmental direction in advance of corresponding shifts in the formulation of fundamental evaluative principles).
>
> (ii) The *last people* example. The last man example can be broadened to the last people example. We can assume that they know they are the last people, e.g. because they are aware that radiation effects have blocked any chance of reproduction. One considers the last people in order to rule out the possibility that what these people do harms or somehow physically interferes with later people. Otherwise one could as well consider science fiction cases where people arrive at a new planet and destroy its ecosystems, whether with good intentions such as perfecting the planet for their ends and making it more fruitful or, forgetting the lesser traditions, just for the hell of it.

Let us assume that the last people are very numerous. They humanely exterminate every wild animal and they eliminate the fish of the seas, they put all arable land under intensive cultivation, and all remaining forests disappear in favour of quarries or plantations, and so on. They may give various familiar reasons for this, e.g. they believe it is the way to salvation or to perfection, or they are simply satisfying reasonable needs, or even that it is needed to keep the last people employed or occupied so that they do not worry too much about their impending extinction. On an environmental ethic the last people have behaved badly; they have simplified and largely destroyed all the natural ecosystems, and with their demise the world will soon be an ugly and largely wrecked place. But this conduct may conform with the basic chauvinist principle, and as well with the principles enjoined by the lesser traditions. Indeed the main point of elaborating this example is because, as the last man example reveals, basic chauvinism may conflict with stewardship or co-operation principles. The conflict may be removed it seems by conjoining a further proviso to the basic principle, the effect (3) that he does not willfully destroy natural resources. But as the last people do not destroy resources willfully, but perhaps "for the best of reasons," the variant is still environmentally inadequate.

> (iii) The *great entrepreneur* example. The last man example can be adjusted so as to not fall foul of clause (3). The last man is an industrialist; he runs a giant complex of automated factories and farms which he proceeds to extend. He produces automobiles among other things, from renewable and recyclable resources of course, only he dumps and recycles these shortly after manufacture and sale to a dummy buyer instead of putting them on the road for a short time as we do. Of course he has the best of reasons for his activity, e.g. he is increasing gross world product, or he is improving output to fulfill some plan, and he will be increasing his own and general welfare since he much prefers increased output and productivity. The entrepreneur's behavior is on the Western ethic quite permissible; indeed his conduct is commonly thought to be quite fine and may even meet Pareto optimality requirements given prevailing notions of being "better off."

Just as we can extend the last man example to a class of last people, so we can extend this example to the *industrial society* example: the society looks rather like ours.

> (iv) The *vanishing species* example. Consider the blue whale, a mixed good on the economic picture. The blue whale is on the verge of extinction because of his qualities as a private good, as a source of valuable oil and meat. The catching and marketing of blue whales does not harm the whalers; it does not harm or physically interfere with others in any good sense, though it may upset them and they may be prepared to compensate the whalers if they desist; nor need whale hunting be willful destruction. (Slightly different examples which eliminate the hunting aspect of the blue whale example are provided by cases where a species is eliminated or threatened through destruction of its habitat by man's activity or the activities of animals he has introduced, e.g. many plains-dwelling Australian marsupials and the Arabian oryx.) The behavior of the whalers in eliminating this magnificent species of whale is accordingly quite permissible—at least according to basic chauvinism. But on an environmental ethic it is not. However, the free-market mechanism will not cease allocating whales to commercial uses, as a satisfactory environmental economics would; instead the market model will grind inexorably along the private demand curve until the blue whale population is no longer viable—if that point has not already been passed.[10]

In sum, the class of permissible actions that rebound on the environment is more narrowly circumscribed on an environmental ethic than it is in the Western super ethic. But aren't environmentalists going too far in claiming that these people, those of the examples and respected industrialists, fishermen and farmers are behaving, when engaging in environmentally degrading activities of the sort described, in a morally impermissible way? No, what these people do is to a greater or lesser extent evil, and hence in serious cases morally impermissible. For example, insofar as the killing or forced displacement of primitive peoples who stand in the way of an industrial development is morally indefensible and impermissible, so also is the slaughter of the last remaining blue whales for private profit. But how to reformulate basic chauvinism as a satisfactory freedom principle is a more difficult matter. A tentative, but none too adequate beginning might be made by extending (2) to include harm to or interference with others who would be so affected by the action in question were they placed in the environment and (3) to exclude speciecide. It may be preferable, in view of the way the freedom principle sets the onus of proof, simply to scrap it altogether, and instead to specify classes of rights and permissible conduct, as in a bill of rights.

3

A radical change in a theory sometimes forces changes in the meta-theory; e.g. a logic which rejects the Reference Theory in a thoroughgoing way requires a modification of the usual meta-theory which also accepts the Reference Theory and indeed which is tailored to cater only for logics which do conform. A somewhat similar phenomenon seems to occur in the case of a meta-ethic adequate for an environmental ethic. Quite apart from introducing several environmentally important notions, such as *conservation, pollution, growth* and *preservation*, for meta-ethical analysis, an environmental ethic compels re-examination and modified analyses of such characteristic actions as *natural right, ground* of right, and of the relations of obligation and permissibility to rights; it may well require re-assessment of traditional analyses of such notions as *value* and *right*, especially where these are based on chauvinist assumptions; and it forces the rejection of many of the more prominent meta-ethical positions. These points are illustrated by a very brief examination of accounts of *natural right* and then by a sketch of the species bias of some major positions.[11]

Hart accepts, subject to defeating conditions which are here irrelevant, the classical doctrine of natural rights according to which, among other things, "any adult human ... capable of choice is at liberty to do (i.e. is under no obligation to abstain from) any action which is not one coercing or restraining or designed to injure other persons."[12] But this sufficient condition for a human natural right depends on accepting the very human chauvinist principle an environmental ethic rejects, since if a person has a natural right he has a right; so too the *definition* of a natural right adopted by classical theorists and accepted with minor qualifications by Hart presupposes the same defective principle. Accordingly an environmental ethic would have to amend the classical notion of a natural right, a far from straightforward matter now that human rights with respect to animals and the natural environment are, like those with respect to slaves not all that long ago, undergoing major re-evaluation.

An environmental ethic does not commit one to the view that natural objects such as trees have rights (though such a view is occasionally held, e.g. by pantheists. But pantheism is false since artefacts are not alive). For moral prohibitions forbidding certain actions with respect to an object do not award that object a correlative right. That it would be wrong to mutilate a given tree or piece of property does not entail that the tree or piece of property has a correlative right not to be mutilated (without seriously stretching the notion of a right). Environmental views can stick with mainstream theses according to which rights are coupled with corresponding responsibilities and so with bearing obligations, and with corresponding interests and concern; i.e. at least, whatever has a right also has responsibilities and therefore obligations, and whatever has a right has interests. Thus although any person may have a right by no means every living thing can (significantly) have rights, and arguably most sentient objects other than persons cannot have rights. But persons can relate morally, through obligations, prohibitions and so forth, to practically anything at all.

The species bias of certain ethical and economic positions which aim to make principles of conduct or reasonable economic behavior calculable is easily brought out. These positions typically employ a single criterion p, such as preference or happiness, as a *summum bonnum*; characteristically each individual of some base class, almost always humans, but perhaps including future humans, is supposed to have an ordinal p ranking of the states in question (e.g. of affairs, of the economy); then some principle is supplied to determine a collective p ranking of these states in terms of individual p rankings, and what is best or ought to be done is determined either directly, as in act-utilitarianism under the Greatest Happiness principle, or indirectly, as in rule-utilitarianism, in terms of some optimization principle applied to the collective ranking. The species bias is transparent from the selection of the base class. And even if the base class is extended to embrace persons, or even some animals (at the cost, like that of including remotely future humans,

of losing testability), the positions are open to familiar criticism, namely that the whole of the base class may be prejudiced in a way which leads to unjust principles. For example if every member of the base class detests dingoes, on the basis of mistaken data as to dingoes' behavior, then by the Pareto ranking test the collective ranking will rank states where dingoes are exterminated very highly, from which it will generally be concluded that dingoes ought to be exterminated (the evaluation of most Australian farmers anyway). Likewise it would just be a happy accident, it seems, if collective demand (horizontally ed from individual demand) for a state of the economy with blue whales as a mixed good, were to succeed in outweighing private whaling demands; for if no one in the base class happened to know that blue whales exist or cared a jot that thesummy do then "rational" economic decision-making would do nothing to prevent their extinction. Whether the blue whale survives should not have to depend on what humans know or what they see on television. Human interests and preferences are far too parochial to provide a satisfactory basis for deciding on what is environmentally desirable.

These ethical and economic theories are not alone in their species chauvinism; much the same applies to most going meta-ethical theories which, unlike intuitionistic theories, try to offer some rationale for their basic principles. For instance, on social contract positions obligations are a matter of mutual agreements between individuals of the base class; on a social justice picture rights and obligations spring from the application of symmetrical fairness principles to members of the base class, usually a rather special class of persons, while on a Kantian position which has some vague obligations somehow arise from respect for members of the base class persons. In each case if members of the base class happen to be ill-disposed to items outside the base class then that is too bad for them: that is (rough) justice.

