Ever since Ross put forward the case for moral pluralism, theorists have worried that such an account of moral duties leaves us with a disparate set of duties without any internal connection among them. As D. D. Raphael put it, pluralism "does not meet the needs of a philosophical theory, which should try to show connections and should tie things up in a coherent system" (Raphael 1981, p. 55). In response to defenses of pluralism in environmental ethics by Christopher Stone (Stone 1987), Gary Varner (Varner 1991), and Andrew Brennan (Brennan 1992), Baird Callicott has argued, like Raphael, that pluralist ethics fail to provide a consistent systematization of moral decision making and can even lead to relativism and nihilism (Callicott 1990, 1994c). For Callicott an environmental ethic should be monistic—committed to a single system of values. More precisely, it should provide clear principles for action, and, in case of conflict among these, it should also provide guidance on which principle has priority over the others. Hence he argues that when, as members of the multilayered communities to which we belong, we are faced with conflicts among different interests, we should give preference to the interests of those communities (and individuals) to whom we are closely related unless some stronger interest is at stake involving communities (and individuals) at a greater emotional distance. Callicott's own proposal has been critiqued as itself involving a kind of pluralism (Domsky 2001, Lo 2001). Nonetheless, the problem remains: If there are various kinds of values, duties, and moral principles, and if these cannot be reduced to a single foundation, how are coherence and unit possible in ethical reflections?

One solution to this problem has been proposed by those environmental pragmatists who claim that the recognition of diverse and incommensurable values does not commit thinkers to a kind of "metaphysical musical chairs" (Callicott 1990) but encourages instead a "metaphilosophical environmental pragmatism" (Light 1996a, 1996b) in which theorists with different underlying metaphysical and value commitments can still reach agreement on practical policies. This form of pragmatism is not dissimilar to the practical pluralism that is explicit in the Deep Ecology platform of Naess and Sessions (as pointed out in Light 2003). As Anthony Weston and Bryan Norton have pointed out, pragmatism as a philosophical stance gives priority to practice over theory and thereby avoids the advocacy of "top-down" solutions to practical problems (Weston 1985, 1992; Norton 1991, 2005).

The label "environmental pragmatism" does not identify a unified school of thought. Some environmental pragmatists align themselves with the tradition of philosophical pragmatism, especially the work of the American philosopher John Dewey (1859–1952) (see Taylor 1990, Minteer and Manning 1999); all or most think that such

pragmatism necessitates a kind of moral pluralism, although at least one theorist thinks that practical pluralism need not be tied to the tradition of philosophical pragmatism at all (Light 1996a). At the heart of many debates involving pluralism and pragmatism lies the issue of reductionism. Systematic philosophy shares with the natural sciences the goal of reducing complex phenomena to simpler ones and to explain complex situations, behaviors, and experiences in terms of a core set of relatively simple concepts or categories. Whether a reductive, systematic approach is appropriate in moral thinking remains a vexed issue, whether in environmental philosophy in particular or in moral theory in general. As Bernard Williams (1985) pointed out, in a new version of Ross's "what we really think" argument, moral reflection seems to carry with it a sense of a system or structure that underlies reasoning and moral sentiments. Yet people recognize, at the same time, that the values, principles, and duties that they consider in a given situation often fail to form a cohesive whole. In some difficult situations apparently incommensurable values seem to pull people in different directions, yielding no clear basis for preferring one over another. The addition of environmental values to earlier values that were concerned only with human beings and their relationships has led to a broadening of people's moral horizons. Whether such breadth makes theoretical reduction more or less likely is still a contested issue.

OTHER APPROACHES AND FUTURE DIRECTIONS

The various schools of philosophical thought arise from diverse methodologies. The analytic or Anglo-American tradition in philosophy emphasizes conceptual clarity, logical rigor, empirical soundness, and scientific validity of arguments. By contrast, continental philosophy (so named because it arises from the work of philosophers from the European continent, most prominently France and Germany) is more critical of claims of scientific rigor (which it sometimes criticizes as "scientism"), is more open to exploring the historical and cultural context of ideas, and is more inclined to explore larger philosophical themes such as the nature of being, existence, and consciousness. Others have been inspired by the assertion of the twentieth-century French philosopher Jacques Derrida, *Il n'y a pas de hors-texte* ("There is no outside-text"); these thinkers focus primarily on the text. Many thinkers embrace more than one of these different ways of writing philosophy, so these labels are not always mutually exclusive.

It was only in the 1970s that philosophers began to rediscover and mine ideas about nature found in Rousseau, Kant, Hegel, Hölderlin, Nietzsche, Benjamin, and Heidegger; thinkers who regard themselves as belonging to the continental tradition have been at the forefront of this development (Foltz 1995; Foltz and Frodeman 2004). Some have argued for the relevance of phenomenology to environmental consciousness and the understanding of the human condition (Evernden 1985, Seamon and Mugerauer 1985, Abram 1996, Toadvine and Brown 2002). A phenomenological approach takes the subject's own awareness and experiences as the starting point for philosophical, aesthetic, and moral reflection. In many ways these approaches recapitulate themes discussed in the analytic literature. For example, does the notion of *Dasein* in the work of the twentieth-century German philosopher Martin Heidegger (1889–1976) provide the basis for an approach to what is intrinsically or inherently valuable? For Heidegger, human beings never just exist, but rather find themselves somewhere: "*dasein*" literally means "being there." Both human awareness and existence are bound up with being in places and so, it may be argued, what is valuable emerges from the interconnection and interaction of humans in their environment. Some writers have suggested that Heidegger's approach can open the way to an account of intrinsic value in nature (Thomson 2004), and others have explored the idea that there is support for deep ecological insights in his thought (Zimmerman 1994).The recovery, reanimation, and novel application of the work of figures such as Husserl, Merleau-Ponty, and Heidegger might seem to bring a new depth and interest to work in environmental philosophy, but there are also critics of such an approach, which, because of its emphasis on the emotional and spiritual links between humans and nature, was once described as "eco-la-la" (Bookchin 1987). Yet Bookchin's own Social Ecology—a view that combines Kropotkin-style anarchism with an ethic of environmental stewardship—seems to share some common assumptions with the theories of Foucault and Derrida, who, like Bookchin, have warned of the hidden traps of liberal democracy and have deconstructed the notions of power and sovereignty in attempting to account for the difficulties of arresting environmentally destructive behavior. Despite Bookchin's qualms, writers whose works emphasize the spiritual and poetic continue to contribute their distinctive voices to the subject (Smith 2001, Casey 1993, 1997, Malpas 1999).

Environmental philosophies often borrow their overall orientation from the author's implicit philosophical, political, and religious identifications. Interpreters of Islamic traditions, for example, echo the ideas of some followers of Deep Ecology in arguing that environmental destruction is an aspect of a wider cultural and moral corruption associated with materialism and spiritual bankruptcy (Wersal 1995). Whether conservation is a politically conservative position and what scope there is for developing "green" forms of socialism and Marxism have been hotly

debated (Dobson 1995, Barry 1999). The green credentials of many religious and cultural traditions have been scrutinized (Callicott and Ames 1989, Callicott 1994b), and some thinkers have proposed that traditional medicine can provide some support for an ethics of place (Brennan 2002). There is a growing interest in comparative studies of environment, religion, and culture, a trend evidenced on two fronts: in the recent publication of a major reference work (Taylor 2005) containing numerous entries on diverse traditions and their environmental beliefs, and in a series of conferences and publications organized by the Forum on Religion and Ecology (2008). Animist and Daoist perspectives have been influential in works that argue that environmental management, development, and commerce should focus on synergy with what is already in place rather than on the demolition, replacement, and disruption that is characteristic of modernity (Mathews 2004, 2005; Harvey 2005).

The call of the wild was a major focus of the early days of environmental philosophy (see Jamieson 1984 for an exception to the trend), but increasing attention is being placed on the built environment (King 2000, Light and Wellman 2003, Fox 2007). Indeed, the questions of wilderness and its moral and aesthetic status were heavily debated in the 1990s and into the first decade of the twenty-first century (Callicott and Nelson 1998, Nelson and Callicott 2008).

The many parallels between natural and human-made things arise in discussions of fakes, restoration projects, and the value of originals (see Elliot 1997, Lo 1999). Original works of art are often sold for huge sums, reflecting their unique status. However, given modern conservation and copying techniques, it is not clear what it is about the original that makes it so valuable. Puzzles about the value of restored and copied paintings, furniture, and buildings run parallel to puzzles about restored and copied landscapes and ecosystems. As a result, restoration, preservation, and conservation have been a focus not only of conceptual puzzles but also of political disagreement, whether in the case of Angkor Wat or ancient forests (Dryzek 1997). To restore ruined temples at Angkor Wat, archaeologists rebuilt them stone by stone and laid new concrete foundations. Controversy abounds over the authenticity of such reconstructions. Likewise, forest restoration politics can become embroiled in disagreement about whether the original species composition has been recreated and to what extent nature restoration involves a "big lie" (Katz 2003, and compare Lo 1999, Light 2003b). Likewise, although poor people are often frugal with resources and extremely good environmental managers (Martinez-Allier 2004), political divisions have arisen between those who regard poverty itself as a driver of environmental destruction and those who see extreme preservationism as a misanthropic contributor to the further displacement and impoverishment of vulnerable communities (Rolston 1996, Brennan 1998, Guha 1999). Such issues pose major questions about environmental justice: The burdens of landfills, chemical plants, and toxic dumps and the loss of environmental amenities often fall disproportionately on the poor and members of certain racial or ethnic groups. (Shrader-Frechette 2005).

Contemporary environmental problems are not simple; they involve intertwined issues of public health and social justice, attitudes to nature, and deep disagreements about matters of science, policy, rights, and ethical obligations. These complexities apply to many areas of contemporary environmental debate: drought, changing weather patterns, the loss of habitat and species, the burden of caring for environmental refugees, the effects of consumerism, and the health problems associated with various forms of pollution (Jamieson 2001). These problems ramify into clusters of interconnected puzzles that are incapable of determinate solution within the scope of any single discipline or framework and may be described as "wicked problems" (Norton 2005, Brennan 2004). In turn, although many of these issues are based on matters of fact, the interpretation of those facts can be skewed by competing scientific, social, and political theories. The resolution of such conflicts and ambiguities demands increased interdisciplinary cooperation between philosophers, political theorists, legal experts and scientists. Such a cross-departmental approach would be consistent with the contemporary trend toward making philosophy more empirical and with Bookchin's suggestion that ecology is both an integrative and a reconstructive discipline. Persistent concerns about climate change, species loss, and environmental degradation are likely to lead to a further integration of the work of thinkers in many fields, scientific and philosophical. As long as scientific facts about the environment pose ethical and philosophical quandaries for philosophers, citizens, and government officials, it is likely that new interdisciplinary research agendas will emerge.

VI. POSTMODERN PHILOSOPHY

Postmodern environmental philosophy (PMEP) is the form of environmental philosophy that draws on postmodern theory (PMT) to challenge assumptions made by many environmentalists about the relation between humanity and nature and to redefine that relation. PMT makes use of the work of a number of thinkers, including Jacques Derrida (1985) and Michel Foucault (1991; Dreyfus and Rabinow 1983), who expanded on ideas developed by Friedrich Nietzsche (1995) and Martin Heidegger (1977), among others.

THE MAJOR CLAIMS OF PMT

PMT makes four major claims:

1. First, humans have no unmediated access to a pregiven, independently existing reality; instead, ''reality'' is a construction resulting from power-inflected truth claims made about various phenomena.
2. Second, there are no ultimate foundations, origins, ends, or essences to which appeal can be made to justify hierarchical ideologies or institutions.
3. Third, the self-grounding, autonomous, patriarchal, anthropocentric subject can be deconstructed—that is, shown to be without stable foundation. Dissolving subjects into the effects of socioeconomic structures and competing language games, PMT simultaneously undermines once-stable objects.
4. Fourth, the deconstruction of foundations undermines master narratives of progress, including those of liberal capitalism and Marxism. Each of these claims has been used by PMEP.

VIEWS OF NATURE IN PMEP

According to PMEP, both humanity and nature are *representations* or *constructions* generated by historically situated linguistic practices, conceptual categories, and sociopolitical interests (Evernden 1992, Cronon 1995, Soper 1995, Morton 2007). Strong versions of the social-construction hypothesis reduce nature to a human product in which everything is a self-reflexive representation generated by power-oriented human discourses and in which virtual reality has equal status with ordinary reality. Steve Vogel, a PMEP theorist and proponent of social construction, has provocatively called for abandoning the very concept of nature, defined as a human-independent reality (Vogel 1996, 2002). Vogel also argues, however, that humankind's capacity to alter the world does not grant a license for people to do whatever they please, but rather imposes a serious moral responsibility: to construct a world in which people would like to see their children live. Would people not want a world that includes habitats for wild and endangered species, as well as clean air, water, and land for all life? According to Vogel, being against nature as essence or foundation does not mean not being in favor of extinction and pollution.

Environmentalists sometimes appeal to science to defend a realist, extrarepresentational dimension of nature, even though elsewhere they accuse science of enabling the exploitation of nature. Many contemporary scientific ecologists, however, influenced by PMT, claim that they study not nature but representations of it, framed by various methods and concepts (Dodson 1997). Whereas scientists formerly represented biospheric nature as balanced, harmonious, and delicate, thereby providing grounds for environmental legislation to protect nature from modern industry, scientists now represent natural systems as both ordered and chaotic, as resilient rather than delicate; otherwise, such systems could not survive recurrent, violent perturbations, which are vital for long-term ecosystem health (Botkin 2002, Worster 1994). Natural perturbations, scientists add, are often less intensive and enduring than are modern anthropogenic disturbances.

Additionally, emerging scientific developments are beginning to challenge other assumptions of modern environmental philosophy. Nanotechnology and synthetic biology represent nature in terms of molecular structures that can be redesigned brick by brick, thus allowing the material construction of new life forms that will overcome the traditional distinction between the artificial and the natural, redefine life in terms of human preferences, and sever connections with the evolutionary lineages that some environmental philosophers maintain are the foundations for the intrinsic value of nonhuman life.

PMEP AND VALUES IN NATURE

The problem of nature's value is central to PMEP's critique of environmental philosophers who, influenced by the nineteenth-century romantic aesthetic of the sublime, ascribe intrinsic value only to wild nature and regard Native Americans as if they, too, were instances of wild nature. Such environmentalists depict virgin land as essentially different from, and far more intrinsically valuable than, land altered by human hands. Lamenting the end of wild or "virgin" nature, such environmentalists have also claimed that efforts to restore human-damaged land cannot make it natural again (McKibben 1989, Katz 1995, Elliot 1997). PMEP criticizes the apparent essentialism at work here, according to which nature influenced by humans is somehow less valuable. In a related manner some environmental philosophers have also claimed that nearly all of North American nature prior to the arrival of European colonists in 1492 was wild because Native Americans lived so lightly on it. In this reprise of the myth of the noble savage, PMEP argues, environmentalists represent Native Americans condescendingly as more akin to buffalo than to historical human agents. Evidence now indicates that Native Americans significantly and intentionally altered the land, though not nearly as much as they would have done had they possessed modern technology (Mann 2006).

According to PMEP, claims about the intrinsic value of either nature or humankind assume foundations where there are none. PEMP maintains that values are contested and constructed, not discovered (but see Rolston 1989). PMEP questions efforts to extend to plants, animals, and even ecosystems moral rights or legal standing as these concepts are understood by modern discourses. For PMEP such a view errs in assuming that there are stable human subjects and stable natural objects. Further, because neither humanity nor nature has or is a foundation, environmentalists cannot appeal to either of them to justify a particular principle. PMEP notes, in addition, that this extension of moral standing to nature is anthropocentric insofar as it identifies a trait in wild animals, plants, or ecosystems sufficiently similar to an intrinsically valuable human trait to justify according moral rights to those nonhumans. PMEP likewise criticizes biocentrism, the idea that life (not humankind) is important, because biocentrism purports to be another ultimate "foundation" for morality. PMEP attempts to conceive of morality without reference to any such ultimate foundations. Finally, according to PMEP, just as modern moral and political theory effaces differences among humans by defining people in terms of the traits of possessed by the typical educated, modern, white European male, so, too, does this extension of moral qualities to nature efface differences between humans and nonhumans.

Deconstructing this white male subject as well as its object—wild nature represented as stable, harmonious, and fragile—PMEP argues that environmentalists made anxious by the experienced deconstruction of their own (modern) subjectivity have projected their anxiety onto a wilderness that they seek to protect both from metaphysical deconstruction and physical damage. For such environmentalists the loss of wilderness is tantamount to death of the subject (Bluehdorn 2000). Ecofeminists and environmental-justice advocates criticize environmentalists who remain identified with the privileged, modern male subject because they overemphasize wilderness protection while overlooking how devastated natural environments afflict women, children, people of color, and the poor (Bullard 2005, Warren 2000, Shiva 2005).

CRITIQUES OF PMEP

Many environmental philosophers have taken issue with major features of PMEP, charging that it undermines the basis for environmental action (Sessions 2006). Viewing nature as a representation, they argue, leaves little room for an independent, extrahuman dimension of nature (Lease and Soulé 1995, Cronon 1996, Peterson 1999, Smith 1999, Kidner 2000, Crist 2004). Critics such as Albert Borgmann (1993) speak of *hypermodernism* when describing strong

constructionist versions of such representationalism. Robert Frodeman (2003) adds that hypermodernism's "anything goes" attitude unwisely abandons the search for ethical limits regarding the treatment of nature and humankind alike.

Some environmental philosophers who were initially attracted to PMEP have concluded that its methods deconstruct *all* truth claims, foundations, and narratives, including those cherished by environmentalists. They argue that deconstructing the subject leaves no basis for ethically grounded political agency, thereby giving free rein to corporations whose leaders retain a strong sense of agency and purpose. Having rejected hierarchy, moreover, PMEP advocates have no basis for claiming that the perspectives of environmental justice, ecofeminism, or third world advocates are somehow either truer or more innocent than other perspectives, whether proenvironmental or antienvironmental. Last, critics point out the problem of endorsing Foucault's idea that a power drive is at work in all organizations. Adhering to this idea means that PMEP advocates must view pronouncements made by Greenpeace as skeptically as they do those made by Conoco.

Despite such concerns about postmodernism, many environmental philosophers have agreed with its oftentotalizing critique of modernity, an outlook shaped in part by the noted German antimodernist philosophers Friedrich Nietzsche (1844–1900) and Martin Heidegger (1889–1976) (Foltz 1995, Parkes 2006). Other environmental philosophers, however, have warned that simply appropriating antimodernist attitudes for environmental purposes is dangerous because such appropriation encourages regressive, misanthropic, and dualistic fantasies of "returning to nature" and even eliminating humankind altogether to save nature (Zimmerman 1994, Acampora 1994, Murphy 2003). Bypassing this trend, *ecophenomenologists* have called on the work of thinkers such as Heidegger and the French philosopher Maurice Merleau-Ponty (1908–1961) (2003) to develop profound, postmodern, nondualistic insights about humanity's place in nature while abstaining from gratuitous criticism of modernity (Abram 1996, Brown and Toadvine 2003). (Phenomenology is a method of investigation that focuses on first-person experience of things. Consider the difference between an objective third-person approach to a thing and a first-person approach. A bridge-builder might represent a particular place as an object that blocks the way for a new span. In contrast, a person raised in that locale might regard the same place as a landmark with great personal and communal significance. Ecophenomenology emphasizes the importance of such first-person experience for understanding the felt "meaning" and value of place, features that cannot be ascertained by natural science or engineering.)

PMEP has contributed to environmental philosophy by deconstructing the purportedly arrogant, self-certain European–North American subject, along with its dubious truth claims, metaphysical foundations, and essences, which had justified modernity's grand narrative of dominating nature for human ends. Although recognizing the importance of such achievements, some PMEP advocates are reconsidering postmodernism's strong versions of social constructivism, its overly enthusiastic deconstruction of subjects and objects, its radical antihierarchalism and related conceptual-moral relativism, and its all-inclusive critique of modernity. Such critical reconsideration has opened the way for a post-PMEP, one version of which is called *integral ecology*. Integral ecology holds that many different perspectives must be included in order to adequately characterize the natural world on which human life depends; that entities have a measure of reality and even autonomy, having roles to play in complex systems; that some perspectives are superior to—because more comprehensive than—others; and that environmentalists must appreciate the productive as well as the destructive side of modernity (Wilber 2001).

ENVIRONMENTAL PLURALISM

Environmental pluralism provides a constructive framework for making decisions in a complicated and divisive world. As worldviews clash, sciences conflict, politics polarize, and institutions entrench, political decisions become dilemmas without obvious solutions. Yet decision must be made: Should we exterminate a species if doing so improves human health? Should we burn trees and bunnies to restore native species and natural fire regimes? Should dams release water for spawning salmon and forgo opportunities to generate clean hydropower and irrigate inexpensive food? Should we subsidize biofuel industries, which produce jobs, enhance national security, and help moderate the climate but convert vast habitats to corn and tree monocultures?

Decision makers facing these wicked choices operate within a segmented and fractured world created by disciplinary, institutional, locale, linguistic, and normative barriers that define communities of practice. Consider the different issues that would be championed when any one of the above mentioned dilemmas gets framed by just one of following perspectives: public health, animal rights, Christian stewardship, environmental justice. Each of these perspectives has an internally consistent, self-reinforcing logic and language to defend and explain observations and actions. Fortunately, despite their differences, these communities of practice often overlap in the preferred outcomes and rationales that they seek to advance. And in that overlap lays the hope of environmental pluralism.

MORAL ENVIRONMENTAL PLURALISM

Moral environmental pluralism accepts multiple competing, overlapping, self-consistent frameworks for differentiating right from wrong, good from bad. No one framework is always best; no one framework subsumes all the others in a hierarchy. Moral pluralism contrasts with moral monism, which is the as yet unfulfilled promise of a unifying ethical theory that can serve as the keystone species of morality, organizing all moral criteria into a hierarchical system from which logical and consistent decisions flow. Moral monism is the understandable search for a golden rule derived from some fundamental truth that reasonable people accept as a

Clear-Cutting of the Spotted Owl's Habitat, Oregon. *Clear-cutting is a method of logging in which all the trees are taken from a specific area, as opposed to a select cut, in which only certain trees are taken, leaving some habitat remaining. Clear-cutting is one practice that can be used to illustrate environmental pluralism. While different interest groups have different opinions on the practice, the decision making processes of environmental pluralism would take into account multiple opinions on clear-cutting, from the forester's social welfare view, to the conservation biologist's ecological values.* **PHOTO BY STEVE HILLEBRAND/U.S. FISH AND WILDLIFE SERVICE.**

tool to resolve difficult environmental problems and dilemmas. Critics of moral monism argue that a unifying system does not yet exist and probably cannot be created, so a theory and practice of moral pluralism is both prudent and necessary. Moral monism is problematic, critics further argue, because it risks excluding or marginalizing some voices, which has the effect of shrinking the political base and creating adversaries instead of allies.

Environmental pluralism, in contrast, contends that the world is infinitely complex, fluid, and negotiated—a circumstance that frustrates any attempt to impose a master narrative as an overarching organizing framework. Reasonable differences of opinion will exist among reasonable decision makers embedded in different communities of practice. Much of professional forestry, for example, has a utilitarian ethic that seeks to maximize social welfare, an economic language to express welfare trade-offs as benefits and costs, and a scientific ability to describe and predict such economic attributes of forests as tree volume, soil productivity, and threats to profit, such as pests and fire. Conservation biology, in contrast, has more of a Leopoldian ethic that respects the integrity of biotic communities, an ecological language to communicate desired conditions of the biotic community, and a scientific ability to describe and predict the content and processes of ecolgocial systems.

Consider the decision to clear-cut trees. Foresters might evaluate the sustained yield of timber, water, animals for hunting, grass for grazing, space for recreation, and other forest products affecting social welfare. Conservation biologists, in contrast, might evaluate the resilience of the forest system to such a disruption of process and removal of content, as well as the sacrifice of habitat made by flaura and fauna dependent on the removed trees and disturbed soil. Two very different understandings of clear-cutting emerge, even though both are internally consistent in the moral and scientific reasoning that they use to identify and defend their preferred outcomes.

Moral pluralism proposes that the diversity of values and principles relevant to moral judgment cannot be

reduced to a single dimension—be it utilitarian pleasure and pain, Kantian respect for rationality, intrinsic value possessed by all life forms, or economic benefits and costs. Longstanding and divisive debates over which monistic dimension trumps all others has distracted ethicists' attention from the moral insights needed to guide practical and pressing environmental decisions. Particularly debilitating is the longstanding debate over whether nature has value independently of humans or whether the value of nature depends entirely on human instrumentality and logic.

Moral environmental pluralism rests on a philosophy grounded in pragmatism and deduces moral principles not from theoretical principles but from negotiated solutions to real management problems. These deductions provide rules of thumb for resolving environmental dilemmas and a language for articulating solutions. Environmental pluralism assists environmental decision makers by helping to identify the values and trade-offs being negotiated. In contrast, moral monism offers solutions that *should* be followed because they are consistent with philosophical principles.

Perhaps the harshest critique of moral pluralism is that it reduces all ethics to rhetoric by promoting relativism. Right and wrong, good and bad, become matters of personal taste and disciplinary preferences. Moral pluralism, according to this critique, enables articulate, sophisticated scoundrels to manipulate deliberations, using whatever ethical principles prove persuasive. On this view, moral pluralism is a giant step backward toward an ethic of might makes right. Those with power—people with legal and technical expertise, political position, and lobbying opportunities—manipulate the system toward their own ends and cannot be held accountable to the higher ideals toward which civilization fitfully progresses. Environmental pluralism, critics further argue, reduces moral reasoning and responsibility to marketing and political populism, a matter of checking the latest opinion poll.

From the vantage point of the pragmatist, and of managers faced with making decisions, this critique of moral pluralism seems impractical. Decisions affecting the quality and future of our environment are made every day, many times a day: decisions concerning forest-road construction, sewage-water discharge rates, poultry-house locations, fertilizer applications, power-plant designs, genetically-modified-crop releases, critical-habitat restorations, mining and drilling operations, and so on. These decisions must be made quickly and with imperfect knowledge. Full knowledge of values and consequences is not possible.

The decision space facing environmental decision makers resembles mountain tops poking above clouds, each mountain representing the collection of facts, values, conceptual models, and methods that create different communities of practice. Competent decision makers can climb to the top of one or two mountains and confidently propose solutions to the narrow range of problems that occur only on those mountains. But the big, complex, and potentially disastrous problems created by 6 billion humans consuming ecosystem services and finite resources don't exist on those mountains; they lie in the thick fog of uncertainty and in the deep valleys of unknowns. Environmental pluralism functions in this terrain; it compares and contrasts alternative moral frameworks and communities of practice for their relevance to the situation at hand.

PROCEDURAL ENVIRONMENTAL PLURALISM

Environmental pluralism accepts that solutions to problems in an uncertain, pluralist world requires open negotiation by earnest and well-meaning people dedicated to navigating the unknowns and finding higher ground in our search for thriving and sustainable communities. Procedurally, environmental pluralism must facilitate collaboration by moving debate beyond the quest for moral certainty, which motivates no-holds-barred conflict, stalemate, litigation, expense, delay, and paralysis in the pursuit of absolute victory. Adversarial politics fueled by interest groups defending all-or-nothing frameworks leave little room for cooperation and can hide agendas, conceal information, guard power, manipulate procedures, and produce ineffective solutions that waste time, money, and talent. Environmental pluralism, in contrast, inspires collaboration as it searches for commonalities, higher ground, and win-win solutions. It requires negotiators to accept the legitimacy of alternative frameworks and look for outcomes that maximize the preferences of diverse stakeholders, who collectively have the ability and will to affect change.

A classic example of a pluralist strategy is replacing command-and-control regulations of pollution with market-based strategies that trade pollution credits. Such a strategy requires considerable collaboration, sharing of information, and respect for the positions advocated by competing communities of practice. For example, it requires human-health advocates accept certain risks from pollution as unavoidable, environmental-preservation advocates accept pollution as a normal part of business, and free-market industry advocates accept that polluting the commons is no longer free and requires payments, as well as sharing with government inspectors proprietary information about industrial processes.

Civic environmentalism and deliberative democracy are promising trends in efforts to reclaim civil society through decentralization and devolution of decision-making authority from the state to local governments,

nongovernmental organizations, and market institutions. This transition reflects the advance of transactive planning and adaptive management as alternatives to centralized and comprehensive rational planning. The goals of these alternative decision-making procedures are to create room and appreciation for civil discourse, to share the responsibility for the definition and solution of problems, to harness local knowledge and agency, to produce equitable outcomes that check abuses of power, and to constantly test our progress as we incrementally advance toward sustainability. The success of these efforts requires environmental pluralism to promote meaningful collaboration by vested stakeholders and to avoid paralysis and polarization.

CONCLUSION

The challenges we face are enormously complex. It seems essential that we collaborate to seek diverse solutions representing a plurality of values and engage in open and regular testing and correction of our progress towards our goals. Environmental pluralism seeks to build a broad political base, encourage experimentation, and strive for the higher ground, where many, but not all, of the preferred outcomes of multiple stakeholders are to be found. It strives to overcome the polarization and paralysis symptomatic of environmental decision making in the early twenty-first century.

ENVIRONMENTAL POLICY

The domain of "environmental policy," as with any major area of public policy, is at once institutionally vast, conceptually intricate, and politically complex. Public policy has been defined as a "course of governmental action or inaction in response to social problems" (Kraft and Vig 2006, p. 4). It finds expression in the vision and agendas of political leaders, in statutes and regulations, and in the decisions and practices of bureaucracies and courts (Kraft and Vig 2006). The subset of *environmental policy* also includes the politics and priorities of scientific decision making relating to the environment, the programs of environmental advocacy groups (e.g., the Sierra Club), the work of research/policy analysis organizations such as Resources for the Future, and institutions representing business and development interests (often opposed to environmental regulation altogether), such as the American Enterprise Institute.

THE EVOLUTION OF ENVIRONMENTAL AWARENESS IN THE UNITED STATES

In the United States environmental policy has become so pervasive that it is easy to forget that most major environmental laws and regulations were passed only in the last third of the twentieth century (although more informal, uncodified environmental policies have a far longer history). It was in 1963 that Lynton K. Caldwell published his landmark essay, "Environment—A New Focus for Public Policy," in which he voiced concerns that public decision makers had to grapple with a growing litany of difficult environmental problems "without the help of a general body of environmental policy to which [they] may

turn for authoritative guidance" (Caldwell 1963, p. 134). Caldwell—the dean of U.S. environmental policy scholars—was especially concerned about the inadequacy of the traditional "segmental" approach to environmental problems: uncoordinated nonecological attempts to understand an ill-defined "public interest" in the environment through ad hoc interventions in transportation, land management, and other domains. He called for a more comprehensive political response that would view public policy problems in their environmental context.

Caldwell's wish was soon granted. The previous year had seen the publication of Rachel Carson's landmark book *Silent Spring* (1962), which alerted the world to the environmental and human health consequences of pesticides (especially DDT), thereby helping to launch the American environmental movement in the late 1960s and 1970s. This emerging environmental awareness was heightened by environmental disasters that occurred in the late 1960s, including the burning of the Cuyahoga River and the Santa Barbara oil spill.

The most significant federal measure during this era was the historic signing of the National Environmental Policy Act (NEPA) by President Richard Nixon on January 1, 1970. The statutory cornerstone of U.S. environmental policy, this law directed all federal agencies to consider the expected environmental impacts of their actions—a requirement that had to be implemented in part by the preparation of an environmental impact statement (EIS).

Coming on the heels of NEPA was the first Earth Day (April 22, 1970), which crystallized the emerging national environmental consciousness and ushered in a new era of activism in U.S. environmental politics. The Nixon administration ended this momentous environmental year by creating a new agency charged with overseeing the nation's environmental protective and regulatory efforts: the U.S. Environmental Protection Agency (EPA), created on December 2, 1970. The rest of the decade saw a steady rollout of major environmental-protection legislation, including the Clean Air Extension Act (1970) and Federal Water Pollution Control Act (also known as the Clean Water Act) 1972, the Endangered Species Act (1973), the Toxic Substances Control Act (1976), and more than a dozen other federal statutes that collectively manifested new and expanding public-policy goals for environmental protection and natural-resource conservation. Less than two decades after the publication of Caldwell's paper, an expansive federal environmental-policy complex was in place, answerable to a growing environmental constituency of citizen-activists, legislators, administrators, judges, scientists, economists, and, eventually, philosophers.

ENVIRONMENTAL ETHICS AND ENVIRONMENTAL POLICY

Caldwell's 1963 essay anticipated the need for strong environmental regulation for two key reasons: (1) The emerging insights of ecological science had created the need for consistent and clear guidance—and thus authority—for public decision makers in addressing environmental problems, and (2) there was a need to identify and accommodate divergent public values and ethical standards in environmental decision making (Caldwell 1963). He clearly envisioned an environmental policy regime founded not merely on science but also on social values—from broadly articulated policy goals to founding ethical principles.

Most environmental activism and policy throughout the world seeks to protect human interests, especially health, welfare, safety, property rights, aesthetics, and cultural/historical values. To this extent, most contemporary environmental policy is *anthropocentric*. This viewpoint was evident early on—for example, in Rachel Carson's assertion in *Silent Spring* (1962) of the human right to be free of harmful pollutants like DDT and in her powerful depiction of the systematic connections between human and environmental health. Although it is possible to interpret passages of Carson's work—and some of the ensuing environmental statutes and policies of the 1960s and 1970s—as aspiring to protect nature for its own sake, the dominant ethical discourse of environmental policy since the early 1960s has been one of "enlightened self-interest" (Cohen 2006, p. 15).

ENVIRONMENTAL PHILOSOPHERS AND THE POLICY PROCESS

Environmental philosophers seek to influence policy at three stages: (1) *agenda setting*, identifying environmental issues; (2) *evaluation*, assessing whether implementations conform to the original intent of policies; and (3) *policy change*, amending policy goals and means in light of new information and/or new value and political environments. In addition, many environmental philosophers also seek to provide a *normative justification* of public policies for environmental protection by offering alternative—usually nonanthropocentric—defenses for environmental policy goals, especially those that have traditionally been justified on anthropocentric grounds (Glasser 1999; Callicott 2009).

In their writing, teaching, and public speaking, environmental philosophers attempt to raise public awareness and formulate compelling arguments in favor of effective laws to protect the environment. These activities aim to influence agendas and policy/program evaluation. As participants in public discourse and debate, environmental philosophers act as policy advocates and, potentially,

as "policy entrepreneurs" (Kingdon 2003)—informal members of the environmental policy community who encourage fresh perceptions and novel policy initiatives. Mark Sagoff (1988, 2004) and Bryan Norton (2002, 2005) are prominent examples of environmental philosophers who have attempted to engage the policy process by providing a philosophical/normative counterpoint to the dominant economic methods of environmental policy analysis and evaluation. Specifically, Sagoff and Norton have advanced deliberative and communal theories of environmental value as an alternative to the individualist, preference-based forms of environmental valuation common within economic analysis.

Given the largely anthropocentric justification of much of environmental policy (considered as environmental regulatory policy—i.e., pollution control and prevention), most environmental philosophers have focused their attention on issues relating to *natural-resource* policy rather than *environmental* policy proper. The former, typically referred to as *distributive policy* (because it involves the distribution of public resources—e.g., access to public lands), concerns the protection, conservation, and recovery of environmental goods such as endangered species, wilderness, and forest and park resources. Because most environmental philosophers espouse a nonanthropocentric view of nature as possessing intrinsic, not just instrumental, value, their focus on issues like preservation of wilderness and the protection of threatened and endangered species is not surprising. Notable exceptions to this general trend, however, include work by Sagoff (1988, 2004) and Kristin Shrader-Frechette (1991, 2002). Sagoff and Shrader-Frechette have devoted considerable attention to the philosophical dimensions of environmental risk and regulation. These topics raise more traditionally anthropocentric questions pertaining to human health and safety, as well as issues of equity and procedural justice.

A DEBATE EMERGES

Environmental philosophers have always sought to influence policy deliberations. By defending nonanthropocentrism and the intrinsic value of nature, they hope to advance a persuasive moral justification for a robust environmental policy regime that is independent of instrumental (i.e., human-serving) values and thereby to provide a more solid foundation for initiatives that seek to protect endangered species, wetlands, and wilderness areas. Many environmental philosophers insist that only biocentric or ecocentric arguments can provide a truly principled basis for environmental policies (see, e.g., Westra 1997; Katz 1997; Callicott 2002).

The 1990s saw the rise of an "environmental pragmatism" that challenged this insistence on the supremacy of nonanthropocentric environmental ethics. Influenced by the work of classic American pragmatists such as Charles Sanders Peirce (1839–1914), William James (1842–1910), and John Dewey (1859–1952), this school sought to make environmental ethics more relevant to practical policy issues (Norton 1991, 2002, 2005; Light and Katz 1996; Minteer and Manning 1999). The new environmental pragmatists argue that a wide anthropocentrism—an expansion of the instrumentalist position on environmental value—is a more effective and more policy-relevant approach to environmental ethical theory than nonanthropocentrism (although see Minteer 2001 for an alternative pragmatic view). This argument typically rests on a claim about the inherent anthropocentrism of the public. Environmental pragmatists assert that citizens are more familiar with and supportive of environmental policy proposals justified in human terms than they are arguments promoting nature's intrinsic value. Bryan Norton (1991), a leading thinker in the pragmatist camp, has even suggested that the policy implications of nonanthropocentric and wide (pluralistic, long-sighted) anthropocentric philosophies are largely indistinguishable in practice—an argument known as the "convergence hypothesis."

OPPORTUNITIES AND NEW DIRECTIONS

Efforts to make environmental ethics more pertinent to environmental policy and decision making have gathered momentum through the first decade of the twenty-first century. This trend includes the work of philosophers outside the pragmatist tradition who share the concern that the field is not sufficiently engaged with concrete issues of public policy (Frodeman 2006). Scholars working in this vein have produced concrete normative analyses of actual environmental dilemmas, studies of the intersection of politics and environmental values in public decision making, and philosophical investigations into environmental science policy.

The increasing attention to policy goals by environmental philosophers is an important stage in the field's development into a more interdisciplinary and practically applicable method of inquiry. It reflects as well the growing concern that the field has not had a significant impact on environmental policy, law, and administration (Hargrove 2003, Minteer 2005, Stone 2005). By focusing more intently on the intersection of environmental values and policy outcomes, environmental philosophers can expand the boundaries of the discipline while also contributing to a more informed and nuanced analysis of public policies.

ENVIRONMENTAL POLITICS

Whereas environmental ethics focuses mainly on values and obligations as they bear on individual choices and actions, environmental politics focuses on processes of collective decision making, including processes leading to basic decisions concerning the arrangement of institutions and matters of law and policy within those institutions.

ETHICS AND POLITICS

Environmental ethicists have traditionally sought to give voice to values in and obligations toward natural entities and systems, often as part of an effort to foster an environmental worldview or ecological consciousness. A persistent question for environmental ethicists is whether and how the values and obligations they articulate can have a widespread impact on how people actually live in the world: Can this new consciousness or these new environmental values and obligations inform collective decisions on matters of law and policy? Can they lead to a transformation of political institutions themselves? If so, how?

Answers to these questions are widely seen as following one of two courses. Mainstream environmentalism seeks to work within existing political and economic institutions, reforming them in more environmentally benign directions and fostering policies to protect this or that environmental value. Many environmental philosophers, however, aim for a more radical transformation of institutions, often as an extension of their radical inquiry into the most basic of contemporary assumptions about matters of ontology and ethics. Arne Naess (1973) explicitly frames his "Deep Ecology" in these terms, eschewing the "shallow ecology" that seeks merely to reform existing institutions piecemeal.

On the radical side, one version of the connection between ethics and politics has it that a change in consciousness or in values leads to changes in behavior, which in turn naturally lead to changes in society and its institutions. This take on environmental politics can be traced back to Aldo Leopold, who wrote in *A Sand County*

Almanac (1949) that "governmental conservation" would always be inadequate: Genuine conservation must begin instead with a change in individual conscience (pp. 213–214). J. Baird Callicott, in his contribution to Marietta and Embree's *Environmental Philosophy and Environmental Activism* (1995) casts academic environmental ethics as nothing less than "the most radical and effective kind" of political activism (p. 19).

Nevertheless, it remains a matter of concern that environmental ethics seems to have little impact on the political arena, even at the level of informing policies and practices within existing institutions. In his occasional editorials in the journal *Environmental Ethics*, Eugene Hargrove (1998) has often lamented the apparent lack of any such impact, though in1998, he noted that the field was having some influence on advocacy groups already committed to conservation.

One response to this apparent ineffectiveness is to propose that environmental philosophy move in a more pragmatic direction. Rather than focusing primarily on academic questions of ontology and moral theory, environmental pragmatists hold that philosophers should use the tools at their disposal to participate in and improve the terms of current debate on matters of practice and policy. The goal of environmental philosophy would then be to foster better, more critical deliberation rather than to foster a particular ecological worldview. Bryan Norton has gone so far as to argue, in *Toward Unity Among Environmentalists* (1994) and subsequent works, that environmentalists with diverse worldviews and different ideas about values and obligations actually do converge on matters of policy. Note that environmental pragmatism can be radical rather than reformist to the extent that it holds that good deliberation may require different kinds of political institutions than those now in place.

Critics of the pragmatist approach object to its open embrace of ethical pluralism, which they see as giving too much ground to the forces of environmental destruction. Callicott (1990) in particular has long insisted on ethical monism, the view that the proper goal of environmental ethics is to articulate the single, correct guiding principle for public policy and to bring it into the political realm by convincing people of its rightness.

POLITICAL LEGITIMACY

A key theoretical question at the intersection of environmental ethics and politics concerns political legitimacy: Who is actually entitled to make decisions about environmental change?

One view holds that decisions ought to be left in the hands of experts and administrators who have the correct ends in view. According to John Dryzek (2005), an extreme form of this view surfaced in the 1970s, when the apparent severity of environmental problems and the pressure of population growth seemed both to justify and to require firm, even authoritarian leadership by an ecologically informed ruling elite as in the case of China's one-child policy. This view raised cries of alarm about "eco-fascism" (which might better be called eco-Stalinism), a charge that has more than once been leveled at some variants of environmental ethics. More prevalent and less radical is the view that most decisions about environmental protection should be carried out by administrative agencies within modern nation-states.

By contrast, pragmatist environmental ethicists seem more often to ally themselves with some form of democratic decision making, whereby the legitimacy of political institutions arises from the consent of the governed. The view that political legitimacy and political change alike come from the bottom up does seem to be much more in keeping with Leopold's suspicion of government-run conservation. Within that broad democratic tendency, however, there is still a great deal of disagreement, in part because there are different models of democracy.

The core idea of liberal democracy, first articulated by John Locke, is that individuals ought to be free to go their own way so long as they do not impinge on the freedom of others to do the same. Liberal political institutions may be described as morally thin, requiring no broad social consensus on substantive ethical matters aside from a basic set of individual rights and liberties. Although there is some disagreement among nation-states on the scope of individual rights and what it means to impinge on them, liberal forms of democracy now dominate the international scene.

Environmental philosophers have raised two main objections to liberal democracy. The first objection is rooted in the strategic concern that liberal political institutions foster divisive interest-group politics in which environmentalists must compete directly with other interest groups for attention and for power. The second objection is that liberal democratic institutions typically have been conjoined with a relatively unrestrained form of capitalism that, in its industrial and postindustrial guise, is often identified as one of the roots of environmental destruction.

Against liberalism, many environmental philosophers have come to advocate participatory or deliberative forms of democracy. Whereas liberalism assumes that people come to the marketplace and the voting booth with a fixed set of interests for which they seek political favor, deliberative democracy seeks to foster critical discourse that can in turn promote a process of social learning. In a deliberative democracy, an ecological turn

in consciousness and values might be more likely to work its way up to the level of policy.

A number of environmental philosophers go a step further, advocating a form of "green" or ecological democracy that is morally thicker than deliberative democracy. This means that some environmental values would be built into political institutions themselves, placing them beyond the reach of the critical deliberation that occurs within those institutions. In *The Green State* (2004), for example, Robyn Eckersley projects the possibility of political institutions in which all those who could be adversely affected by a decision would participate or be represented in the decision-making process—including individuals of other generations and other species.

SOVEREIGNTY

The question of political legitimacy is closely allied with the question of sovereignty. The modern nation-state is usually regarded as sovereign, answerable to no higher authority, but the territory over which it is sovereign is usually a product of historical accident. The result is frequently a scalar mismatch between environmental problems and the institutions that have the power to deal with them. This problem is especially acute in relation to global climate change, about which there is very little that any one sovereign nation can do on its own.

There are a range of options available for correcting this mismatch. Bioregionalism would reconfigure the boundaries of political authority onto the boundaries of natural biomes and watersheds. In the other direction, there is a push for political institutions at the global scale that would have the legitimate authority to address problems like climate change at the expense of the sovereignty of present-day nation states. Not everyone is so eager for such a shift in sovereignty: Eckersley (2004), for one, has argued that the modern nation-state can be both legitimate and effective in protecting environmental values.

PREFERENCES AND PRINCIPLES

Another way of seeing the difference between the dominant liberal approach and its alternatives is to look at the basis on which decisions are supposed to be made. Liberal democratic institutions are seen as aiming at an aggregation of interests, enacting policies that satisfy most of the people most of the time, taking people as they are. This model assumes that each individual is motivated primarily by material self-interest and that his or her interests are firmly fixed. Whether in the political forum or in the marketplace of postindustrial capitalism, this model views people mainly as consumers seeking to maximize their satisfaction by acquiring bundles of goods, including policy outcomes, the value of which is determined by how much people are willing to pay for them.

In matters of environmental policy, the assumptions of market liberalism have promoted a rise in cost-benefit analysis, which prizes those policies that bring the greatest overall benefit at the lowest cost, where costs and benefits are both given in monetary terms. The main practical challenge for cost-benefit analysis is in assigning monetary value to goods and services that are not now included in markets, such as clean air, an unobstructed view of a mountain, or a pristine wilderness.

Environmental philosophers have raised any number of objections to cost-benefit analysis, chiefly that placing a monetary value on natural entities and systems is the most crass form of anthropocentrism and that reducing all human motivation to the pursuit of material self-interest and all value to willingness-to-pay trivializes all of the core principles of human morality, including the dignity of human life.

One extension of these objections against cost-benefit analysis, stated most notably by Mark Sagoff (2004), holds that individuals ought to be regarded primarily as citizens rather than as consumers. As citizens, individuals have within them the possibility of acting on principles about what ought to the case rather than acting only on the preferences or desires they happen to have at the moment.

A number of environmental philosophers reject the aggregation of preferences, whereby the desires of consumers are stacked up on one side or another and policies are tailored to suit the tallest stack. Instead, the argument runs, the values held by citizens are not merely given as facts to be collected and arrayed but are instead chosen on the basis of reasons and so are open to critical reconsideration and revision. Political deliberation then takes the form of offering and considering reasons, reconsidering and revising values, and ultimately integrating values in polices that can protect multiple values and meet multiple obligations.

ENVIRONMENTAL PSYCHOLOGY

Environmental psychology is the study of transactions between individuals and their physical settings. In these transactions individuals change the environment, which in turn changes human behavior and experiences. It has been a recognized academic discipline since the 1960s. The first conferences devoted to what was then called *architectural psychology* were held in 1961 and l966. The first Ph.D. program in environmental psychology was established in 1968. One marker of environmental psychology's youth is that the first Ph.D. in the field was earned in l975. In contrast, the first American Ph.D. in psychology was granted in 1861. By the late 1960s the first professional journals devoted to the field had been established; the most prominent of these are the *Journal of Environmental Psychology* and *Environment and Behavior*.

THE SCOPE OF ENVIRONMENTAL PSYCHOLOGY

Environmental psychology encompasses theory, research, and practice aimed at making buildings more humane and improving people's relationship with their surroundings, natural and built. Society invests enormous efforts in the construction and maintenance of key features of the physical environment such as cities, buildings, parks, and streets. Designing these features to maximize the well-being of both humans and nature is a major objective of environmental psychology.

Environmental psychology usually focuses on the behavior and experience of individuals and small groups, such as office workers, pedestrians, pupils, extraverts, shoppers, neighbors, hikers, dormitory residents, burglars, architects, and commuters. The discipline attends less often to large aggregates of people such as societies or governments or humankind. Most work in the field revolves around two related goals: understanding person-environment transactions and using this knowledge to address real-world issues. Some environmental psychologists feel more comfortable formulating theoretical principles, whereas others are more interested in practical applications. The situation is similar to that in medicine, where some physicians conduct laboratory research and others go into clinical practice.

RESEARCH AND PRACTICE

Both research and practice are important. Research sometimes confirms hunches or corrects misconceptions about person-environment transactions. The following are only a few examples of conclusions from research that run counter to conventional beliefs: Crowding is *not* strongly related to the number of other persons in a space; human territoriality is *not* primarily associated with aggression; paper cups are *not* environmentally superior to Styrofoam cups, and full-spectrum lighting is *not* necessarily better for people in that it does not, for example, improve productivity or health. Every person-environment transaction is governed by a multiplicity of influences. No single factor shapes human experience and behavior.

Other environmental psychologists prefer to apply knowledge. Instead of working in an academic setting, where most researchers work, they venture into private practice or work for governments. After appropriate training they operate as consultants or civil servants. The practicing environmental psychologist makes good use of research findings to develop policy proposals or to assist a client to improve, for example, the design of spaces such as offices, residences, streets, or parks. Some are mainly interested in improving the built environment, and others are dedicated to addressing concerns about the sustainability of global ecosystems.

Although environmental psychology investigates the same major processes as mainstream psychology (for example, human development, cognition, learning, social relations, and abnormal behavior), it does so in the everyday physical settings in which these activities typically occur. In the words of one of the field's pioneers, Roger Barker, "The awful truth dawned upon me that, although I was well informed about the behavior of children when confronted with tests and experiments devised by scientific investigators, I knew no more than a lay person about the situations and conditions the towns provided their children and how the children behaved" ("This Week's Citation Classic" 1980, p. 10).

THEORY

Theory is a diverse and evolving aspect of environmental psychology. Here is a list of seven of the most promising theoretical approaches:

1. The adaptation-level approach begins with the assumption that people become accustomed to a given level of environmental stimulation. The

common occurrence of too much or too little stimulation is the focus of theories of arousal, overload, stress, and restricted environmental input.

2. A second type of theory emphasizes the importance of an individual's real, perceived, or desired control over stimulation and gauging degrees of reactance, learned helplessness, and boundary regulation.
3. Ecological psychology asserts the importance of behavior settings—naturally occurring, small-scale social-physical units consisting of regular patterns of person-environment interaction.
4. The human-interdependence paradigm advances the idea that humans make decisions, consciously or not, to use or overuse natural resources, and that these decisions will have profound effects on the environment and ourselves.
5. Integral approaches such as interactionism, transactionalism, and organismic theory attempt to describe the full, complex interrelationship between persons and settings.
6. Operant approaches downplay abstract principles, instead adopting a direct problem-solving approach that employs behavior-modification techniques.
7. Environment-centered theories such as the spiritual-instrumental model, conservation psychology, and ecopsychology raise the issue of the environment's own welfare and its ability to support human well-being.

METHODOLOGY

Environmental psychologists assume that person-environment transactions are influenced by many different factors that have led to multiple paradigms for studying them. They use a wide variety of research methods, some standard in social science and others devised especially for environmental psychology. A method devised especially for environmental psychology, for example, is post-occupancy evaluation (POE). POE is an assessment of how a newly designed building or outdoor space is working for those who use it (Zeisel 2006). The strong preference for performing research in the everyday world means that field studies are common. Sometimes laboratories and simulated settings are necessary, but they are used primarily when a field study is not possible. Researchers in environmental psychology often undertake experiments that seek to isolate causes and effects. Field experiments, although rarely feasible, are the best route to external validity, which is the generalizability (or applicability) of the findings from one study to a different place, population, or set of conditions. Field experiments often seem to have greater external validity because they are conducted in the same or similar conditions that exist in the place or setting to which one wishes to apply a study's findings. Quasi-experimental research designs that use elements of both experiment and field studies are much more common.

Environmental psychology employs three levels of analysis. At the most basic level are studies of fundamental psychological processes like perception, concern, cognition, and personality as they filter and structure our experiences of the physical environment. Next comes the management of social space: interpersonal distancing (or personal space), territoriality, crowding, and privacy. Third, environmental psychologists concentrate on the ways in which physical settings inform of complex modes of everyday behavior such as working, learning, living in a residence and community, and interacting with nature. The most important insights that arise from these kinds of analysis are better designs of the built environment and improvements in the sustainability of the human management of natural resources.

The face of environmental psychology varies with national and regional concerns, but it retains a fundamental commitment to understanding and improving relations between humans and their environments. Environmental psychology is at the forefront of a movement to make psychology more relevant to everyday life, but it is still challenged to find more ways of transforming knowledge into practice, devising methods that are better able to accomplish its goals, reaching a wider consensus about its nature and mission, and developing more comprehensive theories.

ENVIRONMENTAL RACISM

SEE *Environmental Justice.*

ENVIRONMENTAL SOCIOLOGY

Environmental sociology emerged as a field of study in the 1970s in response to widespread societal awareness of environmental problems and the resulting social mobilization on behalf of environmental protection. Early sociological analyses focused on the rise of environmental degradation as a social problem, including the origins, composition, and activities of the environmental movement; the levels and social bases of public support for environmental protection; and the dynamics of governmental policy making. These efforts involved applying traditional sociological perspectives (e.g., social movements theory) to environmental issues and constituted a ''sociology of environmental issues.''

DEVELOPMENT OF THE FIELD

The energy crisis of 1973–1974 reinforced escalating claims of ''limits to growth'' and stimulated a new dimension in sociological work on environmental topics. The increased salience of resource-based limits to growth, along with rapidly mounting evidence of the seriousness of environmental pollution, led some sociologists to examine the relationships between modern industrial societies and their physical environments. Concern with how modern societies were affecting their environments and with how these societies could in turn be affected by changing environmental conditions (from polluted communities to resource shortages) stimulated analyses of societal-environmental relations and heightened recognition of the need for a true ''environmental sociology.'' Sociological examinations of societal-environmental relations, however, involved a major deviation from disciplinary norms.

Sociology became a distinct discipline about a century ago and subsequently evolved during an era of resource abundance, technological progress, and economic growth. As a result, sociology became grounded in a cultural worldview that assumed that scientific and technological developments had freed industrial societies from ecological limits and that environmental factors were no longer relevant for understanding social change. This assumption was reinforced by negative reactions to earlier excesses of ''environmental determinism,'' such as geographers' efforts to explain cultural differences via climatic variation. Consequently, mainstream sociology came to ignore the physical environment. For sociologists ''the environment'' typically signified the *social context* of the phenomenon being studied.

Sociological interest in the societal impacts of energy shortages and the long-term implications of limits-to-growth thus represented a significant disciplinary development. Work on these topics was quickly supplemented by research on the social impacts of toxic contamination and other forms of pollution, as well as examinations of the societal factors that contribute to environmental degradation and excessive resource use. By the 1980s increasing numbers of sociologists were analyzing the societal causes and effects of environmental problems, and environmental sociology was well established as a distinct area of specialization despite its departure from disciplinary norms.

Because inequality is a core sociological concern, it is not surprising that environmental sociologists emphasize the equity dimensions of environmental problems: the unequal contributions of different sectors of society to environmental degradation and the inequitable impacts of such degradation on different social strata. Evidence that lower socioeconomic strata and minority groups often experience disproportionate exposure to environmental contamination has led to environmental justice becoming a major focus of environmental sociology, encompassing analyses of the ''EJ Movement'' that has arisen in response to these inequities. Increasing attention is being given to the international dimension of environmental inequality, with numerous studies examining the unequal contributions of rich and poor nations to global environmental degradation and the inequitable burden the resulting impacts are likely to have on poor nations.

EVOLUTION OF EARLY EMPHASES

Although empirical research on societal-environmental relations has increased dramatically, often in the form of highly quantitative studies, analyses of the factors influencing societal awareness of environmental problems and actions designed to ameliorate them remain popular among environmental sociologists. Continuing work on public opinion, mobilization of environmental activism, and policy making has been supplemented by studies of the use of scientific information by environmental advocates in framing their claims for media and public consumption. Studies investigating the bases of support, ideologies, and tactics of *antienvironmental* interests are also becoming more common.

Analyses of the social construction of environmental problems were revitalized by the popularity of postmodern approaches in sociology in the 1990s. Efforts to ''deconstruct'' climate change and other problems stimulated a

vigorous debate between proponents of established realist and newer constructivist approaches. Realists argued that deconstructing the concept of nature, an obvious human construction, fails to challenge the reality of human-induced changes in ecosystems that cause problems for human societies. Constructivists responded that they were not denying the "reality" of environmental problems in their efforts to problematize environmental claims and knowledge, whereas realists acknowledged the role of social processes in transforming environmental conditions into "problems." Consequently, the debate has subsided.

There is continuing examination of the processes by which various conditions are constructed as problematic, including analyses of the claims and tactics used by both promoters and deniers of problems such as global climate change. Besides analyzing the competing discourses of the two camps and their relative success in gaining media and public attention, environmental sociologists continue to rely on traditional approaches such as surveys of the public and relevant interest groups in order to understand societal attention to environmental issues. Using both original and secondary survey data, sociologists have tracked trends in public concern about environmental problems and the distribution of such concern across various sectors of society. Along with other behavioral scientists, sociologists have contributed to the conceptualization and measurement of "environmental concern," as well as to theoretical models designed to predict pro-environmental behaviors (including environmental activism) based on a combination of social-structural and social-psychological variables.

While attempts to measure endorsement of an environmental ethic by means of survey research are rare, recent efforts to identify the value bases of environmental concern have examined the relative impact of biospheric, altruistic, and egoistic values. Since there is a loose correspondence between biospheric values and an environmental ethic, this work sheds light on the degree to which such an ethic is emerging among various sectors of society and seeks to understand its impact on relevant attitudes and behaviors.

In contrast to the 1970s, currently there is widespread recognition that environmental problems are "people problems": They are caused by human behavior, are deemed problematic primarily because of their potential harm for humans (and other species), and collective human action is required for solving them. Environmental sociology has made major progress in understanding these crucial issues, and this knowledge is relevant for other disciplines and policy-makers interested in environmental issues.

ETHICAL EXTENSIONISM

Ethical extensionism is an approach to environmental and animal ethics in which the scope of ethical theories is extended to cover beings traditionally thought to fall outside the purview of those theories. As traditionally understood, the dominant moral theories in Western philosophy restrict the class of morally considerable beings to currently existing human beings. Extensionists contend that this restriction is arbitrary and antithetical to those theories. They insist that a proper understanding of these ethical theories requires expanding the sphere of morally considerable beings to include beings other than currently existing humans.

Anthropocentric extensionists expand the sphere of moral concern to include future humans. Nonanthropocentric extensionists maintain that the domain of morally considerable beings must be expanded further to include various nonhuman beings. For example, animal liberationists expand the domain to include conscious sentient animals. Biocentrists extend the sphere of moral concern to include all living organisms.

Proponents of ethical extensions insist that expanding the domain of morally considerable beings in these ways is not an ad hoc amendment aimed at addressing a particular moral issue but is rooted in a principled and rigorously consistent application of classical moral theories. Utilitarian and deontological extensions illustrate this point.

UTILITARIAN EXTENSIONISM

Hedonistic utilitarians maintain that pleasure is the only thing intrinsically good and pain is the only thing intrinsically bad and seek to maximize intrinsic goodness and minimize intrinsic badness. Accordingly, they hold that an action A is right for an agent if and only if, out of all the actions available to that agent, action A maximizes pleasure and minimizes pain for all affected. Despite the fact that the founder of utilitarianism, Jeremy Bentham, explicitly argued that animal suffering should be included in the utilitarian calculus, in practice utilitarians traditionally have factored only human pleasures and pains into their calculations.

Peter Singer (1975) contended that restricting the domain of morally considerable beings to human beings is arbitrary and antithetical to the spirit of utilitarianism. He argued that any being capable of suffering has an interest in avoiding suffering and that any being with interests deserves to have those interests taken into account equally with all other similar interests. Because many of the animals people eat and perform biomedical experiments on are capable of feeling pain, there is no legitimate reason not to take those animals' interest in avoiding pain into consideration when carrying out utilitarian calculations. Because pain is pain no matter what being experiences it, Singer argued, there can be no moral justification for not taking animal pain into account. Singer's conclusion is that utilitarianism, consistently applied, requires people to take into account the interests of all sentient beings and to give equal interests equal weight in utilitarian calculations.

DEONTOLOGICAL EXTENSIONISM

Tom Regan's (1983) case for animal rights can be viewed as an extension of Immanuel Kant's deontological ethic. The "respect-for-persons" formulation of Kant's categorical imperative commands people to treat persons "always as an end and never as a means only" (Kant 1959 [1785], p. 47). In Kant's view persons are subjects deserving of respect, not mere objects to be used and discarded. When an agent treats a person as a mere means, that agent acts wrongly, for he or she treats an intrinsically valuable subject as a mere object. Kant equated *persons* with rational beings but incongruously held that all and only human beings are persons. The problem with Kant's account of personhood—if rationality is understood as an empirically testable capacity to solve practical problems in a rudimentary logical way—is threefold: (1) Not all human beings are rational; (2) not all nonhuman animals lack rationality; and (3) there is no good reason to restrict personhood to rational beings.

Regan (1985) argued that Kant's account of personhood is too strong, at least if personhood is required for full moral considerability. As Regan (1983, 1985) sees it, the issue is less about personhood and more about which beings are owed full direct moral consideration. Nevertheless, he can be viewed as offering an alternative, more expansive account of personhood.

Regan recognizes that on a consistent reading of Kant's criterion (provided that Kant means by rationality some empirically verifiable mental capacity), some human beings (e.g., the severely retarded) would not be persons and thus would not deserve respect under the categorical imperative. Regan contended that rational or not, those human beings are persons deserving of respect. What makes them persons, according to Regan, is the fact that they are experiencing subjects of a life (ESLs), that is, conscious creatures that have an individual welfare that is important to them regardless of their usefulness to others. Such beings are inherently valuable subjects (not mere objects) and deserve to be treated in ways that respect their value. A consistent application of the ESL criterion of personhood indicates that many of the animals people eat and experiment on are persons with inherent value and thus have a right to be treated in ways that respect their value. The upshot of Regan's argument is that the respect-for-persons imperative, properly understood, requires that people respect all ESLs, whether they are human or nonhuman, as inherently valuable ends and never treat them as mere means.

Albert Schweitzer took the Kantian respect-for-persons ethic and expanded it into a reverence-for-life ethic. Harkening back to the post-Kantian metaphysics of Arthur Schopenhauer (1966 [1819]), Schweitzer (1923) reported that he had a profoundly moving experience watching four hippopotamuses and their young plod along that led him to see that all life possesses the same will-to-live that every person possesses. Once one notices that all life has the same will-to-live that one finds in oneself, one will see that morality requires that all life be respected, not just human life.

ANTHROPOCENTRIC AND NONANTHROPOCENTRIC EXTENSIONISM

Joel Feinberg (1974) argued that any being with a good of its own has interests and that any being with interests has rights. He used the second thesis, which he called the "interest principle," to defend both nonanthropocentric and anthropocentric extensions. In regard to the first extension, Feinberg noted that many higher animals "have appetites, conative urges, and rudimentary purposes, the integrated satisfaction of which constitutes their welfare or good" (1974, p. 50). Because these animals have a good of their own, they have interests and a correlative right against people to respect their interests. Feinberg's anthropocentric extension requires extending rights to future human beings. Feinberg observed that whoever these future human beings turn out to be, they will have certain interests, including an interest in a habitable environment, that people can affect

for better or worse right now. Because future human beings have an interest in a habitable environment, Feinberg concluded, they have a right against contemporary people to be left such an environment.

Kenneth Goodpaster (1978) pointed out an inconsistency in the way Feinberg applied his account of interests to defend a biocentric ethic. Feinberg restricted the class of interest possessors to human beings and higher animals, but this restriction is inconsistent with his stated account of interests, which holds that any being with a good of its own has interests. Feinberg argued that "mere things" have no unconscious drives, no latent tendencies, no directions of growth, and no natural fulfillments and that, therefore, mere things lack a good of their own. However, as Goodpaster observed, plants and all other living organisms have unconscious drives, latent tendencies, directions of growth, and natural fulfillments. Thus, they are not mere things. In addition, all living organisms are such that some conditions are good for them and other conditions are bad for them. Hence, they appear to have a good of their own. Consequently, a consistent application of Feinberg's account of interests entails that all living organisms have interests. Goodpaster concluded that because all living organisms have interests, all living organisms deserve moral consideration. He was, however, careful to point out that the fact that all living organisms are morally considerable does not imply that all living organisms have comparable moral significance.

Synthesizing Singer's egalitarianism with Schweitzer's reverence for life and the Feinberg/Goodpaster account of moral considerability, Paul Taylor (1986) developed and defended an egalitarian biocentric ethic. Taylor contended that by adopting the ultimate moral attitude of respect for nature, people naturally will be inclined to behave properly and responsibly toward the natural world. He maintained that all living things are "teleological centers of life" and as such have a good of their own and went on to argue that every being with a good of its own possesses equal inherent worth and deserves equal moral consideration. Thus, Taylor concluded, every living organism deserves equal moral consideration. It might be objected that in extending equal moral consideration to every living organism, Taylor has taken biocentric extensionism to an absurd extreme, but he tries to mitigate this objection by formulating a complex system of rules for adjudicating and resolving the conflicts that inevitably will arise between these equally considerable organisms.

CRITICISMS

Critics of ethical extensionism contend that piecemeal extensions of the dominant individualistic approaches to ethics cannot give rise to an adequate environmental ethic because individualistic ethics, which privilege individuals over ecological wholes, fail to address people's actual environmental concerns. Many environmentalists are not concerned about the welfare or well-being of individual shrubs, bugs, and grubs; rather, they are concerned about species preservation, ecological integrity, and air and water pollution. These critics of ethical extensionism contend that an emphasis on individual welfare and individual rights is one source of many current ecological and environmental crises. Thus, they recommend the wholesale rejection of all the dominant individualistic ethics, even in their more inclusive extensionist versions, in favor of more radical holistic ethics such as Aldo Leopold's land ethic and Arne Naess's Deep Ecological approach.

ETHICS OF CARE

Proponents of an ethic of care consider relationships central to moral life. The disposition to care for particular others and the practice of caring for others are

sources and priorities of morality. Relations give rise to obligations; a caring ethical behavior is one that maintains connection and fosters the well-being of someone to whom a moral agent stands in relationship. Some authors who write about care ethics have limited the moral arena of caring relationships to humans. In environmental ethics attention to human relationality and desire to care has been expanded to include dependent animals (Curtin 1996) and the natural world (Warren 2000), ''in which all such relationships are ultimately nested'' (Mann 2006, p. 356).

EARLY WORKS AND CONNECTION WITH FEMINISM

The two most influential early theorists of care at the turn of the twenty-first century were the psychologist Carol Gilligan (1982) and the philosopher Nel Noddings (1984), both of whom observed that insofar as women are more often caregivers, they are more likely to prioritize care-based considerations than are men. Because women's experiences with care often reflect aspects of traditionally feminine roles, feminist philosophy has been especially attentive to the ethics of care, sometimes supportively and sometimes critically. Ecofeminism, which views the oppression of women and the domination of nature as interrelated, tends to incorporate care-based elements either explicitly or indirectly.

Those elements were articulated in 1982 by Gilligan in *In a Different Voice*. Gilligan did not endorse an ethic of care. Rather, she described a noticeable difference between two patterns of reasoning about moral problems. A ''justice perspective'' reflects traditional Kohlbergian conceptions of human moral development, proceeding through stages beginning with self-interest, through deference to authority, and culminating in universal ethical principles. A ''care perspective'' focuses on context, relationships, and emotional information.

Instead of taking a rule or principle as primarily important and applying it to a situation, a person informed by the care perspective takes the situation and its relationships as primarily important and recommends actions that are based on what the relations require. In Gilligan's study, almost all the males adopted the justice perspective and about half the females were as likely to adopt the care perspective. Gilligan did not rank care over justice but suggested that both voices are complementary and necessary. Her data and methods immediately became the subject of much debate. However, her arguments for seeing care as an alternative moral framework lent themselves to emerging ethical theories of care.

In *Caring: A Feminine Approach to Ethics & Moral Education* (1984) Noddings similarly focused on women's experiences with and interests in caring. She added an argument for the superior value of a care ethic on the grounds that traditional Western philosophical concepts, especially universal prescriptions, rationality as opposed to emotionality, and adversarial rights-based individualism, serve to harm individuals by preventing the very emotional and interpersonal sympathetic connections which promote caring for the well-being of others.

In place of those concepts Noddings developed the key concepts of relationality, affective response, and reciprocity. Relationality denotes the inevitability of the human encounter and relationships, especially unequal relationships, as constitutive of one's identity. Affective response refers to the central capacity to respond emotionally to others; in an ethic of care emotions are valuable sources of information rather than obstacles to rationality, as some Western philosophies have portrayed them. Reciprocity is the most controversial of these concepts, intended to refer to recognizable reception of care rather than to contractual notions of equal repayment. In Noddings's account, for example, even newborn babies reciprocate; she describes the thriving of the cared for as a variety of reciprocity.

Relationality is not limited to human encounters. As early as the 1970s and 1980s environmental ethicists debated varieties of holism, a conception of value that was attached to systems and to relationships within systems as opposed to a tradition of seeing only individuals as having inherent worth. Ecofeminists similarly have argued that relationships are ubiquitous. Some ethicists who argued for holism and ecofeminism therefore extended key concepts of care ethics. Because the care ethic insists on attending to relations between unequals as an integral part of moral life, environmental care ethicists do not have to debate whether humans and nonhumans are equal, as justice-oriented environmentalists often do. Any responsive system or individual being with whom one stands in relation is a candidate for caring.

CRITIQUES AND DEBATES

Most critical debates question the wisdom of valuing feminine care as liberatory or as a solution to the problems of a male-dominated world. The presence of the word *feminine* in the subtitle of Noddings's book has moved some feminist ethicists to suggest that when feminine caring is conducted in a patriarchal context, it leads people to losing themselves in their relationships to others, even to the point of exploitation of the caregiver.

Carolyn Merchant wrote about a related concern: ''An ethic of care, as elaborated by some feminists, falls prey to an essentialist critique that women's nature is to nurture'' (Merchant 1996, p. 8). Merchant offered a fairly comprehensive survey of environmental ethics and incorporated care elements into a ''partnership ethic of earthcare,'' taking pains to assert that women do not possess a special ability to care (Merchant 1996, p. 212).

Environmental ethicists who argue for care also debate the value of reciprocity as a component of caring relationships. Deane Curtin (1996) explicitly rejected the necessity of reciprocity to caring, holding instead that ecological care requires a sensitive and emotional capacity to care for the natural world. Other environmental care ethicists prefer to broaden the definition of reciprocity or offer an alternative, as Bonnie Mann did by prioritizing interdependence, suggesting that "our dependency on the earth" is "the source of the moral call to care" (Mann 2006, p. 143).

Despite these debates regarding how to extend care to the environment, many ethicists and ecofeminists agree that a framework of care offers a preferable method of moral reasoning about the environment. The traditional justice-oriented perspective is used to establish the worth of individuals in nature by identifying some universally shared characteristic that endows rights, often with an eye to debating who wins in rights conflicts. Ethics of care identifies the ways in which natural beings are not isolated but interrelated and not necessarily adversarial, instead possessing natural desires to assure the well-being of others.

EUROPE

This entry contains the following:

I. MEDITERRANEAN

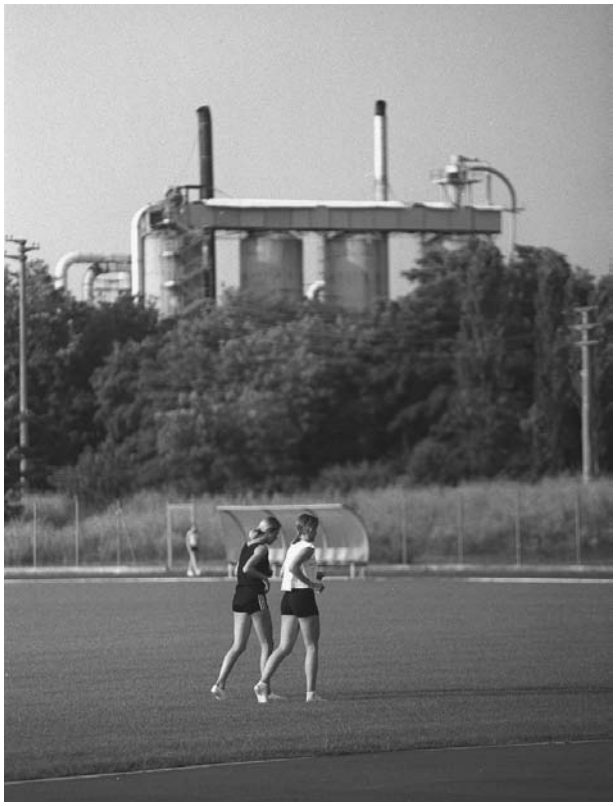
Although Greek and Latin philosophy inform contemporary Western reflections on the relationship between nature and society and between natural and human-made norms, the concept of natural law has been used more as a legitimization of social norms than as a foundation for the protection of nature. This long-standing philosophical tradition has not provided the grounds for a Mediterranean philosophy of the environment. The adjective *Mediterranean* may be used as an interpretive environmental concept that refers to the management of specific environmental issues, such as the sharing of natural resources (coasts, seas, landscapes, species protection, etc.), that require joint policies among the countries facing the Mediterranean Sea. In this context a strategic common vision has led to the adoption of normative and economic measures in agreements of the Council of Europe.

From a cultural point of view the differences between the regions of the Mediterranean area as a whole are more apparent than the similarities. Some Mediterranean countries, such as France, Spain, and Portugal, hardly can be considered Mediterranean because of the major influence exerted by the cultures of their northern areas. Therefore, the term *Mediterranean* is used in this entry primarily to refer to Greece and Italy.

This is the case not only for the environment but also for biotechnology, in which the economic and political presence of the European Union (EU) has led to a harmonized normative framework among member states in both northern and southern Europe. In the context of the common innovation policies endorsed at the European level, the EU has triggered and fueled debate over and the development of different ethical and epistemological positions on the environmentally related topics of risk and safety, intellectual property rights to genetically modified crops and animals, and the role of citizens in the relationship between science and society.

ENVIRONMENTAL ISSUES AND PHILOSOPHIES

The environmental movement in Greece started in the 1970s as it did in many other European countries, but in comparison to those countries it did not become a well-established and deeply rooted green social movement (Koutalakis 2004, Kousis 1999, Roumeliotou 2001). A number of factors have been cited to explain the lack of an environmental consciousness in Greece. The economic situation of that country did not allow the expenditure of funds for environmental protection. The protection of the environment initially was conceived in instrumental/reward terms, namely as an economic



Seveso, Northern Italy. *Joggers run on a sports field built over the Icmesa chemical factory in Seveso. On July 10, 1976, a reactor explosion at the factory released a toxic chemical cloud, causing Italy's worst ecologic disaster to date.* **AP IMAGES.**

necessity potentially increasing opportunities for development, and later in terms of generalized beliefs or values. However, starting in the late 1980s, as a result of the development of democratic forms of civic involvement and the implementation of European environmental policies, environmental thought began to connect science, engineering, policy, and philosophy. Greek contemporary environmental philosophy reflects those heterogeneous beginnings; Michalis Modinos, the founder and publisher of the journal *The New Ecology,* is a geographer, an engineer, a philosopher and an activist.

In Italy environmental concerns emerged after ecological crises in the chemical industry in the 1970s. In 1976 the accidental release of tetrachlorodibenzoparadioxin (TCDD), commonly known as dioxin, in Seveso (Milan) raised citizens' consciousness of the interconnections of the social and natural environments. This led to the enactment by the European Communities of the two so-called Seveso Directives (Directive 82/501/EEC, replaced by Directive 96/82/EC), which were aimed at the prevention and control of major accidents involving dangerous substances and the limitation of their consequences for humans and the environment.

Environmental philosophy and ethics have been imported from North America and Northern Europe. The vehicle for building an environmental perspective and establishing environmental philosophy as an academic field has been the translation of foreign literature, starting with Sergio Bartolommei's translation, in 1987, of Aldo Leopold's *A Sand County Almanac*. This dissemination of literature has allowed the development of writing on the relations between humans, nonhumans, and the environment that have involved or developed the traditions of utilitarianism, theories of rights, and theories of values. These writings generally have supported various forms of weak anthropocentrism, although there also have been discussions of Deep Ecology.

German philosophy, especially Hans Jonas's imperative of responsibility, has been a major influence on authors whose philosophical background is in traditional metaphysics. In these ways of framing environmental issues the concept of nature is a more metaphysical and value-laden notion than is the environment and serves as a link to traditional ontology. Both in Greece and in Italy environmental visions have been framed that are consistent with the idea of human stewardship of nature (Morandini 2007a, 2007b) as well as with ecologically oriented interpretations of God's creation within a Christian theological perspective. In Greek contemporary thought an ecological understanding of Orthodox theology has been proposed as an intrinsic ecological vision of humans and the natural world (Chryssavgis 2003). In Italy there has been an ongoing controversy between Roman Catholic doctrine and most lay philosophies of the life sciences. The Church has supported the natural law tradition as a source for environmental and bioethical values, whereas most secular philosophers oppose its use as a normative concept (Bartolommei 1989, 2003).

Other philosophical works have attempted to go beyond a narrow anthropocentric perspective, often emphasizing perceptual and aesthetic sensibility as an indicator of deeper human dimensions and as a route toward reforming or reframing people's lifestyles. The reappraisal of mental capabilities that seem to resist reductionist explanations was explored by Luigi Lombardi Vallauri (2002) as a potential foundation for a different conception of human beings and their position in the world. The human capacity for wonder about the natural world and animals is seen as a manifestation of an "ontological human noblesse." Human knowledge and self-knowledge generally are conceived of as privileged ontological or biological positions that justify the exploitation of the environment. However, for Lombardi Vallauri these capacities entail more obligations toward the world. In fact, as applications of noblesse oblige, they require greater respect for other species and the environment. According to this perspective, acting ethically is a transformative experience that leads to a fully realized

human condition rather than representing simple compliance with a precept. This is a form of respect that is consonant with the idea of *ahimsa,* or nonviolence. Lombardi Vallauri refers to this condition with the classical Greek word *pleroma,* or plenitude of being.

An approach that is within a more analytical tradition involves a theory of intrinsic value. Laura Mai (2008) proposed that both nonhuman subjects and environmental entities must be approached with a nonnaturalistic form of realism that involves human emotions toward animals and the environment.

ANIMAL RIGHTS AND WELFARE

In the 1980s, the introduction in Italy of philosophies of animal rights and welfare through the work of Silvana Castignone (1985) gave rise to debates and increased consciousness of the treatment of animals in an area that had been insensitive to this issue on both cultural and religious grounds. In its widely differentiated philosophical approaches, ranging from an extension of human rights to welfare theories and practices, this field has been populated by several women scholars and activists. Castignone's work on animal rights encountered resistance in the Italian academic community, where it was perceived more as a personal commitment than as a scholarly contribution. However, cultural and normative developments quickly changed that perspective. Discussions of animal ethics accompanied the implementation in the early 1990s of European conventions and directives that made the philosophy and practice of animal welfare mandatory in animal experimentation, transgenic animals, and animals kept for farming purposes.

Also in the 1990s, in the international philosophical community, work by Paola Cavalieri and Peter Singer (1993) led to the recognition of rights for nonhuman primates. Other approaches include the need to combat suffering in and violence against sentient beings (Battaglia 2002) and the anthropozoological approach of Anna Mannucci (2001), in which the deep anthropological meanings of long-standing relations between humans and nonhumans are analyzed.

ENVIRONMENTAL PHILOSOPHY AND BIOTECHNOLOGY: LAND AS A SOURCE OF TRADITIONS

In Italy environmental disasters caused by the chemical industries initiated debate and led to the enactment of legislation, sometimes on a European scale. With the rise of biotechnology European institutions have worked on regulating biotechnological products and processes in terms of both safety and protection of intellectual property rights (patentability). That legislative effort led to the approval of a directive on the deliberate release of genetically modified organisms (2001/18/EC) and a directive on the legal protection of biotechnological inventions (98/44/EC) (European Communities 1998, 2001).

Those European laws generated resistance and public concern and have become a source for original thought on these issues (Menrad, Agrafiotis, Enzing, Lemkow, and Terragni 1999). The Netherlands, supported by Italy, opposed legislation on "patenting life." The legal controversy ended in 2004, and Italy implemented the directive in 2006. Public discussions about genetically modified organisms (GMOs), especially GM food, have been more complex. In 2004 the Greek government adopted a position against the EU rules, forbidding trade in seeds for several genetically modified corn hybrids. In Italy, after the approval in 2003 of the European regulation on coexistence among GM, conventional, and organic cultivation (Regulation 1829/2003) (European Communities 2003), several regions refused to comply with it. In fall 2007 several nongovernmental organizations, including the Foundation for Genetic Rights, Coldiretti, the World Wildlife Fund, and Slow Food, organized a public campaign to support GM-free agriculture.

The controversial issues of the risks and patentability of GMOs have been the subject of an ample literature on biotechnology and its meaning in terms of the relationship between technoscience and democratic societies. In addition, debate has surrounded the understanding and development of the precautionary principle, a concept established at the European level that is intended to introduce a prudent approach to the unknown potential threats to environmental, human, and animal health triggered by new technologies.

Precaution has provided the ground for conflicts between NGOs and the scientific community that interprets the precautionary principle as a form of antiscientific, irrational and obscurantist thought. It has become a synonym for a debate between those opposed to and those in favor of science.

This reflection on the meaning and implications of scientific uncertainties about the relationship between science and society has led to attempts by some authors (Tallacchini & Terragni 2004) to devise an enlarged perspective on bioethics and environmental philosophy. The precautionary principle thus has become central to the debate about public involvement in science-based decisions as a way to extend and democratize decision-making processes and to the discussion about the benefits provided by GM food in agricultural systems that are based mostly on the quality of local production (Genetic Rights Foundation 2006b).

In Europe the rise of biotechnology in the early 1990s coincided with the attempt, starting with the Maastricht Treaty of 1992, to transform the European

market into a political union as part of the construction of an identity for Europe. Consequently, biotechnology has become associated with the maintenance of different regional identities; it has been perceived of as a threat to the survival of different cultures and values.

In this respect and despite the differences between Greek and Italian environmentalism, there has been a sharing of perspectives involving theorizing about landscape. In both regions there is a vision of the cultural, historical, human-made landscape that is quite different from the American vision of wilderness.

The roles that human-made landscapes in both countries have played historically as structural elements and mirrors of social and cultural identities, along with the increasing loss of these sites, have become major themes for writers such as Michalis Modinos (1996, 1998) in Greece and Eugenio Turri (1979, 2004) and Alberto Magnaghi (2005) in Italy. They and others have called for a geographical philosophy. The tendency of metropolitan and rural postindustrial landscapes to become homogeneous and indistinguishable is associated with a loss of cultural and personal identity and the need for reestablishing an anthropobiocentric dimension of life.

The importance of the landscape as a cultural value also is reflected in the Italian constitution of 1948, which in narrowly anthropocentric wording "safeguards natural beauty and the historical and artistic heritage of the nation" (Article 9). This principle represented the starting point for an attempt to include the environment among constitutionally protected goods. The Greek constitution of 1975 reaffirms the cultural dimension of land in an updated and environmentally aware perspective, stating that "[t]he protection of the natural and cultural environment constitutes a duty of the State" (Article 24).

II. WESTERN

This article covers environmental issues and philosophies in Germany, the Netherlands, France, Spain, and Portugal.

GERMANY

The first conscious recognition of the overexploitation of nature can be found in the writings of the German forester Hans Carl von Carlowitz (1645-1714). In 1713, in the middle of a wood supply crisis, he coined the term *sustainable* (*Nachhalt*). He proposed that the amount of wood harvested should not exceed the amount that could be regrown in the same period of time. He invoked the welfare of future generations in arguing for this policy.

The end of the eighteenth century saw radical modifications in the German landscape, such as the draining of wetlands, diking of the Rhine, and the gradual industrialization of agriculture. From the outset, modernization was perceived ambivalently: on the one hand, scientists and engineers as well as many politicians touted the material gain; on the other, intellectuals—especially in the Goethean romantic traditions—mourned such changes as a cultural loss.

In the years before the First World War, a conservation movement became widespread and sorted itself into several non-governmental organizations. It also exerted some influence on legislation. Noteworthy is a speech made by Ludwig Klages (1872-1956) in 1913, in which he accused Western civilisation of destroying the beauty and plenty of nature at a global scale and at a high speed on behalf of progress, utility, wealth, and civilization. Long before Lynn White's "*The Historical Roots of Our Ecologic Crisis,*" (1967), Klages blamed the destruction of nature on the putative Christian doctrine that man should subdue nature. Klages thought that rationality and even ethics could be blamed for supporting this escalating "war against nature."

Because the time between the world-wars was characterized by sharp political conflicts and a deep economic crisis, many conservationists hoped that conserving nature could become a common and unifying concern. A vegetarian diet, long-distance hiking, nudism and communal living in the countryside were part of the so-called *Lebensreform* and *Wandervogel* movements in Germany.

Perceiving U.S. consumerism to be creeping in from the West and Soviet Communism lurking in the east, many were afraid to lose the national identity. For such reasons, leading conservationists (P. Schultze-Naumburg, W. Schoenichen) supported National Socialism. To many conservationists, the naturalistic doctrines and Fascist ideology of the Nazis seemed very close to holistic approaches in ecology. In 1933, most conservationists supported the new order, some with enthusiasm.

Thus the time between 1933 and 1945 constitutes a second stage of nature conservation. This was conceptualized within the overall doctrine of National Socialism and was indicated by the term *Blut und Boden* ("Blood and Soil"). It is perhaps characterized best by the aim to "Germanize" the occupied regions in Eastern Europe and to transform them into "Aryan" landscapes. Some planners constructed so-called military landscapes, which combined laudable environmental objectives with readiness for warfare. However, most Nazi policies with respect to nature were only symbolic; in reality, the use of nature was intensified, as wetlands were drained and forests were overused. At the end of World War II, the traditions of German nature conservation were thus deeply compromised.

A third stage of nature conservation was post-World War II *Umweltschutz* (environmental protection). In contrast to the explicitly value-laden *Blut und Boden,* this third stage took a more scientific approach and was part of an overall concern with environmental protection, especially issues such as air and water pollution. These problems were seen as by products of the economic success of West Germany. The conservation of species and biotic communities was justified with purportedly value-free functional arguments (e.g. the diversity-

stability-hypothesis). Nature conservation was thus perceived as ''applied ecology.''

In the late 1960s, members of the leftist counterculture rejected consumerism, proposed new lifestyles and protested against nuclear power plants and atomic weapons. This movement put environmental policy makers under pressure. Although much environmental legislation was passed in the 1970s, reform-oriented Social Democrats and Liberals who had done a good job putting environmental issues on the political agenda were heavily criticized for ''not doing enough.'' This peculiar combination of reform-oriented political administration, science-based policy counselling, and a civil society which made use of many strategies of political protest made German environmental policy relatively successful, but could not change the underlying pressures on natural landscapes.

In the former German Democratic Republic (GDR, or East Germany) the situation was different. While pollution was bad in some industrial areas, political protests against pollution were suppressed. Agriculture was intensified to supply the working class with highly subsidized bread and meat. Large areas were set aside for the Soviet army and for sport hunting by the political elite, and thus remained in a relatively natural state. Moreover, in comparison to West Germany, large areas of East Germany were less densely populated. It was a paradox of the communist economy that created extreme pollution in some areas, while other areas remained in a more or less pristine condition.

The political reunification of Germany in 1990 opened up new opportunities for nature conservation in the former GDR. The initiative of a small group of highly motivated people (Michael Succow, Hannes Knapp, Leberecht Jeschke) led to the creation of five national parks and several biosphere reserves. With the collapse of the GDR, pollution and carbon dioxide emissions decreased sharply and rehabilitation, revitalization and restoration of many polluted and destroyed sites took place. In 1994 the protection of the environment was added to the German constitution as an objective of the state.

In 1998, a coalition between Social Democrats and Greens established a federal ''red-green'' government. Between 1998 and 2005 this government initiated substantial environmental reforms: climate change policies; facilitation of renewable energy; a program to phase out nuclear power; a shift in agricultural policies to favor organic agriculture and strict regulation of genetically modified crops. A comprehensive sustainability strategy was established in 2000 at the national level that included a strategy to protect biodiversity. In the ''Grand Coalition'' of Christian and Social Democrats, climate change became a focus of German environmental policy. Further environmental modernization of German industries and consumer goods (such as cars, household devices, and chemical products) were prescribed to reduce material input and energy consumption.

Environmental Zone Warning in Berlin, Germany. *Cars drive past a sign indicating the new pollution class for cars in Berlin. Beginning January 1, 2008, Berlin restricted traffic for high emission vehicles in a new "environmental zone." To drive into the inner city, one must display a special pollutant group sticker on his or her car.* **ANDREAS RENTZ/GETTY IMAGES.**

History of German Environmental Ethics In Germany there is a long tradition of ethical reflections on the relationship between humans and nature. In Weimar's ''classical'' period (roughly 1790-1830), philosophers, scientists and poets (Herder, Schiller, von. Humboldt) gathered around Goethe and debated the scientific, aesthetic, and philosophical aspects of nature. The thinkers of the romantic era (roughly 1800-1820) perceived nature as an awe-inspiring world full of miracles, fairy tales, and mysteries.

The ethical philosophy of Arthur Schopenhauer (1788-1860), formulated in the mid-nineteenth century, was based on compassion, including mercy toward sentient animals. In 1923, Albert Schweitzer (1875-1965), building on Schopenhauer, published *Kultur und Ethik,* which advocated an ethics of reverence toward all life: It is wrong to take life and to destroy life, it is right to preserve life and to care for life.

In 1979, Hans Jonas's (1903-1993) *Prinzip Verantwortung* was published, forming a cornerstone in environmental ethics. Jonas argues that life affirms itself in the processes of metabolism and reproduction. This self-affirmation of life, Jonas argued, should be regarded as an ultimate value that exists ''out there'' in the natural world; it cannot be reduced to human preferences.

Jonas's ethics is, to some extent, biocentric, but Jonas distinguishes between the intrinsic value in nature and the dignity of humans.

Klaus-Michael Meyer-Abich grounded a holistic environmental ethics in the medieval philosophy of Nikolaus Cusanus. Meyer-Abich was engaged in three expert commissions of the German parliament, he was part of the government of the city of Hamburg, and he contributed to Working Group III of the Third Assessment Report of Intergovernmental Panel on Climate Change (IPCC) in 2001. In contrast, Gernot Böhme, in his *Phänomenologie der Natur*, proposed a phenomenological approach to environmental ethics based on the philosophy of Edmund Husserl. In the 1990s, Konrad Ott mapped all the contemporary arguments in environmental ethics to give a comprehensive overview to this new universe of discourse (*Ecology and Ethics*, 1994). Dietmar von der Pfordten (*Ecological Ethic,* 1994) gives an even more comprehensive overview than was provided by Ott.

The first German chair in environmental ethics, held by Konrad Ott, was established at the Ernst-Moritz-Arndt-University of Greifswald in 1997, in the "Landscape Ecology and Nature Conservation" program of the Biology Department. Environmental ethics is also offered at the universities of Tübingen Munich, Basel, Münster, and Kassel.

THE NETHERLANDS

In the Netherlands, a highly multicultural, liberal way of life thrives in a densely populated, widely urbanized space. There is intense agriculture and a coastline well suited for human recreation. Nature conservation cannot address unmodified natural landscapes, since there is no wilderness left. Environmental protection, the relation between environmental conditions and health, treatment of animals, food ethics, a critical approach on biotechnology, and restoration ecology are specific dimensions of Dutch environmentalism. There is also a distinctive environmental question concerning the status of "new nature."

The Netherlands face significant environmental challenges. The country has one of the world's highest per capita levels of industrial carbon dioxide emissions, and the country's rivers have suffered from significant amounts of agricultural and industrial pollution. To address these problems, in 1971 the Dutch created the Ministry of Health and Environment. While almost 6 percent of the nation's land is protected, a number of animal species are endangered, including the Atlantic Ridley turtle and the Atlantic sturgeon.

One distinctive aspect of Dutch nature policy concerns the concept of "new nature." Since the eleventh century more than 4.5 million hectares of new land has been created. This land first became dunes, rivers, forest, and farmland. In time, more industrial development became prominent, sometimes accompanied by severe pollution. Since the 1980s some have advocated returning this land to a more "natural" condition—despite the obvious irony that the natural condition of these lands was to be covered by the sea. This has also involved the release of domesticated animals such as Conic horses and Heck oxen in the hope that they will "re-wild." Questions have arisen concerning what if any ethical obligations are owed to protect species that have been domesticated for a very long time.

Finally, climate change presents an especially serious challenge to the Netherlands. With more than a quarter of the country below sea level, climate change is expected to punish the Netherlands by both rising sea level and the increase in the flow of the nation's rivers. While the greatest effects are expected in the second half of the twenty-first century, there have already been discernible signs of climate change.

Prominent Dutch environmental thinkers include Louke von Wensveen who writes mainly on environmental virtue ethics; Michiel Korthals who specializes in food ethics; and Frans Brom who works in the fields of genetic engineering and agricultural ethics. The expatriate (now in the United States) Irene Klaver works on international water issues.

FRANCE

In part because nature protection was so closely associated with Nazi *Blut und Boden* in Germany, environmental ethics was shunned as crypto fascism (or ecofascism) in France until the early 1990s. Nor in France was there much romantic poetry or philosophy to provide a nascent French environmental philosophy with a deep intellectual history. But by the 1990s the environmental crisis, especially in its second wave (as discovered in the 1980s)—massive species extinction, stratospheric ozone depletion and global climate change—could no longer be ignored by the French intelligentsia.

Michel Serres was the first French philosopher to enter the field with *Le contrat naturel*, published in 1990. The title alluded to *Du contrat social* by Jean-Jacques Rousseau, a prominent eighteenth century French philosopher, noted, among other things, for his version of the social-contract theory of the origin and nature of ethics. Contrary to Hobbes's version of that theory, Rousseau believed that in the "state of nature," prior to the formation of society and civilization, humans were naturally benign and were subsequently corrupted by the vices of civilization; thus, he was thought to have

romanticized the pre-civilized peoples of his imagination as "Noble Savages" (a phrase he himself did not coin). Serres is critical of modern technology and the science that informs it, which, in his opinion, has produced an environmental crisis that threatens not only the quality of human life, but human life itself. His deliberate association of his book with Rousseau's and his criticism of modernity led many of his French readers to think of him as a neoRomantic eschewing rationality in favor of some kind of spirituality or primitivism. In retrospect, however, Serres has turned out to be prescient.