THE SHALLOW AND THE DEEP

SOURCE Naess, Arne. 1973. *Inquiry Magazine (Oslo)* 16: 95–100. Reproduced by permission of the author.

INTRODUCTION *Arne Naess (1912–) was for thirty years professor of philosophy at the University of Olso. He continues to practice philosophy and environmental activism from his home in Norway. Naess is generally considered to be the founder of Deep Ecology. In "The Shallow and the Deep," Naess claims there are two movements in ecology: the shallow ecology movement, which focuses on environmental concerns such as pollution solely in regards to their impact on human welfare, particularly humans in developed countries; and the deep ecology movement, which includes concerns about pollution, but only as one of seven points, with six others to be considered, according to Naess' summary. He makes the further claim that an "ethics of responsibility" requires that environmentalists join the deep ecological movement, not the shallow. These principles of Deep Ecology are suggested by ecology, says Naess, but not derived from ecology; they are philosophical principles, or rather, as Naess says, they are "ecophilosophical." Naess states that these principles provide the framework for the creation of an "ecosophical" worldview.*

The emergence of ecologists from their former relative obscurity marks a turning point in our scientific communities. But their message is twisted and misused. A shallow, but presently rather powerful movement, and a deep, but less influential movement, compete for our attention. I shall make an effort to characterize the two.

I. THE SHALLOW ECOLOGY MOVEMENT:

Fight against pollution and resource depletion.

Central objective: the health and affluence of people in the developed countries.

II. THE DEEP ECOLOGY MOVEMENT:

1. Rejection of the man-in-environment image in favor the relational, total-field image. Organisms as knots in the biospherical net or field of intrinsic relations. An intrinsic relation between two things A and B is such that the relation belongs to the definitions of basic constitutions of A and B, so that without the relation, A and B are no longer the same things. The total-field dissolves not on the man-in-environment concept, but every compact thing-in-milieu concept-except when talking at a superficial or preliminary level of communication.

2. Biospherical egalitarianism-in principle. The ''in principle'' clause is inserted because any realistic praxis necessitates some killing, exploitation, and suppression. The ecological field-worker acquires a deep-seated respect, or even veneration, for ways and forms of life. He reaches an understanding from within, a kind of understanding that others reserve for fellow men and for a narrow section of ways and forms of life. To the ecological field-worker, the equal right to live and blossom is an intuitively clear and obvious value axiom. Its restriction to humans is an anthropocentrism with detrimental effects upon the life quality of humans themselves. The quality depends in part upon the deep pleasure and satisfaction we receive from close partnership with other forms of life. The attempt to ignore our dependence and to establish a master-slave role has contributed to the alienation of man from himself. Ecological egalitarianism implies the reinterpretation of the future-research variable, ''level of crowding,'' so that general mammalian crowding and loss of life-equality is taken seriously, not only human crowding. (Research on the high requirements of free space of certain mammals has, incidentally, suggested that theorists of human urbanism have largely underestimated human life-space requirements. Behavioral crowding symptoms, such as neuroses, aggressiveness, loss of traditions, are largely the same among mammals.)

3. Principles of diversity and of symbiosis. Diversity enhances the potentialities of survival, the chances of new modes of life, the richness of forms. And the so-called struggle for life, and survival of the fittest, should be interpreted in the sense of the ability to coexist and cooperate in complex relationships, rather than the ability to kill, exploit, and suppress. ''Live and let live'' is a more powerful ecological principle than ''Either you or me.'' The latter tends to reduce the multiplicity of kinds of forms of life, and also to create destruction within the communities of the same species. Ecologically inspired attitudes therefore favor diversity of human ways of life, of cultures, of occupations, of economies. They support the fight against economic and cultural, as much as military, invasion and domination, and they are opposed to the annihilation of seals and whales as much as to that of human tribes and cultures.

4. Anti-class posture. Diversity of human ways of life is in part due to (intended or unintended) exploitation and suppression on the part of certain groups. The exploiter lives differently from the exploited, but both are adversely affected in their potentialities of self-realization. The principle of diversity does not cover differences due merely to certain attitudes or behaviors forcibly blocked or restrained. The principles of ecological egalitarianism and of symbiosis support the same anti-class posture. The ecological attitude favors the extension of all three principles to any group conflicts, including those of today between developing and developed nations. The three principles also favor extreme caution toward any over-all plans for the future, except those consistent with wide and widening classless diversity.

5. Fight against pollution and resource depletion. In this fight ecologists have found powerful supporters, but sometimes to the detriment of their total stand. This happens when attention is focused on pollution and resource depletion rather than on the other points, or when projects are implemented which reduce pollution but increase evils of other kinds. Thus, if prices of life necessities increase because of the installation of anti-pollution devices, class differences increase too. An ethics of responsibility implies that ecologists do not serve the shallow, but the deep ecological movement. That is, not only point five, but all seven points must be considered together.

Ecologists are irreplaceable informants in any society, whatever their political color. If well organized, they have the power to reject jobs in which they submit themselves to institutions or to planners with limited ecological objectives. As it is now, ecologists sometimes serve masters who deliberately ignore the wider perspectives.

6. Complexity, not complication. The theory of ecosystems contains an important distinction between what is complicated without any Gestalt or unifying principles—we may think of finding our way through a chaotic city—and what is complex. A multiplicity of more or less lawful, interacting factors may operate together to form a unity, a system. We make a shoe or use a map or integrate a variety of activities into a workaday pattern. Organisms, ways of life, and interactions in the biosphere in general, exhibit complexity of such an astoundingly high level as to color the general outlook of ecologists. Such complexity makes thinking in terms of vast systems inevitable. It also makes for a keen, steady perception of the profound human

ignorance of biospherical relationships and therefore of the effect of disturbances.

Applied to humans, the complexity-not-complication principle favors division of labor, not fragmentation of labor. It favors integrated actions in which the whole person is active, not mere reactions. It favors complex economies, an integrated variety of means of living. (Combinations of industrial and agricultural activity, of intellectual and manual work, of specialized and nonspecialized occupations, of urban and non-urban activity, of work in city and recreation in nature with recreation in city and work in nature. . .)

It favors soft technique and "soft future-research," less prognosis, more clarification of possibilities. More sensitivity toward continuity and live traditions, and more importantly, towards our state of ignorance.

The implementation of ecologically responsible policies requires in this century an exponential growth of technical skill and invention—but in new directions, directions which today are not consistently and liberally supported by the research policy organs of our nation states.

7. Local autonomy and decentralization. The vulnerability of a form of life is roughly proportional to the weight of influences from afar, from outside the local region in which that form has obtained an ecological equilibrium. This lends support to our efforts to strengthen local self-government and material and mental self-sufficiency. But these efforts presuppose an impetus towards decentralization. Pollution problems, including those of thermal pollution and recirculation of materials, also lead us in this direction, because increased local autonomy, if we are able to keep other factors constant, reduces energy consumption. (Compare an approximately self-sufficient locality with one requiring the importation of foodstuff, materials for house construction, fuel and skilled labor from other continents. The former may use only five percent of the energy used by the latter.)

Local autonomy is strengthened by a reduction in the number of links in the hierarchical chains of decision. (For example a chain consisting of a local board, municipal council, highest sub-national decision-maker, a state-wide institution in a state federation, a federal national government institution, a coalition of nations, and of institutions, e.g., E. E. C. top levels, and a global institution, can be reduced to one made up of a local board, nation-wide institution, and global institution.) Even if a decision follows majority rule at each step, many local interests may be dropped along the line, if it is too long.

Summing up then, it should, first of all, be borne in mind that the norms and tendencies of the Deep Ecology movement are not derived from ecology by logic or induction. Ecological knowledge and the life style of the ecological field-worker have suggested, inspired, and fortified the perspectives of the Deep Ecology movement. Many of the formulations in the above seven-point survey are rather vague generalizations, only tenable if made more precise in certain directions. But all over the world the inspiration from ecology has shown remarkable convergences. The survey does not pretend to be more than one of the possible condensed codifications of these convergences.

Secondly, it should be fully appreciated that the significant tenets of the Deep Ecology movement are clearly and forcefully normative. They express a value priority system only in part based on results (or lack of results, cf. point six) of scientific research. Today, ecologists try to influence policy-making bodies largely through threats, through predictions concerning pollutants and resource depletion, knowing that policy-makers accept at least certain minimum norms concerning health. But it is clear that there is a vast number of people in all countries, and even a considerable number of people in power, who accept as valid the wider norms and values characteristic of the Deep Ecology movement. There are political potentials in this movement which should not be overlooked and which have little to do with pollution and resource depletion. In plotting possible futures, the norms should be freely used and elaborated. Thirdly, insofar as ecology movements deserve our attention, they are ecophilosophical rather than ecological. Ecology is a limited science which makes use of scientific methods. Philosophy is the most general forum of debate on fundamentals, descriptive as well as prescriptive, and political philosophy is one of its subsections. By an ecosophy I mean a philosophy of ecological harmony or equilibrium. A philosophy is a kind of sophia wisdom, is openly normative, it contains both norms, rules, postulates, value priority announcements and hypotheses concerning the state of affairs in our universe. Wisdom is policy wisdom, prescription, not only scientific description and prediction.