Just as John Passmore, with his book *Man's Responsibility for Nature* (1974), tried to squelch the emergence of the new holistic non-anthropocentric environmental ethics broached in Australia by Richard and Val Routley (later Sylvan and Plumwood, respectively), so did Luc Ferry in France—not only that of Michel Serres, but that of many Anglophone environmental ethicists—with his book, *Le nouvel ordre écologique* (1992). Reminding his readers of the repugnant *Blut und Boden* environmentalism of the Nazis, Ferry expressly linked contemporary holistic, non-anthropocentric environmental ethics to the holism of German fascism in the 1930s and '40s. The would-be new tyrannical ecological order, Ferry argued, is a threat to the principles of the existing liberal democratic order. Among the Anglophone thinkers Ferry criticizes extensively for their allegedly fascistic tendencies are Aldo Leopold (who, as a matter of fact, visited Nazi Germany in 1935), Christopher D. Stone, J. Baird Callicott, the American Deep Ecologists (George Sessions and Bill Devall) and ecofeminists (collectively).

While Passmore had little adverse effect on the development of Australian environmental philosophy, Ferry apparently had a great adverse effect on the development of French environmental philosophy. Notable among the few philosophers to advance the field in France is Catherine Larrère. Her 1997 book, *Les philosophies de l'environnment*, summarizes several of the leading issues in Anglophone discussion of environmental philosophy with chapters on the intrinsic value of nature, animals and the environment, wilderness and its deconstruction, and the pluralism-versus-monism debate in theoretical environmental ethics.

Bruno Latour, who has a background in philosophy, anthropology, and sociology, is a founder of the new field of "science studies"—the successor to twentieth-century Anglo-American analytic philosophy of science, which treated not science as it is actually practiced, but as an isolated and abstract ideal divorced from its social context. Latour has also contributed to what might be called "environmental politics"—the French alternative to environmental ethics. In *Politique de la nature*, Latour shares the concern of Ferry that authoritative appeals by "scientists" to the "facts" of a reified "Nature" threaten liberal democratic politics. Nature, he claims, is socially constructed—most authoritatively by the scientific sub-set of society.

France shares with other Western European countries, such as Germany, the legacy of modern commercial and industrial development that has left environmental degradation and ecological destruction in its wake. France has, however, had a less robust environmental movement than other countries. While Germany has moved to reject nuclear power, the French public embraces nuclear energy unreservedly. France has fifty-six nuclear power plants generating 76 percent of its electricity, which gives France, a country with few fossil-fuel resources, a modicum of energy independence. As of 2008 no serious accidents had occurred, but the country had not yet come up with the final solution to the problem of nuclear waste disposal.

SPAIN AND PORTUGAL

Spain's most famous twentieth-century philosopher, José Ortega y Gasset (1883-1955), is something of a cult figure in one corner of contemporary environmental philosophy: the ethics and philosophy of sport hunting. Ortega received his philosophical education in Germany; and thus the main body of his work is in the phenomenological-existential tradition of Continental philosophy. In his *Meditations on Hunting*, translated into English and published in 1972, Ortega characterizes sport hunting as a vacation to the Pleistocene and a retreat from the existentially debilitating mass culture of modernity. It is, in his opinion the only way to experience our authentic humanity, to be ourselves as we are sculpted by natural selection and adapted to hunting-gathering as the formative and original human way of life. In the field, as the hunter's attention is unwaveringly focused on his quarry, his senses become more acute and his awareness more heightened than the senses and awareness of a non-hunter out for a walk in the woods. Ortega insists that the only proper response to an animal obsessed with avoiding capture is to try to catch it; and the highest homage we can pay to such a being is to kill it.

Spain's most notable contemporary environmental philosopher is Nicolás Sosa. His book, *Ética Ecológica* (1990), introduced environmental ethics as it had developed in Anglophone philosophy to a Spanish-speaking audience. Sosa, in ways reminiscent of Lynn White Jr.'s subtext in "The Historical Roots of Our Ecologic Crisis," contrasts proposed technical and political approaches to solving the environmental crisis with philosophical and, more especially, ethical approaches and offers a brief for the latter. Sosa takes an eclectic, pluralistic approach as his

purpose is more practical—to find an effective environmental ethic—than theoretical. Sosa deploys Jürgen Habermas' notion of "communicative competence" as the key to developing both an effective and pluralistic environmental ethics by, in effect, transposing the Leopold land ethic into a Habermasian discourse ethic.

There are striking similarities in the independent development of environmental ethics in France and Spain during the 1990s. Both Serres and Sosa were ahead of their Anglophone colleagues in realizing the central challenge to environmental philosophy of globality, especially global climate change. And Sosa, like both Serres and Latour, suggests that the solution is somehow to give voice, through political representation, to the more-than-human natural world: Sosa with his unrestricted Habermasian community of discourse, Serres with his natural contract, and Latour with his notion that science legitimately speaks for nature if properly integrated into the discourse of politics.

Portugal has not yet developed a robust community of environmental philosophers. However, Ortega spent some years in exile in Portugal; and in 2008, the Fundação Serralves sponsored a series of lectures in Porto on environmental philosophy by J. Baird Callicott, Holmes Rolston III and Catherine Larrère.

The Iberian Peninsula also shares with other Western European countries the legacy of modern commercial and industrial development that has left environmental degradation and ecological destruction in its wake, especially in the form of air and water pollution. Spain is currently facing serious water-shortage problems exacerbated by sprawling coastal development aimed at attracting tourists to its Mediterranean resorts. Like France, Spain has had a less robust environmental movement than Germany, and a less robust environmental politics—until recently. Spain is, however, leading the way, among Western European countries, in environmental policy and legislation, having extended "human rights" to all our fellow great apes (chimpanzees, bonobos, gorillas, orangutans, and gibbons) by an act of the Spanish Parliament in 2008, at the behest of the Great Apes Project, spearheaded by Peter Singer and Paola Cavalieri and its Spanish director, Pedro Pozas.

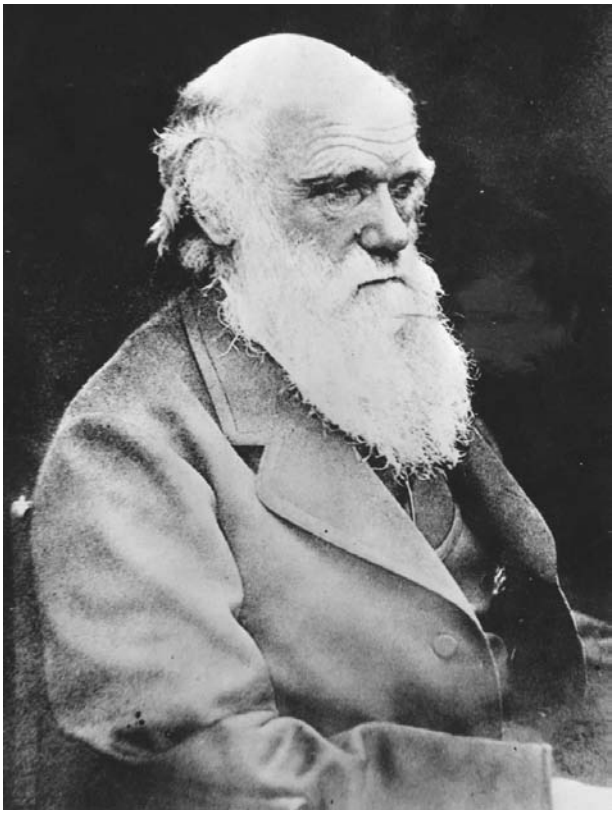
EVOLUTION

Charles Darwin's theory of evolution provides a robust explanation for both the adaptation of organisms to their environments and the diversity of organisms. The implications of evolutionary theory run broad and deep, touching on every aspect of biological understanding and human self-understanding. It has influenced environmental philosophy in at least two ways: by tying ethics to natural roots, and by informing a worldview that emphasizes human kinship with other living things.



Portrait of Charles Darwin, circa 1880. *Charles Darwin (1809–1882) is known as the founder of the theory for the evolution of life. Darwinian evolution has helped to shape modern theories of environmental ethics, such as the idea of biodiversity.* **AP IMAGES.**

BEFORE AND AFTER DARWIN

Prior to the Darwinian revolution, the predominant Western worldview held that the world was changeless and that all of the various forms of living creatures were the immutable products of special creation. The diversity of life, the interactions among living beings, and the adaptation of organisms to their environments were widely taken as evidence that the order of nature must be the product of a designer acting with conscious intention.

By the time Darwin published *On the Origin of Species* in 1859, however, there had already been serious challenges to the predominant worldview. Geologists and other naturalists had come to recognize, for example, that Earth is far older than had generally been believed, and that landforms change by slow and uniform natural processes. A number of biologists, particularly Jean-Baptiste de Monet and Chevalier de Lamarck, had also suggested that species change over time.

What Darwin presented in *On the Origin of Species* was an explanation for how organisms change through uniform natural processes operating over vast stretches of time. Mainly by means of natural selection, he argued, organisms come to be adapted to their environments, and varieties of organisms diverge from one another in characteristics. Offspring are always slightly different from their parents and from their siblings (variation), and the continual struggle for existence ensures that not all offspring will survive (selection). Those individuals that happen to have characteristics that give them some small advantage in the struggle for survival are more likely to pass their traits on to future generations. Over time, all else being equal, those advantageous traits come to dominate a population of organisms; that is to say, the population adapts to its environment. When parts of a population are subjected to different selective pressures, they diverge from one another, eventually becoming distinct species.

Darwin foresaw that applying this same account to human origins could revolutionize human self-understanding. In *The Descent of Man* (1971 [1871]), he cast intellect, morality, and even religion as the products of natural selection. He postulated, for example, that any social animal with sufficient intellect would develop a moral sense, on the grounds that individuals who sympathize with others in their group are more likely to cooperate with them. Membership in a coherent and cooperative group can be advantageous in the struggle for survival. This thread in Darwin's work has been expanded and deepened by research in a field that has come to be called evolutionary psychology, which studies the brain as a physical system and works to explain particular circuits as adaptations to solve particular problems encountered by our ancestors.

One of the main difficulties for Darwin's theory was that he lacked a credible account of the mechanisms of inheritance and variation. It was not until the 1930s that Darwinian evolution merged with Mendelian genetics in what has come to be called the modern or neo-Darwinian synthesis. Since that time, evolutionary theory has secured its position as the unifying core of biology, with implications for medicine, cognitive science, and many other fields.

EVOLUTIONARY ETHICS

In the final section of *A Sand County Almanac* (1949), Aldo Leopold casts ethics as such explicitly in evolutionary terms. He echoes Darwin in his assertion that ethics "has its origins in the tendency of interdependent individuals or groups to evolve modes of cooperation" (p. 202). He then projects the extension of ethics to include the relationship between humans and the land (the land ethic), and he sees this extension as "an evolutionary possibility and an ecological necessity" (p. 203).

J. Baird Callicott has interpreted Leopold's appeal to evolutionary ethics as nothing less than a legitimate way of circumventing the traditional injunction against deriving statements of value and obligation from statements of fact, against deriving *ought* from *is*. In his 1982 essay "Hume's *Is/Ought* Dichotomy and the Relation of Ecology to Leopold's Land Ethic," Callicott traces the lineage of Leopold's argument back through Darwin to David Hume (1711–1776), who maintained that moral claims themselves come down to factual claims about moral sentiments. It is a matter of psychological fact that people are well disposed toward communities of which they are a part. Because of the Darwinian revolution, it is possible to give an evolutionary explanation for this fact. All that is needed to complete a compelling practical argument for the land ethic, Callicott asserts, is to establish that the land is part of a community of which people too are a part.

AN EVOLUTIONARY WORLDVIEW

The ecological worldview that informs Leopold's land ethic can seem static, focused on biotic communities as they are now or as they have recently been. At several points in the *Almanac*, however, a sense of the intertwining of ecology and evolution comes to the fore. "In the beginning," Leopold wrote, "the pyramid of life was low and squat; the food chains short and simple. Evolution has added layer after layer, link after link" (1948, pp. 215–216). Ecology can be said to study the relations among organisms at a particular time, while evolutionary biology studies changes in organisms and the emergence of their mutual relations across time.

For Leopold, evolution provides an important benchmark for evaluating human activities. While evolutionary change is generally slow, humans can now "make changes of unprecedented violence, rapidity, and scope" (1949, p. 217). Also, part of what makes wild nature so compelling is that it is ancient; humans are only recent arrivals. A sense of endless time adds poignancy to the elegiac moments in the *Almanac*: Sandhill cranes, for example, "have their being . . . in the wider reaches of evolutionary time. Their annual return is the ticking of the geological clock" (1949, p. 97).

Leopold also holds that Darwin's theory should foster in humans a sense of kinship and a sense of humility, a sense that we are "only fellow-voyagers with other creatures in the odyssey of evolution" (1949, pp. 109–110). Later environmental thinkers, such as Warwick Fox in his account of transpersonal ecology, place particular emphasis on the kinship of life, rooted in the Darwinian theory of common descent. Whatever the differences between a human being and an oak tree, for example, the two are related through a common ancestor far back in evolutionary time.

Darwinian evolution has also shaped the interests and concerns of the contemporary environmental movement. Biodiversity, for example, is a central issue for many environmentalists, an issue that takes on urgency with the recognition that biodiversity has emerged only slowly over evolutionary time, and that it is unique and somewhat fragile: Once an evolutionary line has ended, it cannot be restored. The sense of deep time and the slow unfolding of natural processes also informs a growing interest among environmentalists in large-scale and long-term problems, such as climate change and the persistence of some human-made materials.

PRE-DARWINIAN EVOLUTION

The term *evolution* frequently enters the literature of environmental philosophy in its older, pre-Darwinian sense. Originally the term denoted a teleological, or goal-directed, process of development, literally the unfolding of an implicit form by stages toward a fixed goal. Embryonic development is a paradigm case of evolution in this sense of the term.

In its mainstream interpretation, by contrast, Darwinian evolution is generally understood to be a mechanistic process tending toward diversity, rather than toward complexity or intelligence. Complexity as such is something like a side effect of the process, and the emergence of any particular complex form, such as the human brain, is wholly contingent.

EVOLUTIONARY PSYCHOLOGY

Evolutionary psychology is the human side to sociobiology, which is the area of evolutionary biology that deals with social behavior. Sociobiology focuses not only on animals in their lives and struggle for existence but also on the ways in which they interact with one another, particularly with members of their own breeding group or species. It is a topic that was dealt with, although not by that name, by Charles Darwin in *On the Origin of Species* (1859)—evolutionary psychology, again not by name, appeared in Darwin's *Descent of Man* (1871)—but it was not until the 1960s that sociobiology, including human sociobiology or evolutionary psychology, became a discipline in its own right. This resulted from certain major conceptual moves. The chief Darwinian mechanism is that of natural selection, which holds that there is differential reproduction in the living world and that the organisms that succeed are those which are especially well adapted to their roles in life; they have features that aid them, such as eyes and teeth and hands and leaves and bark and everything else that makes for good functioning.

ORIGINS AND TENETS OF THE THEORY

It was particularly important to see that in terms of adaptive advantage, natural selection rarely if ever works for the good of the group but almost always works for the good of the individual. In the formulation of the evolutionary biologist Richard Dawkins, it is necessary to take a "selfish gene" perspective on animal behavior, including animal social behavior. It then was realized that even though behavior must be directed to the good of the actor, this can involve cooperation with others, for instance, in child rearing and in fighting against predators. Altruism, as this usually is called, can be a good reproductive strategy. Along with these theoretical developments came major studies of organisms in the wild, and it was realized that long-term behaviors often involve much of the selfishness described above: No one helps another out of niceness but because ultimately there is a benefit for the helper. This is not true in every case, but on average such help pays off.

In 1975 an American specialist on ants, the Harvard biologist Edward O. Wilson, tied these concepts together in a major overview: *Sociobiology: The New Synthesis*. What made his work particularly controversial was the way in which, having surveyed the animal kingdom, he then applied his thinking to human beings. Apparently, human beings also are subject to evolutionary forces and show their heritage in the ways in which they interact socially. The fact that men tend to be stronger and more dominant than women is part of biology no less than is the somewhat subservient role played by women. In 1978 Wilson reinforced that kind of thinking with a Pulitzer Prize–winning book exclusively on the human species: *On Human Nature*. His claims were anathema to many—feminists, Marxists, and social scientists, among others—and by the end of that decade human sociobiology was much debated: praised by some and condemned by others. In the years since that time the controversy has died down somewhat, although human sociobiologists have found it politic to do their work under other names, calling themselves biological anthropologists or evolutionary psychologists, among other variants.

The possible implications of human sociobiology (or evolutionary psychology as we can now call it) for thinking about the foundations of morality have been of great interest to philosophers and other scholars. It seems that morality is predicated on the need not to be selfish, to serve others, yet selfish genes appear to be activated only by personal concerns. As was noted above, however, the situation is more complex. An example would be something as basic to ethics as the love commandment—"Love your neighbor as yourself." If a person does help someone else, that person is putting out resources that might be used more immediately for his or her own benefit. An example would be giving someone food that one might eat oneself. However, the love commandment is meant to apply to others as well, and so other people are expected to help when that person is in need.

One might argue that this is hypothetical and that perhaps it is more practical not to help others and assume that one can get by without help. However, as everyone knows, things are not that simple. All people need the help of others when they are young, when they are sick, when they are old, when they are handicapped (perhaps by the burden of having small children), and so forth. In other words, the evolutionary psychologists suggest that a good Darwinian explanation—work for the benefit of oneself—might demand a great deal of cooperation with one's fellows. This probably is best done from conviction rather than from calculation. In other words, biology makes people do what they do because they think it is right rather than because they think it is in their own interest. Selfish genes do not necessarily imply selfish people.

APPLICATION TO ENVIRONMENTAL ETHICS

According to Wilson, environmental issues figure in this equation. Wilson argues that humans have evolved in a symbiotic relationship with the rest of living nature. Simply and literally put, people cannot live without plants and other animals. Beyond the simple utilitarian factors, Wilson argues, people must take into account the human need of biodiversity. That need speaks to deep social and aesthetic needs within everyone—liking landscapes is a part of human biology—and of course pays major dividends in the search for new drugs and the like. In other words, Wilson argues that evolutionary biology shows that people need a new moral imperative: ''Preserve and cherish nature and above all maintain biodiversity.'' This is not something that runs counter to traditional ethics, like the love commandment, although it certainly runs counter to the human urge to look for quick and easy solutions. Wilson argues that with the development of the human brain, people have reached a new level of evolution that requires them to think about the long-term future and eschew the immediate and comfortable for the distant and important. In short, to understand and counter the environmental crisis, people's first duty is to learn some evolutionary biology.

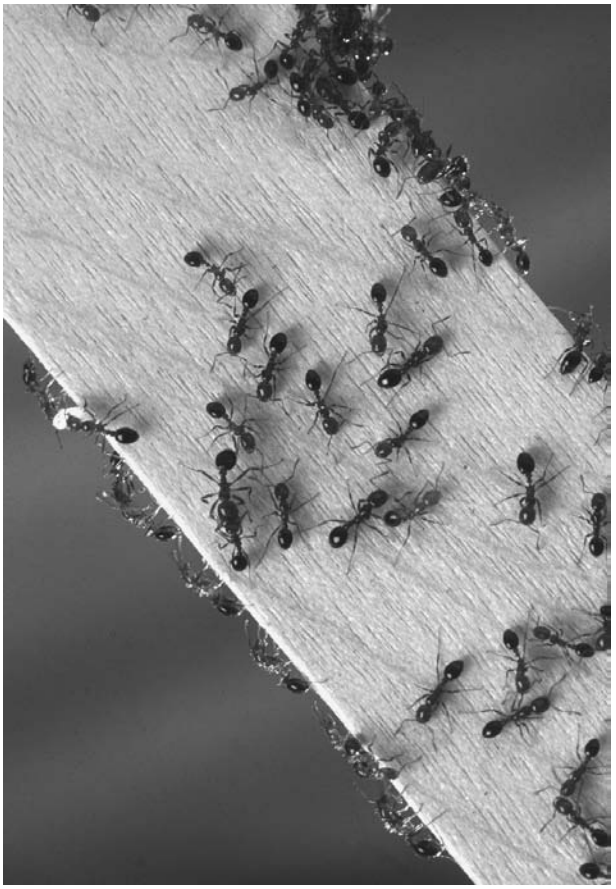
EXOTIC SPECIES

The fire ant (*Solenopsis invicta* Buren) in the southern United States, the zebra mussel (*Dreissena polymorpha*) in lakes and waterways of the midwestern United States, and the seaweed *Caulerpa taxifolia* in Mediterranean waters are commonly cited examples of exotic species. What makes them exotic is a shared property: Each species inhabits but is not considered native within the region listed. In the United States, for instance, *Solenopsis* was first discovered in the late 1920s in Mobile, Alabama, likely introduced accidentally in ships transporting agricultural products from South America (Williams et al. 2001); shipping also carried it to Brisbane, Australia, around 2000 (McCubbin and Weiner 2002). Similarly, shipping was responsible for the zebra mussel's arrival in North American Great Lakes around 1986 (Ram and McMahon 1996). *Caulerpa*, a common aquarium plant, was first detected in Mediterranean coastal waters adjacent to the Oceanographic Museum of Monaco near Nice, France (Francour et al. 1995). Although these species were almost certainly introduced by humans to these areas, this circumstance is not what defines their exotic status (cf. Noss and Cooperrider 1994). If nonhuman processes had introduced them, they would be equally exotic. *Solenopsis* is deemed native rather than exotic in Argentina, Brazil, Paraguay, and Uruguay, and



Red Imported Fire Ants. *The red fire ant (*Solenopsis invicta*) is an insect species native to South America, but found on several continents. The ant was accidentally introduced to the southern United States in the 1930s, traveling in soil on a ship that docked at the Mobile, Alabama port. The ants are a nuisance to humans, pets, and livestock, and cause extensive medical and agricultural damage every year.* **PHOTO COURTESY OF SCOTT BAUER, USDA AGRICULTURAL RESEARCH SERVICE, BUGWOOD.ORG.**

neither the zebra mussel nor *Caulerpa* is regarded as exotic in the Black and Caspian seas or Indian Ocean, respectively.

DEFINING *NATIVE* AND *EXOTIC* SPECIES

As the foregoing examples illustrate, a species is appropriately labeled "exotic" only with respect to regions in which it is not considered native. These regions may change, of course, as migration and extinction change the flora and fauna of regions, so a clear criterion for nativeness is needed. Without an explicit criterion, *exotic* and *native* are problematically imprecise concepts and are, consequently, often used inconsistently by ecologists and conservation biologists (Shrader-Frechette 2001; Colautti and MacIsaac 2004). Unfortunately, no such criterion has emerged. It is often unclear, for instance, what temporal reference is being (and should be) considered the standard for nativeness. Cattle, for instance, are arguably a staple of contemporary U.S. biocultural identity and could be judged native on that basis, yet they are exotic as judged against a U.S. precolonial ecological reference state. Similarly, horses were native in North America during the Pleistocene but were presumably exotic when Europeans reintroduced them after they had been locally extinct for more than 10,000 years.

Analogous reference problems confront restoration efforts that seek to determine what past ecological state of a degraded area should be its restoration target (see Callicott 2002). These problems do not, however, show that *native* and *exotic* are entirely useless concepts within conservation biology or that the distinction between them is baseless. It seems undeniable, for example, that the recent introduction of *Caulerpa* and the zebra mussel into areas in which they are classified as exotic justifies the label.

DISTINGUISHING *EXOTIC* AND *INVASIVE* SPECIES

The fire ant, zebra mussel, and *Caulerpa* are labeled *invasive* more often than *exotic*. How this concept should be defined is controversial (see Richardson et al. 2000), but these species are called invasive in regions in which they are considered nonnative because they have had a significant adverse effect on ecosystems, primarily through high fecundity, high density, rapidly expanding distributions, and competitive advantages over native species. Describing these species as exotic does not, however, imply that their impact must be adverse. In fact, some studies suggest less than one-quarter of exotic species negatively affect ecosystems (Williamson and Fitter 1996). *Exotic* and *invasive* are, therefore, distinct concepts and should not be conflated. This does not mean, however, they are unrelated. Being exotic is necessary for a species to be invasive: Native species obviously cannot invade regions they already inhabit.

What makes species invasive is not well understood (Williamson 1996), but high fecundity and absence of predators, parasites, and competitors that negatively affect a species in its native distribution is clearly an important part of the explanation (Sax and Brown 2000). Invasive *Solenopsis* in the United States, for example, normally outcompetes native ants to the point of competitive replacement (Porter et al. 1988). In the presence of even relatively low densities of parasitoid Phorid flies that parasitize them in their native range, however, invasive *Solenopsis* consume less, grow to smaller size, and are less competitive against native ants (Mehdiabadi and Gilbert 2002, Mehdiabadi et al. 2004). Being introduced into new areas frees exotics from these types of ecological pressures. Nevertheless, native species can sometimes escape these pressures as well. For example, white- and black-tailed tail deer in some parts of the United States (especially areas with severe hunting restrictions) share many of the negative attributes of invasive species because humans have eradicated their native predators. Similarly, natural biological changes like mutation can produce selectively favorable physiological or behavioral properties that provide the same advantages, thereby causing a low-density native species to reproduce and spread more effectively, potentially to the detriment of ecosystems containing it. Both natives and exotics can thus be noxious.

ECOLOGICAL IMPLICATIONS AND ETHICAL EVALUATION OF EXOTIC SPECIES

Despite this possibility, the more significant threat comes from exotic rather than rogue native species given that exotics escape negative ecological pressures more completely and with greater frequency than natives. Highly destructive and invasive species, such as the examples discussed above, are usually exotic rather than native. Even though only a small minority of exotics becomes invasive, the threat they pose to native species, agriculture, and industry is growing as humans become better vectors for exotics through increasing travel and trade (Vitousek et al. 1997). At any instant, for example, the zebra mussel is only one of approximately 3,000 to 7,000 species carried globally in ballast (Carlton 1999). As global trade increases, the number of exotics introduced through shipping increases, and one of the few reliable generalizations to emerge within invasion biology is that more exotics will become established and thus potentially invasive as the number of introductions increases (Lonsdale 1999). This significant and escalating threat justifies

an ethical imperative to prevent and reduce introductions of exotics. *Solenopsis* alone has been implicated in the extinction of several native species in the southeastern United States (Forys et al. 2001).

Ethical evaluation of exotics becomes more complicated once they have established self-sustaining populations in new areas and when it is reasonably clear that they will not become invasive. Even if reference state problems with the native-exotic distinction are ultimately resolvable, it is unclear that a simple preference for native over exotic species is ethically defensible (Sagoff 2003). In one of the founding texts of invasion biology, for example, Elton (1958) appealed to people's aesthetic appreciation and intellectual interest in an area's flora and fauna as one reason for excluding and eradicating exotics. But this rationale cuts both ways. The introduced mute swan and many exotic garden ornamentals, for example, are aesthetically pleasing for much of the U.S. populace, as well as interesting intellectual subjects for relevant research communities. Exotics, even invasives, can also benefit ecosystems to which they are introduced. For example, the substantial economic costs imposed by the zebra mussel clogging intake ports of boats, power plants, and infrastructure waterways are responsible for its label as a noxious pest. As a filter feeder, however, the zebra mussel has cleared much of the excess nutrients and algae caused by sewage and industrial pollution in the Great Lakes, to the benefit of many native invertebrates and fish (Strayer et al. 2004). Absent an unequivocal threat to native species or economic interests, the cultural opposition to exotic species may be nothing more than an indefensible prejudice (Chew and Laubichler 2003).

EXTINCTION

Extinction is a concept that has many nuances and can vary with context. A species is *extinct* when no member of the species remains alive anywhere. If individuals of a species remain alive only in captivity, such as zoos, aquariums, botanical gardens, or other human-controlled environments, the species is said to be *extinct in the wild*. A species is *locally extinct* or *extirpated* when it is no longer found in an area it once inhabited but is still found elsewhere in the wild. Some conservation biologists speak of a species being *ecologically extinct* if it persists in such reduced numbers that its effects on the other species in its community are negligible—for example, when a predator species, such as cheetah, survives at such low densities that it does not significantly affect prey populations. A species is said to be *commercially extinct* if its numbers, once harvested for profit (bluefin tuna, for example) shrink so drastically that they cannot be profitably pursued. A species is considered to be *virtually extinct* when it is reduced to a few individuals that may be incapable of reproduction (e.g., all remaining birds of a species are male, or the last trees of a species are not producing seeds).

GEOLOGIC EXTINCTION EPISODES

Extinction is part of the natural process of species evolution. It is as much a part of the natural life cycle as speciation and has been occurring continually since life first began to diversify from simple organisms. It is not, however, an evenly paced phenomenon: Speciation and extinction may proceed gradually, in tandem, for millennia, but at various times there have been episodes of rapid, mass extinction that far outstrip the pace of species divergence. These past episodes of mass extinction were

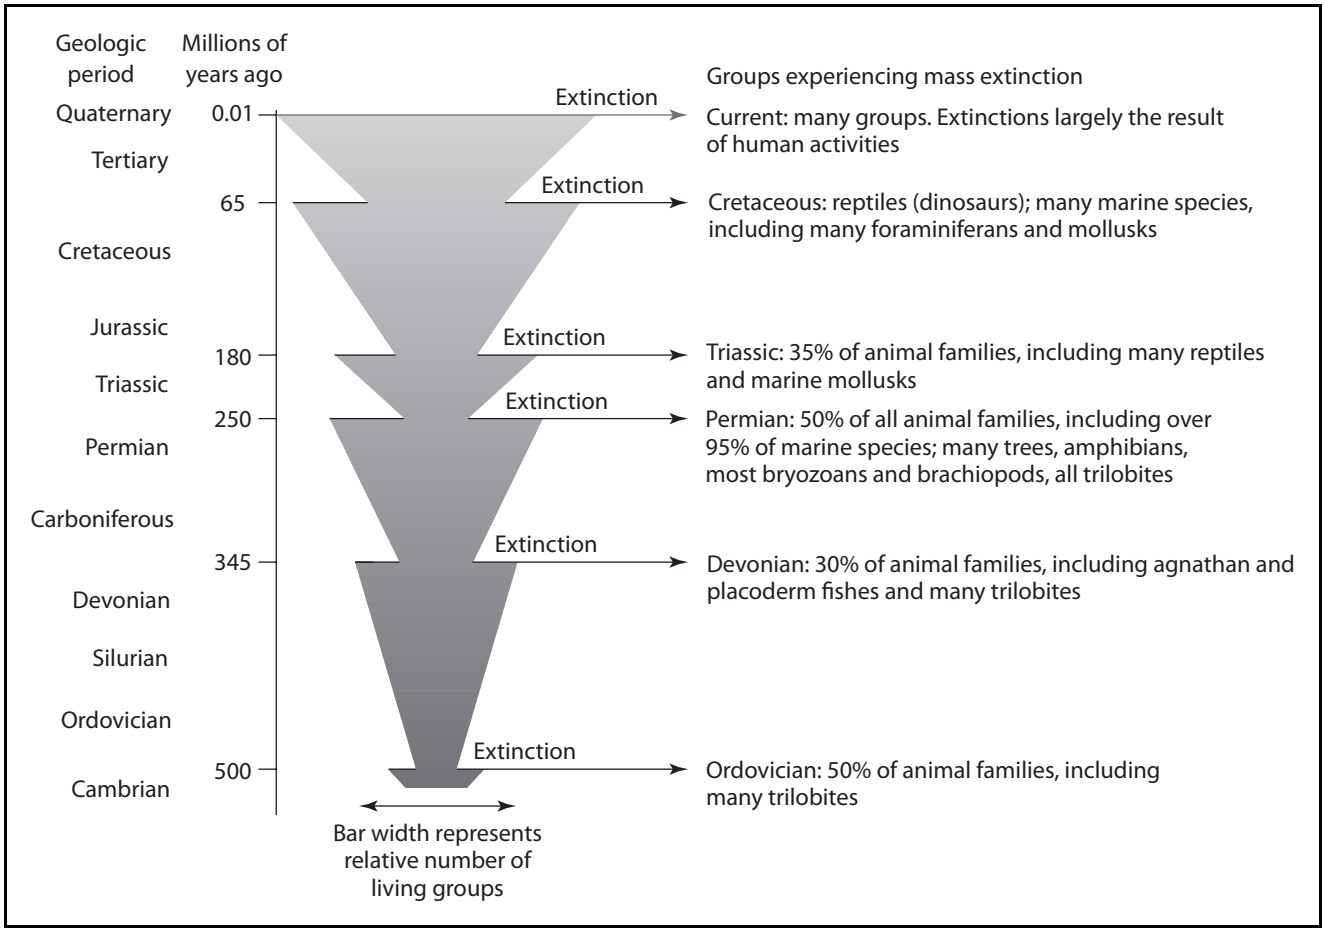

Figure 1. *Although the total number of species groups on Earth has increased over the eons, during each of five episodes of natural mass extinction (named at left), a large percentage of these groups disappeared. The most dramatic period of mass extinction occurred about 250 million years ago, at the end of the Permian period. A sixth extinction event began during the present geological period and will continue for decades to come.* **COURTESY OF SINAUER ASSOCIATES.**

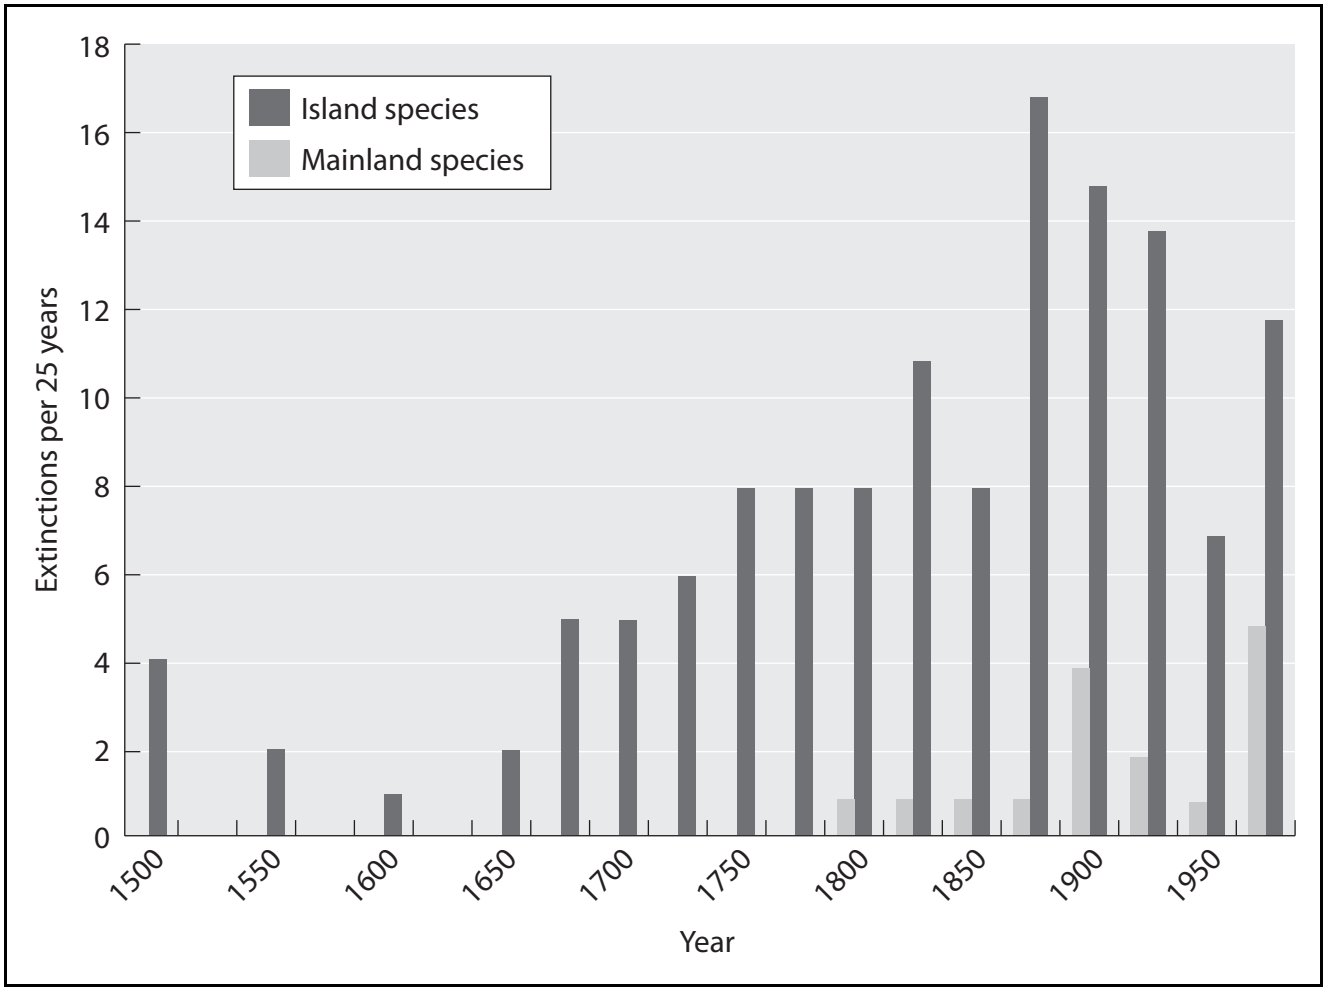

Figure 2. *Extinction rates have been increasing from 1650 to the present. Initial extinctions were on islands, but extinctions of mainland species have been increasing since 1800.* **COURTESY OF SINAUER ASSOCIATES.**

likely caused by asteroid impacts, volcanic eruptions, changes in the atmosphere, or other large-scale events. Most of the time, the pace of speciation exceeds the pace of extinction, leading to net growth in biological diversity. During episodes of large-scale extinction on regional or global levels, however, this growth in diversity does not prevail, and it may take tens of millions of years to recover the level of biological variety lost in a short episode of mass extinction.

Although at least five such extinctions have occurred since life began on earth (see Figure 1), individual extinctions also take place regularly as part of normal competition and evolution. One species may outcompete another or drive it to extinction through predation. A successful species may evolve into another in response to environmental changes or because of random changes in its gene pool. Changes in climate or local habitat may eliminate a key food source, resulting in extinction for a species that depends on that resource. All of these are factors that can and do contribute to the small-scale extinction that is always occurring against the background of evolution.

PREHISTORIC/HISTORIC EXTINCTION EPISODES

Since modern human beings evolved roughly 200,000 years ago, the global diversity of species has progressively declined, particularly during the last 30,000 years and most rapidly in the past 200 years. Human activity is largely responsible for these declines, because humans greatly altered terrestrial and aquatic environments during these time frames. The elimination of large mammals from Australia and the Americas coincided with human colonization of these continents, with 74–86 percent of the megafauna (mammals weighing more than 44 kilograms

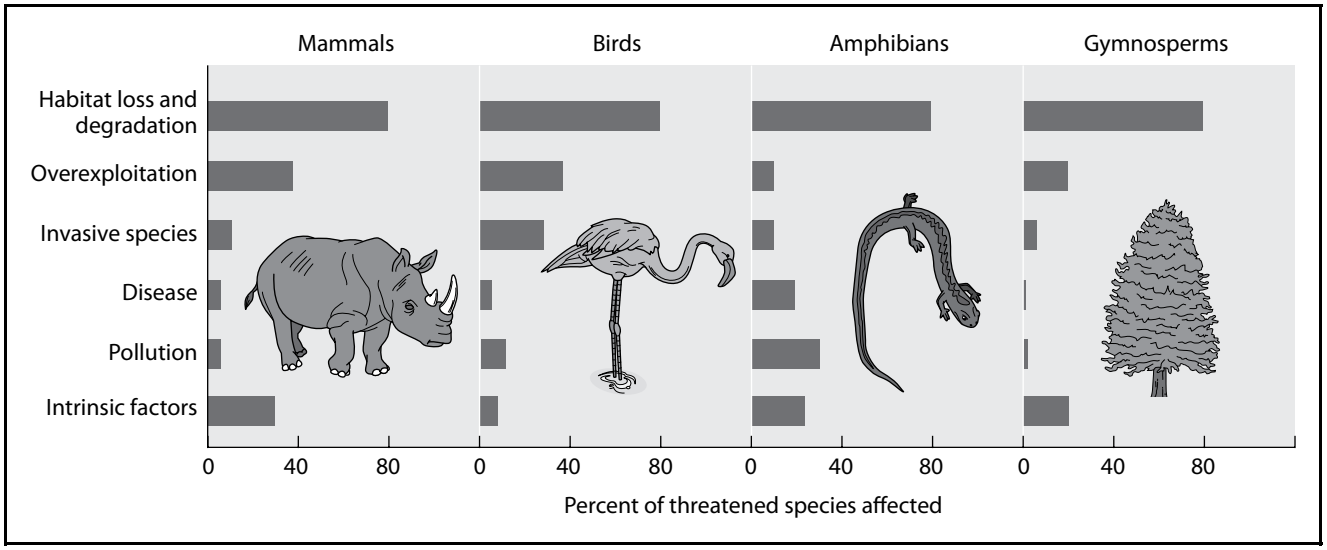

Figure 3. *Habitat loss and degradation is the greatest threat to the world's species, followed by overexploitation. Groups of species face different threats; birds are more threatened by invasive species, whereas amphibians are more affected by disease and pollution. Percentages add up to more than 100 percent because species often face multiple threats.* **COURTESY OF SINAUER ASSOCIATES.**

[100 pounds]) becoming extinct. On all continents paleontologists and archaeologists have found an extensive record of prehistoric human alteration and destruction of habitat that coincides with high rates of species extinctions.

In historic times approximately 206 mammals and birds have become extinct since the year 1600, representing 1.6 percent of known mammal species and 1.3 percent of known birds. It is important to realize that though these numbers seem small, the number of unknown species is vast, and the tally of extinctions among species not known to science is probably significant. More important, the majority of these extinctions took place during a very short period, from 1850 to 1950 (see Figure 2). This increase in the rate of extinction indicates the seriousness of the threat to biological diversity. The apparent decline in extinction rates since 1950 is due to the current practice of not declaring a species extinct until decades after it can no longer be found. Many species not yet listed as extinct—and some that have not yet been documented at all—have been decimated by human activities and persist only in very low numbers. The inability to locate any extant populations of many rare species provides further evidence that extinction rates are accelerating.

CAUSES OF EXTINCTION

There are two causes of extinction: natural and human-caused. The mass extinctions of the geologic past (i.e., those that took place up to about 30,000 years ago) were entirely natural in origin. The source of these extinctions ranged from volcanic activity, asteroid collisions, sea-level changes related to glaciation, chemical alterations of the oceans and atmosphere, and other such global natural phenomena. From approximately 30,000 years ago onward, however, human activities have gradually superseded natural phenomena as the prime movers of extinction. Massive ecological disturbances caused by people have altered, degraded, and destroyed the landscape on a vast scale, driving species and even whole biotic communities to the point of disappearance. Major human-triggered threats to biological diversity are habitat destruction, habitat fragmentation, habitat degradation (including pollution), global climate change, the overexploitation of species for human use, the invasion of exotic species, the increased spread of disease, and combinations of these factors (see Figure 3). These seven threats to biological diversity are all caused by the ever-increasing use of the world's natural resources by an expanding human population.

FUTURE EXTINCTION RATES

Extinction rates will remain high in the twenty-first century because of the large number of threatened species. About 12 percent of the world's remaining bird species are threatened with extinction. Mammal species are in even greater danger, with 22 percent of species under threat; 31 percent of amphibians are at risk. Certain animal groups face gloomier prospects than others, such as three orders that include turtles, manatees, and rhinos. Plant species are also at risk, with gymnosperms (conifers, ginkgos, and cycads) and palms among the especially vulnerable groups. Species on islands are

particularly vulnerable because they often have a limited area, small population sizes, high endemism (that is, they are found in only one location), and a small number of populations. Of all the animal and plant species known to have gone extinct since 1600, almost half were island species. Nevertheless, whereas past extinctions have occurred predominantly on islands, future extinctions will increasingly take place in continental areas as tropical forests and other ecosystems are cleared for human activities.

Predictions of extinction rates based on habitat loss vary considerably. Using the estimate that 1 percent of the world's rain forests are being destroyed each year, scientists have estimated that 0.2–0.3 percent of all species—roughly 10,000–15,000 species, based on a total of 5 million species worldwide—will be lost per year, or thirty-four species per day. The most recent estimates are that species extinctions for the fifty-year period ending with 2050 will be up to 35 percent in tropical Africa, 20 percent in tropical Asia, 15 percent in tropical America, and 8 to 10 percent elsewhere. Extinction rates might in fact be higher because the highest rates of deforestation are occurring in countries with large concentrations of rare species, and large forest areas are increasingly being fragmented by roads and development projects. Regardless of which estimate is the most accurate, all indicate that tens of thousands—perhaps even hundreds of thousands—of species are headed for extinction within the next fifty years. Such a rate of extinction is without precedent since the great mass extinction of the Cretaceous period 65 million years ago.

GLOBAL CLIMATE CHANGE AND EXTINCTION

Global climate change has recently emerged as a new threat with the potential to radically restructure biological communities and change the ranges of many species. The pace of this change could overwhelm the natural dispersal abilities of species and drive them to extinction. There is mounting evidence that species are already responding to warming temperatures, with changes in the distribution of bird, insect, and plant species; reproduction is occurring earlier in the spring. Warming conditions in the ocean are affecting the distribution of species in coastal waters, particularly in coral reefs. The implications of global climate change are far-reaching: Higher temperatures and changing precipitation patterns could lead to crop failures and tree death over large areas, with enormous social, economic, ecological, and political costs. Global climate change will also have an enormous impact on human populations in coastal areas that could be flooded by rising sea levels and in areas that experience large changes in temperature and rainfall. It is likely that, as the climate changes, many existing protected areas will no longer preserve the rare and endangered species that live there, so the extinction rate among these species will likely skyrocket in the absence of countermeasures.

LOCAL EXTINCTIONS

In addition to global extinctions, many species are experiencing a series of local extinctions across their ranges. Formerly widespread species are sometimes restricted to a few small pockets of their former habitats. For example, the American burying beetle (*Nicrophorus americanus*), once found all across central and eastern North America, is now found in only four isolated populations. Biological communities are impoverished by such local extinctions. Similar local extinctions were shown by a survey of one part of the Indonesian island of Sumatra; of twelve populations of Asian elephants known from the 1980s, only three remained there twenty years later. Large numbers of local extinctions are important biological warning signs that something is wrong with the environment. Action is needed to prevent further local and global extinctions. The loss of local populations not only represents a loss of biological diversity, but it also diminishes the value of an area for nature enjoyment, scientific research, and the provision of crucial materials to local people in subsistence economies.

CONCLUSIONS AND STRATEGIES

Conservation biology is the academic field that has developed in the past twenty-five years to deal with this developing extinction crisis. Conservation biologists believe study should be coupled to action. The most important strategy for preventing extinction is to establish protected areas where species can exist without interference from human activity. These protected areas often have to be managed to achieve their goals. Species can also be maintained outside of protected areas if there are compromises that reconcile the needs of human societies with the needs of species. Where such compromises cannot be achieved, species may have to be moved to a different place in the wild where threats to their existence are minimized, or they may have to be preserved in captivity. Most conservation biologists believe that because humans are now responsible for almost all extinctions, humans can and must assume the responsibility for preventing, or at least reducing the rate of, the further disappearance of species.

F

FACTORY FARMS

Confinement animal agriculture—also known as industrialized agriculture, intensive agriculture, factory farming (an appellation disfavored by the industry), and confined animal-feeding operations—is a creature of the second half of the twentieth century. Before that time, agriculture was extensive and pastoral, with animals housed primarily under open, pastoral conditions. The industrialization of animal agriculture was a major break from the agricultural systems that had existed since the earliest domestication of animals. It is thus fair to state that most animal agriculture changed more during the second half of the twentieth century than it did during the preceding millennia.

The key to the success in traditional agriculture was good husbandry of animals. (The term *husbandry* is supposedly derived from the Old Norse phrase "hus-bond": bonded to one's household.) Husbandry meant placing animals into the environment best meeting their biological and psychological needs and natures, and then augmenting their natural abilities to survive and thrive by providing food during famine, water during drought, help in birthing, medical attention, protection from predation, and so on. Since the producer did well if and only if the animals did well, good husbandry was driven by the most effective human concern: self-interest. Husbandry thus embodied an ancient contract between humans and animals, and both parties fared better by virtue of the contract than they would have done outside of it.

The most powerful articulation of the ethic of husbandry may be found in Psalm 23: "The Lord is my shepherd: I shall not want. He maketh me to lie down in green pastures. He leadeth me beside the still waters. He restoreth my soul." Thus, when the psalmist seeks a metaphor for God's ideal relation to humans, he can do no better than the shepherd's relation to his sheep. As we know from the Bible, a lamb on its own would not long survive predation by hyenas, wild dogs, lions, eagles, and other predators; with the aid of a shepherd it lives well. Animals benefit from the ministrations of the shepherd; humans benefit from the animals' products and sometimes their lives, but while they live, they live well.

In the mid-twentieth century, husbandry's care for animals as the basic value for animal agriculture was replaced by industrial values of efficiency and productivity. This was the result of a confluence of many factors. First, the U.S. public had lived through the Great Depression and the Dust Bowl, and for the first time in American history, the specter of insufficient food, unaffordable food, and starvation loomed as viable possibilities. Second, agriculture had to support larger populations with fewer workers. Many people who had worked in agriculture sought better jobs and security from the vagaries of nature by moving to cities. And the two world wars exposed young soldiers to more exciting venues than rural America. As one song after World War I put it, "How you gonna keep 'em down on the farm now that they've seen Paree?" Moreover, as cities grew, urban encroachment on agricultural land became a factor to be reckoned with. A sharp rise in population meant more mouths to feed. Third, the success of industrialization reinforced the belief that it was a template for success in all areas.

The convergence of all of these mutually reinforcing vectors probably made the industrialization of agriculture inevitable. In a telling, emblematic move, academic departments of animal husbandry changed their names to

departments of animal science, defined as the "application of industrial methods to the production of animals."

Initially, industrialized animal agriculture delivered on its promises. Productivity increased dramatically, and this increase in productivity drove the price of animal foods down to the lowest point in history relative to income. Those areas of animal agriculture that changed most dramatically were poultry, eggs, pork, and dairy. The beef industry changed over to concentrated animal-feeding units, feedlots, as the place where cattle were "finished" with grain. (Cheap and plentiful grain came from a parallel industrialization of crop agriculture.)

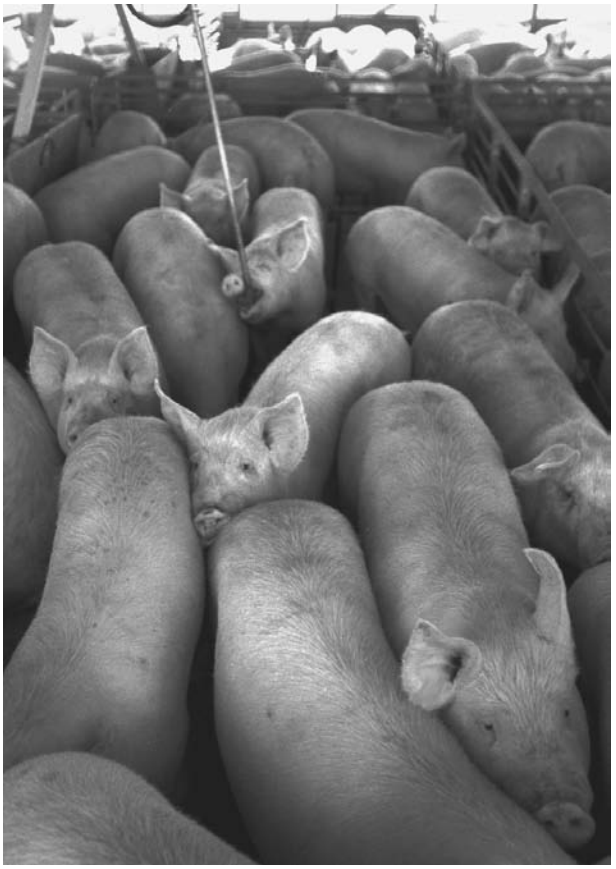
The key to the industrialization of animal agriculture was the concentration of large numbers of animals in small spaces, usually (except for cattle feedlots) indoors. Capital replaced labor, and "animal-smart" people schooled in the husbandry of the type of animal in question were replaced by untrained minimum-wage workers, with "the intelligence being in the system," as one manager put it to this author.

Initial optimism about confinement agriculture then chilled, to the point that the consequences of such an agriculture were viewed as highly problematic in many dimensions, first in Europe and, from the 1990s, in the United States as well. Agriculture became dominated by large vertically integrated multinational corporate entities, and this led to the extinction of small independent producers. This circumstance is dramatically illustrated in the pork industry, in which, in the four decades from the 1960s, the vast majority of small swine producers went out of business (by 2002 there were 87.8 percent fewer swine farms than in 1980), and five companies produced some 90 percent of the pork raised. Small rural communities that thrived when small producers dominated became ghost towns. Since husbandry people were largely unwilling to work in the animal factories, factory farms drew their workers from unskilled, sometimes illegal-immigrant labor paid the minimum wage, and such laborers often experienced a clash of cultures with local people.

Traditional agriculture was sustainable by its own internal logic. Animals consumed pasture, and their wastes nourished the soil. If the farmer exceeded the carrying capacity of the land, the animals would starve, and forage would be destroyed. The result was a balanced ecology, with production limited by available resources and few additional required inputs. In other words, domestic animals became part of the ecosystem in a largely benign manner, as still occurs in properly managed Western U.S. cattle ranching.

In contrast, confinement agriculture requires major inputs of energy, fossil fuel, and water, to increase productivity beyond the inherent carrying capacity of an area. The animals in confinement are fed not on forage, but on grains produced in giant monocultures highly dependent on chemical fertilizers and pesticides, which cause ecosystemic problems of erosion, aquifer contamination, and degradation of soil quality. The manure produced by confined animals (a pig, for example, produces ten times as much waste as a human) leads to problems of waste disposal and eutrophication of waterways by nitrogen leaching into water. The presence of thousands of animals in relatively small confined areas produces air-quality problems as well, which in turn affect the quality of life of persons in the area and the respiratory health of workers and citizens.

The use of technological tools to force animals into environmental conditions they could not survive in without technology, to force square pegs into round holes as it were, creates major problems as well. If farmers had attempted to raise 100,000 chickens in one building 100 years ago, all



Factory Farm outside Milford, Utah. *Hogs at Circle Four Farms in Utah crowd together in indoor pens, ready for slaughter. The industrialization of animal agriculture has led to the existence of factory farms, with the goals of increased efficiency and productivity. However, critics of the practice argue that animal productivity does not equate to animal welfare.*
AP IMAGES.

would have died of disease spread in three weeks. At the beginning of the twenty-first century, these diseases can be controlled with antibiotics and vaccines. Yet it is now clear that such use of antibiotics endangers human health by selecting for antibiotic-resistant pathogens.

Forcing animal square pegs into environmental round holes leads to the most egregious moral problem of confinement agriculture: animal welfare. Because animals are biologically evolved for extensive living conditions, confinement systems create welfare problems. Sows weighing up to 600 pounds, for example, are confined in 2 feet by 3 feet by 7 feet "gestation crates" (and farrowing crates when they give birth) for their entire productive life, unable to move or even turn. Laying hens are kept in tiny cages, with very little space. Dairy cows never see pasture. Broiler chickens are kept in groups of thousands on restricted floor space. In addition, production diseases—diseases that would not be a problem except for the method of production—proliferate, for example, liver abscesses in feedlot cattle fed an unnatural high-calorie, low-roughage diet. Workers are no longer animal-smart. The animal's basic biological and psychological needs and natures are no longer met.

The founders of confinement agriculture made one fatal conceptual error regarding animal welfare. They assumed that animals' welfare was assured if the animals were productive, which was by and large true under the conditions of extensive husbandry. But they illegitimately assumed that productivity under industrial conditions still guaranteed welfare, which is not true, because of the use of the "technological sanders" mentioned earlier (antibiotics, vaccines, air-changing systems). These animals may produce economically, yet they are not well off, as measured by a variety of parameters, including behavioral anomalies and preference tests asking the animals what they prefer.

In Europe, many of the most severe systems have been legally banned. In the United States, a consumer and citizen revolution began in the first decade of the twenty-first century to create a more animal- and environment-friendly animal agriculture. Niche producers raising animals under more natural conditions have proliferated, as have restaurants and grocery stores specializing in such products. Citizen-initiated referenda banning confinement have begun to appear, and public concern was recognized by Smithfield, the world's largest pork producer, when the company announced early in 2007 that it would phase out sow stalls.

For all the reasons detailed above, one can affirm that unrestricted industrial agriculture in its current form represents a failed experiment. While it is unlikely that totally extensive agriculture can be fully restored, it is likely that a new agriculture—blending considerations of sustainability, animal welfare, human and animal health, and social concern for workers and rural communities—will emerge in the future.

FARMS

During the last ten thousand years, farms have been the primary, most practical, and most intimate site of human engagement with the earth. In most cultures one could expect, even among nonfarmers, a common understanding that life (in the forms of food and fiber) and livelihood (in various forms of work) depended on the health and vitality of an agricultural landscape and economy. Dominant cultural forms in politics, education, art, business, and religion reflected, however indirectly or inadequately, a farm sensibility. Indeed, the term *culture*, in its early Middle English usage, originally referred to a cultivated piece of land (and presumably the skills and values necessary to care for it). It is only in the last hundred years or so, as mass urbanization swept across the globe, that most people have forgotten how fundamental agriculture really is.

The roots of any sustainable culture must finally make their way into a field (*ager*) and into rich, healthy organic soil. This is because the soil is the matrix through which life, death, and regeneration continually circulate. Without soil and the billions of microorganisms in it doing their work of decomposing and recomposing, Earth would be overwhelmed by death and incapable of producing more life. When people destroy or compromise the soil base (through soil erosion or salination or nutrient depletion), as they did long ago in the Fertile Crescent and Meso-America, they precipitate cultural collapse. One cannot have healthy plants, animals, and people while degrading the soil upon which all depend. As Albert Howard, the modern father of organic farming, understood, we must treat the health of soils, plants, animals, and humanity as "one great subject" (1947, p. 11).

Environmental movements, particularly as they have developed in the North American context (where the mountains and forests of Yellowstone, the Adirondacks, and Yosemite were the focal points of America's earliest conservation efforts), tend to reflect an urban-versus-wilderness perspective. For many environmentalists of the early twenty-first century, the preservation of wilderness areas and the protection of plant and animal species is the dominant concern. National parks and wilderness preserves are precisely the regions where farming is not permitted. Not surprisingly, farmers and ranchers who clear and cultivate land or pasture their livestock in environmentally sensitive regions have been viewed with suspicion by urban environmentalists. Farmers and environmentalists are rarely the best of friends.

This antagonism is unfortunate, because a focus on wilderness can become an excuse to ignore our need to preserve and maintain our vast agricultural lands, or to forget that farmers can be vital allies in the conservation and protection of our wetlands, forests, and fields. As Aldo Leopold, one of the earliest and most influential American conservationists, argued in "The Farmer as Conservationist" (1939), conservation cannot be merely a "negative exercise of abstinence or caution," but must instead be a "positive exercise of skill and insight" (1999, p. 164). In this recommendation he had farmers principally in mind, because they are the ones in the best position to acquire and pass on the skills and insights needed to care properly for the land. Moreover, good, healthy farms add to the aesthetic quality of many of our landscapes (not a small consideration when we remember the emotional satisfaction that comes with being in a well-maintained rural setting). Governments and their agencies are simply unable to own and work small pieces of land and make them good and beautiful.

A farm perspective is crucial in conservation efforts, because it is through the farmer's sustained attention and commitment to a farm that we begin to understand what appropriate human settlement looks like. Henry David Thoreau (1817–1862) once described the dominant human pattern of relating to land as robbery. Pioneers came to a place and took (often by force) what they wanted or felt they needed, and then moved on to virgin territory, where the rape and exploitation commenced again. This is not settlement in any commendable sense.

The history of agriculture shows over and over again how easy it is to fail at being a good farmer. In the United States, for instance, nineteenth-century farmers had to move west, because the fields and forests of the eastern seaboard were so thoroughly abused and depleted. Not enough attention was applied to what the land can sustainably provide. A careful farmer asks, What does this particular piece of land—because of its specific contour, soil makeup, native vegetation, and climatic conditions—recommend be grown, and can it be grown without unduly damaging the shared biome? How can farming methods improve rather than degrade the soil base? Will this farm practice entail the wholesale displacement of animal species? Will this farming technique or decision ensure that farmers will be able to work this same land for generations to come? These sorts of questions invariably require us to see the land not as a *resource* that we can extract, but as a *source* of life that we must nurture and protect.

A Vast Cornfield in Nebraska. *Farmers have the unique obligation of making many choices relating to environmental ethics. "Good farming" keeps the health of local lands and waterways intact, and is concerned about the well-being of its livestock.* CHERYL A. MEYER, 2008. USED UNDER LICENSE FROM SHUTTERSTOCK.COM.

Farms are not simply food factories producing sellable commodities. They are places where plants, domestic and wild animals, and people must live together harmoniously. When pressures that encourage the abuse of land predominate, as they invariably do in modern extractive economies that reward volume with profit, Leopold advised that urbanites should pay farmers to leave grain or fencerows or marshes or woodlots for wildlife. When farmers conserve soil by resisting the temptation to mine it for all it is worth, they should be financially compensated. His point is that urbanites and farmers need to find ways to work together to achieve healthy lands and communities.

Good farming, in contrast to ecologically destructive forms of industrial farming and agribusiness, has always kept as its primary concern the health of lands and waterways and the contentment of animal livestock. Farmers understand that we draw our life from the land because of the inescapable fact that to live is to eat. To abuse the land and its animals—as we do when we lace our soils with artificial fertilizers and pesticides, or

pollute and drain our waterways and aquifers, or confine hordes of animals in crates or their own muck—is to abuse human health and invite economic and cultural collapse. It is also to eat bad food, food that is not the most nutritional and tasty. In other words, however we design our food and fiber economies, they must be sympathetically attuned to nature's economy if we are to survive for long. Farms are the ideal place for us to learn this art of attunement.

Industrial cultures have long assumed that they can ignore or override the limits and potential of the land. Caught in the grip of widespread ecological amnesia, people are becoming more and more convinced they can thrive without paying attention to or honoring the biological limits and potentials that exist in every place. Our current industrial food system reflects this tendency in food products that contain more artificial flavors and preservatives than do whole foods, foods that everyone would recognize as having come from the soil. Our survival is necessarily tied to eating off the land, which means that we need to exercise sustained care for all the natural sources and places that literally feed our bodies and communities.

Farming can be a vital source for philosophical and ethical reflection, because it is grounded in an intimate and practical connection between humans and the land. As Wendell Berry, the leading agrarian of our time, put it in *The Unsettling of America* (1977), "No matter how urban our life, our bodies live by farming; we come from the earth and return to it, and so we live in agriculture as we live in flesh" (p. 97). We are not tourists or spectators on this earth, nor are we simply consumers who purchase resources, much like shoppers who pick commodities off a store shelf. As Berry advises, there is no greater myth than the idea that "money brings forth food."

To live at all, we must draw our nourishment from the gifts of the land. To live well, and in a manner that ensures the health and beauty of our shared habitats, requires attention, patience, and the insight and accumulated wisdom of generations of people who have worked with the land. The history of farming and the lessons of farm life simply must play a central role in the preservation and restoration of our diverse landscapes.

The agrarian point is not that all people must be farmers (though urban farming and community gardening are trends that should be encouraged). Growing populations of people, as well as a shrinking aptitude for farm work, make such a prospect untenable and unlikely. The more urgent priority is that all people, no matter how urban or suburban their lives have become, adopt farm priorities that see as their foremost, nonnegotiable concern the health of productive lands. Urban dwellers must make the political, economic, and moral choices that will encourage good farming practices and preserve valuable farmland. If we fail in this task, we invite cultural ruin. More immediately, we deprive ourselves of nutritious, tasty food.

FIRE

A natural process that has aided the evolution of all types of ecosystems over the millennia, fire occurs across the world wherever climate allows for the accumulation of herbaceous or woody plant material and at least occasional drying of that material. Fire can open up space for plants to regenerate; return nutrients in dead plant tissue to the ground; and aid germination by triggering seed release, resprouting, and flowering. In some ecosystems, fire is essential to the maintenance of species composition, plant density, structure, and regeneration. Ecosystems that have evolved with fire often have greater animal and plant diversity when they periodically burn.

The most common nonhuman cause of fire is lightning, but other causes include lava and ash from volcanoes, and spontaneous combustion triggered by heat generated from decomposition. Some climates produce

significant amounts of dry lightning (cloud-to-ground lightning without significant rainfall). This is the most common form of lightning to cause fires. Once a fire is kindled in the landscape, the extent and intensity of the fire is related to fuel, topography, wind speed and direction, and relative humidity. These conditions work together to affect the amount of area burned. Before modern fire suppression became possible, it was not uncommon for fires to burn hundreds of thousands of acres before encountering an obstacle or weather conditions that would extinguish them. Because these variables change across the landscape, it is not uncommon to find areas that entirely escape the effects of fire, but that are surrounded by burned areas—a pattern that results in a mosaic of habitat conditions.

Homo erectus has been documented to have used fire as far back as 400,000 years before the present. Evidence suggests that since that time humans and related species have been intentionally or accidentally responsible for increasing the frequency of fires in the ecosystems in which they existed. Native American cultures have been documented to have used landscape-scale fires for at least seventy different reasons, including driving game, attracting game, warfare, insect control, and reducing the severity and risk of unplanned fire.

While humans have caused an increase in fire frequency throughout much of our species' existence, from the twentieth century humans have been directly and indirectly responsible for reducing fire frequency. Increased habitat fragmentation by roads and other development has reduced fire spread and the overall effect of fire on the landscape. After a series of catastrophic wildfires in the United States in 1910, low-intensity prescribed fire for agricultural or silvicultural (forestry) purposes fell out of favor. This was a significant shift for many rural communities where fire had been a part of land management and agricultural practices for centuries.

Fire Prevention Mascot, Smokey the Bear. *Smokey the Bear emerged from Americans' sense of fire as hostile and dangerous after its use in World War II. The U.S. Forest Service's mascot serves as a recognizable face of fire prevention, urging personal responsibility in caring for forests and the animals that inhabit them.* **AP IMAGES.**

SMOKEY THE BEAR

Probably the best-known fire suppression campaign comes from the U.S. Forest Service and its mascot Smokey the Bear. In an effort to reduce accidental human-induced fires in the landscape, this cartoon character urged personal responsibility with the phrase, "Only you can prevent forest fires." These public-service announcements depicted wildfires as destroying forests and the animals that live in them. Stephen Pyne wrote that after Americans witnessed the use of fire as a weapon in World War II, all fire came to be seen as hostile and undesired. Smokey the Bear

> emerged directly out of the wartime emergency; almost on cue, too, Disney Studios releases *Bambi*, in which the same villains who kill Bambi's mother also unleash a terrifying fire that threatens Bambi and his father, a powerful antifire message to young children. Before the war, most Americans, certainly most rural Americans, at least tolerated fire as an instrument of land use; after it, as fire imagery became more horrific and as the rural population drained away to cities and suburbs, Americans distrusted fire. (1995, pp. 198–199)

From 1910 through most of the 1960s, U.S. fire policy called for extinguishing nearly every fire that started as soon as possible. The cost of this policy, both in terms of economic expenditures and the lives of firefighters, grew as fuel loads increased, particularly in areas where fires were historically common. By the 1960s managers and legislators were questioning the goal of full fire suppression, and with the passage of the Wilderness Act in 1964, the National Park Service began to allow lightning-caused or accidental fires to burn through designated wilderness areas of parks. By 1970 the U.S. Park Service specifically changed from a policy of fire

Aftermath of the Yellowstone Fires. *Ten years after the 1988 fires at Yellowstone National Park, the destruction can still be observed. Fortunately, the area is being recolonized quite rapidly by plants and trees, such as these lodgepole pines, near Firehole.* **NPS PHOTO BY JIM PEACO.**

suppression to one of allowing naturally caused fires to burn within the boundaries of national parks. By the mid-1970s the Forest Service had followed suit.

THE YELLOWSTONE FIRES

The most dramatic fires to have hit American television screens and consciousness occurred in 1988 at Yellowstone National Park. From 1865 to 1964 Yellowstone had an extensive program of fire suppression, which resulted in a significant decrease in fires in the park. In 1972 Yellowstone began both to set fires and to allow accidental fires to burn within the park. Through the summer of 1987, this policy resulted in low-intensity burns that affected small portions of the park. In 1988 weather conditions were such that when fires were allowed to burn, they became much larger conflagrations than had previously been experienced since the park had become government property in 1865. Over 36 percent of the park and 245,000 hectares of the greater Yellowstone region burned. At the time of the fires (which continued over three months), there was significant media attention directed to the perceived "destruction" of the Yellowstone ecosystem. Studies since this occurrence, however, have revealed that the ecosystem was able to regenerate from these fires, and in fact some species benefited significantly from them. While immediately following the fire many areas appeared devastated, they were rapidly recolonized, initially by native herbaceous plants and later native trees such as lodgepole pines (*Pinus contorta*, var *latifolia*) and aspen (*Populus tremuloides*). The resurgence of aspen was particularly interesting, as this species, believed to be a holdover from the Pleistocene Epoch, reproduced exclusively from clonal root sprouts. Throughout the park researchers found germination of aspen seeds, beginning immediately after the fire. Native animal species also weathered the fire. While individual animals were undoubtedly killed by the fires, populations of most species had rebounded to prefire levels by 1995.

THE URBAN-WILDLAND INTERFACE

Increasingly, there are many communities and livelihoods centered within or along the urban-wildland interface. In

these areas, homes are often situated within fire-prone ecosystems and are at a significant risk of damage from fires. Much like areas prone to flooding, the often infrequent occurrence of wildfires promotes a feeling of safety and a belief that fires are out of the ordinary, especially when fire frequency goes beyond twenty-year cycles. The location of homes and communities within ecosystems prone to fire has renewed efforts at fire suppression on public land, particularly when it occurs in areas where there is valuable private property at risk.

ETHICAL ISSUES

There are a wide range of ethical issues surrounding wildfires and prescribed fires. For those who feel that human involvement with wilderness areas is unnatural, suppressing lightning-caused fires and setting prescribed fires are seen as attempts to domesticate the wilderness and control wild nature. Increasingly, however, it seems unavoidable that human decisions will affect these areas in some way. The fragmentation of habitats and the suppression of fires throughout much of the United States reduces fire frequency in wilderness areas. Lightning within those relatively small wilderness areas will not be enough to maintain a fire frequency similar to that of historical conditions. Focusing only on lightning-caused fires also ignores the prevalent use of fire as a landscape-shaping tool by cultures around the world over the last 10,000 to 400,000 years, a period during which many systems were shaped by those fires and have come to depend on them. Human-initiated prescribed fires may restore fire frequency, but are often set under conditions when these fires can best be controlled. Such conditions are not likely to be similar to historical conditions when lightning might have begun such fires.

In many ways the ethical concerns surrounding fire come down to the most basic question in environmental ethics: To what extent are human actions natural or justified in the environment? On the one hand, to the extent that humans are perceived as interlopers in nature, there are few fire regimes that can be considered natural. If, on the other hand, humans and their actions, or at least a subset of them, can be considered natural, then the challenge is to identify the level of interaction that will result in desired results stemming from a specific set of philosophical assumptions. In any case, fire is neither good nor bad, but is instead a complex occurrence that must be evaluated on a case-by-case basis.

Anthropocentric value systems will focus on the needs and desires of humans. Under such a value system, fire or fire suppression should be used primarily to protect humans and their property rights, but could also extend to humans' desires to have access to healthy ecosystems for recreation, wildlife habitat, and the production of ecosystem services. Zoocentric and biocentric ethical systems will focus on the effects of fire on individual animals, plants, and their habitats, but can reach conflicting results in cases where, in any one area, both fire and fire suppression will kill some individuals and promote others. Ecocentric ethics will focus on the role of fire in promoting healthy ecosystems and stable biotic communities, but this goal is invested with other challenges. Differences in fire frequency, fire intensity, and fire season can result in changes in community composition and ecosystem functions, and many alternatives can be considered healthy. Selecting the most appropriate way to use or suppress fire in the landscape remains a subjective value judgment that cannot be reduced to objectively verifiable criteria. It is this complexity that makes fire worth studying scientifically, politically, and philosophically.

FISH FARMING

Aquaculture is the cultivation of aquatic populations of freshwater and saltwater organisms (e.g., fish, shrimp, bivalves) under controlled conditions. Aquaculture accounts for more

than 30 percent of all fish consumed by humans (U.N. Food and Agriculture Organization 2003). During the second half of the twentieth century, the Green Revolution promoted the practice of intensively managed monocultures, or the practice of producing a single species over a wide area in controlled environments. In the 1960s monocultures covering vast areas of land and coastal ecosystems began to prevail also in large-scale forestry and aquaculture. Monocultures usually involve introducing and growing an alien species at the expense of native flora and fauna. Consequently, monocultures have been identified as a major driver of biodiversity losses (Primack et al. 2001).

Defenders of monoculture argue that these intensive farming practices are necessary for providing food for a growing human population, at a time when only a small proportion (approximately 15%) of the remaining land on the planet is available for agriculture and when fishery stocks have declined dramatically (Millennium Ecosystem Assessment 2005). In the early 1980s, aquaculture was presented as the coming Blue Revolution that would alleviate world hunger, provide jobs, and fight poverty (Primavera 2005). Yet ecologists and other scholars began to question the effectiveness of some widespread large-scale monoculture practices that had negative environmental, social, or economic impacts.

The explosive expansion of salmon and shrimp farming since the late 1980s has created an intensive debate on associated issues of environmental and social justice, scientific-technological and indigenous ecological knowledge, ecosystems and human health, and biotechnology and animal rights (Rozzi 2003). Contrasting large-scale industrial aquaculture with small-scale sustainable practices in Asia, the Philippine ecologist Jurgenne Primavera since the 1980s has led tireless efforts to replace unsustainable aquaculture practices with sustainable ones. Primavera (2005) has pointed out that fish farming has boomed during the last three decades, and that although farmed fish are produced mainly in developing countries, most of the production is exported for markets in industrialized nations.

Shrimp and salmon are not only the most controversial aquatic monocultures but also among the most lucrative and widely traded aquaculture products (Naylor et al. 1998, U.N. Food and Agriculture Organization 2003). Shrimp are widely farmed in tropical coastal areas of Asia and Latin America, while salmon are raised in temperate and higher-latitude coastal and inland waters of the Northern and Southern Hemispheres.

THE ECOLOGICAL AND SOCIAL CONSEQUENCES OF SALMON FARMING

It is commonly assumed that aquaculture relieves pressure on wild fisheries and adds to the world's food supply. This assumption is generally valid for herbivorous species, but not for carnivorous fish such as salmon (Beveridge et al. 1997). Farmed salmon spend their first year in freshwater ponds, and then for another one to two years of growth, they are transferred to floating cages anchored in coastal bays, where they are fed nutrient-rich diets containing large amounts of fishmeal and fish oil extracted from caught wild fish. Paradoxically, the required input of wild-fish products is up to four times the volume of salmon-fish output. This imbalance exerts pressure on native fish consumed by humans and on trophic chains in marine ecosystems. Therefore, salmon aquaculture depletes rather than augments fisheries resources (Naylor et al. 1998).

Because salmon depend on a diet that is 45 percent fishmeal and 25 percent fish oil, European salmon farming requires stocks of wild fish imported from South America. Initiated in Norway in the 1960s, salmon farming rapidly expanded toward equivalent high-latitude environments in southern Chile in the 1980s. Chile's southern regions offer ideal water temperatures and salinity conditions in sheltered fjords and in channels of the subantarctic Magellan Archipelagoes, one of the most pristine ecoregions of the world (Bjorndal and Aarland 1999, Robles Gil 2002). The aesthetic of these austral landscapes is transformed by the presence of salmon cages along the coast, and marine biodiversity is affected by voracious feral salmon that escape from the cages. In addition, local fishermen are losing access to use rights of coastal areas because concessions of bays are given to the salmon-farming industry.

Salmon farming uses a dilution approach to water pollution. Salmon cages allow feces and uneaten feed to flow directly into coastal waters, which results in substantial discharges of nutrients. The Nordic salmon-farming industry discharges quantities of nitrogen and phosphorous equivalent to the amounts in untreated sewage from populations of 3.9 million and 1.7 million people, respectively (Folke et al. 1994). High stocking densities of caged salmon have facilitated outbreaks of diseases and parasites, which require the use of antibiotics and pesticides that spread chemicals into coastal waters. High concentrations of salmon in cages also raise questions about animal treatment. The living conditions of farmed fish are even worse than those of industrially raised poultry and mammals (Rozzi 2003). Stress hormones and chemicals can build up in the meat of farmed fish, and these may have health effects on people. For human-health, ecological, and ethical reasons, free-living salmon represent a better option. A healthier alternative is provided by Irish organic salmon produced off-shore, 6 kilometers away from the coast in areas exposed to marine currents, where fish must constantly swim against the current. These conditions not only have a positive influence on muscle development and fat content, in addition, fecal and feed wastes are flushed away.

SHRIMP FARMS IN PLACE OF MANGROVES

The white-gold boom of shrimp production in such Asian and Latin American countries as Thailand, Indonesia, and Ecuador has involved extensive deforestation of mangroves for farming pools during the last three decades. Mangrove deforestation attracted worldwide attention when a tsunami crashed into the coastal regions of Asia in 2004. The lifespan of intensive shrimp pools in Asia rarely exceeds five to ten years, but their ecological and social impacts are long-lasting (Naylor et al. 1998).

A notorious example from Ecuador illustrates the main social and ecological problems associated with shrimp farming (Rozzi 2003). Ecuadorian shrimp is famous in international cuisine. Commercial cultivation of shrimp began in Ecuador in 1968, and this country became the world's principal producer of shrimp in 1983. This boom had such a large environmental impact that in 2008 the extent of shrimp pools surpasses that of mangroves along the Ecuadorian coast. Mangroves act as "ecosystem membranes" between tropical terrestrial and marine ecosystems, recycling nutrients and regulating hydrological flows. Their massive conversion to shrimp pools dramatically increased the levels of sedimentation in coastal waters and losses of soil nutrients. Shrimp industries also discharge contaminated waters and divert the course of streams and rivers. These processes drastically affect population levels of algae, fish, crustaceans, and mollusks that depend on mangroves at some phase of their lifecycles.

In addition, the shrimp industry causes serious social problems by limiting the access of local communities to coastal natural resources. The rights of local communities are ignored or easily violated to favor shrimp industries, which limit or forbid access to traditional users of mangroves by means of government concessions. Furthermore, the conversion of mangroves and the pollution of estuarine ecosystems diminish the quality of life for fisher communities by reducing the populations and diversity of species of shellfish, fish, algae, crabs, and oysters traditionally gathered by women in these ecosystems. Consequently, this export boom in Ecuadorian shrimp leads to hunger in local people inhabiting the coastal region of this country. Local communities have opposed this model of development since the 1970s. As a result of such local opposition, the government established a biological reserve of mangrove ecosystems in the province of Esmeraldas in 1995, and in 1999 it issued a presidential decree that forbids cutting mangroves in Ecuador. This decree created hope in coastal communities of Ecuador, Colombia, and other tropical Latin American countries, as well as in Asian nations also affected by losses of mangroves and displacement of local communities associated with large-scale shrimp farming (Primavera 2005).

The protection of mangroves in Ecuador represented a shift in ecological and social values and national policy at the end of the twentieth century. During the first decade of the twenty-first century, protected mangroves have contributed to the regional economy by providing suitable nursery habitats for shrimp larvae and attractive sites for ecotourist activities.

FOOD

Food poses a variety of philosophical issues such as the ethical treatments of animals, the moral and political dimensions of genetically modified food, hunger and obligations to poor, and the role of food in gender and personal identity. Yet food has received scant attention in the philosophical literature compared to subjects like science, technology, and the environment, perhaps because food is perceived to be too physical and transient to deserve serious philosophical reflection or because food production and preparation have traditionally been regarded as women's work and, therefore, unworthy topics for male philosophers. As contemporary philosophy continues to challenge conventional notions of what constitutes "real" and "serious" topics of analysis, and as a feminist "hermeneutic of suspicion" yields important insights previously ignored in mainstream scholarship, philosophers have shown an increasing interest in the moral, political, metaphysical, and aesthetic dimensions of food.

Since World War II changes in the technological and cultural landscape have affected views of food and eating. In the mid-twentieth century the methods and machinery of industrialization were applied to food production, culminating in the so-called Green Revolution, which brought forth great increases in agricultural productivity in both the industrialized and developing worlds. In addition to yielding more food, the Green Revolution also spawned social and environmental changes and raised questions about the appropriate use of land, environmental harms, effects on women, hunger and trade policy, and the ethical treatment of animals.

Further changes in the technological and cultural landscape in the industrialized global north have spurred an increasing awareness of the effects of industrial agriculture, the dubious nutritional value of highly processed foods, the potential health and environmental risks of genetically modified organisms (GMO) and foods, the globalization of food trade and production, and food scarcity and steep price increases in staples brought about by the increasing affluence in China and India and the deepening impact of the biofuels industry on the market for maize.

A Traditional Market in Taipei, 2008. *Food is not a topic that has been traditionally philosophized about, but advancements in technology and culture throughout the world are quickly changing this fact. Rising costs and shortages of food are a major battle being fought by organizations around the world, and other issues, such as nutritional value of processed foods and genetically modified products, have become issues of debate.* **SAM YEH/AFP/GETTY IMAGES.**

NATURAL AND ARTIFICIAL FOOD

Almost everything humans eat has been processed in some way; technologies and techniques transform raw, whole plants or animals into food. Food-processing techniques include cooking, drying, fermenting, slicing, peeling, and butchering. More technologically complex forms of processing includes pasteurizing, canning, freezing, irradiating, and artificially sweetening. Some processed food contains additives, substances designed to help prevent spoilage and contamination or to make food look and taste better. Some processed foods include dietary supplements with nutritional properties, such as vitamins, minerals, proteins, herbs, or enzymes. Among the benefits of food processing are improved preservation, increased distribution potential, fortification, consumer choice, and convenience. Among the harms and risks often associated with processed food are reduced nutritional value, adverse health effects, pollution, and the amount of energy expended in processing.

By contrast, so-called natural foods are purported to be free of artificial ingredients and are often less processed than conventional food. Natural foods—if they are really natural—do not contain artificial food additives, coloring, flavoring, or sweeteners. Nor do they contain refined flour, refined sugar, or hydrogenated oils. "Whole foods" are even less processed or refined. Proponents of a "whole-food diet"

claim it is more healthful than a processed-food diet and results in less harm to the environment.

"Raw foods" are "whole foods" that have undergone little or no processing at all. A "raw-food diet" is one composed of entirely uncooked whole food. Advocates of such a regimen believe that increasing the intake of raw foods produces significant health benefits. They claim that it promotes weight loss, prevents disease, and helps mitigate the effects of chronic illness.

"Organic foods" are supposed to be grown without the use of pesticides, synthetic fertilizers, sewage sludge, genetically modified organisms, or ionizing radiation. Animals that produce organic meat, poultry, eggs, and dairy products are not supposed to be given antibiotics or growth hormones. Organic foods are not necessarily whole foods, nor are whole food necessarily organic. The term *organic* refers to the method of growing food or raising livestock, not to the amount of processing it undergoes.

According to the 1995 U.S. Department of Agriculture National Organic Standards Board, organic agriculture is an ecological production-management system that promotes and enhances biodiversity, biological cycles, and soil biological activity. Organic agriculture is based, in theory, on minimal use of off-farm inputs and on practices and materials that restore, maintain, and enhance ecological harmony and health within the farm and beyond.

Organic agriculture aims to optimize the health and productivity of interdependent communities of soil life, plants, animals, and people. Champions of organic food claim that reducing or eliminating the use of agricultural and industrial chemicals leads to cleaner air, water, and soil, and yields more nutritious, more healthful, and better-tasting food. Critics claim that the health and environmental benefits of organic food are questionable, that it is costly to consumers, and that the slippage in standards for organic production and lack of regulatory oversight leave consumers unsure whether or not their food is as "organic" as advertised.

INDUSTRIAL AGRICULTURE AND ENVIRONMENTAL DEGRADATION

Intensive farming, or the industrialization of agriculture, became the norm in twentieth-century North America, Western Europe, and other developed regions of the world. During the latter half of the twentieth century, this model was exported—some would say imposed on—much of the rest of the world. Industrial agriculture involves highly productive systems based on the use of systematic plant breeding (since the 1990s augmented by genetic engineering); monoculture crops; fossil-fuel energy; farm machinery; artificial chemical fertilizers, pesticides, and herbicides; and mechanized irrigation, processing, and long-distance transportation of both bulk raw foods and packaged processed foods. Intensive agriculture has resulted in higher yields, increased productivity, greater availability, and lower prices, but it has also raised significant health and environmental concerns stemming from the use of chemical fertilizers, pesticides, and herbicides, all of which can pollute the air and soil and contaminate water supplies. These contaminants often enter into the food supply, posing health risks to humans and animals and threatening aquatic habitats and ecosystems. One of most intensive aspects of "intensive farming" is its liberal use of energy, especially the fossil fuels that contribute to increased atmospheric and oceanic carbon dioxide, which in turn cause global climate change, and marine acidification, all with unknown consequences.

Industrial agriculture also exposes the soil to the erosive effects of wind and rain, often leading to a severe loss of topsoil. Erosion has other harmful effects: It washes vast amounts of silt into bodies of water, damaging plant and animal life, and it increases the amount of dust, which is an air pollutant and a carrier of infectious diseases that can cost nations financial and productivity losses.If production is to be sustained, nutrients lost to erosion must be replaced, usually by chemical fertilizers, which compromise water quality and biodiversity and diminish the quality of the soil.

Industrialized agriculture involves the planting of monoculture crops, which are single crops grown over thousands of kilometers of land. Such vast monoculture planting threatens the loss of the genetic diversity represented by "land races," the local varieties of crops once grown on smaller scales on those lands. Monoculture crops create an ecological vacuum that insects and diseases exploit, further reducing the quality of the soil while increasing the possibility of crop failure. These declines in agricultural genetic biodiversity, which in turn reduce natural species biodiversity, have consequences throughout the food chain. Farmers must increasingly rely on chemical fertilizers and pesticides to compensate for the resilience formerly afforded by genetic diversity.

The industrialized production of livestock, poultry, and fish, also known as "factory farming," has many of the same benefits and harms associated with intensive farming. The benefits include efficiency, high yields, widespread availability, low prices, and contributions to local and national economies. Among the harms are the abuse of animals, environmental hazards, health risks to farmworkers, and food-safety problems. Industrial livestock production uses vast amounts of water, fossil fuels, inorganic fertilizers, and field machinery; it involves elaborate technologies such as food manufacturing, packaging, refrigeration, and transportation. The environment surrounding factory farms is often heavily polluted by animal wastes and offal, which foul the air and seep into groundwater and surface waters.

By contrast, "sustainable agriculture" aims to produce food indefinitely without causing environmental degradation. Sustainable agriculture may or may not be the same as "traditional farming," which often has a claim to be sustainable because forms of it have, in fact, been sustained for many hundreds of years; it attempts to combine responsible environmental management, high levels of farm productivity, respect for animals and workers, and support for rural farming communities. Sustainable agriculture might augment or replace traditional methods with postindustrial technologies such as drip irrigation or highly bred perennial polycultures.

In the 1990 "Farm Bill" the U.S. Department of Agriculture defined "sustainable agriculture" as an integrated system of plant and animal production practices having a site-specific applications that will, over the long term, satisfy human food and fiber needs; enhance environmental quality and the natural-resource base upon which the agricultural economy depends; make the most efficient use of nonrenewable resources and on-farm resources and integrate natural biological cycles and controls; sustain the economic viability of farm operations; and enhance the quality of life for farmers and society as a whole.

Farmers who take a sustainable approach substitute knowledge for pesticides and fertilizers. They use crop rotations and other adjustments of the agricultural system to solve problems. Among the benefits of sustainable agriculture are soil enrichment, which produces healthy plants that resist disease; the growth of cover crops (ancillary crops that cover the soil during otherwise fallow seasons), which retard erosion and control weeds; and the use of natural predators to help control pests. Sustainable farming minimizes the use of inputs of pesticides and fertilizers, thereby saving money and protecting the environment.

GLOBAL AND LOCAL FOOD

Trade and the globalization of agriculture are increasingly "delocalizing" the origin of food and the political authority over food policy. Transnational agribusiness and the global political and financial institutions that support them exercise great influence over food production, with growing consequences for food security and safety and the social fabric of communities. One social consequence of intensive agriculture is the consolidation of small farms into large, monocrop operations. As industrialized farming replaces human labor with machinery, each year millions of people are displaced, disrupting societies based on rural farming and swelling the population of urban areas.

The globalized food trade tends not to improve the lot of poor countries; to the contrary, if often aggravates poverty in those nations countries as subsidized foodstuffs from industrialized nations artificially drive crop prices down. Local farmers cannot compete with the factory-farm imports, so poor countries are forced into dependency on wealthier nations for food. A further consequence is that traditional, local diets are being replaced by a globalized, homogenized, animal-sourced diet of supermarket foods infused with high-calorie sweeteners and vegetable oils. These dietary changes and lifestyle changes have led to the globalization of the unhealthy European and North American diet, with attendant rises in rates of obesity, diabetes, and heart disease.

Two food movements have emerged in response to the increasing globalization of food production and commerce. One is the local-food movement. Its proponents maintain that locally and sustainably produced food enhances the economic, environmental, health, and well-being of communities. A locavore is someone who aims to eat only food grown or produced within a short distance from his or her home—preferably within a radius of 100 miles. Local food networks of small farms, community gardens, seed banks, community-supported agriculture, coops, and farmers markets enhance local relationships among farmers and communities while providing alternatives to global food production.

The slow-food movement was started in Italy by Carlos Petrini in the late 1980s as counterforce to the global corporate fast-food juggernaut. This movement champions the consumption of locally grown food that uses land-race seed stocks and traditional methods of production in the particular ecoregions in which they evolved. Its proponents claim that this regional form of agriculture protects the environment; promotes local traditional culinary practices and lifestyles; enhances relationships among farmers, communities, and environments; and yields superior-tasting food.

Critics of the local-food and slow-food movements argue that newly industrialized export-oriented farmers in developing countries are harmed when consumers refuse to support international food production and trade. The moral obligation to alleviate suffering abroad, they argue, takes priority over the obligation to mitigate environmental degradation and to support local "hobby" farmers, who have many economic alternatives that are unavailable in less affluent parts of the world and who are producing expensive fad foods for fashion-conscious, high-end bourgeois consumers in the developed world.

Critics also note that transportation is only part of the total environmental impact of food production and consumption. Thorough environmental assessments of food include analyses of methods of production and amounts of energy used. Often the total energy used in food produced and transported great distances is less than that expended in local production. Proponents and critics alike agree that food and agricultural practices should be

subject to more stringent moral and political scrutiny in order to promote food safety, nutrition, and taste while protecting farmworkers, food producers, animals, and regional biodiversity.

BIOFUELS VS. FOOD

At the turn of the twenty-first century, one of the most hotly contested issues in the ethics of food is the advisability of using foodstuffs such as maize to produce biofuels. Partly as a consequence of this shift in the commodities market, food prices doubled between 2007 and 2008, threatening many poor people throughout the world with chronic hunger, malnutrition, and even starvation. Unlike the controversy over slow and local foods, this debate does not involve individual consumer choice because ethanol, made mostly from maize, is added indiscriminately to gasoline, and ethanol-free gasoline is not offered to consumers as an ethical alternative, even at a higher price. Rather, this is a collective moral issue, to be dealt with at the level of public policy enacted in response to popular outrage over farmers converting food to energy rather than making it available for people to eat.

Critics of the biofuels industry point out that ethanol produced from maize may require more energy to produce—in the form of tractor fuel, petroleum-based fertilizers, the energy involved in distilling it, and other energy-intensive inputs and processes—than is contained in the ethanol derivative. At best, the net energy gain is marginal. Second, other nonfood, less energy-intensive crops such as switchgrass can be used as the raw material for ethanol and other biofuels. The current U.S. policy of encouraging rather than discouraging the growing of maize for ethanol production has been criticized as pork-barrel legislation favoring the economic interests of farm states while masquerading virtuously as a means of achieving U.S. "energy independence."

Another cause of the steep worldwide rise in food prices from 2007 to 2008 is the growing prosperity of the Chinese and Indian populations, which has led to an increased global demand for meat. Producing meat, except on lands incapable of producing crops, involves feeding animals food that might otherwise be available to hungry humans. Only about 10 percent of the "feed" consumed by cows, pigs, chickens, and other animals in factory farming is converted to meat; or, put the other way around, 90 percent of the food value of feed crops consumed by animals for meat production is lost. This indeed can be construed as an individual moral choice. Animal ethicists argue that if the slaughter of sentient beasts cannot penetrate the conscience of the mass of meat eaters, perhaps the prospect of massive human hunger, malnutrition, and starvation will.

A problem remains, however: what economists call the "free-rider" issue. Morally motivated consumers may choose to be vegetarians, but their choice may register such a weak signal in the global marketplace that if many others do not make the same choice, food prices will remain unaffected. In that case government-enforced remedies are the only workable alternative. A luxury tax, for example, might be put on meat to discourage consumption and thus ease price pressure on agricultural commodities, diverting them from animal feedlots and onto the plates of hungry poor people.

FOOD SAFETY

A safe and secure food system is undeniably a public good, and so protection of foods is a major public-policy concern (Caswell 1998). Safe food may also be a basic human right. In an urbanized society, the complexities of the food system, especially its lack of transparency to most of the public, has long obligated governments to ensure safe food

by overseeing farmers and food processors and distributors (Starbird 2005). Several factors have made carrying out this moral responsibility more serious and difficult in the present era. Government agencies responsible for food safety now face (1) increasingly concentrated corporate control over the food chain from farm to market, (2) the introduction of genetically modified foods into the marketplace, (3) a global market in even basic food staples, and (4) a hostile international political climate, especially the proliferation of terrorist activities.