The details of an ecosophy will show many variations due to significant differences concerning not only "facts" of pollution, resources, population, etc., but also value priorities. Today, however, the seven points listed provide one unified framework for ecosophical systems.

In general systems theory, systems are mostly conceived in terms of causally or functionally interacting or interrelated items. An ecosophy, however, is more like a system of the kind constructed by Aristotle or Spinoza. It is expressed verbally as a set of sentences with a variety of functions, descriptive and prescriptive. The basic relation is that between subsets of premises and subsets of conclusions, that is, the relation of derivability. The relevant notions of derivability may be classed according to rigor, with logical and mathematical deductions topping the list, but also according to how much is implicitly taken for granted. An

exposition of an ecosophy must necessarily be only moderately precise considering the vast scope of relevant ecological and normative (social, political, ethical) material. At the moment, ecosophy might profitably use models of systems, rough approximations of global systematizations. It is the global character, not preciseness in detail, which distinguishes an ecosophy. It articulates and integrates the efforts of an ideal ecological team, a team comprising not only scientists from an extreme variety of disciplines, but also students of politics and active policy-makers.

Under the name of ecologism, various deviations from the deep movement have been championed-primarily with a one-sided stress on pollution and resource depletion, but also with a neglect of the great differences between underand over-developed countries in favor of a vague global approach. The global approach is essential, but regional differences must largely determine policies in the coming years.

IS THERE AN ECOLOGICAL ETHIC?

SOURCE Rolston III, Holmes. 1975. *Ethics* 85(2): 93–109. Reproduced with permission.

INTRODUCTION *Holmes Rolston III (1932–) taught philosophy for nearly fifty years at Colorado State University, retiring in 2008 as University Distinguished Professor. His writings have been central to the development of environmental ethics. In "Is There an Ecological Ethic?" Rolston questions first whether an ecological ethic would only be* about *the environment, or whether it would rather be formed* by *the environment, that is, by ecology. Interested in this relationship between science and morality, facts and values, Rolston states that traditionally facts fall under the domain of the sciences while values fall under ethics; but in the case of an environmental ethic, such distinctions prove complex if not artificial. Rolston distinguishes between two possible types of an environmental ethic. The first he claims is primarily anthropological and only secondarily ecological, in that humans become interested in an ecological ethic for the purpose of protecting their own interests and only secondarily the interests of nature. The second blurs these distinctions uniting the ultimate good on humanity* and *the environment in the realization that maximizing the one is the same as maximizing the other. In the latter sense, which is primarily ecological, humanity may construct value, but only in obedience to ecosystemic principles; we do not derive, but rather we discover, moral imperatives in nature. Facts and values are found simultaneously existing in nature.*

THE EARTH CHARTER

SOURCE 2000. *Earth Charter Commission, 2000.* Reprinted with the permission of Earth Charter International Secretariat.

INTRODUCTION *The origins of the Earth Charter lie in the 1987 World Commission on Environment and Development's call for a new set of principles to encourage and guide sustainable development. From that point until its completion and launch in 2000, it was developed and supported by a diverse group of individuals and institutions. The charter claims that humanity is at a critical point in its history and is in need of fundamental changes to our "values, institutions, and ways of living." It attempts to outline a code of ethics to guide us into a future just and sustainable world. The Earth Charter consists of a total of sixteen principles, organized under the four headings of Respect and Care for the Community of Life; Ecological Integrity; Social and Economic Justice; and Democracy, Nonviolence, and Peace. It claims that these principles are interdependent, and that the global community must realize its own internal interdependence with the planet. The Earth Charter expresses the hope that it will serve as a foundation for a "new beginning," inspiring new policies toward the achievement of a "sustainable global society founded on respect for nature, universal human rights, economic justice, and a culture of peace."*

PREAMBLE

We stand at a critical moment in Earth's history, a time when humanity must choose its future. As the world becomes increasingly interdependent and fragile, the future at once holds great peril and great promise. To move forward we must recognize that in the midst of a magnificent diversity of cultures and life forms we are one human family and one Earth community with a common destiny. We must join together to bring forth a sustainable global society founded on respect for nature, universal human rights, economic justice, and a culture of peace. Towards this end, it is imperative that we, the peoples of Earth, declare our responsibility to one another, to the greater community of life, and to future generations.

Earth, Our Home

Humanity is part of a vast evolving universe. Earth, our home, is alive with a unique community of life. The forces of nature make existence a demanding and uncertain adventure, but Earth has provided the conditions essential to life's evolution. The resilience of the community of life and the

well-being of humanity depend upon preserving a healthy biosphere with all its ecological systems, a rich variety of plants and animals, fertile soils, pure waters, and clean air. The global environment with its finite resources is a common concern of all peoples. The protection of Earth's vitality, diversity, and beauty is a sacred trust.

The Global Situation

The dominant patterns of production and consumption are causing environmental devastation, the depletion of resources, and a massive extinction of species. Communities are being undermined. The benefits of development are not shared equitably and the gap between rich and poor is widening. Injustice, poverty, ignorance, and violent conflict are widespread and the cause of great suffering. An unprecedented rise in human population has overburdened ecological and social systems. The foundations of global security are threatened. These trends are perilous—but not inevitable.

The Challenges Ahead

The choice is ours: form a global partnership to care for Earth and one another or risk the destruction of ourselves and the diversity of life. Fundamental changes are needed in our values, institutions, and ways of living. We must realize that when basic needs have been met, human development is primarily about being more, not having more. We have the knowledge and technology to provide for all and to reduce our impacts on the environment. The emergence of a global civil society is creating new opportunities to build a democratic and humane world. Our environmental, economic, political, social, and spiritual challenges are interconnected, and together we can forge inclusive solutions.

Universal Responsibility

To realize these aspirations, we must decide to live with a sense of universal responsibility, identifying ourselves with the whole Earth community as well as our local communities. We are at once citizens of different nations and of one world in which the local and global are linked. Everyone shares responsibility for the present and future well-being of the human family and the larger living world. The spirit of human solidarity and kinship with all life is strengthened when we live with reverence for the mystery of being, gratitude for the gift of life, and humility regarding the human place in nature.

We urgently need a shared vision of basic values to provide an ethical foundation for the emerging world community. Therefore, together in hope we affirm the following interdependent principles for a sustainable way of life as a common standard by which the conduct of all individuals, organizations, businesses, governments, and transnational institutions is to be guided and assessed.

PRINCIPLES

I. RESPECT AND CARE FOR THE COMMUNITY OF LIFE

1. Respect Earth and life in all its diversity.

a. Recognize that all beings are interdependent and every form of life has value regardless of its worth to human beings.

b. Affirm faith in the inherent dignity of all human beings and in the intellectual, artistic, ethical, and spiritual potential of humanity.

2. Care for the community of life with understanding, compassion, and love.

a. Accept that with the right to own, manage, and use natural resources comes the duty to prevent environmental harm and to protect the rights of people.

b. Affirm that with increased freedom, knowledge, and power comes increased responsibility to promote the common good.

3. Build democratic societies that are just, participatory, sustainable, and peaceful.

a. Ensure that communities at all levels guarantee human rights and fundamental freedoms and provide everyone an opportunity to realize his or her full potential.

b. Promote social and economic justice, enabling all to achieve a secure and meaningful livelihood that is ecologically responsible.

4. Secure Earth's bounty and beauty for present and future generations.

a. Recognize that the freedom of action of each generation is qualified by the needs of future generations.

b. Transmit to future generations values, traditions, and institutions that support the long-term flourishing of Earth's human and ecological communities. In order to fulfill these four broad commitments, it is necessary to:

II. ECOLOGICAL INTEGRITY

5. Protect and restore the integrity of Earth's ecological systems, with special concern for biological diversity and the natural processes that sustain life.

a. Adopt at all levels sustainable development plans and regulations that make environmental conservation and rehabilitation integral to all development initiatives.

b. Establish and safeguard viable nature and biosphere reserves, including wild lands and marine areas, to protect Earth's life support systems, maintain biodiversity, and preserve our natural heritage.

c. Promote the recovery of endangered species and ecosystems.

d. Control and eradicate non-native or genetically modified organisms harmful to native species and the environment, and prevent introduction of such harmful organisms.

e. Manage the use of renewable resources such as water, soil, forest products, and marine life in ways that do not exceed rates of regeneration and that protect the health of ecosystems.

f. Manage the extraction and use of non-renewable resources such as minerals and fossil fuels in ways that minimize depletion and cause no serious environmental damage.

6. Prevent harm as the best method of environmental protection and, when knowledge is limited, apply a precautionary approach.

a. Take action to avoid the possibility of serious or irreversible environmental harm even when scientific knowledge is incomplete or inconclusive.

b. Place the burden of proof on those who argue that a proposed activity will not cause significant harm, and make the responsible parties liable for environmental harm.

c. Ensure that decision making addresses the cumulative, long-term, indirect, long distance, and global consequences of human activities.

d. Prevent pollution of any part of the environment and allow no build-up of radioactive, toxic, or other hazardous substances.

e. Avoid military activities damaging to the environment.

7. Adopt patterns of production, consumption, and reproduction that safeguard Earth's regenerative capacities, human rights, and community well-being.

a. Reduce, reuse, and recycle the materials used in production and consumption systems, and ensure that residual waste can be assimilated by ecological systems.

b. Act with restraint and efficiency when using energy, and rely increasingly on renewable energy sources such as solar and wind.

c. Promote the development, adoption, and equitable transfer of environmentally sound technologies.

d. Internalize the full environmental and social costs of goods and services in the selling price, and enable consumers to identify products that meet the highest social and environmental standards.

e. Ensure universal access to health care that fosters reproductive health and responsible reproduction.

f. Adopt lifestyles that emphasize the quality of life and material sufficiency in a finite world.

8. Advance the study of ecological sustainability and promote the open exchange and wide application of the knowledge acquired.

a. Support international scientific and technical cooperation on sustainability, with special attention to the needs of developing nations.

b. Recognize and preserve the traditional knowledge and spiritual wisdom in all cultures that contribute to environmental protection and human well-being.

c. Ensure that information of vital importance to human health and environmental protection, including genetic information, remains available in the public domain.

III. SOCIAL AND ECONOMIC JUSTICE

9. Eradicate poverty as an ethical, social, and environmental imperative.

a. Guarantee the right to potable water, clean air, food security, uncontaminated soil, shelter, and safe sanitation, allocating the national and international resources required.

b. Empower every human being with the education and resources to secure a sustainable livelihood, and provide social security and safety nets for those who are unable to support themselves.

c. Recognize the ignored, protect the vulnerable, serve those who suffer, and enable them to develop their capacities and to pursue their aspirations.

10. Ensure that economic activities and institutions at all levels promote human development in an equitable and sustainable manner.

a. Promote the equitable distribution of wealth within nations and among nations.

b. Enhance the intellectual, financial, technical, and social resources of developing nations, and relieve them of onerous international debt.

c. Ensure that all trade supports sustainable resource use, environmental protection, and progressive labor standards.

d. Require multinational corporations and international financial organizations to act transparently in the public good, and hold them accountable for the consequences of their activities.

11. Affirm gender equality and equity as prerequisites to sustainable development and ensure universal access to education, health care, and economic opportunity.

a. Secure the human rights of women and girls and end all violence against them.

b. Promote the active participation of women in all aspects of economic, political, civil, social, and cultural life as full and equal partners, decision makers, leaders, and beneficiaries.

c. Strengthen families and ensure the safety and loving nurture of all family members.

12. Uphold the right of all, without discrimination, to a natural and social environment supportive of human dignity, bodily health, and spiritual well-being, with special attention to the rights of indigenous peoples and minorities.

a. Eliminate discrimination in all its forms, such as that based on race, color, sex, sexual orientation, religion, language, and national, ethnic or social origin.

b. Affirm the right of indigenous peoples to their spirituality, knowledge, lands and resources and to their related practice of sustainable livelihoods.

c. Honor and support the young people of our communities, enabling them to fulfill their essential role in creating sustainable societies.

d. Protect and restore outstanding places of cultural and spiritual significance.

IV. DEMOCRACY, NONVIOLENCE, AND PEACE

13. Strengthen democratic institutions at all levels, and provide transparency and accountability in governance, inclusive participation in decision making, and access to justice.

a. Uphold the right of everyone to receive clear and timely information on environmental matters and all development plans and activities which are likely to affect them or in which they have an interest.

b. Support local, regional and global civil society, and promote the meaningful participation of all interested individuals and organizations in decision making.

c. Protect the rights to freedom of opinion, expression, peaceful assembly, association, and dissent.

d. Institute effective and efficient access to administrative and independent judicial procedures, including remedies and redress for environmental harm and the threat of such harm.

e. Eliminate corruption in all public and private institutions.

f. Strengthen local communities, enabling them to care for their environments, and assign environmental responsibilities to the levels of government where they can be carried out most effectively.

14. Integrate into formal education and life-long learning the knowledge, values, and skills needed for a sustainable way of life.

a. Provide all, especially children and youth, with educational opportunities that empower them to contribute actively to sustainable development.

b. Promote the contribution of the arts and humanities as well as the sciences in sustainability education.

c. Enhance the role of the mass media in raising awareness of ecological and social challenges.

d. Recognize the importance of moral and spiritual education for sustainable living.

15. Treat all living beings with respect and consideration.

a. Prevent cruelty to animals kept in human societies and protect them from suffering.

b. Protect wild animals from methods of hunting, trapping, and fishing that cause extreme, prolonged, or avoidable suffering.

c. Avoid or eliminate to the full extent possible the taking or destruction of non-targeted species.

16. Promote a culture of tolerance, nonviolence, and peace.

a. Encourage and support mutual understanding, solidarity, and cooperation among all peoples and within and among nations.

b. Implement comprehensive strategies to prevent violent conflict and use collaborative problem solving to manage and resolve environmental conflicts and other disputes.

c. Demilitarize national security systems to the level of a non-provocative defense posture, and convert military resources to peaceful purposes, including ecological restoration.

d. Eliminate nuclear, biological, and toxic weapons and other weapons of mass destruction.

e. Ensure that the use of orbital and outer space supports environmental protection and peace.

f. Recognize that peace is the wholeness created by right relationships with oneself, other persons, other cultures, other life, Earth, and the larger whole of which all are a part.

THE WAY FORWARD

As never before in history, common destiny beckons us to seek a new beginning. Such renewal is the promise of these Earth Charter principles. To fulfill this promise, we must commit ourselves to adopt and promote the values and objectives of the Charter.

This requires a change of mind and heart. It requires a new sense of global interdependence and universal responsibility. We must imaginatively develop and apply the vision of a sustainable way of life locally, nationally, regionally, and globally. Our cultural diversity is a precious heritage and different cultures will find their own distinctive ways to realize the vision. We must deepen and expand the global dialogue that generated the Earth Charter, for we have much to learn from the ongoing collaborative search for truth and wisdom.

Life often involves tensions between important values. This can mean difficult choices. However, we must find ways to harmonize diversity with unity, the exercise of freedom with the common good, short-term objectives with long-term goals. Every individual, family, organization, and community has a vital role to play. The arts, sciences, religions, educational institutions, media, businesses, nongovernmental organizations, and governments are all called to offer creative leadership. The partnership of government, civil society, and business is essential for effective governance.

In order to build a sustainable global community, the nations of the world must renew their commitment to the United Nations, fulfill their obligations under existing international agreements, and support the implementation of Earth Charter principles with an international legally binding instrument on environment and development.

Let ours be a time remembered for the awakening of a new reverence for life, the firm resolve to achieve sustainability, the quickening of the struggle for justice and peace, and the joyful celebration of life.

Annotated Bibliography

Compiled by Holmes Rolston III

1. REFERENCE WORKS

The most comprehensive bibliography is that of the International Society for Environmental Ethics, with more than 15,000 entries, updated annually. The bibliography is searchable and available from http://www.cep.unt.edu/bib.

Brennan, Andrew, ed. 1995. *The Ethics of the Environment*. Brookfield, VT: Dartmouth Publishing Company. International Research Library of Philosophy. *A large, single-volume collection of about three dozen basic and classic papers through 1995.*

Callicott, J. Baird, and Clare Palmer, eds. 2005. *Environmental Philosophy: Critical Concepts in the Environment*. London; New York: Routledge. *This is the most comprehensive collection in a single multivolume work. Nearly a hundred of the now-classic and important articles in the field are reprinted in five volumes.*

Jamieson, Dale, ed. 2001. *A Companion to Environmental Philosophy*. Malden, MA: Blackwell. *This is a major reference work with three dozen articles covering various aspects of environmental ethics. Topics covered include classical concepts of nature in philosophy and religion, and contemporary environmental ethics, not only in philosophy but also in literature, aesthetics, and economics. The volume deals with wilderness, population, sustainability, global warming, environmental justice, and related subjects.*

2. SYSTEMATIC OVERVIEWS

Attfield, Robin. 1992. *The Ethics of Environmental Concern.* 2nd edition. Athens: University of Georgia Press. *The first edition, one of the early systematic works in the field by a British philosopher, was published by Columbia University Press and Blackwell, Oxford, UK, in 1983.*

Brennan, Andrew. 1988. *Thinking about Nature: An Investigation of Nature, Value, and Ecology*. Athens: University of Georgia Press. *An effort to think ecologically about value and ethics by a then-British philosopher who later moved to Australia.*

Callicott, J. Baird. 1994. *Earth's Insights: A Survey of Ecological Ethics from the Mediterranean Basin to the Australian Outback*. Berkeley: University of California Press. *An exercise in comparative environmental philosophy. It explores and critically evaluates environmental ethics grounded in all the world's major religious traditions (Judaism, Christianity, Islam, Hinduism, South Asian and East Asian Buddhism, Daoism, and Confucianism) and representative indigenous traditions (from Polynesia, North America, South America, Africa, and Australia) and tests their ecological merits against the Leopold land ethic, which is recommended as the international gold standard for environmental ethics.*

Des Jardins, Joseph R. 2001. *Environmental Ethics: An Introduction to Environmental Philosophy*. 3rd edition. Belmont, CA: Wadsworth/Thomson Learning, 2001. *Third edition of an introduction addressed to those previously unacquainted with the field.*

Devall, Bill, and George Sessions. 1985. *Deep Ecology: Living as if Nature Mattered*. Salt Lake City, UT: Peregrine Smith. *Long a standard introduction to Deep Ecology, a philosophical position that seeks to raise ecological*

consciousness and reveal the unity of humanity and nature, a consciousness thought of as an enlarged ecological self.