In the past, most of the problems with food safety were associated with bacterial/viral contamination or spoilage. In many parts of the world, these are still the main sources of food-borne health risks. In modern societies with industrialized agricultural systems, risks from microbial contamination and spoilage still exist, but other contaminants pose greater concern. Among these are agricultural chemicals (such as pesticides, herbicides, fungicides), industrial chemicals (such as mercury and other heavy metals entering the food chain via air and water pollution), and foreign material (such as animal excrement, toxic plant material, and other undesirable biological material) (Henson and Caswell 1999). Ethical and public-policy problems arise in part from the fact that different agencies are responsible for different links in the food-system chain, with different risk factors tied to different links. The Animal and Plant Health Inspection Service and the Food Safety and Inspection Service of the U.S. Department of Agriculture are responsible for insuring that healthy animals and nontoxic plants are used in agricultural production. The Environmental Protection Agency is responsible for industrial and other environmental contaminants. And the Food and Drug Administration is the ultimate arbiter of whether or not processed and new food products are safe for public consumption. The Food and Drug Administration also determines whether certain foods need to be labeled as having certain ingredients, beyond their nutritional composition.

All three agencies have faced an especially difficult situation since the introduction in the 1980s of genetically modified plants (and more recently animals). In the view of at least some people, foods that contain such material as seeds or oils or even proteins derived from genetically modified plants and animals are ethically unacceptable. The U.S. Department of Agriculture supported and encouraged farmers to adopt genetically modified crops as a way of reducing use of pesticides and herbicides, and the Environmental Protection Agency supported this policy. However, the Food and Drug Administration has faced considerable pressure from consumer advocates and citizen groups to prevent genetically modified material from entering the food system, or at least to label foods that contain genetically modified material as such. After deciding that most genetically modified organisms are safe for human consumption—a controversial decision in its own right—the Food and Drug Administration decided that labels are unnecessary (Hoban 1998).

The no-labeling decision of the Food and Drug Administration appears to contradict a basic ethical consideration: People have a moral right to choose what they put in their bodies, especially what they eat. If some people object to genetically modified organisms or biotechnology generally on religious or cultural grounds, or perceive risks in genetically modified organisms, then governments must respect their right not to consume such items. Even if those who object to genetically modified organisms are scientifically incorrect in their assessment of risk, they are nevertheless entitled to have their rights protected. This is an ongoing ethical dilemma that the Food and Drug Administration will face as long as genetically modified foods are allowed on the market and are not labeled as such (Thompson 2007).

Since the September 11, 2001, terrorist attacks on the United States, the notion of food safety has taken on a new meaning, closely associated with what used to be called food security. Because of how vulnerable consumers are to intentional food contamination with anything from toxins to carcinogens, there have been calls for stepped-up efforts to protect agriculture, monitor food processing more closely, and inspect food distribution centers more aggressively, especially entry points for imported foods. However, as the global market intensifies and expands, to the point where the United States imports much of its basic staple commodities from other nations with less-rigorous safety standards than our own, questions have arisen as to whether, or even if, regulatory agencies can act on their ethical responsibilities to secure the public good efficiently and effectively.

FORESTS

Forests are ecosystems dominated by trees; the technical definition specifies a tree-canopy cover of at least 10 percent. For millennia forests have provided food, medicinal plants, and wood to humans living in and near them; they have proved so valuable that humans have overexploited them. By the Middle Ages thousands of square kilometers of forests had been cut in Europe. At about the same time catastrophic deforestation took place in central Mexico that may have contributed to the collapse of the Maya civilization. In the *Critias*, written in the fourth century B.C.E., the ancient Greek philosopher Plato tells of the fifth-century deforestation of his native Attica and the attendant ecological damage, principally massive soil erosion. Deforestation has increased sharply during the twentieth and twenty-first centuries, threatening the very survival and evolutionary potential of many species, including human beings.

LOCATIONS AND BIODIVERSITY OF THE WORLD'S FORESTS

In 2007 the Food and Agriculture Organization of the United Nations (FAO) estimated worldwide forest cover at 39 million square kilometers, which is 30 percent of the earth's land area, with two-thirds of the forested lands distributed in only ten countries. If only intact forests (those not modified by humans) are counted, the estimated land area covered by forests is about 15 million square kilometers, or 10 percent of Earth's landmass (Greenpeace 2006). The three major forest biomes, described below, are tropical forests, temperate forests, and boreal forests.

Tropical Forests Some 56 percent of the world's forests (21.8 million square kilometers) are tropical and subtropical. Tropical forests are found between the Tropic of Cancer (23.4° north latitude) and the Tropic of Capricorn (23.4° south latitude); subtropical forests are located between the tropics and 30° north or south latitude. There are two major types of tropical and subtropical forests: Deciduous forests grow where the climate is humid but has a pronounced dry season, and rain forests grow in areas with more than 2 meters of rain per year and no dry season. Tropical rain forests are found in Central and South America (especially Brazil), central and western Africa, eastern Madagascar, Southeast Asia, New Guinea, and northeastern Australia. In Central America, Madagascar, and the Philippines forests are located within the paths of tropical cyclones (also called hurricanes or typhoons), which can uproot or break trees. Trees in rain forests located within cyclone paths are shorter, on average, than trees in other rain forests. The Amazon rain forest, covering 5.5 million square kilometers, makes up more than half of Earth's remaining tropical rain forest. It is so large that its trees produce 20 percent of Earth's atmospheric oxygen and remove approximately 62 tons of carbon per square kilometer per year from the atmosphere.

Per unit area, tropical rain forests contain more species of plants, animals, and fungi than any other terrestrial biome. Two-thirds of Earth's plants and animals, including more than 175,000 vascular plant species (flowering plants, gymnosperms, and ferns) and more than 170 primate species (apes, monkeys, and lemurs) are found in tropical rain forests. Tropical rain forests are also home to approximately 50 million indigenous peoples.

Temperate Forests Temperate forests once covered large expanses of western and central Europe, southern China, Japan, and eastern and western North America, approximately between 30° and 55° north latitude. Smaller areas of temperate forests are found in New Zealand, eastern Australia, southern Chile, Argentina, and South Africa. Today only 11 percent of the world's forests (4.3 million square kilometers) are temperate forests. Some 80 percent of the temperate forest biome is in the northern hemisphere, with the largest remaining forests in western North America. Although only 20 percent of temperate forests are in the Southern Hemisphere, they are ten times more species-rich per unit area than those in the Northern Hemisphere.

The world's largest and oldest organisms are found in temperate forests. Chile's west-coast Valdivian forest (the world's largest pristine temperate rain forest) contains 3,500-year-old *Nothofagus* (southern beech) and *Fitzroya* (Patagonian cypress) trees that average 60 meters in height and 5 meters in diameter. In California the coast redwood (*Sequoia*) can reach 110 meters in height and 8 meters in diameter, and the bristlecone pines, some of which are more than 4,800 years old, are the oldest organisms on Earth.

Depending on geography, climate, and soils, temperate forests are dominated by broadleaf deciduous "hardwood" trees (Europe and eastern United States), evergreen needleleaf "softwood" conifers (western North America and New Zealand), or a mixture of both. Other temperate forests (China, southern Chile, South Africa, and eastern Australia) are dominated by broadleaf evergreen tree species. Fire is a major disturbance in temperate forests, especially those dominated by evergreen coniferous trees, with the fire interval (the time between two fires at a given location) ranging

Humboldt Redwoods State Park, California. *Forests throughout the globe are being threatened by fires, acid rain, global warming, and deforestation. The American national park has become the most widespread model of forest conservation in the world.* **RICH REID/NATIONAL GEOGRAPHIC/GETTY IMAGES.**

from a few decades to a century or more. Fires in coniferous forests can be "stand-replacement" disturbances that kill many of the adult trees and trigger the germination of a new cohort of seedlings. Indeed, many conifers (redwood and knobcone pines, for instance) require fire to regenerate, either because their seedlings cannot get started in the thick forest litter or because their cones will not open and release their seeds unless they burn, or both.

Coniferous temperate forests are also prone to large-scale cyclical insect pest infestations that can kill entire stands, especially when trees are already stressed by drought or atmospheric pollution. Fire-suppression policies may also be responsible for pest outbreaks because natural fires keep insect pest populations low and break forest landscapes into mosaics of stands of different ages, keeping pest outbreaks spatially restricted.

Boreal Forest, or Taiga Some 33 percent of the world's forests (12.9 million square kilometers) are boreal forests that grow in a nearly continuous belt of trees between 55° north latitude and the Arctic Circle, through Norway, Sweden, Russia (where the boreal forest is called *taiga*), Alaska, and Canada. This biome includes the coldest human settlements on the planet, with winter temperature falling below minus 65 degrees Celsius in parts of Siberia. The boreal forest is dominated by conifers such as larch, spruce, fir, and pine, but broadleaf trees such as birch, alder, willow, and aspen also abound. Trees have adaptations for survival in harsh winters, including tapered conical shapes that shed heavy snow loads. Wildlife includes large herds of caribou and predators such as wolves and bears. Migratory birds use numerous large lakes and wetlands in the summer. Several aboriginal communities live in the boreal forest, especially in Canada, where aboriginal First Nations make up 14 percent of the population.

HUMAN IMPACTS ON FORESTS

Humans have burned, cut, and otherwise affected forests for thousands of years. Only 4 percent of the world's forests are in Europe today because of a long history of forest removal dating back to the Greek and Roman empires, when the growth of cities and the building of military ships required larger and larger supplies of lumber and firewood. Although natural phenomena such as droughts may have also played a role, the decline of the Sumerian civilization (in what is now Iraq) around 2000 B.C.E. and of the Mayan Empire (in what is now southern Mexico) in the eighth and ninth centuries C.E. were due partly to uncontrolled forest exploitation, soil erosion, and the resulting increase in the salinity of arable lands that triggered large-scale food shortages and famines. Since the Industrial Revolution, however, the variety and scale of human impacts on forests has increased dramatically.

The industrial release of sulfur dioxide and nitrogen oxides from power plants creates acid rain, which has affected large forested areas in industrialized regions, especially eastern North America and Europe. Acid precipitation damages leaves, stressing trees and making them more vulnerable to diseases and fires or killing them outright. A third of Germany's forests, including the famous Black Forest, and more than 10 percent of Switzerland's forests have been affected. In the United States forests in New England and the Appalachian Mountains have been affected by acid rain, and rivers and lakes have also become more acid, killing fish and other aquatic wildlife and plants. Ozone, a pollutant generated by car exhaust in areas with sunny climates, can also damage tree leaves and affect forests.

Fire suppression, mostly in the temperate forests of western North America and Europe, has replaced natural fire regimes (fire frequency, season, and intensity) that played a critical role in fire-adapted forest ecosystems. Fire control has altered the succession of species in these forests, has suppressed the regeneration of fire-adapted tree species, and has allowed the accumulation of flammable litter, increasing the size and severity of fires when they burn out of control in dry and windy weather.

Global climate change has been linked to worldwide forest damage and forest biodiversity loss, and it may become the primary cause of forest loss. From Costa Rica, where "cloud forest" amphibian species are becoming extinct because of the rising altitude of clouds, to western Canada, where unusually large bark beetle outbreaks killed 130,000 square kilometers of pine forests in 2007, global climate change is having increasingly severe impacts on Earth's forests. Dead trees further contribute to global climate change by releasing into the atmosphere carbon previously fixed in wood and soils.

The major human impact on the world's forests, however, comes from deforestation. The FAO estimates that the global rate of deforestation is about 130,000 square kilometers (the size of Louisiana) per year, which means that from 1990 to 2005, the world lost 3 percent of its forests. The main causes of deforestation include tree harvesting for wood or paper pulp, clearing for agriculture or livestock production, urban development, and tree harvesting for firewood. From 2000 to 2005, the yearly deforestation rate in the Amazon forest alone was 22,400 square kilometers (the size of New Jersey); making room for livestock pastures or soybean production accounted for 90 percent of this activity. Tropical deforestation has caused the extinction of many animal species and threatens others, including the mountain gorilla of central and east Africa and the Sumatran tiger.

Temperate and boreal forests are also being cut at an alarming rate. Nearly 9,000 square kilometers of Canada's boreal forest are logged every year for paper and timber, destroying habitats for caribou, grizzly bears, wolverines, and other wildlife, thereby threatening these species with extinction. In the Southern Hemisphere thousands of square kilometers of Chile's forests have been logged to make wood chips for export; these areas have been replaced with plantations of exotic species such as Monterey pine (more than 10,000 square kilometers have been planted) that cannot support the rich animal and plant biodiversity found in the native forests. Half of the coastal Valdivian forests of Chile have been cleared, and in the U.S. Pacific Northwest only 15 percent of the original forests remain.

FOREST CONSERVATION

People on all continents have practiced some form of forest conservation for several millennia. Protection laws regulated the use of forests in ancient Persia as early as 1700 B.C.E., and Celtic tribes in Europe had set aside sacred forests by about 500 B.C.E. Scholars have documented rules against overharvesting of trees among some North American Indian tribes and the designation of sacred forest groves with tree-cutting taboos—some still in force—in and around burial sites in Africa and Madagascar. Around 250 B.C.E. in India the earliest written laws sanctioning the conservation of forests and the regulation of hunting were promulgated under the Maurya dynasty. Throughout the tropics agroforestry (the cultivation of crops and trees together) has been practiced for hundreds of years, preserving many native tree species from extinction.

The tension between the modern European and North American conservation movement and the rights of indigenous people was foreshadowed in the writings of the American naturalist and preservationist John Muir (1838–1914), who, upon encountering a group of Mono Indians on the trail, reflected, "Somehow they seemed to have no right place in the landscape, and I was glad to see them fading out of sight down the pass" (1992, p. 343). The conservation policies of the U.S. government focused on landscapes, and the legislation that created national parks in the nineteenth century did not recognize traditional indigenous hunting-and-gathering rights in those areas.

Many parks protecting forest ecosystems were created in the late 1800s and early 1900s in the United States, Australia, Canada, Sweden, and South Africa, where Kruger National Park was established in 1926. In contrast to the United States and Canada, where national parks were carved out of largely pristine landscapes, national parks in Europe often incorporated human-modified landscapes such as farms, managed forests, and even villages. Nonetheless, the American national park system has become the most widespread model of forest conservation throughout the world. From 1962 to 2003, the number of "protected areas" worldwide increased from about 1,000 to more than 100,000, mostly in terrestrial ecosystems, including nearly 8 million square kilometers of forests, of which more than 4.5 million kilometers are in tropical forests (approximately 20 percent of the tropical-forest biome) and more than 3 million are in temperate forests (approximately 12 percent of the temperate-forest biome).

In developing countries, where populations are mostly rural and depend on land and natural resources for survival, the effectiveness and equity of the national park model, with its emphasis on removal of human land-based subsistence, has been the subject of much research and debate. The intensity of that debate sprang, in part, from the radicalization of a section of the environmental movement in the 1960s. Arguments for valuing forests intrinsically (the ecocentric viewpoint) rather than for their value to humans (the anthropocentric viewpoint) were articulated

by proponents of Deep Ecology, who sometimes advocated the use of monkeywrenching or ecotage, the sabotage of human activities perceived as threatening natural ecosystems. Some monkeywrenching methods used in the 1980s included driving metal spikes into trees of U.S. Pacific Northwest old-growth (pristine) forests to prevent logging. Internationally, the Deep Ecology view that humans should be removed from ecosystems targeted for conservation influenced the methods used to establish parks and forest reserves. In Africa especially, there were expropriations of indigenous peoples from newly created parklands. In Tanzania the establishment in 1960 of Arusha National Park involved the forcible removal of Meru villagers and Maasai herders, and in the Democratic Republic of the Congo the establishment in 1970 of Kahuzi-Biéga National Park resulted in the displacement of more than 13,000 Twa, Shi, Tembo, and Rega inhabitants.

THE HUMAN CONTEXT OF FOREST CONSERVATION

There is widespread agreement about the worthiness of the goal of conserving the world's forests and their plant and animal biodiversity, but there is also widespread disagreement about the best means to this end. Steven Brechin and his coauthors (2003) suggest that too many conservation programs focus on conservation objectives (the "what") and not on the social and political processes that can help realize those objectives (the "how"). In several instances, they argue, expediency has rationalized conservation without due consideration for indigenous rights. Neither the Meru of Tanzania, the Twa of the Democratic Republic of the Congo, nor the Chimane of Bolivia were consulted before being expelled from the forests that had supported their traditional livelihood. In all cases these communities ended up poorer and more marginalized.

Conservation biologists such as Thomas Struhsaker (1998) or John Terborgh et al. (2002) argue that incorporating economic development for, or sustainable resource use by, local communities (a "conservation through development" model) cannot substitute for totally protecting forests and will eventually drive ecosystems in protected areas to extinction. They suggest that even though indigenous people have lived at sustainable levels within their forest environments in the past, there is no guarantee that they will continue to do so, given global pressures for modernization and integration into the modern economy.

Paul Wolvekamp (1999) counters that many indigenous cultures are, in fact, responsible for the pristine condition of many forests. The Kayapó indigenous people of Brazil, for instance, have protected the boundary and integrity of the 110,000 square kilometers of the Kayapó Reserve forest against the encroachments of logging and mining. Wolvekamp argues, therefore, that it is counterproductive for western-based conservation organizations to advocate the removal of indigenous groups from protected areas or to urge the cessation of their traditional use of the forests. He suggests such proposals lack legitimacy because the carbon footprint of large-scale tourism in parks—considering the air travel involved—is more deleterious than the global impact of indigenous communities living inside these parks.

James Fairhead and Melissa Leach (1996) document the damaging consequences of the dogma that indigenous people can only mismanage their forests; they report that this outlook led to a misreading of the forest-savanna transition of Guinea, in western Africa, as the product of human-caused deforestation. Fairhead and Leach show, rather, that farmers had a long tradition of creating and maintaining forests around their villages. Nancy Peluso (1992) found that the many instances of deforestation she studied in Java resulted from inappropriate top-down state control of forests previously managed appropriately by peasants. She and Roderick Neumann (1998) have also challenged the often-assumed correlation between indigenous population growth and increased deforestation, arguing that it is untested and often at odds with local realities.

Janis Alcorn (1993) and Steven Brechin and his coauthors (2003) have suggested that indigenous expropriations, especially when enforced militarily, have undermined the perceived legitimacy—and therefore the effectiveness—of forest conservation programs. Michael Soulé (1991) agrees with Alcorn that many park-style conservation projects have failed and have undermined the ability of indigenous communities to protect forests. Because nature conservation is essentially a mechanism of resource control, Brechin proposes that forest conservation strategies must be both ecologically sound and socially just to gain legitimacy in the eyes of all stakeholders. To succeed in the long term, Alcorn argues, such programs must involve local communities and indigenous people. Brechin sees nature conservation as a complex social enterprise that requires negotiated compromises, not one-sided, state-imposed, short-term solutions; he contends that the social cost of global forest conservation should not be borne solely by the indigenous forest communities.

NEW DIRECTIONS IN FOREST CONSERVATION

Soulé argues that nature conservation should be adapted and tailored to various geographical and political contexts. Accordingly, it is worth reviewing a small sample of forest conservation efforts in which local communities have been an integral part of the solution.

Tropical Forests In Madagascar partnerships among the Department of Water and Forests, the University of Antananarivo, nongovernmental organizations (NGOs) such as the Worldwide Fund for Nature, and local communities have made successful use of the *Dina*—a traditional system of rules and regulations governing rights of usage, timing, quantity, and frequency of harvest—to guide resource use by villagers. Such contracts have been implemented in the Manambolo Valley (a biodiversity corridor linking the Andringitra and Ranomafana National Parks) and in the Tampolo littoral forest, protecting rain forests and their unique plants and animals, including several species of lemurs. In eighteen other tropical countries, the NGO Rainforest Foundation adopted a rights-based, social-justice forestry strategy to halt rain forest loss by helping forest-dwelling communities establish land-tenure rights and greater control over the use of forest resources.

To promote social equity in bioprospecting (the search for medically promising plant compounds for commercial use), the National Biodiversity Institute (INBio) of Costa Rica, an NGO, was established in 1989. INBio helps rural communities become active participants and beneficiaries, based on the assumption that the sustainable use of natural forest compounds can benefit local communities economically and reduce the financial pressures that can drive some forest communities to cut trees for cash. Similarly, "extractive reserves," pioneered by Mary Helena Allegretti and Chico Mendes (murdered in 1988 for his opposition to deforestation of the Brazilian Amazon for cattle ranching), are forest reserves where local residents are allowed to tap trees for rubber, gather fruits and nuts, hunt wildlife, and harvest wood within sustainable limits, providing forest-generated income to local communities and diminishing incentives to deforestation.

As long as soils are not seriously compacted by heavy equipment or damaged by erosion, tropical forests can recover from logging or agriculture. Carl Sauer (1958) suggested that many tropical forests once classified as pristine had in fact been widely manipulated and transformed by South American Indian communities with fire and plantations of useful tree species. Recent findings that large sections of the Amazonian rain forest are in fact secondary forests (forests that grow back following a disturbance) have supported Sauer's hypothesis. Robin Chazdon (1998) therefore suggests that today's tropical forest conservation agenda should be visionary and not focus exclusively on protecting "pristine" forests; disturbed forests and secondary forests that have a good potential for recovery could also be protected, to become the "pristine" forests of tomorrow.

Temperate Forests In 1992, in cooperation with the Environmental Defense Fund, the Wasco, Warm Springs, and Paiute tribes of Oregon developed a management plan for the Warm Springs Reservation, 60 percent of which is forested. The tribes, which earn a large part of their income from timber sales, voluntarily reduced the timber harvest by half and established best-management practices for future timber sales. The plan sets new guidelines for managing protected forests, fisheries, and other nonforest resources.

Boreal Forests The Boreal Forest Conservation Framework (BFCF) is an NGO that acts as a liaison between Canadian conservation organizations, industry groups, First Nations, and local governments in support of research and forest conservation. The BFCF seeks to protect more than half of Canada's boreal forest in a network of large, interconnected forest areas while maintaining long-term economic benefits for communities and respecting the land rights of aboriginal groups. Thousands of miles away, in the taiga of the Russian Far East, the Udege aboriginal group spearheaded the creation of the Russian Far Eastern Association for the Use of Non-Timber Forest Products. The group's main goal is to link village organizations, traders, processing plants, and scientific institutes to develop nontimber-based indigenous economies and reduce logging, thus preserving the forest habitats for endangered species such as the Amur tiger, cranes, and salmon.

CONCLUSION

Conserving the world's forests is an enormous social enterprise with an urgent ecological goal. Losing the world's forests would be an ecological catastrophe. Averting that disaster while preserving the rights and dignity of indigenous peoples remains the unfulfilled challenge to the scholars, activists, NGOs, and governments that know that the health of Earth's ecosphere—indeed, perhaps the very survival of life on the planet—hinges on the health of the world's forests.

FRANKFURT SCHOOL

Critical theory, which was developed in the Frankfurt Institute for Social Research (hence its later name, the Frankfurt School), is a body of broadly neo-Marxist social theory. The distinctive features of critical theory were its critical analysis of the Enlightenment and the dominant ways of acting and thinking associated with it and its linking of social theory to social criticism of the prevailing "modern" social order both in the liberal-capitalist West and in the authoritarian-communist East. It included thinkers such as Max Horkheimer (1895–1973), Theodor Adorno (1903–1969), Herbert Marcuse (1898–1979), Walter Benjamin (1892–1940), and Jürgen Habermas (born 1929).

Horkheimer and Adorno's *Dialectic of Enlightenment* (1973) was an examination and explication of the "dark" side of modernity: the costs and dangers of advanced technological industrial society and its dominant modes of thought and behaviors. The danger they pointed out is quite stark. For them, the "fully enlightened world radiates disaster triumphant" (p. 3), a sentiment with which many radical greens would agree in regard to the local and global environmental degradation and destruction modern industrial societies have caused.

According to Andrew Biro, "Like both Rousseau and Marx before them, Horkheimer and Adorno question the association of increased mastery over nature … with a betterment of the human condition" (Biro 2005, p. 123). For Horkheimer and Adorno the technological sophiscation, economic organization, and politicial institutionalization associated with that mastery have no necessary connection with universalizing the benefits of that mastery (here they echo the Marxist critique of the necessary inequalities of capitalism) and such mastery is misplaced and dangerous as the basis for structuring the relationship between society and nature. Also, and connecting with the point raised above in relation to Sigmund Freud, Biro points out, "The lesson of *Dialectic of Enlightenment* is that if we think of nature as 'other' to be controlled, the technology we develop will inevitably be turned to control the nature that resides within the self" (p. 148).

As S. Vogel puts it, "the Frankfurt school's critique of contemporary society was offered up in a certain sense 'in nature's name'—both that of the damaged inner nature of humans stuck in the fatal dialectic of enlightenment and an outer nature robbed of all qualities save those that render it amenable to human use" (Vogel 1997, p. 175). As a result of the logic of the Enlightenment, the only value the natural environment can possess is instrumental value; that is, the natural world possesses value only insofar as it is useful for human purposes or ends.

The "disenchantment of nature" (the cultural transformation of nature from a morally significant realm with its own intrinsic value to nature viewed solely as a set of resources for human use and enjoyment, as discussed in the last chapter of Horkheimer and Adorno's *Dialectic*), as one of the main consequences of modernity, was something not just to be regretted (the romantic reaction) but also dangerous for both human society and the nonhuman world. In particular, the critical theory perspective of the Frankfurt School suggested that the increasing rationalization that was central to the successful technical manipulation of external nature had a tendency to spill over into other

spheres of human life in which it was not appropriate and in fact was dangerous.

The basic problem was that the instrumental use of nature led to the development of institutions and modes of thinking and acting that were "transferred" illegitimately to human social and personal relations. The domination and exploitation of the natural environment leads to the domination and exploitation of humans, a point echoed by various green thinkers from deep ecologists to ecoanarchists. Enlightenment-derived institutions as modes of rationality suited to human-nature exchanges contained the possibility of being used in human social relations, in which they were dangerous and harmful. As Horkheimer and Adorno put it, "Men have become so utterly estranged from one another and from nature that all they know is what they need each other for and the harm they do to each other" (Horkheimer and Adorno 1973, p. 253).

Although Adorno in particular is pessimistic about any reconciliation with nature (such a project had to wait for later critical theorists such as Marcuse and Habermas), the importance of the early Frankfurt School in relation to social theory and the environment lies in updating and greatly developing the essentially Marxist notion that the root of the link between society and nature lies both within social relations internal to the organization of society and at the same time within the way society views, uses, and abuses its natural environments (Biro 2005).

FREE MARKET ENVIRONMENTALISM

Free market environmentalism (FME) begins with the belief that market institutions can and do promote environmental quality effectively. Proponents of FME see private property rights as holding individuals and firms accountable for their environmental impacts and rely on markets to provide crucial information about environmental conditions to society. FME stresses principles of individual liberty, voluntary exchange, and common law liability. FME typically stands in contraposition to command-and-control regulatory approaches to environmental policy, arguing against the inefficiencies of bureaucracy, centralization, and regulation.

THEORY

In place of regulation or taxation, proponents of FME recommend altering incentives to conserve environmental resources by extending property rights and markets into domains that have been external to market processes. The FME vision rejects assertions that markets are to blame for environmental problems. Instead, environmental problems are viewed as opportunities to institute property rights, internalize externalities, and let markets improve environmental quality and welfare. Free market environmentalists emphasize the institutional context of decision making and argue that market institutions provide the best incentives and information about ecological conditions and scarcity. Market arrangements tend to reward good decisions and ecological stewardship and penalize waste and degradation.

Central to FME are well-defined, enforced, and sellable or transferable private property rights. Secure private property rights encourage stewardship, as degradation and poor management undermine market value. They also reward ecoentrepreneurs who reduce consumption and waste, find better uses or substitutes, improve productivity, or conserve for times of scarcity. Limitations on property rights such as use-it-or-lose-it rules governing permits for grazing, timber, or water rights and limited liability arrangements are seen as distorting conservation incentives.

This approach draws heavily on the Coase theorem, which holds that an optimal level of pollution is achieved through bargaining regardless of who owns the right to pollute as long as certain conditions are met (Coase 1960). With well-defined property rights and low transaction costs, individuals internalize their environmental costs by bargaining in a market. This amounts to a strict polluter pays policy. In a Coasian system the amount of pollution is not set by regulators or by firms with disregard for victims but through negotiations and a voluntary exchange of rights between interested parties. The rights to pollute are owned and exchanged voluntarily, falling into the hands of polluters, victims, or other parties, depending on who bids the highest. The level of pollution traded in this market may be more or less than what a regulator would allow.

APPLICATIONS

As an alternative to the command-and-control environmental policies that dominated the 1970s and 1980s, market-based approaches exist around the world and many more are emerging. Several nations employ individually transferable quotas that are set by government regulators to enable the trading of commercial fishing rights. Also, the United States has implemented a trading scheme for rights to emit sulfur dioxide. Large-scale successes have inspired ongoing efforts to use market-based approaches in other areas, such as a cap-and-trade policy for dealing with carbon emissions.

It can be argued that these markets for harvesting or emissions are only partial markets because they ultimately rely on technocrats or nonmarket mechanisms to establish the overall cap, or target quantity. A pure FME approach would task the market with setting the cap. Akin to shoemakers being compensated for their efforts by those wanting shoes, the owners of the rights to a clean stream could exchange some of those rights to polluters, in principle leading to a market clearing in which as much pollution is generated as its victims will tolerate. Such markets govern Scottish rivers and streams and are used in the western part of the United States for maintaining instream flows.

Other market institutions, both new and old, have been marshaled to promote environmental quality. Land trusts and organizations such as the Nature Conservancy are considered exemplars of private efforts to protect the environment through the use of private property rights and voluntary exchange. Those interested in protecting natural resources can do so simply by purchasing them or purchasing and not using the development rights—known as conservation easements—and holding them in perpetuity. Conservation trusts that advance environmental goals through the marketplace are proliferating in the United States. These green payments (akin to polluter pays) favored by FME are seen in various forms, such as user fees for recreationists, bottle bills, payments by the Defenders of Wildlife to ranchers who suffer losses from endangered wolf populations, and water markets in the western United States.

Free market environmentalists often criticize central planning and regulatory institutions for mismanaging environmental resources. FME advocates call for green scissors, referring to the cutting of environmentally and economically wasteful subsidies and regulations. They call attention to the poor environmental performance of regulatory agencies and managers of public lands. They see the failure of centralized regulation and public management as arising from institutions with incentives misaligned with conservation.

DEBATES AND CRITICISMS

Pragmatic concerns about FME usually start with transaction costs. The Coasian bargaining central to the efficacy of the market-based approach hinges on minimal costs in reaching and enforcing voluntary agreements in the market. In practice this may be unrealistic, although high costs also may plague the alternatives. Multiple polluters contracting with thousands of private parties may create overwhelming transaction costs. Similarly, the rule of law and functioning markets depend on costly government, especially a highly responsive judiciary. The polluter pays principle of FME requires clear and defensible property rights, low-cost application of tort law principles, and monitoring of environmental trespasses. These conditions often are lacking in environmental contexts.

The practical limitations of applying common law liability may be most serious when the source of environmental harms or the effects of pollution are difficult to identify. FME advocates see the costs and complexities of enforcing property rights regimes as being outweighed by the social and environmental gains arising from voluntary trading, especially compared with the alternative of governments dictating pollution levels without conferring private tradable rights.

Critics have found shortcomings in FME on ethical grounds. Markets for pollution often are seen as immoral or as tacitly endorsing pollution. Moreover, market processes provide only for anthropocentric values. Markets also may be blind to important social inequities such as marginalization of the poor. FME proponents often acknowledge this and favor the use of poverty policy, not environmental policy, to address poverty.

The FME paradigm offers no guarantees that certain outcomes will be achieved. Holding people accountable and fostering voluntary exchange may produce results that some find objectionable. Markets, for instance, provide no special protection against irreversible changes such as extinctions, although regulatory or other institutions also may not provide such guarantees. Critics of FME also contend that placing control of natural resources in private hands creates a reliance on individuals who may not be sufficiently enlightened, knowledgeable, farsighted, patient, or altruistic. FME advocates often counter that regulators and technocrats are often worse in terms of those qualities and that market incentives discipline individuals in ways bureaucracies do not.

Ultimately, markets are easier to establish and property rights are easier to define for some resources and activities than for others. Implementing idealized markets for resources such as global climate and biodiversity presents enormous practical and political challenges. Advocates of FME contend that although markets are not a panacea, they should be used to promote environmental goals when possible.

FUTURE GENERATIONS

Global climate change, fossil-fuel depletion, overpopulation, loss of biodiversity—these issues trouble thoughtful individuals, not only for their impact upon themselves or even their children and grandchildren, who will escape the worst consequences, but also for the consequences to persons far into the future whose lives will not be concurrent with our own. Because of advances in science and technology, the current generation may bear a greater burden of moral responsibility toward its successors than that of any previous generation. This is because science has provided us with unprecedented knowledge of the consequences of our acts and policies, and technology has provided us with the means to effect or avoid these consequences. *Knowledge* of consequences and *capacity* to affect future outcomes are two essential criteria of moral responsibility (Partridge 1994).

THE STATUS OF FUTURE PERSONS

Our responsibility to future generations is a common topic in political rhetoric and public discourse. When discussed in these contexts, future persons are usually regarded as essentially the same as our contemporaries, fundamentally of a common humanity. Accordingly, it is widely assumed that responsibilities to future persons are not all that different from responsibilities to contemporaries of other cultures.

Most philosophers who have studied the question of the duty to posterity do not share this view. Instead, they recognize that future persons have a moral, epistemological, and even ontological status that is radically different from the status of our contemporaries. First of all, future persons cannot be identified as individuals and thus must be conceived abstractly. Second, because they are not actual—that is, they do not exist at the present time—there is considerable controversy regarding which, if any, rights claims future persons might have on our generation. Third, our relationship with future persons is *nonreciprocal*: While we may act upon them, they do not act upon us. Fourth, we are ignorant of the conditions of their lives, their values, and their culture—the more so as we project further into the future. Finally, the very existence of future persons depends on our present policies of population control.

THE FUTURE-PERSONS PARADOX

All effective policies regarding remotely future generations entail a profound paradox, generally overlooked in nonphilosophical discussions, namely, that such policies will result in different individuals living in the future. This fact follows from the contingent nature of human conception. When conception takes place, one sperm cell among about 200 million wins the lottery, as it were. Should conception take place a day, an hour, or even a fraction of a second earlier or later, a genetically different individual will result.

Suppose, for example, that the United Nations, or even just one or a few industrialized nations, undertakes a concerted effort to mitigate the consequences of climate change. The simple publication of this policy will cause different individuals to be conceived throughout the world, all the more so as the policy is implemented. In time, this effect accelerates exponentially. In a relatively few generations, some say as few as six (Schwartz 1978), the world will be populated by entirely different individuals than would exist had no such policy been adopted "for the benefit of future generations."

According to the person-affecting principle (Temkin 1993), widely accepted by moral philosophers and appealing to common sense, a morally praiseworthy act benefits a person or persons, while a morally blameworthy act harms a person or persons. Thus an act or policy that neither benefits nor harms anyone is of no moral significance, and thus is not morally required or forbidden.

Now the paradox. A policy enacted today with the goal of improving the life prospects of future persons will benefit no one, nor will a failure to enact such a policy harm anyone, for no future individuals will be made better or worse off by a policy decision at the present time. Instead, policy A (e.g., mitigating global climate change) will result in future populations of individuals that are better off, and policy B (business as usual) will result in future populations of entirely different individuals who are worse off.

Some philosophers conclude from this that there are no obligations to future generations (Schwartz 1978). Others find reason in this stark conclusion to reject the person-affecting principle (Parfit 1984, Kavka 1982, Partridge 1998). They argue that because the identity of remotely

future individuals is unknown and unknowable, and because our part in determining the eventual genetic makeup of those individuals is inescapable, the choice before us is whether to bring about future populations of prosperous and happy individuals, or future populations of miserable, albeit entirely different, individuals. The former alternative is the morally required choice, even though no future individuals will personally benefit from such a policy.

THE RIGHTS OF FUTURE PERSONS

Do future persons have rights to clean air, energy resources, and a nonthreatening climate? And do these rights entail claims upon the current generation? Many philosophers have argued that future generations do not have rights, not because future persons are not entitled to these benefits, but more fundamentally, because the concept of rights cannot meaningfully be attributed to future persons. Only actual persons can be said to have rights (De George 1979). Future persons will have rights only at such time in the future as they come into existence.

In rebuttal, one must first point out that the concept of rights is complex. There are many varieties of rights, some of which apply to future generations and others that do not. Most directly, one must distinguish active rights from passive rights. Obviously, future persons cannot act in the present. Therefore, future persons do not now have active rights (to do or not do such and such). But they might have passive rights (to be benefited, or at least not to be harmed). The aforementioned rights to clean air, energy resources, and an agreeable climate, all of which we might or might not provide for the future, constitute valid rights claims of future generations upon our contemporaries (Partridge 1990).

DISCOUNTING AND POLICY ASSESSMENT

How does one assess social benefits and harms? The economist's answer is to assimilate costs and benefits under a single metric: willingness to pay. This procedure, called "cost-benefit analysis," is the dominant method of government-policy assessment. The monetization of policy alternatives has the advantage of commensurating all values under a single measure, quantifying and allowing mathematical analysis of policy, and thus arriving at clear and determinate conclusions (Partridge 2003).

The economic assessment of policy inexorably leads to discounting the future, that is, assuming that the value of future costs and benefits, from the perspective of the present time, diminishes with the passage of time. Future discounting is reflected in interest rates. Assume, for example, an annual interest rate of 5 percent. This means that for $100 today to be equal to an amount in a year, $5 must be added to the $100, in other words, that the value of $100 today decreases to approximately $95 in a year's time.

If a human life is given a dollar value (as it must for insurance policies and in civil suits), then at a 5 percent discount rate, the value of 1 human life today is equal to the value of 2 lives in 14 years, 130 lives in 100 years, more than 1,000 lives in 200 years, and more than 1 billion in 500 years (Parfit 1984, p. 357). By this accounting, small dollar benefits of nuclear power today are greater than the discounted cost of millions of lives due to radioactive poisoning hundreds of generations in the future.

Why should the value of a human life be at all affected by the time at which it is lived? Why, in general, should a time in the sequence of generations be relevant to that value? Derek Parfit argues that it should not be (1984, p. 486). Several factors that accompany the passage of time are sensitive to the passage of time, he writes, among them probability, opportunity costs, excessive sacrifice, uncertain knowledge, but this list does not include time itself.

In addition, critics of the economic assessment of policy point out that numerous values are totally independent of economic analysis. Among them, the value of truth (to a scientist), justice, love, loyalty, nature, and above all, moral value (the worth of individual persons).

JUSTICE BETWEEN GENERATIONS: JOHN RAWLS AND CONTRACT THEORY

John Rawls's landmark book *A Theory of Justice* was one of the few philosophical treatments of the issue of justice between generations when it was published in 1971. Since then philosophical interest in the issue has increased substantially. Rawls's analysis of justice proceeds from this fundamental question: If you were given the choice of a society to live in, not knowing your status in that society, what kind of a society would you choose? The subtlety, complications, and controversy of Rawls's theory follows from elaborations of "what kind of a society," "not knowing your status," and the implied question "By what rules of rational choice and according to what knowledge might one make the best choice?" The answer to this question, devised by Rawls to be the answer of any person, yields principles of justice applicable to all persons. Rawls calls this perspective of rational choice, which includes all relevant general knowledge and excludes all particular personal knowledge, "the original position."

Applying the original position to the sequence of generations yields this question: What would a hypothetical future person, acknowledging that the same rules apply to all generations, require of the present generation? Such rules constitute a hypothetical contract among generations. From this original position, Rawls derives these principles

of justice between generations: "Each generation must . . . preserve the gains of culture and civilization . . ., maintain intact those just institutions that have been established . . ., [and] put aside in each period of time a suitable amount of real capital accumulation" (1971, p. 285). By "capital," Rawls means "not only factories and machines, and so on, but also the knowledge and culture, as well as the techniques and skills, that make possible just institutions and the fair values of liberty" (p. 288). Not included among these principles, but surely equally important, is the responsibility of each generation to bestow to succeeding generations a viable, well-functioning, and sustainable global ecosystem.

A SUSTAINABLE FUTURE: POLICY GUIDELINES

If we reject future discounting and thus treat succeeding generations as being of equal value, our policies regarding the future must entail sustainable resources and populations.

Leaving "Enough and as Good" In his *Two Treatises of Government* (1988 [1689]), John Locke sanctions the acquisition of property, provided one leaves "enough and as good" for others. If this proviso is applied to future generations, the obvious problem is, how can we possibly share with future generations depletable resources available to us today? A fair distribution of petroleum and coal, for example, to all future generations would leave each of us today with a cup of petroleum and a few lumps of coal. The answer to the problem is that we owe future generations, not a share of available oil and coal, but rather what these resources provide us, namely, energy. This implies that we owe the future the means to find and develop new sources of energy, and this in turn implies that we should pass on well-funded educational institutions and robust facilities of research and development. Our obligation also entails a policy of recycling and recovering mineral resources and of using renewable resources.

Do No Harm The further we project into the future, the less we are able to anticipate the goods of future generations: their pleasures, satisfactions, tastes, and aspirations. It is much easier, however, to identify what will harm humans of any generation. Most fundamentally, this would be physical injuries and disease and a deterioration of the physical and biotic environment that sustains humans.

Doing Well by Doing Good Lack of motivation is foremost among the practical impediments to responsible provision for the future. With an abundance of problems facing us here and now, how can we expect the present generation to make sacrifices for persons whom we will never personally know and whose values we might not share? This problem is capably addressed by adopting policies that benefit both the present and the future. This would include generous public support for education, and in particular, for scientific research and technological development. This research and development should address the problems facing us today or in the near future, as well as in the remote future. The most prominent of these problems are renewable energy, climate change, and ecological protection and renewal.

Preserving Natural Capital Nature normally performs essential functions for humankind. Among these functions are climate regulation, air and water purification, groundwater accumulation, carbon sequestration, pest control, pollination, oxygen production, and wetland production of marine nutrients. It has been estimated that the global economic value of these functions is in excess of $33 trillion, approximately twice the annual gross global product of all Earth's economies (Costanza et al. 1997). Undisturbed, nature produces these indispensable services continuously, without depletion. Surely the preservation of this natural capital must be included among our primary responsibilities to future generations.

G

GAIA HYPOTHESIS

The Gaia hypothesis is the proposition that all life on Earth functions in essential ways as a single living organism. According to the originator of the hypothesis, British inventor and geoscientist James Lovelock, "The entire range of living matter on Earth, from whales to viruses, and from oaks to algae, could be regarded as constituting a single living entity, capable of manipulating the Earth's atmosphere to suit its overall needs and endowed with faculties and powers far beyond those of its constituent parts" (Lovelock 1979, p. 9).

GAIA HYPOTHESIS AND GAIA THEORY

In his 2006 book *Animate Earth*, ecologist Stephan Harding defines Gaia theory as the view that the "sum of all complex feedbacks between life, atmosphere, rocks, and water give rise to Gaia, the evolving, self-regulating planetary entity that has maintained habitable conditions on the surface of our planet over vast stretches of geological time" (Harding 2006, p. 64). Gaia theory goes beyond the original Gaia hypothesis in several key ways. For one, it includes abiotic elements. Harding adds that "all the rocks on the Earth's surface, the atmosphere and the waters have been altered by life, and vice versa" (p. 64). Some Gaians argue that even the movement of tectonic plates is influenced by life processes (Margulis 2004). In addition, Gaian Theorists can appeal to extensive empirical support accumulated since Lovelock's first formulations (Schneider and Boston 1991; Schneider et al. 2004), but also tend to speak much more circumspectly than Lovelock originally did about Gaia's emergent "faculties and powers."

ORIGINS

In the early 1960s, while working for the National Aeronautics and Space Administration (NASA) to conceptualize experiments to detect life on Mars, Lovelock realized that one of the clearest signs of life on our own planet, as it might be viewed from space, is the chemical disequilibrium of the atmosphere. Without life, Earth's atmosphere would consist almost entirely of carbon dioxide, whereas in fact it consists mostly of nitrogen and oxygen. The radical chemical instability of the entire mix signals processes at work beyond physical chemistry.

Lovelock and his early collaborator, microbiologist Lynn Margulis, quickly began to fit other terrestrial improbabilities into the picture. The current atmospheric composition appears to have been constant almost from the moment aerobic organisms appeared. Global temperatures likewise have been maintained well within the range that suits living organisms, as has the salinity of the oceans. Yet these balances have been sustained in the face of highly variable inputs. Since the emergence of life, the Sun's output has increased by at least 25 percent, and there have been regular perturbations in Earth's orbit, comet impacts, volcanic eruptions, variable mineral runoff into the oceans, and so on.

Lovelock and Margulis argue that life processes produce and sustain these otherwise entirely improbable balances (Lovelock 1991). Atmospheric composition and global temperature may be regulated by differential growth rates in plants that change the albedo (reflectivity or heat-absorption) of the surface. Plants, along with animals, also exchange carbon dioxide for oxygen, or vice versa, and produce methane and other greenhouse gases. Shell formation in the

oceans helps regulate salinity of the seas. Research since 2000 has uncovered increasingly subtle and previously unsuspected feedback loops, such as the influence of dimethyl sulfide emissions from ocean algae—sensitive to temperature variations in the waters—on the formation of temperature-regulating cloud cover (Lovelock 2006). For Gaia theory, then, the Earth System as a whole is homeostatic (it maintains stable and "hospitable" internal conditions despite varied inputs)—a key feature of life. Earth truly begins to appear as a kind of superorganism. The name *Gaia* invokes the Greek Earth goddess of that name—a mythic connection suggested by Lovelock's friend and neighbor in Wiltshire, United Kingdom, the novelist and classicist William Golding.

DEBATES AND DEVELOPMENTS

A widespread early objection to the Gaia hypothesis was that it imagines life deliberately manipulating conditions to suit its needs, and thus is illegitimately teleological. Lovelock's response was that even simple cybernetic systems are capable of finely tuned adaptation without conscious intention. To illustrate the point he developed a model called Daisyworld, demonstrating that a world with merely two colors of daisies can maintain level planetary temperatures over a wide range of solar inputs. If the planet begins to heat up, the light daisies spread, as they are better able to reflect sunlight and avoid overheating. Planetary albedo therefore inches up, cooling the planet. Likewise, spreading dark daisies can keep temperatures from falling too low. Adding many daisy color variants, and even animal grazers and predators, only increases the stability of the temperature-regulation (Harding 2006; Lovelock 2006). Daisyworld has now become so mainstream that multiple versions are available on the Internet as software for ecology courses. The appearance of teleology has been reduced by the use of less poetic, newer names for Gaia theory, such as "Earth systems science" and "geophysiology."

Commentators distinguish a variety of Gaia hypotheses. One version asserts simply that life changes the abiotic environment, rather than just adapting to the conditions it finds. The critic James Kirchner calls this version "Weak Gaia" (Kirchner 1991, p. 38), though Lovelock has declared that it is all he really claimed—and disputes the label "weak," arguing that this recognition represents a profound and fertile paradigm-shift (Lovelock 2004, p. 2f). Somewhat different is the claim that life plays a key role in maintaining the stability of the natural environment (Kirchner calls this "Homeostatic Gaia") or some of its holistic processes. A stronger version holds that life *optimizes* the conditions for itself in this way ("Optimizing Gaia"). What Kirchner calls "Coevolutionary Gaia" asserts a tight relation between Gaian processes and evolution. While some Darwinians argue that evolution could not give rise to a planetary superorganism, others argue that it literally *must* (Volk 1998). These latter claims are naturally hard to evaluate when we have only one example (so far!) of a Gaian system from which to generalize (Boston and Thompson 1991; McKay and Stoker 1991).