Ehrenfeld, David. 1978. *The Arrogance of Humanism*. New York: Oxford, UK: Oxford University Press. *Ehrenfeld, a biologist, not a philosopher, proved quite influential in awakening scientists to the anthropocentrism in their science and opening up the larger question of intrinsic values in nonhuman nature.*

Hargrove, Eugene C. 1996. *Foundations of Environmental Ethics*. Denton, TX: Environmental Ethics Books. *A far-ranging investigation of the intellectual history of environmental attitudes, with a focus on aesthetic arguments as a historical and contemporary foundation of environmental ethics.*

Johnson, Lawrence E. 1990. *A Morally Deep World: An Essay on Moral Significance and Environmental Ethics.* Cambridge: Cambridge University Press. *A rights-based theory of environmental ethics, extending rights to the kinds of things typically thought incapable of possessing them. Nonhuman animals and ecosystems are viewed as morally significant beings with interests and rights. Written for general readers.*

Kohák, Erazim. 2000. *The Green Halo: A Bird's-Eye View of Ecological Ethics*. Chicago: Open Court. *Originally written for students in a Czech university. The author fled Czechoslovakia with the coming of the pro-Soviet regime, long taught philosophy in the United States, and returned after the Soviet collapse. His life in multiple worlds gives him facility with Soviet ideology, continental philosophy (especially phenomenology), Central and Eastern European thought, as well as British and American philosopy, all brought to bear on environmental ethics.*

Mathews, Freya. 1991. *The Ecological Self*. London: Routledge. *A metaphysics of interconnectedness, based on the fundamental ecological intuition that humans are in some sense "one with" nature and that everything is connected to everything else; this work rejects the dominant atomistic metaphysics implicit in European and North American philosophy.*

Naess, Arne. 1989. *Ecology, Community, and Lifestyle: Outline of an Ecosophy*. New York: Cambridge University Press. *Translated and revised by David Rothenberg from* Okologi, Samfunn, og Livsstil, *published in Norwegian in 1976. The original Naess article envisioning a Deep Ecology is "The Shallow and the Deep, Long-Range Ecology Movements: A Summary,"* Inquiry *16 (1973): 95–100.*

Norton, Bryan G. 1991. *Toward Unity among Environmentalists*. New York: Oxford University Press. *Norton seeks to unite environmentalists in the common cause of environmental protection and appreciation despite their multiple and varied value systems. Notwithstanding these diverse worldviews, he believes that there can be converging policies (his "convergence hypothesis"). Norton illustrates his thesis using Muir, Pinchot, and Leopold, and applies it to growth, pollution, biodiversity, and land use.*

Palmer, Clare. 1997. *Environmental Ethics*. Santa Barbara, California: ABC-CLIO. *This reference work is especially good as a basic resource guide to materials, chronology, major figures, and principal issues.*

Passmore, John. 1974. *Man's Responsibility for Nature*. New York: Scribners. *One of the earliest works in the field, by a prominent Australian philosopher. Passmore argues that classical humanistic ethics can be applied to new environmental problems, a view challenged by many who hold that environmental ethics has many novel, nonanthropocentric dimensions.*

Plumwood, Val. 2003. *Feminism and the Mastery of Nature*. London: Routledge. *A magisterial critique of dualism as an ingrained habit of thinking, including male-female and human-nature instances of dualistic thinking.*

Rolston III, Holmes. 1988. *Environmental Ethics: Duties to and Values in the Natural World*. Philadelphia: Temple University Press. *One of the earliest systematic works in environmental ethics, ranging across animals, plants, endangered species, ecosystems, environmental policy and business, and a personal environmental ethic. Rolston throughout claims there are intrinsic values in nature that humans ought to respect, in addition to considerations about how humans are helped or hurt by the condition of their environment.* (*A critique of Rolston's work is found in Preston, Christopher J., and Wayne Ouderkirk, eds. 2006.* Nature, Value, Duty: Life on Earth with Holmes Rolston III. *Dordrecht, The Netherlands: Springer.*)

Rolston III, Holmes. 1994. *Conserving Natural Value*. New York: Columbia University Press. *This survey is written for use in introductory college classes on biological and natural-resource conservation and environmental philosophy, ethics, and policy. There is extensive use of cases to provoke thought, and Rolston also applies his ethics using a number of axioms designed to help those who confront practical decisions.*

Stone, Christopher F. 1987. *Earth and Other Ethics: The Case for Moral Pluralism*. New York: Harper and Row. *This book, by a lawyer, introduces a view of normative ethics that is pluralistic regarding the entities and situations that are morally relevant, foreshadowing later focus on a pragmatic environmental ethics. Different moral systems, he argues, must be used depending on levels of concern and relevant conditions of decision.*

Sylvan, Richard, and David Bennett. 1994. *The Greening of Ethics: From Human Chauvinism to Deep-Green*

Theory. Cambridge, UK: White Horse Press. *Environmental ethics from "down under" (Australia), claiming that the European/North American worldview is topsy-turvy. The authors set out a course for Australia's independent national development. They find environmental ethics in shallow, intermediate, and deep forms, and the authors delineate their deep-green theory.*

Taylor, Paul. 1986. *Respect for Nature: A Theory of Environmental Ethics*. Princeton: Princeton University Press. *The classic defense of biocentrism. All living organisms seek their own good and are centers of inherent worth that warrant respect. The biocentric outlook denies human superiority, in theory at least, and calls for a radical bioegalitarianism, although Taylor recognizes situations in which humans, based on the principle of self-defense, can sacrifice the basic interests of wildlife to further their own basic interests.*

Wenz, Peter S. 2001. *Environmental Ethics Today*. New York: Oxford University Press. *Wide ranging: overpopulation, free markets, human rights, future generations, global warming, animal liberation, medical research with animals, species diversity, the land ethic, hunting as a conservation strategy, aesthetics, and conservation. Wenz argues that a synergy can and ought to exist between respect for people and respect for nature. He contends that simultaneous respect for people and nature improves outcomes for both.*

3. COLLECTED ESSAYS OF A SINGLE AUTHOR

Callicott, J. Baird. 1989. *In Defense of the Land Ethic: Essays in Environmental Philosophy*. Albany, NY: SUNY Press. *A collection of previously published essays by the leading philosophical interpreter of Aldo Leopold.* (*A critique of Callicott's work is found in* Land, Value, Community: Callicott and Environmental Philosophy, *eds. Wayne Ouderkirk and Jim Hill. 2002. Albany, NY: SUNY Press.*)

Callicott, J. Baird. 1999. *Beyond the Land Ethic: More Essays in Environmental Philosophy*. Albany, NY: SUNY Press. *A second collection of Callicott's essays, most of them written between 1989 and 1999 and previously published.*

Rolston III, Holmes. 1986. *Philosophy Gone Wild*. Buffalo, NY: Prometheus Books. *A collection of fifteen essays articulating and justifying values in nature, generally progressing from the more theoretical to the more personal. Values in nature, following nature, subjective versus objective values, endangered species, nature and human emotions; immediate personal experience of nature.*

Sagoff, Mark. 1988. *The Economy of the Earth: Philosophy, Law, and the Environment*. New York: Cambridge University Press. *In this collection of his previously published essays, Sagoff concentrates on the interconnections between environmental policy, law, economics, and environmental ethics. There is a systematic attack on the basic assumptions of welfare economics and cost-benefit analysis as a basis for environmental policy. Values are community-based, intersubjective goals that evolve throughout the history of the community, state, or nation and cannot be reduced to consumer preferences.*

Sagoff, Mark. 2004. *Price, Principle, and the Environment*. New York: Cambridge University Press. *A collection of nine previously published essays further developing his critique of a purely economic approach to environmental concerns, particularly the claim that all values are preferences subject to expression in a monetary metric.*