GAIA AND CLIMATE CHANGE

Gaia is resilient. Life responds as a whole to defend itself and has done so successfully for hundreds of millions of years, sometimes under much more massive assaults than at present. Thus, though his 1979 work did identify what he called planetary "vital organs"—the wetlands, continental shelves, and rainforests—where caution is necessary, Lovelock's early thinking did not underwrite environmentalism as it usually is understood. Lovelock did not propound a land ethic, for example, or special standing for other-than-human individuals or even many species or ecosystems (Lovelock 1979).

However, Lovelock's *The Revenge of Gaia* (2006) announced a major reversal. Systems thinking implies that a system may remain stable for a long time, even with a variety of inputs and stresses, but then abruptly shift into some other, sharply different state. (Though we have learned to speak of Earth's homeo*static* processes, the technically proper term is homeo*rrhesis*, since the equilibrium points can shift.) Lovelock now believes that human disruption of Gaian processes has reached such a scale and intensity that we have already passed key system "tipping points." Global climate change not only is real but is likely to be amplified, by the same feedback processes that for so long held it stable, into a vastly worse (for humans) set of changes than most climate modeling now predicts. As polar ice melts and the snows retreat, for example, more exposed ocean and soil absorb more sunlight, warming the region still more. Even small amounts of glacial melting in Greenland have already changed the entire structure and flow rates of glaciers, greatly accelerating melting. Many more "positive" (self-accelerating) feedback processes are being discovered.

In the face of large temperature increases and a huge rise in sea level, Lovelock predicts, most of Earth will become barren and people will be able to survive only at the poles. Crash programs might forestall some of the worst and most rapid effects, he argues, but they will have to be radical programs such as replacing fossil fuels with nuclear power (the only way to seriously reduce carbon dioxide emissions, he argues), synthesizing food to reduce overfarming, and launching orbiting sun-shades (Lovelock 2006). Gaia will survive in any case, and some humans may also survive, but the survival of civilization, Lovelock fears, is a poor bet. As of this writing, these bleak predictions have only barely been assimilated by many Gaian thinkers, and a developed critical assessment has not yet emerged.

Receding Exit Glacier, 2004. *The sign marks where Exit Glacier, in the Kenai Fjords National Park in Alaska, used to reach in 1978; its location in 2004 was a half mile back. James Lovelock believes that human disruption of Gaian processes has contributed to the devastating effects of global climate change, which he believes will only become more amplified over time.* **© ASHLEY COOPER/PICIMPACT/CORBIS.**

ETHICAL IMPLICATIONS

Personifying "Gaia" explicitly draws upon the respect for persons built into traditional ethics. If Earth can be viewed as an integrated, organic being, then *she* has a claim on our respect, and acknowledging something like the "personhood" of the entire planet might even bring environmental ethics to the (seeming) endpoint of a long series of recognitions of other- and larger-than-human persons (Roszak 1978). Aldo Leopold expressed just such a sentiment quite beautifully in his relatively unknown essay "Some Fundamentals of Conservation in the Southwest": "Possibly, in our intuitive perceptions … we realize the indivisibility of the earth—its soil, mountains, rivers, forests, climate, plants, and animals, and respect it collectively not only as a useful servant but as a living being, vastly less alive than ourselves in degree, but vastly greater than ourselves in time and space—a being that was old when the morning stars sang together, and, when the last of us has been gathered unto his fathers, will still be young" (Leopold 1991 [1923], p. 95).

Alternatively, it could be argued that environmental ethics really needs to move beyond what might be called *person*-centrism entirely—perhaps a residual form of anthropocentrism itself (Weston 1987). Other and quite different sorts of entities, such as vast and intricate planetary systems, may require moral consideration in very different terms. Insofar as later Gaians construe homeostasis in ways that do not involve any hint of teleology, Gaian thinking has moved away from a personlike model as well.

Some Gaian thinkers propose an exalted role for humans within Gaia. Lovelock wrote that "the evolution of *homo sapiens*, with his technological inventiveness and his increasingly subtle communications network, has vastly increased Gaia's range of perception. She is now through us awake and aware of herself. She has seen the reflection of her fair face through the eyes of the astronauts and the TV cameras of orbiting spacecraft." (Lovelock 1979, p. 148). The evolution of human consciousness might represent a new phase in Gaia's own evolution: the development of planetary self-consciousness and mind. The Internet could be thought of as a Gaian nervous system in the making. Gaia may even reproduce itself through the

human colonization of other planets. A fictional work of Lovelock's, cowritten with the science writer Michael Allaby in 1984, proposes to use global warming to literally "terra-form" Mars into another Earth (Allaby and Lovelock 1984). This idea continues to be seriously debated at NASA and elsewhere (Morton 2002).

Others read the Gaia hypothesis in a much more modest light. Humans are extreme latecomers in the Gaian story, and until the last geological split-second or so, we have made only the most infinitesimal contribution to any of the great cycles that keep Earth in balance. With the coming of industry, (some) humans began to become destabilizers, and though the system has a place for destabilizers, their role is often short-lived. At best, on this view, we are small parts of a much vaster and sublimely indifferent—now perhaps somewhat hostile—system. As Crispen Tickell puts it, "Gaia has no particular tenderness for humans" (Tickell 2004, p. 224).

On either view of the place of humans within Gaia, new ethical responsibilities and a new vision of ourselves are incumbent upon us. On the more exalted view, we now need to articulate and apply our awareness of Gaia as our largest ethical point of reference. Indeed the development of environmental ethics itself has been pictured as an expression of this very planetary self-awareness now awakening through us (Harding 2006). Environmental ethics not only speaks for Earth but in a sense may represent Earth itself speaking.

The more modest view also embraces a new ethic, but *humility* is its key theme. Tickell goes on: "There has . . . been some talk, notably among the religiously inclined, about an alleged human obligation of 'stewardship' of the Earth. If so, the Earth has had to wait a long time for the arrival of the stewards. Certainly the trilobites managed for over 250 million years without them" (Tickell 2004, p. 225). In a similar vein, Lovelock himself has declared that "humans are about as qualified to be stewards of the Earth as goats are to be gardeners" (quoted in Tickell 2004, p. 225, but he does not offer a citation). Rather, our first and urgent task is to get ourselves under control. At best we might aspire to "plain biotic citizenship" (Leopold 1949, p. 204). From this point of view, the new awareness to which we are challenged is chiefly awareness of *ourselves* in a Gaian context, implying a radical and new kind of circumspection and care.

Philosopher-magician David Abram draws from the Gaia hypothesis a vision of intimacy with Earth, a vast webwork of interconnection that is alive and aware in *all* of its parts. He writes that "we must remember and reacquaint ourselves with the very medium within which we move. The air can no longer be confused with mere negative presence or with the absence of solid things: henceforth the air itself is a density . . . a thick and tactile presence. . . . We are immersed in its presence as surely as fish are immersed in the sea" (Abram 1985, p. 96). Human awareness is distinctive, to be sure, but so is every species' mode of awareness, and all of us together constitute Gaia's mind. For Abram, the Gaia hypothesis is an invitation to recover what he calls our "sensuous immersion" in the natural world. This same Gaian interconnection also gives us a direct link to the suffering of Earth. Our own bodies are entirely parts of the vast physiology that is the planet, and just as all the cells of an individual body can be shocked and stressed by damage to another part of that body, so an individual can be shocked and stressed by what is done to Earth as a whole.

The idea of Earth as a superorganism is not new. Historically it has taken many forms, from the original goddess who lends Lovelock's hypothesis her name, through Thales, Plato, Hutton, Leopold, and many others (Scofield 2004; Harding 2006). Giordano Bruno burned at the stake for advocating one version of it. Add to this ancient intuition the power of modern systems thinking, extensive scientific observation and analysis, and the urgency of the moment, and we find ourselves with a vital new philosophical as well as geophysiological paradigm.

GENETICALLY MODIFIED ORGANISMS AND BIOTECHNOLOGY

Genetically modified organisms (GMOs) are plants, animals, and microbes whose genetic code, or DNA, has been altered, using biotechnology. Ethical issues associated with GMOs and biotechnology have been in the public spotlight since the 1980s, and many of these issues are environmentally focused. This entry addresses the nature of biotechnology and the ethics behind scientific and public-policy issues.

The structure of deoxyribonucleic acid (DNA) was discovered by James D. Watson and Francis Crick in the early 1950s. By the late 1970s scientists were developing mechanisms for recombining DNA, that is, moving DNA material, genes, from organism to organism, even across species boundaries. Genetic engineering, or recombinant DNA (rDNA), did not gather much public awareness or public-policy concern until 1980, when the U.S. Supreme Court issued its *Diamond v. Chakrabarty* (447 U.S. 303 [1980]) decision, allowing genetically modified organisms to be patented. Ananda Mohan Chakrabarty, a genetic engineer working for General Electric, had developed a bacterium (derived from the *Pseudomonas* genus) capable of breaking down crude oil, and he proposed to use this bacterium in treating oil spills. Chakrabarty's success in obtaining a patent for this potential environmental silver bullet was watched closely by individuals, research institutions, and corporations involved in the life sciences. In fact, *Diamond v. Chakrabarty* spurred the development of the global biotechnology industry (Busch, Lacy, Burkhardt, and Lacy 1991).

It is fair to say that most current controversies over biotechnology in general, and GMOs in particular, are the result of different assessments of the ethical acceptability of what biotechnology has and might produce. Many of these issues stem from the fact that genetic engineering for food, agriculture, and pharmaceuticals is now a large and powerful global business enterprise.

THE SCIENCE OF GENETIC ENGINEERING

According to the Office of Technology Assessment of the U.S. Congress, "Biotechnology is any technique that uses living organisms or parts of organisms to modify products, to improve plants or animals, or to develop microorganisms for specific uses" (1988, p. 3). Under this definition, several disparate procedures count as biotechnology, including fusing protoplasts, growing whole plants from tissue cuttings (cultures), and harvesting enzymes from the metabolic functions of bacteria. Some people count traditional plant breeding, crossing, as biotechnology. Most scientists and observers note that the major function of biotechnology is genetic engineering, more specifically, transgenetic engineering. Transgenesis is the process of removing genetic material (DNA) from one species (the host) and transferring it to another species (the target) using some biological agent, usually a bacterium (the vector).

In simple terms, the process of genetic engineering begins with scientists identifying an organism, say a crop plant species, which they desire to see exhibit certain traits, either new ones for that species or enhanced traits that the species already possesses. For example, tomato plants are susceptible to tomato mosaic virus, which significantly reduces the productivity of the plant by

reducing the efficiency of its photosynthesis. Scientists then find other species of plants that seem to resist or combat tomato mosaic virus and analyze the DNA of the host plants to determine what sequence(s) of genes are responsible for regulating the chemical/microbiological process that leads to resistance. From there, scientists use enzymes to cut the responsible DNA sequence out of the nucleus of the host, and use a bacterial vector (usually an agrobacterium, whose pathogenic, mutagenic, and/or carcinogenic properties have been neutralized) to transfer the genes from the host to the nucleus of the target. The target plant cells, which now include the gene sequence(s) of the host, are cultured into plants, which are then tested for their resistance or ability to combat tomato mosaic virus. If the initial DNA sequence was properly identified and the process has been properly carried out, the new tomato plant will have increased resistance to tomato mosaic virus.

Important elements in this form of genetic engineering are, then, knowing what properties or traits are desirable for which plant species, and knowing where the DNA is to be found for the transfer successfully to occur. One key element, from both a practical as well as philosophical perspective, is that DNA is the universal building block of all living things, so that in theory, DNA from any living source might be inserted into any other living source, according to what scientists, farmers, or pharmaceutical manufacturers desire. Practically, this means that the possibilities for transgenetic engineering are vast. Philosophically, this means that genetic material from virtually any plant or animal species can be transferred to any other plant or animal species. Jeremy Rifkin (1984), a major critic of biotechnology, coined the term *algeny* to reflect the brave new world of potentially infinite interspecies DNA transfers. Rifkin thus equated the potentially world-transforming nature of biotechnology with alchemy, the attempt to turn one substance to another, particularly lead into gold. The foolish and dangerous nature of alchemy served as the basis of his critique of algeny. We shall return to this point later.

There are other biotechnological procedures worth mentioning. Among them are gene-deletion techniques (designed to remove unwanted traits from organisms) and cloning (the creation of identical twins from the cells/DNA of a host organism). Cloning received much public attention with the creation of Dolly the sheep in 1996 from the mammary cell of an adult sheep. The U.S. Food and Drug Administration approval of cloning food animals is under close scrutiny by both proponents and opponents of biotechnology.

In sum, while biotechnology may encompass many different procedures, in practice, transgenetic engineering is by and large the most useful and most used biotechnology today. Scientists and many potential client groups continue to be excited about the prospects of this new tool in the toolbox. As scientists are prone to note, biotechnology is considered to be just the next advance in genetics and microbiology, and will take science to new levels of useful and potentially profitable outcomes. The process of genetic engineering is becoming so common that it undoubtedly will continue. In the minds of many observers and concerned citizens and policy makers, the direction of this science needs to be carefully monitored, if not controlled. Algeny may be useful, but may also be a Pandora's box.

A SERIES OF ISSUES

Biotechnology in general has come under philosophical and ethical scrutiny in part because of issues that have arisen concerning particular products (including some GMOs), mainly those used in the food-production system. (Pharmaceutical and medical biotechnology has received relatively little attention and ethical critique.) One of the earliest GMOs was Flavr Savr tomatoes, developed by the biotechnology company Calgene (one of the first biotech firms). Flavr Savr tomatoes were engineered to prolong the shelf life of fresh-market tomatoes. Traditional tomatoes must be picked from the vine while still green to maintain their firmness during transport to the supermarket. The tomatoes are then sprayed with ethylene, their natural ripening agent, to turn the tomatoes red. Flavr Savr tomatoes were designed to ripen on the vine longer while maintaining their firmness so that an actually ripe, full-flavored tomato could be delivered to supermarket shelves. As beneficial to consumers as this product appeared to be, immediate concerns arose: Was this tomato dangerous to human health? Should we have concerns about toxins, allergies, or nutrition? What are the dangers to the environment? What about gene transfer across different organisms? Public reaction and the subsequent failure of Flavr Savr tomatoes in the market led to the withdrawal of this product from the market in 1997. The issues that Flavr Savr tomatoes presented set the stage for public attitudes and ethical concerns regarding most other products of food and agricultural biotechnology.

Bovine somatotropin (BST), or bovine growth hormone (BGH), met with more heated reactions. BST is a nonsteriodal hormone, produced in the pituitary glands of cows, that regulates metabolism and, indirectly, the production of milk in dairy cows. Scientists with Monsanto Corporation were able to insert DNA for the active protein in BST into the nonvirulent bacterium *E. coli*, thereby synthesizing a pure form of recombinant BST (rBST) that could be injected into dairy cows. It was found that BST-treated cows could increase milk production by up to 40

percent with only a small increase in feed consumption (around 15%). Again, what appeared to be a benefit for farmers (more milk and greater profits) evoked widespread concern and ethical critique (Comstock 2000). For example, one health-related Web site (Lipschutz-Robinson 2007) cites these problems associated with BST/BGH:

- Cows get sick from rBGH. Monsanto has been forced to admit to about 20 veterinary health risks on its Posilac label, including mastitis and udder inflammation.
- Pus from mastitis induced by rBGH and antibiotics used to treat the mastitis contaminate rBGH milk.
- The genetically engineered hormone can contaminate rBGH milk, since it can be absorbed through the gut and induce immunological effects.
- Chemically and nutritionally, rBGH milk is very different from natural milk.
- In rBGH milk there are high levels of the insulin-like growth factor 1 (IGF-1), excess levels of which have been incriminated as a major cause of breast, colon, and prostate cancers.
- Factory farms producing rBGH milk pose a major threat to the viability of small dairy farms.

As it turned out, the U.S. Food and Drug Administration approved the use of BST, and many dairy farmers adopted the technology. A few states, such as Wisconsin, required that milk from BST-treated cows be labeled as such, but public furor subsided in the late 1980s, and labels differentiating BST from non-BST milk have all but disappeared in the United States, although Europe continues to ban imports of meat, milk, and dairy products from BST-treated cows.

Flavr Savr tomatoes and BST dairy products were examples of biotechnology products that had direct consumer contact, and concerns tended to focus on human-health issues. Another class of agricultural biotechnologies has faced a different set of concerns. One of the first biotechnology products to receive attention because of potential environmental problems was the bacterium ice minus. *Ice minus* was the name given to a nonharmful bacterium found on the leaves of many crop plants, *Pseudomonas syringae*, which forms ice crystals at near-freezing temperatures, damaging the plants. *P. syringae* was genetically modified so that the ice-producing properties were removed from the bacterium, which could then be applied to crop plants to serve as a sort of blanket against cold temperatures. Although ice minus was tested thoroughly and behaved as expected in laboratory and greenhouse conditions, the public expressed outrage when it was discovered that scientists were field-testing this GMO on the roofs of laboratory buildings. Fearing that the altered bacterium might escape and confer frost resistance on weeds and other nonbeneficial organisms, environmental groups sued to stop this practice and to prevent field tests. The U.S. Environmental Protection Agency finally gave approval to field tests for ice minus, but by then concerns about the environmental impacts of GMOs had become a major consideration in public conversation and in regulatory circles.

Environmental concerns about GMOs became even more focused in the case of the most successful agricultural-biotech products to date: Roundup-Ready crops (corn, sorghum, cotton, soy, canola, and alfalfa). Roundup is a patented form of the herbicide glyphosate, originally developed by Monsanto Corporation. In the late 1970s Monsanto scientists were able to isolate the gene for herbicide tolerance and insert that gene into the crop plants listed above. The result is a crop plant that can withstand being sprayed with Roundup. In effect, Roundup kills all weeds (including microflora) while leaving the crop alone. Farmers hailed Roundup-Ready technology as a way to drastically reduce herbicide applications and thereby reduce costs, and the Environmental Protection Agency found Roundup to be far less environmentally hazardous than most of the other herbicides used in the production of crops for which Roundup-Ready technology had been developed. Concerns were raised, however, about human and animal health effects. Most of those objections were scientifically refuted. Of more serious concern were the effects on ecosystems and aquatic life. Since Roundup is a systemic herbicide—it kills plants by inhibiting the production of an amino acid essential in photosynthesis—the risks of exterminating "weedy" plants that are nevertheless essential in plant-insect-bird food chains are real, as is the potential effect on aquatic systems whose microflora are the staple foods of much aquatic life. Debate about these effects continues, even as some Roundup-Ready crops, such as soybeans and canola, constitute over 60 percent of the varieties grown in the United States.

Similar issues were raised in connection with Bt crops, which were genetically engineered to produce the enzyme active in *Bacillus thuringiensis*, a pesticidal bacterium long-used in organic farming and gardening. The Bt enzyme reacts with digestive enzymes in the gut of pest insects to produce toxins that force the insect to stop eating and starve to death. Commonly, a Bt solution was sprayed on crops, which, when their leaves were attacked by certain insect larvae, caused the insects to die. Scientists were able to engineer plants to contain the toxic enzyme from Bt, thereby conferring insect resistance on the plant. In 2007 versions of Bt cotton, Bt corn, and Bt potatoes were grown in the United States, Canada, and several other nations.

Genetically Modified Corn, near Santa Rosa, California. *In order to use fewer chemicals and save money, the owner of this Sonoma County dairy farm began growing genetically modified corn, finding it more resistant to weeds and a cleaner feed for his dairy cows. Genetic engineering of food products has become a controversial ethical issue due to the possible hazards both for human health and the environment.* **AP IMAGES.**

Objections to the Bt enzyme originally were focused on possible health effects, but after it was shown that the digestive enzymes in humans would not produce toxins even if the leaves of Bt plants were consumed by people, attention turned to environmental impacts. The incident that brought Bt crops to the public's attention was a 1999 report that showed monarch butterflies to be severely threatened by Bt technology (U.S. Department of Agriculture, Agricultural Research Service). Monarch butterfly larvae feed on milkweed plants, and milkweed is frequently found near cornfields in the major corn-growing areas of the United States. Pollen from Bt corn drifts onto milkweed plants, and when larvae feed on milkweed leaves, they are poisoned, just like pest insects on corn. Public concern about the threat to the monarch butterfly led to several studies and an eventual recommendation by the Department of Agriculture and the Environmental Protection Agency that cornfields maintain a buffer between crop plants and fencerows, and take other precautions to prevent pollen drift. However, there continues to be concern about the impacts of Bt and other biotechnology products on nontarget plant and animal species. In addition to such concern, there is now widespread awareness and regulatory interest in what has come to be called "genetic pollution"—the movement of genetic material from a deliberately engineered plant to wild relatives of that plant and other plant varieties as well. Even if there are no proven human health effects of a polluted nontarget plant species, concerns remain.

The Starlink controversy is an example of genetic pollution in a different form: What happens when GMOs not approved for human consumption inadvertently make their way into the food supply? Starlink corn, engineered and introduced by Aventis Corporation, is a Bt/glyphosate-tolerant corn hybrid approved by Food and Drug Administration for use in animal feed. As noted above, Bt toxins have not been considered a health risk. However, tests submitted by Aventis to the Environmental Protection Agency suggest that the version of toxin in Starlink may be more stable and digestion-resistant than other members of the Bt toxin family, and hence more likely to cause allergies in humans. For this reason the Environmental Protection Agency did not allow the use of Starlink in human food. In 2000, however, Starlink material was detected in taco shells sold by Taco Bell. There was a great public outcry, and eventually the taco shells (and many other yellow-corn products) were recalled from the market. How Starlink made its way into the food chain is not clear, although it is possible that some Starlink growers sold corn to a Mexican company that milled it for Taco Bell. Regardless, now most corn buyers and processors must routinely test for the presence of Starlink corn. If it is detected, the corn is sold for feed or nonfood industrial uses.

Flavr Savr tomatoes are no longer available, and ice minus and BST are no longer as controversial as they were when first introduced. The Starlink controversy is over. However, Bt crops and Roundup-Ready crops (generically, glyphosate-tolerant crops), all major parts of U.S. agriculture, continue to evoke discussion and critique. Since U.S. agriculture is so highly productive, U.S. farmers and the U.S. government are always looking for ways to market agricultural commodities abroad. Historically, the United States has found ready markets for meat, grains, vegetables, and fruit across the globe. However, in some parts of the world, GMOs and biotechnology in general are looked upon with some suspicion, if not outright disdain.

Indeed, for reasons not always clear to U.S. growers and officials of the U.S. Department of Agriculture, the European Union has been hostile to GMOs and genetically engineered agricultural commodities. The European Union has placed stringent limits on genetically modified crops and other products, in some cases (e.g., BST dairy products and meat) banning them entirely. Although the United States continues to challenge European Union trade prohibitions through the World Trade Organization, so far Europe has managed to keep most U.S.-created genetically modified products out of the continent.

An interesting result of the official European stance toward genetically modified foods occurred in 2002. Southeastern Africa was experiencing a severe drought and sought international relief. The United States offered to send maize through the U.N. World Food Program, but Zambia and Zimbabwe rejected the aid. Both nations expressed concerns about the potential genetic pollution of their indigenous maize crops and the potential loss of European markets for their products. Although most African nations are actively engaged in agricultural-biotechnology research and development (as resources permit), concerns about human health and environmental safety are as strong there as anywhere else. As a result, Africans have adopted a precautionary approach similar to the Europeans', which helps account for their reluctance to accept U.S.-produced genetically modified maize. Eventually both nations agreed to accept U.S.-produced corn meal to help alleviate hunger, but allowed no kernels to be imported (Njoroge 2002).

ETHICAL CONSIDERATIONS IN PUBLIC DEBATE AND PUBLIC POLICY

The public controversies surrounding GMOs show that people's attitudes toward and beliefs about GMOs frequently differ and even contradict each other (Hoban and Kendall 1993). Indeed, behind critiques and defenses of everything from Flavr Savr tomatoes to genetically modified maize are essentially ethical positions and judgments. The main argument in support of agricultural biotechnology has been a consequentialist-utilitarian one: Biotechnology is a means of improving the efficiency and perhaps environmental friendliness of modern food and fiber production, which translates into lower producer costs and lower consumer prices. Since achieving these goals enhances human welfare, biotechnology is prima facie good for society (National Agricultural Biotechnology Council 1995).

In contrast, criticisms of biotechnology and GMOs tend to be based on one of three ethical stances (Thompson 1997). (1) Some criticisms are based on the nature of the technology itself. (2) Some concerns are based on people's rights to be able to choose the products they consume, and the potential difficulty of being able *not* to choose genetically modified foods. (3) Some objections are based on potential environmental and/or social consequences of GMOs.

Jeremy Rifkin's notion of algeny captures part of the idea that there is something inherently wrong with GMOs. The main concern is that biotechnology is playing God, illegitimately interfering in the natural order. In this view, manipulating DNA is doing something only God should do—create life forms. God or evolutionary process produced species, each within special ecological niches. Altering species, especially in transgenesis, threatens to disrupt creation or eons of natural selection and diversification. As such, biotechnology is inherently unethical, immoral, or even sinful.

The second kind of ethical objection to GMOs is based on people's rights and autonomy—their moral entitlement to be able to choose. As biotechnology-based foods have become so prevalent, it is increasingly difficult for people who have ethical objections to GMOs, such as believing them to be unnatural, to avoid consuming those foods. The fact that genetically modified foods are not labeled in the United States means that consumers are effectively forced to consume them—a fact that violates their rights. And violations of rights are unethical.

The third ethical critique of GMOs concerns their potential social, economic, and especially environmental consequences. As discussed above, there were concerns that rBST would place small dairy farms at an economic disadvantage. Also noted was the impact of Bt crops on monarch butterflies. The fact that GMOs are still relatively new indicates that their potential long-term environmental and social consequences have not yet been assessed, nor can they be. GMOs and biotechnology are not necessarily unethical, but they may place people and the environment at risk, which is unethical. Consequently, we should adopt a go-slow policy with regard to permitting the use of biotechnology, prohibiting some GMOs entirely.

Defenders of biotechnology have replies to each of these objections. Regarding the objection of playing God, they note that humans have always interfered in nature, and have genetically altered plants and animals through traditional breeding for millennia. Regarding choice, if there is nothing wrong with biotechnology, why do people need a choice? To demand to be able to avoid genetically modified products is silly or irrational. And concerning consequences, the fact is that biotechnology is precise and controlled, so that scientists and regulators do in fact know in advance what the consequences of a given GMO will be. At the very least, government regulators make sure that products (genetically modified or otherwise) are not allowed on the market until they are

deemed safe, that is, posing minimal or no risks. Again, biotechnology is ethically acceptable because of the overarching benefits it confers on people.

To date, there have been no health or environmental catastrophes associated with genetically modified products. Proponents cite the adequacy of public and private institutional mechanisms for assuring safety and beneficial consequences. Since 1986 the U.S. government has maintained the Coordinated Framework for Regulation of Biotechnology, which is intended to maintain the positive track record for food and agricultural biotechnology (U.S. Department of Agriculture 2007). Depending on the product, the Animal and Plant Health Inspection Service of the U.S. Department of Agriculture, the U.S. Environmental Protection Agency, or the U.S. Food and Drug Administration is responsible for ensuring public health and safety.

Even though there is regulatory oversight, public-interest and activist groups continue to press the federal agencies involved, and continue to publicize ethical debate. In part, this is because biotechnology and GMOs are almost exclusively developed, owned, and marketed by a small group of large multinational corporations: Monsanto, Dow, Aventis, and DuPont, to name a few. Groups such as the Rifkin's Foundation for Economic Trends; the Union of Concerned Scientists; Greenpeace; the Consumers Union; Environmental Defense; and the Environment, Technology, and Concentration Group continue to pressure the government and these corporations to make sure that biotechnology and GMOs are safe and in keeping with the public interest. All these groups issue frequent communiqués, maintain active Web sites, and are vocal in the media as new products emerge from the food- and agricultural-biotechnology enterprise. The point is to make sure that all actors in this system behave ethically.

To summarize, although biotechnology may be a simple tool in the toolbox, allowing food and agricultural scientists to achieve plant and animal improvements that they see as beneficial to the public, several biotechnology products that have made their way into the market have been the subject of serious ethical critique and widespread public debate. Much of the ethical critique has focused on human-health issues, but environmental concerns have been just as important in the continuing discussion of food and agricultural biotechnology. The issue facing us is whether future products of food and agricultural biotechnology will have beneficial consequences, or will continue to be perceived as posing risks to health, environment, or to people's free choices, which exceed said benefits.

GLOBAL CLIMATE CHANGE

The possibility of anthropogenic (human-caused) climate change has been recognized since at least 1896, when the Swedish Nobel Prize–winning physicist Svante Arrhenius speculated that burning fossil fuels such as coal and oil might

increase atmospheric carbon dioxide, affecting both climate and terrestrial biological systems. Arrhenius estimated that a doubling of atmospheric carbon dioxide would increase the mean surface temperature of Earth by about 4 to 6 degrees Celsius, a figure that is very close to those produced by contemporary climate models. In 1963 a Conservation Foundation meeting warned of "potentially dangerous atmospheric increases of carbon dioxide" (Conservation Foundation 1963, pp. 19–20) and a 1979 report from the American National Academy of Sciences stated that a "wait-and-see policy may mean waiting until it is too late" (National Academy of Sciences 1979) to avoid significant climate changes. In 1988 Senator Tim Wirth of Colorado introduced a bill calling for a 20 percent reduction in carbon dioxide emissions by 2000 from 1990 levels. Although the bill failed, it had fifteen cosponsors, both Republicans and Democrats. In 1992 virtually all the countries in the world signed the Framework Convention on Climate Change (FCCC), in which they pledged to "prevent dangerous anthropogenic interference with the climate system."

Drought in Tanzania, 2004. *Children walk past a carcass in the Malambo district of Ngorongoro, one of Africa's most popular tourist destinations. The region is also home to the Maasai, a traditionally pastoral tribe whose livelihood is heavily affected by drought. Some theorists contend that it is the poor countries of the south that suffer the most from global climate change.* **TOM STODDART/GETTY IMAGES.**

THE ISSUE

Climate change is a difficult, complex, and challenging problem for several reasons. One reason is that Earth responds on different time scales than do political systems. Once carbon dioxide is emitted, it remains in the atmosphere for centuries, and other greenhouse gases (GHGs) can remain in the atmosphere for millennia. Because GHGs have such long residency times in the atmosphere, their effects on climate extend far into the future. Even if all GHG emissions ceased immediately, there would be at least another 0.7 degree Celsius of warming in addition to the 0.8 degree Celsius of warming that already has occurred.

Emissions will not cease immediately. Globally, emissions are increasing, as are atmospheric concentrations of carbon dioxide. In the mid-eighteenth century there were 280 parts per million (ppm) of carbon dioxide in the atmosphere, while at the start of the twenty-first century the number was more than 383 ppm. Only the most optimistic people talk about stabilizing the atmospheric concentration of carbon dioxide at 450 ppm. If it were possible to do that, there would be about a 50 percent chance of limiting the warming to about 2 degrees Celsius, the figure that has become the benchmark for "dangerous anthropogenic interference with the climate system." Any rapid warming, including the one that already has been experienced, causes harm to people and nature, but once the threshold of 2 degrees Celsius is crossed, the harms become universal, widespread, and acute, and the risks of catastrophic climate change grow exponentially.

Climate change will affect everyone, but the people who will suffer most are those who have done the least to bring it about. Poor countries will suffer more from climate change than will rich countries, just as they suffer more from climate variability and extreme events. Honduras suffers more from hurricanes than does Costa Rica, Ethiopia suffers more from drought than does the United States, and no country is affected more by floods than Bangladesh. In 1998, 68 percent of the land mass of that country was flooded, affecting about 30 million people, and that was only one of seven major floods that occurred over a twenty-five-year period. A rise in the sea level of 1 meter, which is plausible under many climate-change scenarios, could inundate 11.5 percent of the land in Bangladesh and 12 to 15 percent of the arable land in Egypt. Among the 300 million people who live fewer than 5 meters above sea level, 80 percent are in developing countries. A Ugandan president, Yoweri Museveni, is reported to have called climate change "an act of aggression by the rich against the poor" (Clark 2007).

When seen in this way, it seems clear that climate change is a dramatic challenge to the moral consciousness of humankind. It not only challenges people to act in a morally responsible way but it also challenges the very idea of moral responsibility.

A PARADIGMATIC MORAL PROBLEM

The paradigm of the moral problem discussed in this section is a case in which an individual acting intentionally harms another individual. Both the individuals and

the harm are identifiable, and the individuals and the harm are closely related in time and space.

> Example 1: Jack intentionally steals Jill's bicycle—An individual, acting intentionally, has harmed another individual. The individuals and the harm are clearly identifiable, and they are closely related in time and space. If the case is varied on any of these dimensions, it still may be seen as posing a moral problem, but its claim to be a paradigm moral problem will be weaker. Consider some other examples, each of which varies the paradigm on a single dimension.
>
> Example 2: Jack is part of an unacquainted group of strangers, each of whom, acting independently, takes one part of Jill's bike, resulting in its disappearance.
>
> Example 3: Jack takes one part from each of a large number of bikes, one of which belongs to Jill.
>
> Example 4: Jack and Jill live on different continents, and the loss of Jill's bike is the consequence of a causal chain that begins with Jack ordering a used bike at a shop.
>
> Example 5: Jack lives many centuries before Jill and consumes materials that are essential to bike manufacturing; as a result, it will not be possible for Jill to have a bicycle.

Although it may seem that moral considerations are at stake in each of these cases, that is less clear than is the case in Example 1, the paradigm case. The view that morality is involved is weaker still, perhaps disappearing altogether, if one varies the case on all of these dimensions simultaneously.

> Example 6: Acting independently, Jack and a large number of unacquainted people set in motion a chain of events that prevents a large number of future people who will live in another part of the world from ever having bikes

For some people the perception persists that this case poses a moral problem. This is the case because the core of what constitutes a moral problem remains. Some people have acted in a way that harms other people. However, most of what typically accompanies this core has disappeared. In this case it is difficult to identify the agents, the victims, or the causal nexus between them; thus, it is difficult to deploy the usual moral concepts and assign responsibility and blame.

These thought experiments help explain why many people do not see climate change as an urgent moral problem. Structurally, the moral problem of climate change is similar in many important respects to Example 6. A diffuse group of people are setting in motion forces that will harm a diffuse group of future people. Indeed, if anything, the harms caused by climate change will be much greater than the loss of the opportunity to have a bicycle. Still, people tend not to see this as a moral problem because it is not accompanied by the features that are characteristic of a moral problem. Climate change is not a matter of a clearly identifiable individual acting intentionally in a way that inflicts an identifiable harm on another identifiable individual who is closely related in time and space. If people are to see climate change as confronting them with a clear case of moral responsibility, they will have to revise or reform these concepts.

REAL-WORLD CASE

One response would be to say that climate change is not primarily a matter of individual moral responsibility but a question of political justice among states. Indeed, it might be thought that this is truer to the sentiment that Museveni expressed. Moreover, data can be mobilized that seem to show that this view is correct. When one looks at per capita or even total GHG emissions by country, the rich nations of the North dominate. However, when one looks at the actual and expected damages from climate change, it is the poor nations of the South that do and will suffer the most.

When we look at some countries in particular, the case seems even stronger. A rise in the sea level of 1 meter will flood one-third of the coastline of Bangladesh, creating another 20 million environmental refugees. In addition, saline water will move deeper inland, fouling water supplies and crops and harming livestock. This will occur as cyclones and other natural disasters become more frequent and perhaps more intense. Bangladesh will suffer in all these ways, yet its carbon dioxide emissions per capita are one-twentieth of the global average. A typical American emits 80 times as much GHG as does a typical Bangladeshi. However, although Americans will suffer from climate change, Bangladeshis will suffer vastly more. In light of this it seems natural to say that, although most of the emitting is done by the rich countries of the North, most of the climate-change-related dying is done in the poor countries of the South.

However, when one looks at the data in more detail, complications emerge. First, per capita emissions do not march in lockstep with gross domestic product. The nation of Trinidad and Tobago emits more per capita than the United States, and Malaysia emits more per capita than France. Moreover, the atmosphere does not care where GHGs originate. A molecule of carbon dioxide emitted from the exhaust pipe of a sport-utility vehicle (SUV) in Kenya is indistinguishable from one emitted from the exhaust pipe of an SUV in the United States. A coal-fired electrical

generating plant in South Africa affects climate as much as one in Germany.

From this perspective, climate change, rather than being caused by rich countries, is caused by rich people wherever they live. The richest 500 million people emit half the fossil carbon worldwide, and not all of them live in North America, Europe, Australasia, or Japan. Indeed, there are more high emitters in China than there are in New Zealand and probably more than in Australia. Because the United States has greater economic inequality, more extreme poverty, and fewer government services than do some poor countries (e.g., Cuba), more people will suffer from climate change in the United States than in some developing countries.

Once again it can be seen that climate change poses questions of global justice but strays from the paradigm. Greenhouse gas emissions are not like weapons of mass destruction launched by one country against another. The nation-state perspective is one important way of looking at climate change because nation-states are casually efficacious, but they are not the primary bearer or beneficiary of moral responsibilities. Climate change challenges not only people's sense of justice but their concepts of justice as well.

Climate change divides the future from the past as well as the rich from the poor. Those who will suffer most from climate change are those who will live at the end of the twenty-first century and beyond, and they largely will be the descendants of those who currently are living in poverty on the periphery of the developed world. What is required to "prevent dangerous anthropogenic interference with the climate system" is for people who are rich by global standards to restrict their emissions radically to benefit future generations of poor people.

This creates a problem of motivation. Burning fossil fuels primarily benefits those who burn them, while the damages are suffered largely by those who come afterward. The climate change that contemporary people are experiencing was caused largely by their parents and grandparents. The much greater level of emissions today will affect contemporary people's children and grandchildren. Because restricting emissions primarily benefits those who come later, it can be asked how it is in the interests of contemporary people to do so, especially if it is assumed, as most economists do, that their descendants will be richer than they are. From this perspective, asking people to sacrifice for future people is like asking the poor to sacrifice for the rich.

In addition to the divisions that climate change creates in the human community, it divides humans from nature. The biggest losers from climate change will be the plants and animals that are now barely surviving. At the beginning of the twenty-first century 700 mountain gorillas were clinging to life in two small areas of misty, densely vegetated forest in Uganda and Rwanda. What will happen to them when their reserves dry out and warm up as a result of climate change? Orangutan habitat is being destroyed in Indonesia to plant palm oil for biofuels as part of the attempt to mitigate climate change. Scientists predict that one-quarter of all species face extinction by the middle of the twenty-first century because of climate change. Things could be even worse if people do not act immediately to address the problem.

RESPONSES TO CLIMATE CHANGE

Three types of responses to climate change have been identified: mitigation, adaptation, and geoengineering. Mitigation involves reducing emissions and stabilizing GHG concentrations more than would be implied by a business-as-usual scenario. Adaptation involves positive adjustments in biological or cultural systems in response to actual or expected changes in climate. Geoengineerng involves the intentional large-scale manipulation of the climate system.

The consensus view is that if there is to be a reasonable chance of averting the most extreme risks of climate change, global emissions will have to peak in 2025 and decline by 50 percent by 2050 and the global economy must be virtually decarbonized by the end of the twenty-first century. Thus, cheap energy–high consumption lifestyles cannot be sustained in Europe and North America or replicated by developing countries without causing a climate cataclysm. People will have to find another way to live, and poor countries will have to find another model to guide their development.

Although environmentalists emphasize the low-hanging fruit and science enthusiasts put their faith in technological breakthroughs, the transition to a carbon-free energy system will entail real costs. If China and India cannot burn their vast stores of cheap coal, their development path will be more difficult and costly. If Brazil cannot exploit the Amazon in the way Americans exploited the U.S. West, they will forgo the use of one of their most valuable resources. Even a "Manhattan Project" that produced hydrogen cars and biodegradable products would shift resources from one part of the economy to another, displacing workers who have contributed no more to the problem than those who would benefit from the new economy. Although conservation often is presented as cost-free, it means something different to a poor person in a drafty house who relies on an old polluting car than it does to an investment banker who superinsulates his or her house and installs solar collectors on the roof.

Considerations such as these bring up questions of justice. How should people distribute the ever-shrinking rights to emit greenhouse gases? What principles should

Farmers Planting Seaweed in Bali, Indonesia, 2007. *Indonesia is particularly vulnerable to the impact of climate change, as global warming threatens to raise sea levels and flood coastal farming areas, threatening food security. Moreover, a rise in sea level would put thousands of farmers in the country at risk of losing their livelihood.* **SONNY TUMBELAKA/AFP/GETTY IMAGES.**

govern that distribution? Should the "luxury" emissions of the rich be treated comparably to the "subsistence" emissions of the poor? How should subnational inequality be treated in comparison to international inequality?

Many analysts endorse "contraction and convergence," an approach that calls for contracting emissions immediately and eventually converging on equal per capita emissions for everyone in the world. How could the proposed 50 percent reduction in emissions be achieved by 2050? Former French President Jacques Chirac hinted at the possibility of a global carbon tax, and others have speculated about a global emissions trading scheme that would connect the European Union system with the emerging North American carbon markets. There are a great many technical difficulties with both approaches, and some people object to the idea of buying, selling, or taxing carbon, seeing it as a way for rich people to buy their way out of their moral obligations. How does China, where the use of coal is increasing faster than gross domestic product and is now the world's largest emitter but still relatively low in terms of per capita emissions, get integrated into this type of system?

Whether or not the nations of the world succeed in mitigating their emissions, it is clear that adaptation will play a major role in the greenhouse world. Although it is not noticed by many people, adaptation raises many of the same questions of justice as mitigation. Unless catastrophic climate change occurs, rich countries largely will be able to adapt to climate change. They will build seawalls to protect their coastal areas, compensate farmers and foresters who lose their livelihoods, and invest more in developing and maintaining water resources. However, poor countries do not have the resources to adapt. For example, it has been estimated that Bangladesh needs $4 billion to begin to adapt to climate change by building embankments, cyclone shelters, roads, and other infrastructure. However, in 2007 Bangladesh's total national budget was less than $10 billion.

Will the developed countries and rich people who are the major causes of climate change be willing to finance adaptation for poor people and poor countries? They may have self-interested reasons to do so. Climate change will cause environmental refugees and political instability in a world that is already uncertain, but nations and individuals do not always act on the basis of rational self-interest. In many countries, such as the United States, there has been a systematic backing away from providing public goods such as libraries, parks, and schools. Financing adaptation projects in faraway places would have even less appeal.

Because so little is being done to mitigate or adapt to climate change, geoengineering is gaining prominence. Moreover, the idea that in the end science will save people from themselves is a popular one, at least among Americans. Different approaches to geoengineering have been mooted—reflecting solar radiation with space mirrors, seeding the atmosphere with sulfate aerosols, fertilizing

the oceans with iron, removing carbon from the atmosphere—but in general the science is relatively undeveloped.

The most important moral and political question about geoengineering concerns how the decision to implement a program will be made and by whom. It would seem that any decision to change global climate should be made with the participation of all the people of the world, as expressed through legitimate political institutions. But what are those legitimate political institutions? Do they exist? What decision rules should they follow? By and large, those who think of geoengineering as a promising approach to climate change have ignored these questions.

POLITICAL CHALLENGES

Climate change challenges the political system in addition to the problems that it poses to people's moral consciousness. Are European and North American democracies able to act on the time scale required to address climate change? Would liberal values have to be sacrificed? Would citizens have to change their values?

Reflecting on these questions leads to further questions about what development means and what kinds of lives are worth living. U.S. President George H. W. Bush is reported to have said in the run-up to the Rio Earth Summit of 1992 that "the American way of life is not up for negotiation." That categorical statement begs the question of whether the American way of life should have been up for negotiation. Is the American way of life superior to all other ways of life? Is it the only one worth living, even for Americans? There is little evidence in favor of affirmative answers to these questions. Surveys suggest that Scandinavians are happier than Americans and that, once basic needs are met, economic status is associated only very loosely with happiness.

From Plato to the present time reflection on the nature of the good life has been at the heart of philosophical inquiry. Some, such as John Stuart Mill, have argued that economic growth, the reigning ideal of progress and development, can be antithetical to the quality of life. Such ideas sound strange in a world in which the front page of the newspaper has been taken over by the business section, as if this week's economic indicators were the most important information. Whether up for negotiation or not, the American way of life will change, as will the ways of life of other nations, and it is important to think about what comes next and how to manage the transition.

Climate change is occurring, and serious impacts are being experienced, especially in polar regions and small island nations. Unless emissions are reduced significantly, the impacts will be severe and possibly catastrophic. People will have to adapt, and those already living on the margin have little capacity to do so. Can contemporary political systems respond to this challenge? In the second and third decades of the twenty-first century the answer will begin to emerge as GHG concentrations in the atmosphere continue to increase.

GLOBALIZATION

Globalization refers to the increasing unification of the world's economic order through reduction of such barriers to international trade as tariffs, export fees, and import quotas. The goal is to increase material wealth, goods, and services through efficiencies catalyzed by international specialization and competition. According

to the theory of comparative advantage of David Ricardo (1772–1823), specialization promotes efficiency. The theory maintains that even if one country could produce everything more efficiently than its best potential trading partner, trade would increase efficiency if the first country concentrates on producing what it makes most efficiently and trades with the other country for some of its other needs. Competition also promotes efficiency. In free markets, competition requires firms to improve products or lower prices to retain customers. International competition increases the number and types of competitors.

GLOBALIZATION'S DURABILITY

Some thinkers maintain that globalization will inevitably continue, but this confuses globalization with what Ulrich Beck calls *globality*. *Globality* refers to the increasing global interdependence resulting from human population increase together with powerful technologies, swift transportation, and instant communication. Globality decreases people's ability to isolate themselves from political instability, technological change, environmental pollution, health crises, and the like, wherever they occur. So long as our civilization lasts, globality will increase.

An element of globality is globalization, interdependency in the production and consumption of goods and services offered for sale in a supposedly free market. Unlike globality, however, globalization does not steadily increase. It was greater at the beginning, than during the middle, of the twentieth century. Wars, national pride, security fears, and the economic interests of powerful groups can inspire national protectionism, which is a retreat from global economic interdependence.

The World Trade Organization exists to promote globalization. Member nations commit to lowering tariffs and other barriers to free trade, including government subsidies to favored industries. Early in the twenty-first century, expansion of globalization under the aegis of the World Trade Organization stalled as a result of agricultural subsidies in the United States and the European Union. Its future has been challenged also by national security concerns related to terrorism (for example, about a Middle Eastern country owning American ports) and related to energy supplies (for example, about dependence on foreign sources of oil and natural gas).

ENVIRONMENTAL IMPACTS

According to Thomas Friedman (2005), globalization allows any country to get rich, regardless of natural-resource limitations, if property rights are secure, the rule of law prevails, taxes are low, interference with international trade is minimal, and governments balance their budgets. Failure to obey these rules results in the flight of financial capital needed for efficient production and viable competition in global markets. Friedman and the World Trade Organization essentially endorse laissez-faire economics on a global scale. Regional trade agreements, designed to promote international trade within a geographic region, such as the North American Free Trade Agreement (NAFTA), also embody the laissez-faire ethos. They promote national policies designed to attract investors.

This approach replaces governance by states with governance by international institutions to maximize investment income. Governance by states typically includes regulations and taxes designed to discourage negative externalities, such as environmental pollution. Corporations must internalize (pay the cost of) such externalities rather than impose such costs on the public. In contrast, the international institutions that replace states, such as the World Trade Organization, generally oppose such governmental constraints. Governments that force companies to internalize the costs of production tend to impair their companies' global competitiveness, as competitors from other countries can avoid such costs. Environmentally oriented countries thus may suffer failing companies, reduced tax revenues, declining investment, and increased poverty. Under reduced environmental regulations, however, overall efficiency can suffer. The public suffers the cost of avoidable harms, such as increased air and water pollution, which corporations lack incentives to curtail.

A provision of the North American Free Trade Agreement exacerbates this problem. In general, in the United States and other countries, companies do not receive compensation from the government when they are subject to reasonable environmental regulations. Because such regulations are deemed necessary to prevent companies from harming the public, companies must pay for the cost of compliance or suffer losses resulting from reduced opportunities. But the North American Free Trade Agreement contains a provision that requires governments to compensate companies for losses incident to regulations. For example, a U.S. company sued a Mexican municipality that refused to allow development of an area as a toxic waste dump. The company won $15.6 million. It would have had no case against an American municipality with the same regulation, because NAFTA rules apply only internationally. NAFTA's rules and the awards they allow discourage reasonable environmental regulations.

Regimes promoting globalization compromise environmental concerns also because they focus primarily on commerce, whereas national governments promote a variety of values, including some related to the environment, such as retaining species diversity, protecting favored species, preserving natural beauty, and conserving

Container Ships in the Port of Oakland, California. *Advocates of globalization claim that as societies become wealthier through free trade, they can devote more resources to environmental protection. As a rich state, California has among the highest environmental standards in the United States.* **ALFREDO SOSA/THE CHRISTIAN SCIENCE MONITOR/GETTY IMAGES.**

natural resources. The World Trade Organization generally treats government responsiveness to such concerns as unjustified impediments to free trade. It does this in part by distinguishing products from the processes used to create those products. Trade restrictions are acceptable if products offered for trade are dangerous or otherwise harmful. But harms caused by processes used to create products are not considered legitimate reasons for restricting imports. For example, the United States wanted to restrict imports of Mexican tuna that had been caught in nets that killed dolphins. More dolphin-friendly nets were available. But American interest in protecting dolphins was not considered a legitimate basis for import restrictions. Eventually a compromise was reached outside the aegis of the World Trade Organization.

Another example of commercial concerns trumping environmental concerns is rejection by the European Union of American beef grown with the use of hormones made available through genetic engineering. From the perspective of the World Trade Organization, the only legitimate concern about the beef was its safety, which a panel of experts affirmed. For their continued refusal to allow importation of such beef, the European Union was penalized (restrictions on some of their exports). Yet environmentalists may have many concerns about genetic engineering besides the safety of the product. Ecofeminists, for example, may consider genetic engineering an additional form of mastery of nature that tends to harm subordinated groups. Environmentalist Christians may consider genetic engineering as manifesting insufficient appreciation of God's gift of nature to humanity. Followers of Aldo Leopold's land ethic may consider genetic engineering to exemplify a conqueror mentality, which Leopold thinks backfires eventually. And many environmentalists advocate precaution, rejecting such innovations as genetic engineering unless they meet definite needs, because human beings cannot predict long-term consequences. None of these environmental considerations are allowed in deliberations of the World Trade Organization.

Supporters of globalization point out that the free market can be used to promote environmental and other

goals. Bad publicity and the threat of a consumer boycott dissuaded Shell Oil, for example, from dumping a decommissioned oil storage platform in the North Sea. Nike was persuaded to improve the pay and working conditions of its Indonesian workforce. Bad publicity for tuna inclined its producers to adopt more dolphin-friendly methods of capture. In addition, some corporations are proactive, making deals with environmental organizations to capture consumers who favor green corporations. These include McDonald's, International Business Machines (IBM), Hewlett-Packard, Dell, and Starbucks.

There is little doubt that enormous good has come from bad publicity, threatened consumer boycotts, and corporate leadership. However, free-market approaches are insufficient to protect the environment. Corporate commitment to environmentalism is conditioned by consumer attitudes, which are fickle. Consumer boycotts, for example, require the mobilization of public sentiment, and the public cannot concentrate simultaneously on all the different ways that corporations can assail the environment. Governments, by contrast, can simultaneously maintain rules on many different matters, to which affected industries must conform. This system affords more durable and consistent protection. In sum, joint decision making through political processes are the major means of protecting noncommercial values, including those related to the environment, so globalization cannot marginalize politics without harming the environment.

THE GENERATION AND DISTRIBUTION OF WEALTH

Advocates of globalization reply that as societies get wealthier through free trade, they can devote increasing resources to environmental protection. One trend evident in the 1990s was for small states highly integrated in the global market to have the highest environmental standards. These states included the Netherlands, Denmark, Sweden, South Korea, and, among Third World countries, Costa Rica. Within the United States, California, a rich state, has among the highest environmental standards. Environmental protection and wealth generated from global trade seem to go hand in hand. On this reasoning, environmentalists should applaud globalization as a means to more universally available wealth coupled with greater environmental protection.

This raises two questions. First, does globalization really spread wealth around the world? Second, does greater wealth generated by increasing global commerce really benefit the environment? The actual, as opposed to theoretical, economic benefits of globalization are contested. The world's very poorest people, those living on less than $1 per day, has decreased in recent decades, but the number living on less than $2 per day has not. The income gap between the richest one-third of nations and the poorest one-third has declined, but the gap between the richest one-tenth and the poorest one-tenth has increased. Moreover, it is uncertain how much these trends resulted from globalization. Under protectionist policies in the 1960s, Latin American economies grew at about twice the annual rate of the globalization-dominated 1990s. The U.S. economy grew very quickly under its own protectionism in the early twentieth century. Sub-Saharan Africa has generally become poorer during globalization, but it was getting poorer before as well.

China is the biggest economic winner in globalization so far, and to a lesser extent Southeast Asia and India. Exclude China from the figures, and globalization's record for enriching the poor is unimpressive. Increasing inequality is another problem. Ninety-five percent of people now live in countries where inequality is increasing. In poor countries, increasing inequality is particularly dangerous for the environment. Globalization typically denies peasants traditional access to local resources, because commercial interests want to use those resources to make money. Even though these peasants may have increased purchasing power, measured in monetary terms, they may be more destitute than before because they are denied access to resources that were formerly free, such as fields, woods, and pastures traditionally used to grow crops, gather wood, and graze animals. Their only recourse for survival may be to raise crops in unsuitable locations, such as hilly regions and rain forests, eroding topsoil and threatening endangered species. In sum, globalization may not be effective in making the world's poor rich enough to afford environmental protection.

COMBATTING ENVIRONMENTAL DECLINE

From an environmental perspective, however, globalization's success at enriching the world's poor may be worse than its failure to do so, as China illustrates. One problem is pollution. By 2004, 16 of the world's 20 most polluted cities were in China. Another problem is resource depletion. In 2004 there was a net increase of between 800 and 1,000 cars per day on the streets of Beijing. If China's increased use of automotive transportation continues, China in eight years will go from importing 7 million barrels of oil per day to importing 14 million barrels, the increase equaling the daily oil output of Saudi Arabia. China's use of fossil fuels is expected to overtake that of the United States, exacerbating the problem of global climate change. In addition, China uses its relative prosperity to buy palm oil from Indonesia and Malaysia, soybeans from Brazil, and timber from central Africa. The production of these items decimates rain forests and other

important habitats. Finally, China is running out of water. Water tables are generally down in India, Mexico, and the United States, but the problem is more severe and immediate in Northern China. An environmentally controversial water-diversion project is underway to use South China water resources in North China, but the more basic problem is that China has about 20 percent of the world's people, but only 7 percent of the world's available fresh water. And global climate change is diminishing some of that resource, as Himalayan glaciers are melting.

If the goal of globalization is to offer the First World lifestyle to everyone—cars, shopping malls, air conditioning, big houses—the environmental consequences of success could be catastrophic. An environmentally more benign alternative would be for the First World to develop a different sense of human flourishing centered on environmentally benign technologies and lifestyles. This would allow everyone around the world to enjoy the same lifestyle without ruining the environment. People would live in more compact settlements, have smaller homes, walk more, use readily available public transportation, eat more locally grown food, and so forth. Human health, education, and communities could flourish under these conditions.

This, however, is essentially a rejection of globalization in favor of bioregional alternatives where people live within the sustainable limits of their own regions of earth and trade at a distance only when absolutely necessary. People could have materially sufficient and culturally rich lives with smaller economies owing to less need to exchange goods and services. The Deep Ecologist Arne Naess, among others, advocates such a lifestyle, simple in means and rich in ends. But those promoting globalization reject this alternative because in smaller economies, returns on investment are reduced, as are tax revenues. The interests of globalization and government may combine to perpetuate the belief that high consumption is essential to the good life.

People who favor globalization but recognize environmental dangers suggest that politics be reinserted into commerce through new multinational institutions that protect the environment and other values, not just commerce. The economist Joseph E. Stiglitz, for example, suggests that such international institutions mandate product labeling that gives consumers information about the origins of products. Consumers could then choose products that better reward Third World workers or better protect the environment. The idea is to allow consumer choice to move corporations from free trade to fair trade. He also suggests establishing an international court where class-action suits could be brought against violators of new international environmental standards.

Successful international cooperation has some precedent in efforts to reduce ozone depletion and save some species from extinction, such as whales and elephants. But the United States so far has rejected many international initiatives that may weaken state sovereignty, including a treaty to eliminate land mines, the Kyoto Protocol to reduce emission of greenhouse gases, and the International Criminal Court to prosecute crimes against humanity. Without American participation, binding agreements that require trade to be fair and ecologically responsible will likely have little effect. On the other hand, common effects can produce concerted action, especially when elites with the greatest impact on decision making are jeopardized along with everyone else. But it is uncertain whether such elites will feel threatened, as they did regarding ozone depletion, before globalization does enormous and irreparable damage to the environment.

Another possibility is to require globalization to be more free-market-oriented. In spite of advocates' claims that globalization embodies free enterprise, it is highly subsidized by governments, especially in the areas of energy and transportation. For example, the U.S. government offers oil companies a tax break called the oil depletion allowance. It subsidizes the production of the oil substitute ethanol, made primarily from corn. It does not require oil companies, utility companies, manufacturers, or consumers to internalize the cost of illnesses produced by exhaust fumes and stationary sources of air pollution. Nor do they internalize the eventual costs of global warming caused by most current forms of energy production. In addition, the United States maintains a very expensive military presence in oil-rich areas of the world to assure continued oil supplies. And the road taxes paid by large trucks come nowhere near the cost of the damage they do to roads. A fully loaded large truck causes almost 10,000 times more damage per mile than an average passenger car.

If these costs were built into the price of products that travel long distances, the price structure of products would favor consuming more locally produced items. As it is, each item in a typical meal in the United States has traveled an average of 1,500 miles. Bioregionalism (people concentrating their commerce closer to home) may actually be what a really free market would produce. But this alternative requires powerful industries, with influential lobbyists, to relinquish government subsidies. Their self-interest may overcome an ideological commitment to free markets.

Globalization may not last. Security concerns may convince governments to reduce the international flow of goods and services, or powerful lobbies may convince states to protect domestic industries. Unfortunately, the decline of globalization may be unrelated to environmental concerns until such problems become acute.

GLOBAL WARMING

SEE *Global Climate Change.*

GREEN BUSINESS

Green business (or commerce) involves the commercial provision of goods and services in a manner that minimizes environmental damages or provides environmental benefits beyond the requirements of the law. In some cases companies dedicate themselves to minimal or net-positive impacts on the environment. Their product or service could be nearly anything; what matters are the environmental impacts of production, distribution, use, and disposal. Ecotourism, organic/sustainable foods, and socially responsible investment funds are examples of green-business products and services. A company's environmental practices can be a selling point for consumers and investors who prefer "green" products. The customers' knowledge of the minimal or positive environmental impacts of the company's practices is often crucial to the brand.

Green businesses also provide less-polluting alternatives to existing products. Renewable solar and wind energy technologies can supplant nonrenewable and environmentally unfriendly fossil fuels and potentially disastrous nuclear reactors in many applications. Products made from recycled materials, such as outdoor benches and machine components, can replace items made from original materials. Another category of green business involves helping other companies comply with environmental regulations: Such businesses sell remediation equipment or provide services such as pollution monitoring and environmental consulting.

WHY GREEN BUSINESS?

A green business has several possible advantages: It can

- reduce environmental-damage liability risks and the costs of production (if original materials are more expensive than recycled materials) and regulatory compliance;
- improve brand image;
- forestall additional environmental regulations;
- help recruit and retain valued employees;
- promote creative approaches to new product categories; and
- provide a competitive advantage in pursuit of public-sector contracts.

In this last case businesses with a stellar reputation for environmental performance may have a bidding advantage for large public projects if the decision makers are elected officials and an environmentally concerned public can influence the selection.

From a social and political perspective green businesses cause less environmental damage, allow regulators to focus on other environmental problems, reduce public health costs connected to industrial pollution, and develop technologies and systems that reduce the cost of environmental protection. From a consumer perspective green products may have lower energy costs and be less dangerous to use. They also provide opportunities for recycling and offer the consumer the satisfaction of buying products that are consistent with his or her environmental values.

A BOOMING MARKET FOR GREEN BUSINESS

Green business is a rapidly growing, multibillion-dollar sector of the economy. Nearly $1 billion of venture capital was invested in clean energy technologies in 2005 (Gangemi 2006). By 2006 U.S. organic food sales had reached $16.7 billion and were growing at an annual rate of roughly 20 percent (Organic Trade Association 2007). In 2007, 260 socially responsible investment funds controlled assets of $202 billion; overall socially responsible investment reached $2.7 trillion (Social Investment Forum 2008). The potential for further rapid growth is large; organic foods, for example, make up just 3 percent of all U.S. food sales.

Creditable monitoring is needed to support green business claims. Monitoring typically occurs through industry groups, nongovernmental organizations, and government

agencies. One example is the certification program of the U.S. Green Building Council's Leadership in Energy and Environmental Design (LEED). LEED-certified buildings pass inspections related to energy efficiency, water and materials use, innovative building design, and indoor air quality.

Regulatory agencies have been adopting tougher standards in judging the performance of green business products. One example is the rapid expansion of the renewables portfolio standard (RPS) regulations. This is a mandatory, market-based requirement to increase the quantity of renewable-resource energy used to produce electricity. This regulatory requirement both responds and provides incentives to the green energy sector, driving down the cost of green energy while driving up its consumption. U.S. states first launched RPS programs in approximately 2000; by 2008, numerous European nations and over 20 U.S. states had RPS programs and federal RPS legislation was pending.

Informing the public in a timely and effective manner of the latest innovations in production is another challenge facing green business. Many labeling programs have emerged to inform the public about the broader environmental impacts of the product. Governments require energy-efficiency labeling of household appliances and have developed rebate programs for appliances that meet strict energy-efficiency standards.

ETHICAL ISSUES AND GREEN BUSINESS

The primary ethical question surrounding green business is how much discretion private entities should have in making environmental-protection choices. The self-imposed standards of green businesses supplement those already mandated by government regulations. For nations with a mature capacity to regulate industry, the green-business sector need not aspire to supplant official regulations that protect human health and the environment. But for nations that lack regulatory capacity, the self-imposed regulations of green businesses may furnish a de facto standard of environmental performance.

A second ethical question involves the nature and extent of reporting. Green businesses are, of course, part of the private sector. Protection of brand reputation and trade secrets are first-order concerns of private companies. Self-reporting of environmental performance in the absence of third-party verification raises the possibility of self-serving misrepresentation, sometimes called greenwashing. Official verification of private-sector claims provides benefits both to the public and to the firms that faithfully report their performance. The green business concept has matured to the point that most major green labeling programs, such as the sustainable forestry initiative, have some form of outside verification of claims.

A third ethical question is whether green business standards and expectations are a barrier to smaller firms. Improvements in environmental performance often require carefully coordinated combinations of advanced technologies, integration with existing technologies and practices, and novel financing. Highly capitalized firms with integrated laboratory, production, distribution, and financing arms have a clear advantage. Smaller, less technologically advanced firms, however, may offer benefits to society by providing lower-cost products, employing less-skilled workers, and being located in poorer regions or nations. The success of green businesses in raising environmental-performance standards may entail a trade-off with other beneficial social outcomes expected of markets, including distribution of wealth to poorer regions of the world that cannot, for example, produce state-of-the-art energy-efficiency products.

A fourth question—perhaps the most fundamental—is what kinds of ethical principles should underlie green business practices. In the cases of very old companies or companies with long-term, stable ownership and management, green business practices can be considered an expression of Kantian duty or stewardship: a self-imposed obligation, the moral worth of which is its own reward. The business itself becomes an expression of the overall values—and environmental values—of the owners/managers. An example of a firm with long-term stability in leadership that includes a stewardship ethic is Granite Construction, an integrated mining, processing, and infrastructure building company highly respected for its environmental performance in a resource-intensive industry. In the case of many other businesses, in which commitments to maintaining profitability are paramount, green business choices, or lack thereof, can be viewed in the utilitarian mode of improving society through voluntary, individual market transactions regardless of environmental outcomes. An example of a firm in which ownership transitioned from long-term, stable, sustainability-oriented leadership to a shorter-term, profit-oriented, and more environmentally damaging approach is California-based Pacific Lumber Company. From the 1930s to the 1980s, the company was managed by the Murphy family, which insisted on a 100-year sustainable harvest model. In 1986, Pacific Lumber was purchased by Maxxam, Inc., which altered harvest management practices to maximize short-term profits. Two decades of regulatory battles over clear-cut practices resulted in the company declaring bankruptcy in 2007. The stewardship ethic of the long-term owners was not sustainable once ownership changed hands and a commitment was made to short-run financial profitability.

GREEN CHEMISTRY

Whereas conventional industrial chemistry sometimes has been used to create highly persistent toxic compounds with little regard for their effects on living organisms, green chemists attempt to develop chemicals that are inherently safe—benign by design. Chemical design thus involves the ethical choice of whether to make nontoxicity a fundamental requirement. The term *green chemistry* was introduced by the U.S. Environmental Protection Agency (EPA) in the early 1990s as part of a broader effort at pollution prevention. Some Europeans refer to the endeavor as *sustainable chemistry* to avoid political connections with leftist Green parties. In contrast to the older *brown chemistry*, green chemistry (Anastas and Warner 1998) seeks to:

- Design chemical products that have little or no toxicity and degrade into innocuous substances to prevent accumulation in the environment;
- Make chemicals from renewable sources such as corn and soybeans;
- Synthesize chemicals using manufacturing methods that create no hazardous waste by-products;
- Increase energy efficiency by manufacturing at room temperature and pressure.

ORIGINS AND EXAMPLES

Everyday examples of chemical greening include formaldehyde-free housing insulation, cleaning compounds derived from citrus, and plastics designed to biodegrade instead of piling up in landfills (Stevens 2002). More esoteric changes occur in chemical manufacturing, such as ibuprofen synthesis that does not produce tons of cyanide and formaldehyde as unwanted by-products. Dangerous solvents such as benzene, toluene, and perchloroethylene (for dry cleaning of clothes) gradually are being replaced by safer solvents, including ordinary water (Nelson 2003).

With thirty thousand chemicals in widespread commercial use, and myriad others in specialized applications, no one knows whether zero toxicity will prove feasible. However, green chemists are finding enough new approaches that phasing out all the persistent bioaccumulative toxics is beginning to appear doable (Thornton 2000). Many government environmental agencies worldwide are encouraging chemical greening, including the EPA, which offers annual awards to green chemistry innovators in both business and academia. The Green Chemistry Institute probably has done more than any other organization to promote chemical greening. The Canadian Green Chemistry Network, the Mediterranean Countries Green Chemistry Network, and the Green & Sustainable Chemistry Network in Japan are among several dozen international organizations that stimulate research and encourage voluntary reforms within industry.

THE ROLE OF CHEMICAL PROFESSIONALS AND ORGANIZATIONS

Virtually no professional chemists or engineers have engaged in public speaking and political organizing to shift the environmental movement toward a focus on detoxification. The failure of chemical professionals to help the public, journalists, and elected representatives understand the prospects for chemical redesign could be construed as a violation of the Chemical Professional's Code of Conduct, which asserts, chemists "have a responsibility to minimize pollution and to protect the environment" (American Chemical Society 2007). These tasks cannot be done by lone individuals without supportive regulations, tax codes, and social norms to induce changes in chemical research and development, manufacturing, and use. Professional associations such as the American Institute of Chemical Engineers focus not on public service but on the career advancement of their members, research conferences, and services to business. Chemistry is the science traditionally most closely connected with the corporate world, and chemical professionals working for industry outnumber those working for environmental organizations by roughly ten thousand to one.

Practitioners of brown chemistry do not perceive themselves as behaving unethically, and most would not dump hazardous wastes or falsify paperwork deliberately. However, chemists and engineers play key roles in an

ethically problematic system of invention, manufacture, use, and disposal that diffuses around the planet each year some ten billion pounds of toxic chemicals. If those amounts could be traced back to the four hundred thousand individuals employed worldwide as industrial chemists and engineers, each professional would be responsible for a hundred pounds of toxics per working day. The figure would be higher if one added deliberate releases of pesticides and herbicides, chemicals not tracked by government regulators, and chemicals leaching from consumer products.

The toxic planetary system has been co-constructed by industry executives and their customers and by government officials and voters who have failed to make brown chemicals illegal. Polar bears and humans would not have perfluorinated compounds in their fatty tissues if chemical experts had attempted to invent bioaccumulative chemical methods for cooking microwave popcorn and manufacturing carpets. If more chemists had adopted green methodologies, the endocrine systems of mammals and amphibians would be less disrupted and environmental mutagenesis and cancer would be less prevalent.

PHILOSOPHICAL ISSUES

The ethical advantages of green chemistry should appeal to philosophers concerned about sustainable relationships between humankind and the planetary ecosystem (Cairns 2003). However, philosophers of chemistry have devoted little attention to controversies concerning chemical politics and ethics, focusing instead on subjects many people might consider antiquarian, such as the origins of the periodic table of elements. In reading the philosophy journal *Foundations of Chemistry,* one cannot detect that the domain being studied pertains to global toxification. Even though the journal *Environmental Ethics,* which is devoted to studying the moral relationships of humans to the environment and to nonhuman life-forms, has covered hundreds of topics from endangered species and the intrinsic rights of nature to vegetarianism and ecofeminism, in three decades it has included virtually nothing on chemical ethics.

Environmental philosophers of biocentric and anthropocentric persuasions alike might find their scholarship enlivened by dealing with green chemistry. What obligations do professors have toward students in teaching brown-versus-green chemistry? Do some research trajectories merit higher priority than others? By what democratic processes could public interests be better combined with the academic freedom of chemistry professors? A physician can lose her or his license to practice by failing to provide adequate care to a single patient; what equivalent standards might apply to chemical professionals who can harm thousands of people at a time? Do organizations of professional chemists and engineers have special moral obligations that are proportionate to their greater resources?

Philosophers working outside the liberal tradition might ask: If mass publics are incapable of governing a synthetic planet, are there plausible neotechnocratic alternatives? Does chemical greening require a shift away from market-oriented economies dominated by business corporations? If local majorities want to move expeditiously toward chemical sustainability, do they have a right to nullify hostile state, federal, and international law? Conversely, do chemical greening opportunities suggest that nation-state democracy is outdated, and can global governance legitimately be asserted over the chemically irresponsible?

Overall, green chemistry joins with human cloning, surveillance, nanotechnology, the coming age of androids, and other twenty-first-century risks and opportunities to raise a master question: What social norms, laws, and institutions would constitute an ethically acceptable system for directing innovation wisely and fairly?

GREEN POLITICS IN GERMANY

The term *green politics* describes a set of political issues rather than a coherent ideology. Green politics is concerned mainly with environmental and ecological goals.

It also stresses issues of peace, feminism, civil liberties, social justice, and grassroots participation. The success of green politics represents a fundamental change in postwar politics that cannot be explained in terms of traditional socioeconomic divisions. The emergence of green politics in the 1970s was closely related to the rise of environmental, pacifist, feminist, and grassroots democracy movements. In the wake of those movements green parties were founded in many nations in the early 1980s. The term *green* traces back to the German party *Die Grünen* (the Greens), which was the first successful green party. The German party remains one of the most important and influential green parties worldwide.

BACKGROUND

The success of green politics and the emergence of the Green Party in West Germany were associated with an important change of values in the 1970s. As the student movement of the late 1960s and the APO (Extraparliamentary Opposition) weakened, the so-called new social movements emerged. Strongly supported by left-wing students and youth from the middle classes, those protest movements brought a new political and social awareness along with a new cultural identity to West Germany. During the mid-1970s opposition to the North Atlantic Treaty Organization (NATO) and the civil and military use of nuclear power became important issues, along with environmentalism, pacifism, general criticism of politics, and gender issues.

Those social and protest grassroots movements were the forerunners of the German Green Party. Even before the official founding of the party, so-called green and colorful lists were formed after 1977, mainly including those involved in antinuclear protests. Fast electoral success on the local, *Länder* (state), and European levels was crucial for the formation of the Green Party. As a result of laws on party funding, state financing played an important role. Consequently, the 1979 European Parliament election, in which the Greens won 3.2 percent of the vote, financed the party's early organizational development: In 1980 the Greens received nearly 70 percent of their revenues from the state and less than 16 percent from membership fees and donations. The formal founding of the Green Party took place in January 1980 when a thousand delegates gathered at the first party convention in Karlsruhe. Reflecting its ideological diversity, four pillars of the party were articulated: environmental, social, grassroots democratic, and nonviolent. Important figures in the early years included Heinrich Böll, Petra Kelly, and Joseph Beuys.

THE HISTORY OF THE GERMAN GREEN PARTY

The self-styled antiparty party achieved electoral success very quickly. In the 1983 federal election the Greens won 27 seats (5.6%) in the Bundestag. In Hesse they were part of a government for the first time at the *Länder* level (1985–1987). Joschka Fischer was appointed environment minister in that red-green coalition. He functioned as the informal party leader until 2005, although he never held an important party office.

After German reunification the West German Green Party failed to win 5 percent of the vote in the 1990 federal election and thus, under German law, lost its representation in the Bundestag: While Germans discussed the reunification process, the Greens focused on climate issues in their electoral campaign with the slogan "Everyone is talking about Germany; we're talking about the weather." Because of special election rules, in this first all-German federal election Alliance 90/Greens—Civil Movement, a combination of the East German civil rights movement Bündnis 90 (Alliance 90) and the independent East German Green Party, won eight seats in the Bundestag. In 1993 Alliance 90 and the Green Party merged into Alliance 90/The Greens (Bündnis 90/Die Grünen). The newly formed party won 7.3 percent of the vote nationwide in the 1994 federal election. When the Christian Democratic chancellor Helmut Kohl was voted out after sixteen years in office in 1998, the Greens joined the federal government in coalition with the Social Democratic Party for the first time, a coalition in which they remained until 2005. Fischer was appointed foreign minister and vice chancellor.

Despite that electoral success the party failed to stabilize its membership, especially in eastern Germany, after the mid-1990s. It has remained a mainly West German party in terms of its membership and electorate. As a result of fundamental changes in the German party system, especially the emergence of an all-German postcommunist party (Die Linke), the relevance of the Greens has been decreasing since 2005. In the European Parliament, however, more than one-third of the green members come from Germany and the parliamentary group's copresident is the German-French Daniel Cohn-Bendit. The German greens also played an important role in forming the European Green Party in 2004.

CENTRAL VALUES, MAIN CONFLICTS, AND NEW DEVELOPMENTS

Demographic analysis shows that in the first decade of the twenty-first century members of the German Green Party were mainly middle-aged, highly educated academics with an above-average income and that they shared left-wing and postmaterialistic ideas in many cases. Nevertheless, there has never been a coherent green ideology. The four pillars of the party's political agenda have not been used to form a stable ideological framework. Consequently, green

politics and the history of the German greens are affected strongly by policy conflicts. For a long time the consensus was that "green politics is neither left nor right but out in front." The party program dating from 2002 stated: "We are united by a set of basic principles, not an ideology."

In the early 1980s conservative, more right-wing members left the Green Party and reunited as the Ecological Democratic Party (Ökologisch-Demokratische Partei). That early schism arose largely from cultural conflicts about the forms of protests the Green Party should support, such as civil disobedience. Afterward, especially in the early 1990s, as part of the party merging process, many left-wing greens dropped out. The ideological polarization decreased in the late 1990s. At the same time that process enabled the party to create the nationwide red-green coalition.

From the mid-1980s to the late 1990s, conflicts between left-wing ideologists and office-seeking realists dominated the Green Party. Programmatic shortcomings resulted from that conflict. Only in 2002 was the Green Party able to discuss and finalize its second party program after 1980. Meanwhile, only short statements and electoral manifestos filled that gap. In the 2002 program the Green Party emphasized basic aspects of green politics: "We combine ecology, self-determination, expanded equitability and a vibrant democracy. With the same intensity, we are committed to non-violence and human rights." Grassroots democracy as affirmed in the 1980s is no longer a basic pillar of German greens. The party's interpretation of nonviolence has changed as well, having become less absolute.

Even though it is not disputed among Green Party members that the point of the party is to win elections and govern, joining a standing government is still a matter of conflict. During the red-green coalition there was a shifting mixture of political success and political failure. Participation in NATO actions in Kosovo in 1999 and Afghanistan in 2001 almost split the party, but achieving an intermediate-term shutdown of German nuclear plants was considered a great success. In reaction to a general change in the party system, coalitions with Christian Democrats on the *Länder* level became feasible. Green politics in Germany is no longer a dogmatic left-wing affair; it is a pragmatic approach to politics that is based on a half dozen basic positions.

GREENPEACE

Greenpeace is an international nongovernmental organization (NGO) that is committed to protecting the global environment and promoting peace. It originated in Vancouver, Canada, and has established national and regional offices in forty-one countries and a central headquarters in the Netherlands. It has close to three million members worldwide. It is known for its confrontational nonviolent, direct-action, and media-savvy strategies for exposing and promoting solutions to global environmental problems.

ORIGINS AND ORGANIZATION

Greenpeace grew out of the Don't Make a Wave Committee (DMWC), a group of peace activists committed to stopping the United States from testing nuclear weapons under the Aleutian Islands near Alaska. The DMWC feared that the tests would set off massive tidal waves. The group's most dramatic action was to sail two ships toward the test site to disrupt the detonations. The ships never reached the site, nor did they succeed in stopping the tests. However, people mobilized around the action and the voyages received significant media coverage. The action is credited with creating enough public pressure to persuade the United States to cancel planned testing. In 1972 the DMWC expanded its agenda to include a host of environmental concerns and formally dissolved to become Greenpeace, a name coined by Bill Darnell to express the group's dual commitments.

Greenpeace International, the organization's main coordinating body, works with national and regional offices to craft shared campaign strategies, but individual offices work largely independent from one another to devise local strategies and actions. In 2006, Greenpeace had close to 3 million members and an operating budget of approximately $196 million. The largest regional or national office is Greenpeace USA, which, in 2006 had roughly 300,000 members and an operating budget of nearly $15 million. In contrast to many other environmental activist groups, Greenpeace receives most of its funds (90 percent) from voluntary individual donations and does not accept money from governments or corporations.

Greenpeace Activists in Berlin, Germany, 2007. *Members of the nongovernmental environmental organization Greenpeace paint a BMW pink to dress it up as a "climate pig." The protest is aimed against the German car industry, which the activists accuse of producing climate-damaging cars. Greenpeace has established offices in forty-one countries, and numbers close to three million members worldwide.* **AP IMAGES.**

ISSUES AND ACTIONS

Greenpeace organizes its work around six primary issue or campaign areas: (1) climate change; (2) ancient forests; (3) oceans; (4) peace and nuclear disarmament; (5) agriculture; and (6) toxic chemicals. Within each of those campaigns the group works on a host of subissues, including genetically modified organisms (GMOs), persistent organic pollutants (POPs), and ozone depletion. Greenpeace lobbies national governments, attends international forums on global environmental issues, accompanies national negotiating delegations to international conferences, and tries to influence governments to advance environmental protection. Additionally, Greenpeace works throughout civil society to build public support for environmental well-being and pressure corporations to adopt more ecologically sound standards of conduct. It also conducts or supports original research into technological innovations and policy prescriptions that advance environmental sustainability.

One of Greenpeace's most effective actions was its 1979 effort to stop French atmospheric nuclear testing in the South Pacific. David McTaggart sailed a yacht into the exclusion zone at Moruroa atoll in French Polynesia. McTaggart's action, like that of the DMWC earlier, received significant media coverage. It also received strong resistance from the French. The result is that it projected a negative public image of atmospheric testing and nuclear weapons in general. Many credit the Moruroa incident and the Greenpeace organized antinuclear campaign efforts that followed with persuading New Zealand to declare itself a nuclear-free zone. Another notable set of Greenpeace actions involve efforts to stop whalers on the high seas. Using inflatable dinghies, Greenpeace activists have tried to protect individual whales by positioning themselves between whale pods and Soviet, Japanese, and Norwegian ships. They also have tried to board whaling ships in acts of civil disobedience. Additionally, campaigners have unfurled banners from the tops of smokestacks, scaled skyscrapers of corporate enterprises, and plugged up industrial discharge pipes. Such actions represent Greenpeace's commitment to bear witness to environmental abuse and bring widespread public attention to hidden environmental degradation.

The practice of bearing witness originates in the early days of Greenpeace, when many of its members

were influenced by Quaker practices. The idea of bearing witness is that when observing an injustice, one cannot turn away in ignorance but must, if one is unable to stop such action, stand by and attest to it. When Greenpeace bears witness by trying nonviolently to disrupt environmentally unjust behavior or documenting such actions, it broadcasts its actions worldwide through various media. Greenpeace ships, for instance, have satellite hookups that allow video footage to be sent instantaneously to media outlets throughout the world, and almost all its actions take place in the presence of photojournalists.

Since Greenpeace emerged, environmental activists have proliferated. There are tens of thousands of environmental NGOs around the world that work in the service of environmental protection. One can distinguish such groups according to the depth of critique they level against societies' environmental practices and the kinds of strategies they employ.

Many associate Greenpeace with the more radical wing of the environmental movement because of its commitment to direct action and civil disobedience. There is a significant difference, however, between Greenpeace and other confrontational groups such as Earth First! or Earth Liberation Front (ELF). This revolves around the use of violence. Some Earth First! and ELF members condone violent tactics, especially against property, as legitimate tools of political expression. They see violence as a way to dramatically draw attention to issues and as a means for immediately stopped ecologically harmful practices. Greenpeace disagrees. Its direct actions and forms of civil disobedience may, at times, violate existing laws; they are not violent, however, and aim deliberately to avoid harm to people, animals, and property.

Greenpeace's commitment to nonviolence has been tested over the years. In its early days Paul Watson, a member of the board of directors, advocated and at times practiced violent tactics, notably against hunters of baby harp seals. After being voted off the board, Watson went on to found a more radical organization, the Sea Shepherd Conservation Society. Over the years the society quarreled with Greenpeace about how aggressive tactics should be and what counts as violence. This led to their taking different approaches to the same issue. In the 1980s, for example, Greenpeace organized a boycott of fish products from Iceland to protest that nation's whaling policies. In contrast, the Sea Shepherds sank half of the Icelandic whaling fleet.

Although Greenpeace has been committed to nonviolence, violence has been directed against the organization. One incident involved the French government planting explosives on a Greenpeace ship in a New Zealand harbor. The ship was part of Greenpeace's antinuclear campaign against French atomic testing in Polynesia. A Greenpeace photographer was killed, and the French government publicly apologized for its actions and paid NZ$13 million to the government of New Zealand and over 2 million francs to the family of the photographer. The event cast Greenpeace activists as martyrs and helped them gain worldwide publicity and a significant increase in voluntary donations.

There is strong evidence that Greenpeace has played a central role in securing international legal agreements on issues such as whaling and ocean fishing, burning and dumping hazardous substances at sea, international trade in toxic waste, and persistent organic pollutants. Its campaigns and lobbying have been credited with bringing about a moratorium on the planting of genetically engineered crops in Europe, ensuring the support of the Mexican government in controlling pirate fishing of its waters, promoting an international ban on the trade in so-called conflict-timber from West Africa, working to improve the environmental practices of corporate entities such as Apple Computers, spearheading the shutdown of Cargill's soy-processing plant in the Amazon, and encouraging a European phase-out of soft polyvinyl chloride (PVC). More generally, Greenpeace can be credited with educating and inspiring environmentally concerned people around the world.

CRITICISMS

Critics of Greenpeace object to its activist strategies, accuse it of exaggerating scientific information, and contest the group's campaign priorities. For example, observers have criticized Greenpeace for its outspoken opposition to the first Gulf War, misuse of information in insisting that Shell Oil decommission an oil rig on land rather than at sea, and strong stance against GMOs.

Greenpeace has become an international presence on the world environmental scene. It engages in most global environmental issues and partners with many environmental organizations. It has been visionary in establishing offices in countries with little formal, organizational environmental presence and using dramatic direct actions, captured by the media, to highlight environmental assaults on the planet.

GUHA, RAMACHANDRA
1958–

Ramachandra Guha was born on April 29, 1958, in Dehra Dun, in the Uttar Pradesh, India. A leading environmental historian and sociologist, he has held academic positions in India, Europe, and the United States. Guha writes from a social-ecology perspective and argues that environmental issues must be considered in the context of the social conditions that arise from and cause the society's ecological conditions. India's environmental issues revolve around forests, dams, pollution, and biodiversity, all of which, in Guha's view, entail social conflicts over access to natural resources. He argues that, although material conditions do not exclusively determine social structures, it is impossible to understand social conditions without considering the underlying ecological conditions.

Guha's work presents a consistent ethical and ecological critique of colonialism and neocolonialism. British colonial policy contributed to considerable environmental degradation in India, particularly of India's forests. British demand for commercial wood products and timber led to vast deforestation, and deforestation disproportionately affects those whose livelihood depends on the forest. Although many have written persuasively about negative social effects of colonialism, Guha's work explores the relationship between social and ecological issues.

Although India gained its independence more than fifty years ago, European interests in Indian natural resources, including ecotourism, perpetuate social inequities between the First and Third worlds. Large-scale projects such as dams, animal preserves, and state forests continue to transfer control of and benefits from such resources from peoples who rely on them to biospheric omnivores who consume a large portion of the world's resources.

Guha's first book, *The Unquiet Woods: Ecological Change and Peasant Resistance in the Himalaya* (1989) explores the social dimensions of forestry in Uttaranchal, detailing the nature and form of peasant-based social protests against commercial forestry. He views the forest rebellions as peasant-driven rather than driven by interests of the Congress Party, which controlled the government, an outlook that reflects his association with the Subaltern Studies project. This work blends two previously distinct foci: the sociology of lower-class protest and environmental history—viewing peasant resistance in the context of its ecological setting—and the relationship between the simultaneous processes of social and environmental change in the Indian Himalayas.

This Fissured Land: An Ecological History of India (1992) and *Ecology and Equity: The Use and Abuse of Nature in Contemporary India* (1995), both of which Guha coauthored with the biologist Madhav Gadgil, address the relationship between society and environmental exploitation of India. *This Fissured Land* presents an ecological history of changing human interactions with living resources, exploring the ecological dimensions of social life and the conflicts that arise between the groups who use the resources. *Ecology and Equity* offers a theoretical framework to understand the ecological basis of India's complex social structure. Gadgil and Guha divide India's population into three ecological and sociological categories: omnivores, ecosystem people, and ecological refugees; they argue that social conflict and environmental degradation result from unequal access to natural resources. These categories are based on relative resource use and the ability to transform nature into artifact. They rethink debates regarding Indian development with insights gained from an ecological interpretation of past Indian development schemes.

Guha's 1999 biography of Verrier Elwin—*Savaging the Civilized: Verrier Elwin, His Tribals and India*—depicts the life of the Oxford-trained missionary and amateur anthropologist who defended the rights of India's indigenous populations to practice traditional forms of shifting cultivation. Under the British colonial administration and the newly independent Indian government, controversy raged over the extent to which indigenous peoples should practice sovereignty over their own lands or be assimilated into Indian society. Elwin's advocacy exemplifies "the other side of the Raj," British subjects who resisted the British imperialism, but whose resistance has not typically been included in subaltern treatments.

Guha's book *How Much Should a Person Consume? Environmentalism in India and the United States* (2006) compares the dominant environmental philosophies of the United States ("wilderness-oriented") and India ("agrarian"). This work draws on and expands on material from his *Environmentalism: A Global History* (2000). Guha argues that the U.S. environmental movement does not address the social dimensions of environmental issues and critiques the emphasis on wilderness and recreation usage as isolationist and privileged. Tiger preserves or wilderness preserves, for example, are based on a wilderness aesthetic that idealizes pristine landscapes, and ecotourism replicates colonial use of natural resources. To create such preserves,

indigenous peoples are evicted from their ancestral lands and lose access to traditional means of support.

Guha's critics have noted that his Marxist and economic interpretation of movements such as Chipko ignore religious or eco-feminist dimensions of these movements. Guha's criticism of Arundhati Roy in 2000 regarding the Narmada dam provoked discussion and criticism regarding one's authority to speak on issues of social justice.

H

HABITAT LOSS

Habitat loss is the transformation of marine or terrestrial areas from states suitable for the persistence of biota to those which are not. Habitat loss can be anthropogenic (due to human activity) or not; for instance, it can be due to geological activity over which humans have no control. The accelerating pace of habitat loss since 1960, particularly in the tropics, has been a major factor contributing to the emergence of contemporary biodiversity conservation movements and the forms those movements have taken (Gómez-Pompa, Vázquez-Yanes, and Guevera 1972, Janzen 1986).

DEFINITIONS OF HABITAT LOSS

Habitat loss can be conceptualized along a continuum ranging from transformation to a state unsuitable for the persistence of almost any form of life to one that is unsuitable for the persistence of a particular species. (While there is nothing conceptually incoherent about referring to the habitat of individual organisms [though "home range" is the more usual term], concern over habitat loss is rarely expressed at the individual level.) The habitat of an individual species corresponds to its realized geographical niche: the part of its fundamental ecological niche (as defined by its autoecological requirements) that comes to be contingently occupied by the species (Soberón and Peterson 2005). Typically, in discussions of biodiversity conservation the context indicates the type of habitat loss that is intended, whether it is for a single species or a broad range of species. In different countries policies focus on different types of habitat loss.

In the United States and in other countries in which biodiversity conservation efforts often are directed at individual species (most often endangered, threatened, or endemic species) habitat loss typically refers to the loss of suitable habitat for such species. Designating a "critical" habitat for those species becomes a major conservation concern. In these contexts the normative basis for concern about habitat loss can be concern for individual species or for general biodiversity, that is, all biota. The broader goals of the second category include the individual species of interest. Until the emergence of conservation biology as an organized discipline in the 1970s and 1980s most conservation efforts were concerned with this type of habitat loss.

MAINTENANCE OF HABITAT TYPES

Since the early 1980s much of conservation planning has been directed toward the maintenance of habitat types, as defined by using a wide variety of ecological criteria, such as vegetation and soil type, elevation, temperature, and precipitation (Sarkar 2005). In such contexts habitat loss refers to the transformation of the habitat type that presumably leads to degradation of suitable living conditions for entire suites of species. Such planning protocols are based on the normative assumption that what matters are all components of biodiversity, not just individual species.

Three developments have motivated this important shift. First, there has been a general expansion of normative concern for the persistence of all species and other biota from the traditional concern with the persistence of just charismatic or otherwise useful species, for instance, game species. Second, there was a realization that designating critical habitat precisely for individual species is a labor-intensive process that takes a long time. Thus, in light of the continuing high rate of habitat loss, it was unlikely that

Deforestation in the Anapu Region of the Amazon. *Brazil's Amazonian rainforest, shown here in 2005, is a highly contested environmental ecosystem. The fight is between those who want to see Brazil's economic development include the Amazon region, and those who want to continue to conserve the biggest forest in the world. According to a government report in 2005, Brazil has lost 26.130 square kilometers of rain forest due to deforestation, an area similar to the size of El Salvador.* **ANTONIO SCORZA/ AFP/GETTY IMAGES.**

critical habitats could be identified and protected for large numbers of species before habitat loss put those species under threat of extinction. Third, there was a realization that conservation efforts should include the welfare of species for which no information was available, including species that had not been scientifically identified yet.

Nonanthropogenic habitat loss for individual species and for biota as a whole has always been part of the evolutionary history of the planet. Species have become extinct as their habitats have shrunk and disappeared as a result of geological and other changes. Asteroid impacts have contributed to habitat loss besides influencing extinctions directly. Whether this type of habitat loss raises normative issues is controversial. Human agency is not responsible for the effects of nonanthropogenic habitat loss, and extinction is a standard evolutionary process. However, human agents may incur moral responsibility when they have the power to counteract extinctions that result from such habitat loss.

ETHICAL ISSUES IN HABITAT LOSS CAUSED BY HUMAN ACTIVITIES

Anthropogenic habitat loss can be direct or indirect. It is direct when human activity alters the physical structure of habitats in the temporal and spatial vicinity of that activity. It is indirect when the effects are felt later or at a distance in space. For instance, habitat loss due to climate change is an indirect effect of human energy consumption and other activities. Much of the concern over habitat loss in the first decade of the twenty-first century has been driven by the perceptions that the rate of direct habitat loss increased greatly during the second half of the twentieth century and that contemporary transformations of land- and seascapes are irreversible and often result in environments that are unsuitable for virtually any form of life (Margules and Sarkar 2007). In that sense this habitat loss has no precedent in the evolutionary history of the planet and should be a matter of special concern.

Significant causes of this direct habitat loss have included resource extraction, especially logging and mining, and conversion of land- and seascapes for agriculture and human habitation and recreation. The increased rate of habitat loss is due to expanding resource use caused by overconsumption and overpopulation (Cohen 1995). Technological advances have enabled this rate to continue to increase exponentially for the last several centuries.

In the developed countries of the North, besides energy consumption, the expansion of cities through urban sprawl has been a major cause of habitat loss, particularly in North America. Thus, habitat loss is linked directly linked to the cultural choices humans make about how they want to live. However, in these countries a drastic decrease of consumption levels can be achieved without seriously affecting human well-being. In sharp contrast, in the developing countries of the South reduction of consumption is usually not an option if minimal standards of human well-being are to be maintained (Martínez-Alier 2005). Preventing habitat loss thus must be weighed against other legitimate normative goals for social policy, such as ensuring food, water, shelter, and at least minimal health care and education for all individuals.

Not only are demands for decreases in consumption often lacking in normative justification, in many cases economic growth and the attendant increase in consumption are imperative to alleviate poverty and disease. Expansion of agriculture is a pressing need in areas with hunger or malnutrition. Achieving such growth without permanently depleting environmental resources is the goal of sustainable development (World Commission on Environment and Development 1987). One consequence of these imperatives is that protecting all critical habitats may not be a reasonable normative goal for every species of interest (or every component of biodiversity), a position contested by those who maintain that biodiversity has intrinsic value on a par with and independent of all human interests.

Similarly, the determination of appropriate strategies for preventing habitat loss has been a matter of contention between biodiversity conservationists from the North and social ecologists and other activists from the South, along with some marginalized groups at the fringes of the North, such as the First Nations of North America. The traditional Northern model of habitat protection has been exclusionary, setting up wilderness area and national parks that do not allow permanent human presence (Callicott and Nelson 1998). There are ethical, scientific, and pragmatic arguments against this "wilderness" model (Guha 1989, Sarkar 1999). The ethical arguments include the right of cultures to continue to live on and utilize ancestral lands and the right of individuals to utilize available natural resources for food, shelter, and other basic necessities. These problems are particularly salient in the South because some of the most biologically important habitats are in southern countries (because of the latitudinal diversity gradient) and are often used by marginalized peoples to sustain their meager livelihoods. Mark Dowie (2005) documented how conservation measures carried out by distant governments and big North-based nongovernmental organizations have created a new class of conservation refugees.