4. ANTHOLOGY OVERVIEWS, COLLECTED ESSAYS BY MULTIPLE AUTHORS, TEXTBOOKS

Armstrong, Susan J., and Richard G. Botzler, eds. 2003. *Environmental Ethics: Divergence and Convergence*. 3rd edition. New York: McGraw-Hill. *Third edition of an anthology that has proven a classic anthology in previous editions. More than sixty articles. Comprehensive, but coverage is often limited.*

Attfield, Robin, and Andrew Belsey, eds. 1994. *Philosophy and the Natural Environment*. Cambridge, UK: Cambridge University Press. *Values in nature, restoration, awe in nature, order and disorder in nature, global environmental justice, genetic engineering, persons in nature, anthropocentrism, and more. This collection originated from the Royal Institute of Philosophy Conference, "Philosophy and the Natural Environment," held at the University of Wales in Cardiff in 1993.*

Chappell, Timothy D. J., ed. 1997. *Respecting Nature: Environmental Thinking in the Light of Philosophical Theory.* New York: Columbia University Press. *Features theory in environmental ethics in relation to classical philosophy. Plato and environmental ethics, nature as a social construct, aesthetics of environment, sustainability, animal welfare, whaling, zoos.*

Elliot, Robert, ed. *Environmental Ethics*. 1995. New York: Oxford University Press. *This collection focuses on philosophically seminal articles rather than seeking more comprehensive coverage by incorporating extracts from several dozen articles. Values in nature, anthropocentrism in environmental ethics, animal welfare, restoration, stability in natural systems, ecofeminism.*

Foltz, Bruce V., and Robert Frodeman, eds. 2004. *Rethinking Nature: Essays in Environmental Philosophy*. Bloomington: Indiana University Press. *Emphasizes continental philosophy. Aesthetics, ontology, phenomenology, gender and the environment, and the role of science and technology in forming knowledge about the natural world.*

Frodeman, Robert, ed. 2000. *Earth Matters: The Earth Sciences, Philosophy, and the Claims of Community*. Upper Saddle River, NJ: Prentice-Hall. *Brings together fifteen essays on environmental matters from a multidisciplinary group of authors, including scientists, policy analysts, and philosophers*.

Gruen, Lori, and Dale Jamieson, eds. 1994. *Reflecting on Nature: Readings in Environmental Philosophy.* Oxford. *Highlights the problems of environmental justice and sustainable development from a multicultural perspective; features feminist and minority scholars and scholars from developing countries. Biodiversity loss, the significance of wilderness, population and overconsumption, and the human use of animals*.

Light, Andrew, and Rolston III, Holmes, eds. 2003. *Environmental Ethics: An Anthology*. Oxford: Blackwell. *Forty classic and recent full-length articles in environmental ethics organized for classroom use. What is environmental ethics? Who counts morally? Intrinsic value in nature, environmental pluralism, Deep Ecology, ecofeminism, restoration, wilderness, sustainability, social choices, and environmental values*.

List, Peter C., ed. 1993. *Radical Environmentalism: Philosophy and Tactics*. Belmont, CA: Wadsworth. *Radical activism in environmental ethics critically examined*. The Monkey Wrench Gang *(Edward Abbey). Greenpeace; Earth First!; the Sea Shepard Society (Paul Watson); civil disobedience and tree spiking; activist protests against the destruction and pollution of natural systems*.

List, Peter, ed. 2000. *Environmental Ethics and Forestry*: *A Reader*. Philadelphia: Temple University Press. *Both forestry and philosophy have been rethinking their foundations; each needs the other. John Muir versus Gifford Pinchot; Leopold's land ethic; values in forests, both instrumental and intrinsic; aesthetic experience in forests; global forests; foresters as advocates. A particular feature is examination of codes of ethics as formulated by foresters*.

Pierce, Christine, and Donald VanDeVeer, eds. 1995. *People, Penguins, and Plastic Trees*. 2nd edition. Belmont, CA: Wadsworth. *Long a best-selling text, first published in 1986 and widely regarded as the easiest text to use with freshmen and sophomores. Ecofeminism, Deep Ecology, Native American land ethics, critiques of industrialized nations by those in less-industrialized nations, environmental racism, sustainability, biocentric views, intrinsic value, biodiversity, animal liberation, land ethics*.

Pojman, Louis, P., and Paul Pojman, eds. 2008. *Environmental Ethics: Readings in Theory and Application.* 5th edition. Belmont, CA: Thomson/Wadsworth. *A perennially popular anthology that has gone through five editions since 1994. The Pojmans include articles on both sides of issues. The historical roots of our ecological crisis, animal rights, biocentrism, the land ethic, Deep Ecology, intrinsic natural value, ecofeminism, the Gaia hypothesis, biodiversity, obligations to future generations, Asian concepts of nature, world population, hunger, sustainable development*.

Schmidtz, David, and Elizabeth Willott, eds. 2002. *Environmental Ethics: What Really Matters, What Really Works.* New York: Oxford University Press. *Sixty-two selections, addressing the principal areas of inquiry in the field. Value in nature, the land ethic, animal liberation, environmental holism, rights in nature, wilderness, biodiversity, sustainability, poverty, cost-benefit analysis, and more*.

VanDeVeer, Donald, and Christine Pierce, eds. 2003. *The Environmental Ethics and Policy Book: Philosophy, Ecology, Economics.* 3rd edition. *Environmental ethics with a focus on how it affects public policy. Future generations, sustainability, corporate responsibility, population, consumption, marine environmental ethics, genetically modified foods, transgenic organisms, the impact of fast food production, patenting life. Jewish, Christian environmental ethics, aboriginal ecological knowledge. One feature is an Internet environmental resources section*.

Weston, Anthony, ed. 1999. *An Invitation to Environmental Philosophy*. New York: Oxford University Press. *Offered as an alternative to heavy academic anthologies, this compact anthology features five original essays by prominent environmental philosophers; intended as a first invitation to environmental philosophy*.

Zimmerman, Michael E., et al., eds. 2005. *Environmental Philosophy: From Animal Rights to Radical Ecology*. 4th edition. Upper Saddle River, NJ: Pearson/Prentice Hall. *Fourth edition of a time-tested and popular anthology. Animal welfare, biocentrism, the land ethic, ecofeminism, continental environmental philosophy, ecophenomenology, ecofascism, free-market versus political environmentalism, sustainability, social ecology*.

5. CASE STUDIES

Derr, Patrick G., and Edward M. McNamara. 2003. *Case Studies in Environmental Ethics*. Lanham, MD: Rowman and Littlefield. *More than forty cases, typically three or four pages each: includes Hawaiian feral pigs, oil and the Arctic National Wildlife Refuge (ANWR), golden rice, Bhopal, monkeywrenching, great apes, the Delhi Sands fly, and a host of other topics*.

Gudorf, Christine E., James E. Huchingson. 2003. *Boundaries: A Casebook in Environmental Ethics*. Washington, DC: Georgetown University Press. *The Everglades, Java forests, endangered ecosystems and endangered cultures in Madagascar, nuclear waste, coral reefs, hydropower versus free-flowing rivers, genetically modified foods, hunting in India, xenotransplants*.

Newton, Lisa H., and Catherine K. Dillingham, eds. 1997. *Watersheds: Classic Cases in Environmental Ethics.* 2nd edition. Belmont, CA: Wadsworth. *Impressive detail and documentation of dozens of specific cases in environmental ethics combined with insightful ethical analysis*.

6. ANIMALS AND ENVIRONMENTAL ETHICS

Hargrove, Eugene C. 1992. *The Animal Rights/ Environmental Ethics Debate: The Environmental Perspective*. Albany: State University of New York Press. *A collection of essays by a number of environmental philosophers offering criticism of and various alternatives to nonanthropocentric ethics limited to animals and excluding other nonhuman natural entities such as plants; higher levels of biological organization, such as species and ecosystems; and nature as a whole*.

Regan, Tom. 2004. *The Case for Animal Rights*. Berkeley: University of California Press. *A philosophically rigorous argument that animals have rights. First published in 1983, this book complemented Peter Singer's utilitarian* Animal Liberation*; these were the two most influential books concerned with animal ethics in the second half of the last century*.

Singer, Peter. 2002. *Animal Liberation*. 2nd edition. New York: Ecco (HarperCollins). *The book that launched contemporary ethical concern for animals, first published in 1975. Singer argues from a utilitarian viewpoint that humans are morally obligated to minimize animal suffering*.

Sterba, James P., ed. 1995. *Earth Ethics: Environmental Ethics, Animal Rights, and Practical Applications*. Upper Saddle River, NJ: Prentice-Hall. *Three dozen contributors analyze animal liberation, animal rights, their reconciliation with environmental ethics, anthropocentrism versus nonanthropocentrism, Deep Ecology, ecofeminism, biodiversity, climate change, economics, and environmental quality*.

Waldau, Paul, and Kimberley C. Patton, eds. 2006. *A Communion of Subjects: Animals in Religion, Science, and Ethics.* New York: Columbia University Press. *Animals are subjects who experience the world and have been pervasively incorporated into human belief systems, myths, and rituals, traditions that can serve as a basis for contemporary respect and conservation*.

7. BIODIVERSITY, WILDERNESS, RESTORATION, AESTHETICS

Callicott, J. Baird, and Michael P. Nelson, eds. 1998. *The Great New Wilderness Debate*. Athens: University of Georgia Press. *A large anthology on wilderness, covering the spectrum of views about the character and importance of wilderness conservation. Some contributors argue that wilderness is a European and North American idea, socially constructed. Others argue that indigenous peoples had so managed wilderness that primeval nature seldom continues in present wilderness landscapes. Others find substantial tracts of spontaneous wild nature, where ecosystemic processes are the dominant determinants, and the effect of humans is minimal*.

Carlson, Allen, and Sheila Lintott. 2008. *Nature, Aesthetics, and Environmentalism: From Beauty to Duty*. New York: Columbia University Press. *This collection combines the most important historical essays on nature appreciation and the best contemporary research in the field. Aesthetic of nature in relation to art and science; positive aesthetics, the view that all wild landscapes are beautiful; moral duties deriving from the aesthetics of nature*.

Elliot, Robert. 1997. *Faking Nature: The Ethics of Environmental Restoration*. London and New York: Routledge. *Natural value cannot be restored because original naturalness is a basis for intrinsic value in nature. Restored nature, however desirable, is second best because uninterrupted historical genesis cannot be restored; it is a faked nature because of this lost value*.

Nash, Roderick. 2002. *Wilderness and the American Mind*. 4th edition. New Haven, CT: Yale University Press. *A classic study, first published in 1967, by an environmental historian of changing ideas about wilderness in American thought*.

Nelson, Michael P., and J. Baird Callicott, eds. 2008. *The Wilderness Debate Rages On*. Athens: University of Georgia Press. *Organized into four parts, the first of which documents a little-known history of wilderness-preservation advocacy by ecologists that, had it been able to influence national policy, would have resulted in a very different system of wilderness preserves, focused nonanthropocentrically on critical habitat for threatened species and representative ecosystem types rather than on anthropocentric recreation. Also includes more non-European and liminal critiques of the wilderness idea, philosophical debate about the wilderness idea, and alternatives to the wilderness idea*.

Norton, Bryan G., ed. 1986. *Preservation of Species: The Value of Biological Diversity.* Princeton, NJ: Princeton University Press. *Scientific and social dimensions of extinction, management decisions regarding species*

preservation, ethical justification of species preservation, instrumental (such as economic) reasons versus the intrinsic value of species, aesthetic values in species preservation.

Oelschlaeger, Max. 1991. *The Idea of Wilderness from Prehistory to the Present*. New Haven, CT: Yale University Press. *An intellectual history drawing on evidence from philosophy, anthropology, theology, literature, ecology, cultural geography, and archaeology.*

Rolston III, Holmes. 1985. "Duties to Endangered Species." *BioScience* 35: 718–726. *Duties to humans concerning endangered species, although important, must be complemented by duties directly to species. This requires an account, biologically, of what species are, and, ethically, of why species are morally considerable. Species are dynamic natural kinds, historical life lineages, that humans ought to respect. Another author in this special issue of* BioScience *is Edward O. Wilson.*

Throop, William, ed. 2000. *Environmental Restoration: Ethics, Theory, and Practice*. Amherst, NY: Humanity Books/Prometheus Press. *This anthology examines whether restoring nature is viable, legitimate, and practical.*

Willers, William B., ed. 1999. *Unmanaged Landscapes: Voices for Untamed Nature*. Washington, DC: Island Press. *Unmanaged landscapes are the focus of the struggle to protect and restore wildness, the autonomy of nature, and to allow for its preservation and return on a grand scale.*

8. ENVIRONMENTAL JUSTICE, ENVIRONMENTAL VIRTUE ETHICS

Attfield, Robin, and Barry Wilkins, eds. 1992. *International Justice and the Third World: Essays in the Philosophy of Development*. London: Routledge. *The contributors ask about justice among societies of unequal power and worry that development efforts, resulting in indebtedness of the developing world, are often exploitative. What are the relations between just development and environmental conservation?*

Bullard, Robert D., ed. 2005. *The Quest for Environmental Justice: Human Rights and the Politics of Pollution.* San Francisco: Sierra Club Books. *An anthology by a sociologist, one of the first people to become deeply concerned about the way in which the poor disproportionately bear the burdens of environmental degradation.*

Sandler, Ronald. 2007. *Character and Environment: A Virtue-Oriented Approach to Environmental Ethics*. New York: Columbia University Press. *Any ethic of character can and should be informed by many environmental considerations. A pluralist, virtue-oriented environmental ethic accommodates the richness and complexity of human relationships with the natural environment and provides effective and nuanced guidance on environmental issues.*

Sandler, Ronald, and Philip Cafaro, eds. 2005. *Environmental Virtue Ethics*. Lanham, MD: Rowman and Littlefield. *Contributors discuss the role that virtue and character have traditionally played in environmental discourse and reflect upon the role that it should play in the future. Environmental virtue ethics theory, particular environmental virtues and vices, and applying environmental virtue ethics to particular environmental issues.*

Shrader-Frechette, Kristin. 2002. *Environmental Justice: Creating Equity, Reclaiming Democracy*. New York: Oxford University Press. *Fundamental ethical concepts such as equality, property rights, procedural justice, free informed consent, intergenerational equity, and just compensation have been compromised for a large segment of the global population, among them Appalachians, African Americans, workers in hazardous jobs, and indigenous people in developing nations. Burdens like pollution and resource depletion need to be apportioned more equally.*

Wenz, Peter S. 1988. *Environmental Justice*. Albany, NY: SUNY Press. *Competing principles of distributive justice as they might guide environmental decisions: libertarian theory, laissez-faire economics, human rights, utilitarian theory, cost-benefit analysis, virtue ethics, John Rawls's theory of justice. Wenz offers concentric-circle theory of environmental justice.*

Westra, Laura, and Peter S. Wenz, eds. 1995. *Faces of Environmental Racism: Confronting Issues of Global Justice*. Lanham, MD: Rowman and Littlefield. *Racial minorities in the United States are disproportionately exposed to toxic wastes and other environmental hazards. Internationally, wealthy countries of the north increasingly ship hazardous wastes to poorer countries of the south. These authors argue that environmentalism and concern for human beings and justice can be entirely compatible.*

9. RELIGION AND NATURE

Foltz, Richard C., ed. 2003. *Worldviews, Religion, and the Environment: A Global Anthology*. Belmont, CA: Wadsworth/Thomson Learning. *First peoples, Buddhism, Chinese traditions, Japanese traditions, Judaism, new cosmologies, globalization, ecojustice. More than sixty contributors.*

Gottlieb, Roger S. 2006. *A Greener Faith: Religious Environmentalism and Our Planet's Future*. New York: Oxford University Press. *Theologians are recovering nature-honoring elements of traditional religions and*

forging bold new theologies connecting devotion to God and spiritual truth with love for God's creation and care for the earth.

Northcott, Michael S. 1996. *The Environment and Christian Ethics*. Cambridge, UK: Cambridge University Press. *Environmental ethics from a perspective of Christian ethics, written by a theological ethicist with a thorough familiarity with the philosophical literature. The resolution of the environmental crisis requires the rediscovery of value and moral significance in the nonhuman natural world, an independence located in divine beneficence. Christians have often been the cause of environmental degradation, but the primal Hebrew vision and early Christians both had great respect for creation*.

Oelschlaeger, Max. 1994. *Caring for Creation: An Ecumenical Approach to the Environmental Crisis.* New Haven, CT: Yale University Press. *Only the churches, as the repository of moral values that lie outside the economic paradigm, can provide the social and political leadership and power to move our society to ecological sustainability. All faiths have an emphasis on caring for creation on which we can draw, and religion is necessary if we are to solve the environmental crisis politically*.

Rasmussen, Larry L. 1996. *Earth Community Earth Ethics*. Maryknoll, NY: Orbis. *An insightful analysis, from a theological perspective, of social justice and ecological concerns. Underlying themes are "justice, peace, and the integrity of creation" (World Council of Churches), areas in which Rasmussen has been influential. Humans have sought arrogant dominion over nature, denying the wholeness of creation. There is need now for symbols that effect a reenchantment of the world*.

Taylor, Bron, ed. 2005. *Encyclopedia of Religion and Nature*. 2 vols. London: Thoemmes Continuum. *An encyclopedia that is chronologically, geographically, and theoretically comprehensive, with a thousand entries from more than 500 contributors*.

Tucker, Mary Evelyn, and John Grim, eds. 1997–2002. *Religions of the World and Ecology*. 10 vols. Cambridge, MA: Harvard University Press. *Ten volumes, each on a major world religion*.

10. ECOFEMINISM

Clayton, Patti H. 1998. *Connection on the Ice: Environmental Ethics in Theory and Practice*. Philadelphia: Temple University Press. *Ecofeminist environmental ethics compared with other major types of environmental philosophy, taking as a critical case the rescue of three whales trapped in ice in Alaska. The real world displays quite multifaceted human-nonhuman relationships*.

Plumwood, Val. 2002. *Environmental Culture*. New York: Routledge. *A detailed and passionate argument for forms of culture that are logically and pragmatically superior to those cultures built on the rationalism, idealism, and empiricism that encourage moral distance. Humans are dependent on nature, men are dependent on women, and those with economic and decision-making power are dependent on the disempowerment of others. Sustainable cultures must care for creation*.

Ruether, Rosemary Radford. 1994. *Gaia and God: An Ecofeminist Theology of Earth Healing*. San Francisco: HarperOne. *European and North American theology often has a patriarchal tradition of dominance, but the classical Christian traditions also struggled with injustice and sin and sought to create just and loving relations between people in their relations with the living earth (Gaia). Christians today can use this heritage, enlarging it for a better vision of an abundant life on a sustainable earth*.

Warren, Karen, ed. 1994. *Ecological Feminism*. New York: Routledge. *The conceptual underpinnings of women-nature connections and the importance of seeing sexism and the exploitation of the environment as parallel forms of domination. Ecofeminism and the reconstruction of environmental ethics.*

Warren, Karen J. 2000. *Ecofeminist Philosophy: A Western Perspective on What It Is and Why It Matters*. Lanham, MD: Rowman and Littlefield. *Ecofeminism and animal welfare, vegetarianism, ecosystem ecology, Leopold's land ethic, ecojustice, patriarchy, spirituality*.

11. SUSTAINABILITY, FUTURE GENERATIONS

Burkhardt, Jeffrey. 1989. "The Morality behind Sustainability." *Journal of Agricultural Ethics* 2: 113–128. *Obligations to future generations entail more than sustaining sufficient food production or an adequate resource base; they extend to a continuing tradition of care and community*.

Daly, Herman E., and John B. Cobb Jr. 1999. *For the Common Good: Redirecting the Economy toward Community, the Environment, and a Sustainable Future*. 2nd edition. Boston: Beacon Press. *A steady-state economist and a theologian combine for a searching evaluation of whether and how far the global economy contributes to the common good, both social and environmental*.

Millennium Ecosystem Assessment. 2005. *Living Beyond Our Means: Natural Assets and Human Well-Being: Statement from the Board*. Available from *http://www.millenniumassessment.org/en/index.aspx. This is a summary document of a huge project sponsored by the United Nations and a host of organizations and*

corporations and involving more than 1,300 experts worldwide. There are multiple volumes, both in print and online. The focus is scientific, but there is a sustained effort to apply these results toward a humane environmental policy.

National Commission on the Environment. 1993. *Choosing a Sustainable Future: The Report of the National Commission on the Environment*. Washington, DC: Island Press. *A private-sector initiative convened by the World Wildlife Fund that concludes that the natural processes that support life on earth are increasingly at risk.*

Norton, Bryan G. 2005. *Sustainability: A Philosophy of Adaptive Ecosystem Management*. Chicago: University of Chicago Press. *Sustainability ought to be the cornerstone of environmental policy and requires shared, multidisciplinary deliberation over environmental goals and policy. Such communication is now fragmented by disciplines and ideologies. Norton offers a vision of a nonideological vocabulary that can accommodate the scientific and evaluative environmental discourse.*

Partridge, Ernest, ed. 1981. *Responsibilities to Future Generations: Environmental Ethics*. Buffalo, NY. *What do humans owe to posterity? Two dozen contributors seek an answer. Concern for future generations is a vital dimension of the ecological crisis, essential to sustainability. Although humans' ability to affect the future is immense, their ability to foresee the result of their environmental interventions is incomplete. This poses challenging moral questions and novel responsibilities.*

12. GLOBAL ENVIRONMENTAL ETHICS, CLIMATE CHANGE

Adger, W. Neil, Jouni Paavola, Seleemul Huq, and M. J. Mace, eds. 2006. *Fairness in Adaptation to Climate Change*. Cambridge, MA: The MIT Press. *All countries will be endangered by climate-change risks from flood, drought, and other extreme weather events, but developing countries are more dependent on climate-sensitive livelihoods such as farming and fishing and hence are more vulnerable. Nevertheless, the concerns of developing countries are marginalized in climate-policy decisions.*

Attfield, Robin. 2003. *Environmental Ethics: An Overview for the Twenty-First Century*. Cambridge, UK: Polity Press. *A survey and synthesis of the enormous range of challenging issues: local and global environmental problems; theories of value, stewardship, anthropocentrism and biocentrism; sustainable development; population; global citizenship. Attfield advocates what he calls biocentric consequentialism.*

Dallmeyer, Dorinda, and Albert Ike, eds. 1998. *Environmental Ethics and the Global Marketplace*. Athens: University of Georgia Press. *Contributors present arguments for creating global business practices that work in harmony with the environment; discussions of free trade, private ownership, sustainability, environmental justice.*

Engel, J. Ronald, and Joan Gibb Engel, eds. 1990. *Ethics of Environment and Development: Global Challenge and International Response*. Tucson: University of Arizona Press. *This anthology, published in association with the International Union for the Conservation of Nature and Natural Resources, contains more than twenty articles with an international focus on forms of development that are compatible with wildlife conservation.*

Northcott, Michael S. 2007. *A Moral Climate: The Ethics of Global Warming*. London: Darton, Longman and Todd. *Response to the challenge of global warming requires learning to put the common good ahead of selfish interests, weaving together the physical climate and the moral climate. Relieving climate change opens opportunities for solving other problems: world poverty, the rich/poor divide, the overuse of resources, and the appreciation and conservation of nonhuman creation.*

Pojman, Louis P. 2000. *Global Environmental Ethics*. Mountain View, CA: Mayfield. *Classical ethical theories are challenged by both the global scale and the environmental dimensions of contemporary problems. Discussions of greenhouse effects, ozone depletion, population, world hunger, energy use, animal welfare, endangered species, wilderness, sustainability.*

Index

Bold *volume and page numbers (e.g.* ***1:1–3****) refer to the main entry on the subject. Page numbers in italics refer to illustrations, figures, and tables. Page numbers followed by the letter t indicate a table within the article.*

The field of environmental ethics is a new but now well-established sub-discipline of philosophy. Emerging in the mid-1970s, the field coalesced with the inaugural volume of the journal *Environmental Ethics* in 1979 and developed rapidly. By the turn of the century, most colleges and universities offered courses, if not major programs of study, in this important discipline.

The *Encyclopedia of Environmental Ethics and Philosophy* addresses the needs of upper high school students and undergraduates, researchers, teachers, and professors, as well as general readers, by examining the philosophical and ethical issues underlying contemporary and historical environmental issues, policies, and debates. The encyclopedia covers concepts, institutions, topics, events and people, including global climate change, animal rights, environmental movements, alternative energy, green chemistry, ecology, and ecosabotage.

The *Encyclopedia of Environmental Ethics and Philosophy* was guided by an editorial board of scholars, who worked with more than 250 contributors from the world's leading universities. Each of the more than 300 articles contains a bibliography for further reading. More than 200 photographs, illustrations, and sidebars augment the text. Appendices include an annotated bibliography, a glossary, and a collection of classic articles and documents. The text is fully indexed for ease of research, and a thematic outline categorizes entries under broad subject areas for an alternative access path.

J. Baird Callicott, Regents Professor and chair of the Department of Philosophy and Religion Studies at the University of North Texas, is one of the founders of academic environmental philosophy, having taught the first environmental ethics course in the United States in 1971, at the University of Wisconsin-Stevens Point. His Ph.D. in Philosophy is from Syracuse University (1971). Dr. Callicott is a contributor to many journals including *Conservation Biology* and *Environmental Ethics*. His books include *In Defense of the Land Ethic: Essays in Environmental Philosophy* (1989) and *Beyond the Land Ethic: More Essays in Environmental Philosophy* (1999). He is co-editor of the book *The Wilderness Debate Rages On: Continuing the Great New Wilderness Debate* (2008).

Robert Frodeman is former chair of the Department of Philosophy and Religion Studies at the University of North Texas. He specializes in environmental philosophy and science policy. His Ph.D. in Philosophy is from Pennsylvania State University (1988). He is Director of UNT's Center for the Study of Interdisciplinarity, which seeks to develop the theory and practice of interdisciplinary research and education. Dr. Frodeman is editor of *Earth Matters: the Earth Sciences, Philosophy, and the Claims of Community* (2000), co-editor of *Rethinking Nature* (2004), and author of *Geo-Logic: Breaking Ground between Philosophy and the Earth Sciences* (2003).

The *Encyclopedia of Environmental Ethics and Philosophy* joins the suite of other Macmillan applied ethics titles: *Encyclopedia of Bioethics* and the *Encyclopedia of Science, Technology, and Ethics*.