Scientific arguments against the wilderness model include the acknowledgment that many areas now perceived to be wildernesses attained their present form because of intensive human management in past eras. Most of the North American landscape is an example of this kind. Additionally, maintaining biodiversity does not necessary require absence of human activity or presence in a habitat: rather, strategies for maintaining viable populations of biota should be based on empirically ascertained ecological needs of species (Sarkar 2005). Finally, pragmatic arguments include the effectiveness of including local residents in all conservation efforts, and the history of political conflicts generated by attempts to exclude traditional residents and users from potential conservation areas.

Ethically responsible policies for reducing habitat loss and achieving habitat restoration where possible thus must navigate carefully between these problems. Habitat protection must be done in a way that achieves sustainability while ensuring that the basic needs of humans continue to be met and without abrogating the rights of individuals living or working in contested habitats. The ideal of distributive justice requires an emphasis on the rights and interests of those individuals who are least privileged, for instance, those living in marginal habitats in Southern countries.

HARGROVE, EUGENE

1944–

Eugene Hargrove, who was born on October 22, 1944, in Detroit, Michigan, grew up in St. Louis, Missouri. For three decades, as the founder and editor of the journal *Environmental Ethics*, he has been the principal figure in setting the context for the development of environmental philosophy. He is known especially for research into the history of the ideas behind environmental thought, such as aesthetic appreciation of nature in landscape and wildlife art. Hargrove also has been pivotal in graduate education throughout his career, having founded the first doctoral program with a specific focus on environmental ethics.

Hargrove received his bachelor's (1966), master's (1967), and doctoral (1974) degrees in philosophy from the University of Missouri. He did postdoctoral work on the philosopher Ludwig Wittgenstein at the University of Vienna and was a Rockefeller Foundation fellow in environmental affairs in 1976 and 1977. Hargrove founded the journal *Environmental Ethics* at the University of New Mexico, with publication beginning in 1979. This was the first journal wholly dedicated to environmental philosophy, and for three decades it has been considered by many scholars to be the most important. It has provided a forum for the discussion of environmental ethics and fostered the emergence of a new subfield in philosophy. The success of the journal has stimulated the publication of several complementary journals. Hargrove created a nonprofit organization, Environmental Philosophy, Inc., to own and manage the journal, which he moved in 1981 to the University of Georgia, with its Institute of Ecology.

In 1989 Hargrove relocated, with the journal, to the University of North Texas, where he served as chair of the philosophy department. That department also stayed in close association with the programs in ecology at that university. Hargrove created the Center for Environmental Philosophy to promote the field and Environmental Ethics Books, a reprint books series. He has been concerned with applying environmental ethics and introducing it into public primary and secondary schools and into graduate programs that train environmental educators and other professionals.

Hargrove's views are elaborated in *Foundations of Environmental Ethics* (1989) as well as two dozen professional papers. He is the editor of three anthologies: *Beyond Spaceship Earth: Environmental Ethics and the Solar System* (1986a), which is concerned with ethical and environmental issues related to the U.S. space program; *Religion and Environmental Crisis* (1986b), an attempt to go beyond the Lynn White debate whether Christianity with its teaching about human dominion over nature bears major responsibility for causing the environmental crisis; and *The Animal Rights, Environmental Ethics Debate: The Environmental Perspective* (1992a), which discusses environmental ethics in relation to animal liberation and rights. Robin Attfield has provided an important commentary on Hargrove's work (Attfield 1994, chapters 5, 6, 14).

Hargrove's environmental philosophy features what he calls "weak anthropocentric intrinsic value," by which he means that all values encountered in nature are generated by humans in their encounter with nature, which always is seen from a human perspective. In such interactions nature is valued instrumentally, although it can and should be valued intrinsically as well. That intrinsic value is weak in the sense that it depends on the human presence, in contrast to a strong nonanthropocentric intrinsic value, which others suppose they can find inherent in plants, animals, species, and ecosystems with a good of their own in the absence of humans. Hargrove allows that such autonomous intrinsic values may exist but thinks that humans are not in an epistemological position to know such values or their bearing on how people should behave. He urges: "A simple reminder that humans are fully capable of valuing things noninstrumentally and have been doing so for thousands of years is all that is needed" (Hargrove 1992b, p. 199). Hargrove's historical research on the sources of environmental ethics in classical American landscape painters of the frontier provides support for that viewpoint.

Early in his career Hargrove was an active caver and an environmental activist for the National Speleological Society, especially in the period 1971–1974. His interest

in caves has given him a perspective that goes beyond that of the usual aboveground land ethic because caves are anomalous as ecosystems. Cave conservation respects life in caves but is concerned equally with mineral formations. Weak anthropocentric appreciation of nonliving cave formations may be needed to protect a cave—"hollow spaces in layers of sediment" (Hargrove 1992b, p. 192). His ongoing concern with environmental ethics in space (empty space, lifeless planets) provides further evidence of his ability to extend environmental thought. In 2007 Hargrove received funding from the National Science Foundation to hold a workshop on "Space Science, Environmental Ethics, and Policy."

HETCH HETCHY

In the late nineteenth century two strains of thought about nature prevailed in the United States. The first was that careful management of natural resources was essential to the long-term expansion of the American economy and to the welfare of society. This conservation movement was led by the first chief of the U.S. Forest Service, Gifford Pinchot (1865–1946), who was appointed to that post in 1905 by President Theodore Roosevelt (1858–1919). The approach established by Pinchot and Roosevelt brought increased regulation and management of vast acreages of forest and grazing lands by government scientists and other experts. They believed that the combination of government oversight and large corporate interests could efficiently manage nature to serve national prosperity in perpetuity.

The second impulse was to set certain lands aside entirely from development. Derived from eighteenth-century European Romanticism, preservation had acquired uniquely American qualities. Literary and artistic depictions of nature figured prominently in the early cultivation of America's cultural identity. Middle- and upper-class Americans found picturesque and sublime landscapes a source of both national pride and a refuge from the increasingly harried pace of urban life.

THE FOUNDING OF YELLOWSTONE NATIONAL PARK

The establishment of Yellowstone National Park in 1872 represents the first grand achievement of the preservation

Hetch Hetchy Valley, Yosemite National Park, California. *Hetch Hetchy, described by John Muir as "one of Nature's rarest and most precious mountain temples," has been a controversial topic regarding environmental ethics. Over 80 years ago, the valley was dammed and flooded to supply drinking water and hydropower to the San Francisco Bay area; much of the valley still lies under water today.* **AP IMAGES.**

ideal. Yellowstone's early history, however, reveals a tension between preservation and development that surfaced more dramatically in Yosemite National Park's Hetch Hetchy Valley. Congressmen established Yellowstone Park only after the U.S. Geological Survey assured them that the volcanically geothermal region was without value for either agriculture or mining, leaving tourism as its only economically redeeming function. For the next two decades park defenders were hampered by the inherent limits of that original economic justification for the park. Faced with repeated attempts by mining and railroad interests to overly commercialize the park and then to penetrate or slice off a portion of the reserve, those defending Yellowstone's inviolability ironically resorted to utilitarian arguments to fend off the proponents of utilitarian exploitation of the area.

YOSEMITE AND SAN FRANCISCO'S QUEST FOR WATER

By 1900 the question of whether the boundaries of national parks were sacrosanct had been positively resolved in Yellowstone but still loomed in Yosemite. In contrast to the struggle in Yellowstone, where corporate interests could be branded as rapacious invaders, here the issue was clean water for the city of San Francisco. Since the 1880s city engineers had envisioned the possibility of damming the high-walled Hetch Hetchy Valley, 150 miles to the east, as the best way to solve San Francisco's perennial water-supply problem. Damming the Tuolumne River at the lower end of the valley would create a reservoir to serve a growing population. The problem was that Hetch Hetchy was inside the boundaries of the newly established (1890) Yosemite National Park. For San Franciscans the public good to be gained by damming the valley—for the needs of the many—far outweighed the value of preserving it for the pleasure of a few.

John Muir (1838–1914), who had come to national attention with his earlier writings on the natural glories of the Yosemite region, did not see it that way. In 1903 Secretary of the Interior Ethan Allen Hitchcock (1835–1909), agreeing with Muir and his fledgling Sierra Club, refused to grant the right of way for the dam and reservoir to the city, asserting that he could not violate the original intent of Congress to protect the area.

The devastating 1906 earthquake that struck San Francisco was followed by a citywide fire, and there was not enough city water to control it. The destruction of the city by earthquake and fire and the public health crisis that came in its wake—aggravated by a lack of safe drinking water—changed everything. With the routine occurrence of typhoid outbreaks caused by unsafe urban drinking-water supplies, the argument made by city officials for a reliable source of clean, fresh water received a sympathetic hearing. Furthermore, most conservationists argued that western waters that flowed to the sea represented an inefficient "waste" of a vital resource. Their grand vision, inscribed in the Reclamation Act of 1902, was to "reclaim" vast areas of arid land in the American West through massive dam and irrigation projects.

Hetch Hetchy Reservoir in Yosemite National Park, 1987. *Hetch Hetchy has been the subject of environmental controversy since the late nineteenth century, when a proposal to dam the valley to provide water to San Francisco created an early rift between environmental perservation and human resource interests. More recently in the early 2000s, groups have proposed measures to "restore" the Hetch Hetchy Valley.* **© GALEN ROWELL/CORBIS SYGMA.**

HETCH HETCHY: CONSERVATIONISM VS. PRESERVATIONISM

When San Francisco's plea for the right of way to build the reservoir was made again in 1908, a new secretary of the interior, James R. Garfield—appointed by President Roosevelt—received it favorably. In many ways Roosevelt was the central figure in this struggle. A firm believer in resource conservation, he also created new national parks and established the nation's first wildlife refuges and national monuments. His pronouncements on the value of wilderness and wildlife were often accompanied by declarations of the more practical, material benefits of government management of the nation's natural resources. Forested watersheds were to be protected for the benefits

that would accrue to farmers, commercial navigation, and home building. The support of Roosevelt, the nation's most famous outdoorsman, for the Hetch Hetchy project carried considerable weight. The Hetch Hetchy controversy rendered the chasm between preservation and conservation impassable. Garfield's approval of the city's request prompted Muir and Robert Underwood Johnson, editor of the *Century Magazine*, to launch a five-year-long national campaign to defend the valley and, as they saw it, the very integrity of the national park idea. For preservationists the proposal to flood Hetch Hetchy Valley represented the most egregious sign of an urban civilization slouching toward decadence. In congressional hearings over the Garfield decision, valley defenders held up Hetch Hetchy as a sacred symbol of unspoiled nature, a bulwark against the juggernauts of urbanism and industrialism. Invoking the divine association that such places of grandeur had assumed in American culture, Muir and others condemned the proposal as an ungodly, satanic act that would destroy one of God's own "temples." Others clamored against the private interests that purportedly stood to profit from the dam. Letters and telegrams opposing the dam poured into congressional offices from civic groups, scientists, and travelers. Editorial boards of leading newspapers and magazines inveighed against the project. The popular groundswell killed the legislation in 1909.

But proponents of the dam would not surrender. In 1913 San Francisco's congressman, John E. Raker, introduced the bill that finally delivered victory to the dam's advocates. Raker grounded his argument in economics. He trumpeted the enormous monetary value (in the millions, he said) of an impounded reservoir versus the paltry $300,000 value he ascribed to the valley in its present "swampy" state. Most dam advocates, including Pinchot, acknowledged their support for parks—when not in conflict with other, more pressing human needs. Further, they argued that the dam held aesthetic and recreational value; the valley's "old barren rocks" and "swampy floor" would be greatly enhanced by the reservoir.

The opposition reprised its nationwide campaign of protest against the "sordid commercialism" the dam had long come to symbolize. Impressive though it was, the effort failed. Congress voted decisively in 1913 in favor of granting the city the right of way through Yosemite to construct the dam. President Woodrow Wilson signed the Raker Act, which led to the flooding of Hetch Hetchy, signaling defeat for preservationists.

The campaign to save Hetch Hetchy drove a deep wedge between conservationists and preservationists. The controversy revealed the limits of the "worthless lands" rationale for establishing parks and wilderness areas—an issue with which preservationists continually contended. Hetch Hetchy forced the nation's elected officials to consider the higher value of untouched wilderness and demonstrated the broad support that the ideal had acquired in American culture. Forty years later, when another proposed dam threatened to invade the sanctuary of a national preserve (Dinosaur National Monument), preservationists recalled Hetch Hetchy, rallied national support, and this time prevailed.

HINDUISM

Hinduism is distinctive among the great religions of the world in having no explicit creed, founder, or centralized authority. It is a complex tradition in which local indigenous devotional practices stand alongside, and are sometimes integrated within, sophisticated philosophical systems. Some scholars refer to Hinduism not so much as a singular religion as a confederation of worshipping communities held together by shared literary, philosophical, and ritual traditions. Its antiquity is comparable to the ancient traditions of Egypt or Mesopotamia. Unlike them, however, it is a continuous, living, and dynamic tradition continually responding to new conditions. Hinduism has not made a strong effort to proselytize members of other faiths. Thus, except for devotional movements, such as the International Society for Krishna Consciousness, that have attracted followers in the Europe, United States, and Latin America, the reach of Hinduism as such has been confined to India and to Indian immigrant communities abroad.

Nevertheless, from the time Hinduism came to be known in Europe and North America, scholars have taken a keen interest in the philosophical ideas of Hinduism and its remarkable artistic and cultural achievements. Interest in the significance of nature in the Hindu religious traditions and the importance of Hindu ideas for the environment have been of particular interest to environmental philosophy, particularly the Deep Ecology of the Norwegian philosopher Arne Naess.

CULTURAL SETTING OF HINDUISM

There is no specific time and place in which Hinduism can be said to have begun. Sometimes called Sanatan Dharma, or "the eternal teaching," it is appropriately understood simply as the life and culture that, before the advent of other religious traditions, embodied the values, concerns, hopes, and ideals of the people of the Indian subcontinent. Hindu worship centers on rituals that celebrate the importance of natural phenomena, critical changes in the rhythm of nature, the key moments in the life of the individual in the community, and decisive events in narrative traditions recognized both by local communities and by the larger society. In these traditions aspects of the flora and fauna of India, rivers, trees, plants, mountains, and animals play a significant role.

During the nineteenth century many scholars held that the philosophical and cultural achievements of ancient India were the work of invaders or immigrants who entered the region from the third through the second millennium B.C.E. That view was discredited in the 1920s with the discovery of an advanced civilization that flourished in the Indus Valley, in what today is Pakistan, from 2500 to 1500 B.C.E. Archaeological investigations of the Indus Valley civilization (2500–1500 B.C.E.) have revealed cities with straight streets, a central bath, a sophisticated system of wastewater management, and evidence of a written language not yet deciphered. The absence of elaborate temples or palaces suggests a relatively egalitarian society. Artifacts suggest worship of a mother goddess and a strong regard for fertility as well as spiritual ideas and practices that appear in Hinduism today.

INFLUENCE OF HINDUISM IN EUROPE AND NORTH AMERICA

From the early nineteenth century, when Hindu texts came to be known in Europe and North America, philosophers in those areas took a strong interest in the philosophical ideas of India. With the influence of Hindu writings available to him, Ralph Waldo Emerson (1803–1882) rejected the Western notion of deity as the Supreme Being that stands over nature and embraced the idea of divinity in nature itself. The interest of such thinkers led to an appreciation of the intellectual content of Hinduism, but largely to the neglect of the patterns of worship and devotion that motivated much of Hindu religion.

Interest in the environmental values of Hinduism emerged in the 1960s amid claims by some environmentalists that because the Judeo-Christian tradition held the idea of God as a being outside of nature who created humans as uniquely endowed with a soul, and who placed them in charge of nature to use it as they pleased, this tradition was largely responsible for the present ecological crisis. Because these thinkers saw the traditions of Asia as different from those of the Judeo-Christian tradition, Hinduism came to be explored for the insight it might offer toward the development of a viable environmental ethic.

In this context, writing about Hinduism tended to reflect the influence of the nineteenth-century about India known as *orientialism*. In this discourse two opposing images of India often confronted each other. One was a view of India as an alternative to the exhausted materialism and utilitarianism of European–North American civilization. In this view India was the venue of enchanting landscapes and esoteric teachings. Its doctrines were intuitive, mysterious, profound, and luminous. In the texts of India available to him, Arthur Schopenhauer (1788–1860) found deep, original, and sublime thoughts that stirred his spirit to its depths. But the same discourse also generated the image of India as the "irrational other." Lord Thomas Macaulay (1800–1859), the architect of the British educational system in India, argued that the whole of Sanskrit literature, replete with its grotesque and immoral mythologies, was not to be compared with the intellectual content of a common English schoolbook.

Writing concerning the Hindu view of nature through the 1980s tended to reflect these opposing views. For some, Hinduism presented a view of nature in which every mountain, rock, and tree was to be respected, venerated, and presumably protected. For others Hinduism was hopelessly occupied with liberation from the material world and therefore irrelevant to environmental concerns. Environmental writing since the 1980s has tried less to infer a single disposition of Hinduism toward the environment than to understand such issues as the environmental significance of particular texts and practices, the impact of environmental degradation upon Hindu worship, and the ways in which particular Hindu ideas and practices have supported local environmental initiatives.

HINDU VIEWS OF NATURE

The history of India reveals differing views of nature developed over an enormous span of time. Many Hindu traditions have supported strategies of resource use that have helped sustain India's biological diversity and have supported communities that depend on it. A strong interest

Hindus Celebrating the Ardh Kumb Mela. *Indian Hindu devotees participate in ritual bathing at Sangam (the confluence of the Ganges, Yamuna and mythical Saraswati rivers in Allahabad, January 28, 2007) during the Ardh Kumbh Mela festival (Half Pitcher festival). The Hindu tradition regards all rivers as sacred. With a majority of its population practicing Hinduism, India is seen as a center of the religion. The Hindu regard for nature will likely play a part in environmental debates as India continues to increase its population and development.* **MANAN VATSYAYANA/AFP/GETTY IMAGES.**

in nature is evident from the earliest period of Indian civilization. Among the remains of the Indus Valley civilization, small square or rectangular steatite seals (measuring 3.8 to 7.6 centimeters across) depict trees, water, and goddess figures standing in close relation with one another. Some of them seem to depict Earth as a mother giving birth to a tree and contain scenes composed of animals, trees, and human beings, usually interpreted as revealing the common rhythm in human, animal, and vegetative life. The relationship of trees, water, and the goddess in the remains of the Indus Valley civilization resemble later images of the Ganges River as a goddess pictured beneath a tree.

Hinduism has an impressive literary history, and, although it is not a text-oriented religion, its textual history provides a convenient framework for understanding the significance of nature in the tradition. The earliest literary source of Hinduism, the Rig-Veda (composed c. 1800–800 B.C.E.) contains hymns of praise and adoration to a number of the phenomena of nature depicted as deities. Indra is the seasonal monsoon rain, pictured as a colossal male figure destroying the demon that withholds the waters from the thirsty land. Surya is the sun, the Maruts are the storm spirits, and Apas is the waters. Prithivi the Earth is praised as the mother who sustains the world and all that dwells upon her.

The Rig-Veda and other ancient Vedic (or wisdom) collections lavish praise on such rivers as the Yamuna, the Saraswati, the Indus, and the Ganges. The Hindu tradition regards all rivers as sacred. Along the banks of rivers across India, ancient temples and contemporary religious practices express deep piety toward rivers as Mother, the source of life, the deity who cleanses defilement and sin. Vedic sources also portray the universe as a living organism in which every part is related to the life of the whole. Vedic literature develops the view that all of life is sacred because all living beings reflect the one divine reality from which all of life has come; it therefore prohibits injury to living things.

In the Upanishads, which are philosophical supplements to the Vedic hymns, (composed c. 800–600 B.C.E.), the attitude of adoration toward the natural world is

retained. But the Upanishads are a diverse body of documents. The teachings of the Upanishads range over such topics as the ultimate ground and source of the visible world, the nature of the true self that resides in the depths of the human person and in other living creatures, the condition of the embodied self in the visible world, and the path that leads to the liberation of the self from its bondage to otherwise endless rebirths in the visible world called *samsara*. Here, alongside the attitude of adoration of nature, we find a disposition toward nature less consistent with the Rig-Veda and other Vedic collections.

Despite the variety of insights of the Upanishads, their attitude toward the natural world can be gathered together in terms of two diverging tendencies. On the one hand, the natural world and all that it contains is, or is the manifestation of, *Brahman*, the ultimate reality. Here the phenomena of nature are sometimes presented as analogies that aid in the recognition of the relationship of the visible world to its ultimate ground. Just as birds resort to a tree for a resting place, so everything resorts to that supreme self (Brahman). As herbs arise from the earth, as hairs arise from the body, so from The Imperishable does everything here arise. Like sparks from a blazing fire, manifold beings are produced from the Imperishable. Other passages emphasize that, although the supreme self is the essence all things, it is also other than anything that can be seen or conceived of. In some of the Upanishads, this reality is to be sought by means of penetration into the depths of the inner self. Although the Upanishads do not all agree upon a single method for the pursuit of this ultimate reality, many recommend renunciation of the material world, which is seen as a provisional and transitory reality. For this reason, some of the Upanishads tend to minimize the importance of the material world and the physical body in which the embodied soul is condemned to repeated lives.

By the second century C.E., the Hindu tradition had begun to mediate between these opposing tendencies by articulating not one but four ends or purposes to human existence (*catush purushartha*):

1. *kama*, sensuous and aesthetic pleasures;
2. *dharma*, the duties and values of temporal moral existence;
3. *artha*, prosperity;
4. *moksha*, release from the cycle of rebirth.

Around the same period the tradition came to understand earthly life as laid out in terms of four stages:

1. the *brahmacarya,* or student, beginning around the age of twelve;
2. the *grihastha,* or householder, beginning with marriage;
3. the *vanaprastha,* or the forest dweller, an optional stage that normally begins when a person has fulfilled the duty to establish and raise a family;
4. the *sannyasin*, the final optional stage, in which the person has renounced the world in pursuit of *moksha*.

Because the four ends of life are relevant to the different stages of life, the tradition emphasizes both the importance of the material world, including the dharmas—which are relevant to the maintenance of the natural, social, and political order—and the final goal of liberation.

The tendency to renounce the material world in pursuit of moksha found expression in philosophical ideas that eventually influenced some European and North American intellectuals. Shankara, who lived a mere thirty-two years in the eight or ninth centuries C.E. and took sannyasin vows at an early age, was the exponent of a school of Indian philosophy known as Advaita Vedanta, or unqualified nondualism—what European and North American scholars have sometimes called *monism.* Shankara held that there is only one reality, Brahman, that the world of everyday experience is a mere appearance of that reality under the conditions of the ignorance (*Avidya*), which is a common characteristic of temporal existence. Committed to the goal of moksha, he encouraged his followers to cultivate an attitude of indifference—even disgust—toward the material world. Some scholars have attributed the deplorable condition of India's environment to the influence to such thinking. Shankara's thought, however, is not completely incompatible with concern for nature. Although Shankara spoke disparagingly of the material world, neither he nor the Hindu tradition recommended world renunciation as the norm for society as a whole. Moreover, among his followers, his rhetoric was intended to discourage attachment to the material world. Thus those who would follow him in world renunciation were bound to radically reduce their environmental impact. The earthly life of the sannyasin is one of self-control, nonviolence, simplicity, and frugality.

The articulation of the four ends and the four stages of life reflect the influence of the *Ramayana* and the *Mahabharata* (composed c. 500–100 B.C.E.), the two most extensive works in Indian literary history. These epics tell stories of the response of idealized characters to challenges that illustrate and provide a context for reflection upon fundamental dharmas, or values, concerning both the temporal world and the aim of human life. Both epics tell of an extended exile in the forest in which much of the action is set. Although the forest evokes fear, it is also admired for its fecundity and beauty. In the forest the characters rise to challenges and encounter the divine. Critical events in these narratives occur in forest locations that are still sites of

religious pilgrimage. Thus, in the grand narratives of the tradition, the landscape of India has an integral significance.

In a critical episode in the *Mahabharata* called the *Bhagavad-Gita* (Song of the Blessed One), Krishna appears as the Supreme Lord of the universe and instructs Arjuna, one of the five central characters of the story, about the critical moral and religious teachings of the tradition: the importance of engagement with the world in an attitude of renunciation and the importance of devotion to God in any of his manifold forms. In this important work, Lord Krishna supports the religious significance of the natural world, proclaiming himself to be the taste in the waters, the light of the sun and moon, the pure fragrance in earth, brightness in fire, and the life in all beings (*Bhagavad-Gita* 7: 8–9).

The importance of the natural world is further reflected in the Puranas (Ancient Stories, composed c. 300–900 C.E.). The *Bhagavata-Purana* (also called the *Shrimad Bhagavata*) tells the story of the birth of Lord Krishna and his childhood in the forests of Vrindavan on the banks of the Yamuna River, now grotesquely polluted with sewage from the city of Delhi 130 kilometers upstream. His teachings are set in these forests, for which he expresses admiration and love. This Purana tells of a colossal venomous serpent that encroached upon the Yamuna and poisoned its waters. The alarmed Krishna dived into the poisoned waters and, after an enormous struggle, prevailed against the serpent and danced on its many heads. For those engaged in the ecological restoration of the waters and land of Vrindavan, Krishna is an inspiration and symbol of hope.

In the *Matsya-Purana*, the goddess Parvati plants an Ashoka tree and cares for it. As it prospers, other deities and the sages question her attention to this tree. Parvati replies that a person who digs a well in a place where water is scarce lives in heaven for as many years as there are drops of water in the well. She states that a large reservoir is worth ten wells, that a son is the equal of ten reservoirs, and that a single tree is the equal of ten sons.

In many of the Puranas, animals are the *vahanas,* or vehicles, and therefore the symbols of the gods. They are featured in narratives both in the Puranas and the epics: the bull is the *vahana* of Lord Shiva, the cow is the *vahana* of Lord Krishna, the elephant of Indra, the lion of Parvati. Often a particular animal has religious meaning because of its role in the religious narrative. The monkey is the living representation of Hanuman, the monkey God who, in the *Ramayana,* assisted Lord Rama when the demon Ravana abducted his wife, the goddess Sita. These animals appear prominently in contemporary religious life.

It is perhaps in the Shastras, or writings concerning dharma (duty) and artha (prosperity) that the most explicit injunctions toward the protection of nature can be found. In the *Arthashastra* (c. 300 B.C.E.), fines are recommended for offenses such as disposing of dust on roads; urinating or defecating near a well, pond, or temple; and for inappropriately disposing of a dead animal. Its concern for forest resources is expressed in its sanctions against the destruction of trees, groves, and forests. For the cutting of the tender sprouts of fruit trees, flowering trees, or shade trees in parks near a city, it recommends a fine of 6 *panas*. For the minor branches of such trees, the fine is 12, and for the large branches of such trees it is 24. For the cutting of the trunk of such trees the fine is 48–96, and for the felling of such trees the fine is 200–500 *panas*. For trees that mark boundaries or are worshipped, the sanctions are doubled.

Although it is impossible to know the ancient value of the *pana*, it is significant that damage to forest resources were taken seriously enough that a fine should have been imposed. The fact that the fines increase geometrically with the size of the damaged branches suggest that trees were objects of value. The imposition of especially severe penalties for damaging a tree that has religious significance indicates not only that trees were objects of worship but also that the provisions of law supported the worship of trees. Widely considered the most authoritative of the ancient *Dharmashastras*, the Laws of Manu (c. 100 B.C.E.) states that anything that contains blood or poison—or impure objects such as urine, feces, spit—is never to be disposed of in water.

ENVIRONMENTAL CHALLENGES SINCE THE NINETEENTH CENTURY

After the colonization of India by the British, a philosophy that viewed nature largely in terms of its economic value for industry tended to marginalize the views of communities that expressed their dependence upon the environment in religious terms and that supported its protection. From the middle of the nineteenth century, British interests exploited India's forests for a burgeoning shipbuilding industry at home and an expanding railway network in India. Timber was in demand for railway ties and as fuel for the locomotives. In many parts of India, forest movements opposed increasing government controls that restricted community access to forests for local needs. Beginning in the 1920s, Mohandas K. Gandhi argued that India should be a republic of economically independent and self-governing villages. He promoted *sarvodaya,* or universal uplift, through the recovery of local and cottage industries and the ideals of life expressed in the ancient writings of the tradition.

With India's achievement of national independence in 1947, state forest departments became the largest landholders in the nation. Under pressure toward economic development, established forest industries supported continued exploitation of forest resources to the

detriment of local communities. Unregulated industrial development contributed to further degradation of forests, waterways, and land. Environmental awareness began to emerge as conflicts over natural-resource use were played out against a background of increasing ecological degradation.

After Gandhi's assassination in 1948, his European disciples Mira Behn (Madeleine Slade) and Sarala Behn (Catherine Heilemann) settled in the western Himalayas, where they established ashrams intended to realize the kind of independent and self-reliant communities that Gandhi had envisioned. Sarala Behn's efforts toward the empowerment of rural women and Mira Behn's writing concerning the ecology of the hills contributed to the emergence of movements (especially the Chipko movement) for the rights of local people and the preservation of the forests upon which they depend. They also contributed to a rising environmental consciousness that inspired environmental activism in other parts of India.

In some places degradation of landscapes of religious significance has also raised environmental concern. Deforestation around temples of national importance has provoked ambitious tree-planting programs. Pollution of India's rivers, traditionally seen collectively as the goddess who supports and purifies all who depend upon her, presents a major problem to the worshipers of these rivers. In the region of Vrindavan, the birthplace of Krishna, the Yamuna is unfit for ritual bathing. Although some religious authorities claim that the pollution of the river cannot detract from its spiritual significance, others have argued that the toxins are harmful to the goddess herself and call for radical action. Some environmentalists believe that the Hindu regard for nature can help to spur an adequate response to the many environmental problems of India's increasingly urban and industrial economy. India's need to balance the imperatives of rapid economic expansion with its traditional regard for nature constitutes a striking challenge to the living and dynamic tradition of Hinduism.

HOLISM

Although the centrality of holism in both ecology and environmental ethics is indisputable, the meaning of the concept within each field is difficult to define with precision.

HOLISM AND REDUCTIONISM

Holism might be understood best in contrast to reductionism. Reductionism is arguably the central approach to Western science, traceable back to the ancient Greek Milesian school of thought (c. sixth century B.C.E.), which attempted to discern the fundamental stuff out of which all else emanates. Reductionistic science assumes that the experienced world is understandable only through an examination of its component parts, and that through such an examination we discern the reality of the whole. For an environmental reductionist, for example, a species is nothing but a placeholder for a collection of specimens.

The popular expression of reductionism is that the whole is merely the sum of its component parts.

In *Nature's Economy* (1994) the environmental historian Donald Worster portrays holism as a reaction to the influence of reductionism, from Gilbert White's "Cult of Selborne" reacting against the perceived evils of Linneaen fragmentation to John Ray and Henry More rejecting the reductionism of a Newtonian-Baconian mechanistic view of nature. He observes that "the idea of holism ... has ebbed and flowed with extraordinary persistence throughout the modern period" (Worster 1994, p. 21).

In contrast to reductionism, holism asserts that the whole is greater than the sum of the parts: Holists believe that certain properties or qualities that emerge at the level of the collective do not exist in the parts and also are not predictable from a knowledge of the properties or qualities of the parts before their integration into wholes. For example, a holist might point to the quality of life as a property of a living organism that does not exist in the atoms or in the molecules of which living organisms are composed.

Although it sometimes is assumed that both the science of ecology and environmental ethics are inherently holistic, both contain theories that range from the manifestly holistic to the strictly reductionistic. Among classic examples in ecology, Frederic E. Clements's "superorganismic" conception of the biota (the idea that what now are called ecosystems are themselves living organisms) is manifestly holistic, whereas Henry A. Gleason's "individualistic concept" of the biota (the idea that certain plants and animals often are found together because they are adapted individually to similar environmental conditions) is strictly reductive. Among classic examples in environmental ethics, Aldo Leopold's land ethic (which makes the "integrity, stability and beauty" of "the biotic community" the measure of right and wrong) is clearly holistic, whereas Paul W. Taylor's biocentrism (which provides equal intrinsic value for all living beings individually) is strictly reductive. It is therefore a mistake to assume that holism is a defining characteristic of ecology or that all environmental ethics are holistic.

ETHICAL HOLISM

Ethical holism stands in opposition to ethical reductionism: The belief that only individuals as more or less traditionally conceived (e.g., human individuals, other individual animals, and individual plants) matter morally. The focus of most popular environmental concern is on wholes: on species, such as the black-footed ferret, not on individual ferrets; on forests, such as the plains of the Yellow Dog River in Michigan's Upper Peninsula, not on individual trees; on whole ecosystems, such as the Florida Everglades; and even on titanic features of the environment such as the atmosphere, the ocean, and climate. Ethical holists assign moral significance to wholes over and above the individuals they encompass.

Ethical holists assert that environmental wholes are direct objects of moral concern, often claiming that they have intrinsic value. As was noted above, however, not all environmental ethicists are holists. An ethical reductionist might argue, for example, that the good of a species can be accounted for by considering the good of the individual specimens that make it up. As to objects of popular environmental concern such as the atmosphere, the oceans, and the biosphere as a whole, a reductionist might argue that protecting them from damage is necessary to ensure the well-being of individual humans or, in the case of reductionistic animal ethicists, the welfare of individual animals. By contrast, an ethical holist would argue that a species, an ecosystem, a biotic community, or even nature as a whole deserves ethical consideration. Ethical holisms appear to be premised on corresponding ontological holisms.

ONTOLOGICAL HOLISM

Ontological holism is the claim that the reality of the whole transcends the reality of its constituent parts. The principal support for ontological holism is the alleged existence of emergent properties belonging to wholes that neither exist among the parts nor are predictable from knowledge of the properties of the parts and the way the parts relate to one another. Ontological reductionism, in contrast, is the claim that the properties of wholes are always reducible to—that is, are found in or predictable from—the properties of their component parts. Only the parts are real; the whole is not. A social reductionist, for example, would argue that individual human beings are real but human societies are not; societies are simply aggregates or collections of interacting individual human beings. An ecological reductionist would argue that individual plant and animal species populations are real but biotic communities are not; a biotic community is, as Gleason put it, a "coincidence" of species populations that are adapted to the same environmental conditions, such as temperature and rainfall.

To counter reductionism, holists invoke the emergent properties of wholes. A social holist might point out that societies exhibit properties, such as political institutions, that are not found in individual human beings. A biological holist might point out that a species has a minimum viable population (the smallest number of specimens necessary to assure the perpetuation of the species for the foreseeable future), a property not found in any of the specimens. An ecological holist might point out that ecosystems modulate local climates—areas of standing forests, for example, have

lower summer temperatures than areas in the same climate region that have had their forest cover removed—but that the individual trees do not modulate their local climate. Because reductionists cannot deny the existence of whole-level properties, dispute centers on the predictability of those properties from the interaction of the properties of the parts.

Holists also contend that wholes exert downward causation on their parts. A social example would be the way political institutions shape the physical and mental properties of individual people. Would a contemporary Swede be the same individual if his parents had thrown in with the Communist revolution in China when he was born in the 1940s and he had experienced the physical hardships and relentless political indoctrination of the Cultural Revolution in the 1960s? Thus, the properties of the society that individuals find themselves in exert downward causation on the individual humans who compose those societies. An evolutionary example would be the way a species supposedly adapts to an ecological niche in a biotic community. If the niche is what the species is adapted to and is conceivable only as an emergent property of the community, the community is real because it exerts downward causation on its parts: the individual species that compose a biotic community, whether or not the niche property is predictable from knowledge of the community's parts and their mutual relationships.

As the last example suggests, ontological holists implicitly assert the existence of a hierarchy of wholes. Individual species populations are the parts of a biotic community, whereas specimens are the parts of a species population. That invites holists to reduce ontological reductionism to absurdity. What are the parts of specimens? Their individual living cells is one plausible answer. In that case, are only cells real whereas specimens are not? And what are the parts of cells? Their individual molecules. And the parts of molecules? Their individual atoms. This regression is not infinite, but it terminates in something so remote from the ordinary experience and conception of reality—subatomic particles, quarks, or superstrings—that only the most obdurate reductionist would endorse such an ontology. Thus, social reductionists appear to be merely arbitrary, drawing the line at individual human beings, not the individual cells of which humans are composed, but refusing to acknowledge the reality of social wholes composed of individual humans. Ecological reductionists such as Gleason appear to be equally arbitrary, drawing the line at individual species populations, not the individual specimens of which they are composed, but refusing to acknowledge the reality of biotic communities composed of individual species populations.

RADICAL (METAPHYSICAL) HOLISM

Radical holism is the assumption that the embeddedness of organisms in their ecological matrix serves essentially to erase the individual. That is, ecological interconnectedness eliminates the individual, which is subsumed by the reality of the whole. Popular expressions of this might include the slogan "all is one" or metaphorical expressions such as the "web of life," a web lacking nodes that one might recognize as individuals, or, as Worster characterizes holism, a view "in which all nature is approached as a *single indivisible unity*" (Worster 1994, p. 21; emphasis added).

One also can glimpse flirtations with this more untempered form of holism in certain variations of the environmental ethic of Deep Ecology. Arne Naess, the founder of this school of thought, was influenced, through his study of the philosophy of Mohandas Gandhi, by ancient Indian metaphysics, according to which there is one being, *Brahman,* and all plurality is *maya:* illusory appearance. In his essay "Deep Ecology: A New Philosophy of Our Time?" (1984) the Deep Ecologist Warwick Fox provides an example of a holism that borders on the radical or metaphysical variety when he comments on what fellow Deep Ecologists Bill Devall and George Sessions endorse in their book *Deep Ecology* (1985) as "the central intuition" of the theory:

> It is the idea that we can make no firm ontological divide in the field of existence. In other words, the world simply is not divided up into independently existing subjects and objects, nor is there any bifurcation in reality between the human and the nonhuman realms. . . . To the extent that we perceive boundaries, we fall short of deep ecological consciousness. (Fox 1984, p. 66)

Some ecofeminist philosophers have strenuously objected to the radical holism of Deep Ecology because it not only obliterates distinctions between humans and nature but also obliterates distinctions among humans. They point in particular to important gender and class distinctions and the different ways in which men and women relate to nature (Salleh 1984).

Holistic theories of environmental ethics have been subject to the charge of environmental fascism. In *The Case for Animal Rights* (1983) the animal-welfare ethicist Tom Regan levels this charge against holistic theories in general and specifically against the holistic Leopold land ethic:

> [It is difficult to reconcile] the *individualistic* nature of moral rights with the more *holistic* view of nature emphasized by many of the leading environmental thinkers. . . . It is difficult to see how the notion of the rights of the individual could find a home within a view that, emotive connotations to one side, might be fairly dubbed "environmental fascism." (Regan 1983, pp. 361–362).

Some proponents of holism in environmental ethics have acknowledged that certain holistic theories of environmental ethics may be ecofascist, especially radical holism, but that the Leopold land ethic is not (Nelson 1996; Callicott 1999). Leopold regarded the land ethic as an addition to, not a substitute for, the human-centered ethics that has been inherited from the past. Thus, concern for the "integrity, stability, and beauty of the biotic community" (the principal measure of right and wrong in the land ethic) (Leopold 1949, pp. 224–225) does not necessarily trump concern for human welfare and human rights. Although Leopold did not work out a system for adjudicating conflicts between the indications of a holistic environmental ethic and the indications of an individualistic human-oriented ethic, J. Baird Callicott (1999) tried to do that on his behalf and thus rescue the land ethic from any hint of ecofascism. However, according to Michael Nelson (1996), that may take the teeth out of the land ethic (that is, make it less robust) and render it "a paper tiger."

HUDSON RIVER SCHOOL

The Hudson River school was a name used to refer to a large group of landscape painters in the United States whose work was popular from 1820 to 1875. It was not an actual school, institution, or organization. The name originally was intended as an insult, indicating that the members of the group did not travel far from New York. Initially artists chose the Hudson River Valley, the Catskills, and the Adirondacks as their primary subjects, but many later ventured into the western United States. The central figure in the movement, considered the founder, was Thomas Cole. After his death, Asher Durand became the leader of the group, primarily because of a series of essays on landscape painting he published in the art magazine the *Crayon* (Durand 1855).

FROM LUMINISM TO IMPRESSIONISM

Hudson River paintings are characterized by the presence of intense light that serves two functions: highlighting the materiality of the physical world and adding a spiritual element. Because of their emphasis on intense light, all the painters in the Hudson River school were classified as luminists by John I. H. Baur in 1954. When luminism gave way to impressionism, artists began painting the light itself rather than the objects.

The Hudson River painters originally were influenced by three European landscape artists: Titian, Salvator Rosa, and Claude Lorrain. Most notably, Rosa became the model for the sublime, and Lorrain the model for picturesque beauty.

Two contemporary European artists were also influential: J. M. W. Turner and John Constable. American painters were inspired by Turner's romanticism and treatment of light and admired Constable's photographic realism and approach to natural beauty. A remark by Constable was quoted frequently by American painters: "No, madam, there is nothing ugly; I never saw an ugly thing in my life." That remark was taken to mean that everything in nature was beautiful if viewed from the proper perspective, a view that has come to be called positive aesthetics (Carlson 1984).

There was a close relationship between landscape painting and literature, especially the writings of William Cullen Bryant, Henry David Thoreau, and Ralph Waldo Emerson. That relationship is commemorated in Durand's painting *Kindred Spirits* (1849), in which Cole and Bryant are depicted standing together on a rock outcrop in the Catskill Mountains.

The Oxbow, *1836.* *Thomas Cole is considered the founder of the Hudson River school of art, and is famous for the realism in his landscape paintings. Paintings such as* The Oxbow *provided the most influence on other artists within the school.* **© FRANCIS G. MAYER/ CORBIS.**

REALISM AND IDEALISM

There was considerable tension between idealism and realism in the early days of the Hudson River school. In landscape painting idealism translates into composed painting, in which the elements of a painting do not represent an actual place. Realism involves the depiction of actual places that are easily recognizable to the viewer. Cole believed that composed paintings involved creativity in terms of the selection and placement of objects, whereas realism was simply imitation, involving no creativity. However, his paintings depicting real places, such as *The Oxbow* (*the Connecticut River near Northampton*) (1836), are among those for which he was most famous and provided the basis for his strongest influence on other artists. Cole, disgruntled about the preference for those pictures, lamented that because of the low tastes of the American people he was not able to become the great painter he should have become. The public wanted things (representations of real places), not thoughts (creatively inspired imaginary places). Ultimately, realistic representation triumphed within the group as a result of the views of Durand (1855).

The focus on representation also contributed to an emphasis on scientific illustration. Frederick Edwin Church, the only pupil of Cole, led the way. Inspired by Alexander Humboldt's *The Cosmos* (1845–1847), in which that scientist lamented that he had not taken a landscape painter with him on his expedition to Latin America, Church went to South America, retraced Humboldt's steps, and painted much of what Humboldt had written about. Many of those works were in fact composed paintings, but Church considered them to be scientific summaries of the landscape. Encouraged by Church, Martin Heade traveled to South America, also with scientific intent, with a special interest in studying hummingbirds. Heade's work displays the influence of scientific illustration from earlier in the century, for example, works by scientists involved in the American Philosophical Society, the forerunner of the Smithsonian Institution.

When Yosemite was discovered, members of the Hudson River school, most famously Albert Bierstadt, traveled there to paint the valley and the sequoias of Mariposa Grove. There the artists interacted with photographers for the first time, enhancing the photographic quality of their representations. For example, Bierstadt's *The Great Tree, Mariposa Grove* (1875) was based in part on C. E. Watkins's photograph *The Grizzly Giant, Mariposa Grove* (1864). When the geological surveys in the next decade were organized, landscape painters such as Thomas Moran and William H. Holmes traveled with the scientists to Yellowstone, the Grand Tetons, and the Grand Canyon. Interaction between artists and photographers also occurred on those surveys, for example, between Moran and William H. Jackson.

EFFECTS ON NATURE PRESERVATION

The impact of those paintings and photographs on nature preservation in the United States becomes clear when one reflects that most of the places painted or photographed during that period became national parks and national monuments, beginning with Yosemite and Yellowstone. The Adirondacks, heavily painted by artists of the Hudson River school, eventually was protected by an amendment to the state constitution. Concern by artists, particularly Church, led to the protection of Niagara Falls by an international treaty with Canada.

The shift from luminism to impressionism and eventually abstract expressionism was a shift away from nature to a focus on the self, a change not followed by the general public. As a result, the ability of representations of natural places and objects to generate national concern for nature preservation remains a powerful political legacy of the Hudson River school's influence on people's ways of perceiving and relating to nature.

HUNGER

Hunger is a global problem, in the forms of both undernourishment and long-term malnutrition, besides that of famine, which happens when a social or economic crisis involving malnutrition causes deaths from starvation or related diseases. Malnutrition involves insufficient consumption of nutrients to maintain healthy bodily functions, generates a range of debilitating afflictions, and is characteristically associated with poverty. It affected around 854 million people in the world in the period 2001–2003, some 14 percent of the total population. While the highest percentages of malnutrition are found in sub-Saharan Africa, the greatest numbers of malnourished people live in India, China, and Bangladesh (Food and Agriculture Organization of the United Nations 2006). Moral obligations to prevent this evil impact upon, and are sometimes held to compete with, those of environmental ethics. Simultaneously, hunger deprives humanity of the energies of people who could otherwise participate in sustainable practices, and can spur desperate people to acts of environmental despoliation. Diverse causal theories of undernourishment and of famine support different understandings of our obligations, their relation to human population growth comprising a central issue; such theories will shortly be discussed. In addition, proposals for solving problems of hunger through increased use of genetically modified food will also be considered, since this could on some views alleviate and on others contribute to global problems.

Philosophers in the 1970s (such as Peter Singer) focused on obligations to relieve famine, but this approach risks neglecting underlying factors such as long-term malnutrition and underdevelopment and their causes, genuine as such obligations may be (Crocker 1996). Philosophers have more recently debated priorities between saving nature and feeding people (Rolston 1996), but such debates too risk neglecting systemic factors and political solutions (Carter 2004). Just as global climate change cannot be resolved by lifestyle changes at the individual level, so too problems of hunger cannot be resolved by charity or acts of self-sacrifice alone, or by regulating admission to nature reserves either, but through solutions that go to the roots of the matter.

CAUSAL THEORIES

Hunger is sometimes attributed to population growth and to particular countries (or to the planet as a whole) having exceeded their "carrying capacity," predicted in different terms by Thomas Robert Malthus in his "Essay on the Principle of Population" (1798). This view in recent times has often been associated with Garrett Hardin's "The Tragedy of the Commons" (1968), with population playing the role of an unregulated commons that it pays everyone to exploit and supplement, leading ultimately to human numbers outstripping food supply. Aid to countries where this is happening is considered to make matters worse, and withholding assistance actually to do more good (Hardin 1996).

But the concept of carrying capacity, viable as it may be in biology, has been argued to be inapplicable to human populations and the territories they inhabit, since the number of humans capable of being sustained can be changed by practices such as aid and trade, while the number sustainable by the planet is in part a function of agriculture and technology (Aiken 1996; Cohen 1995). Besides, sufficient food is produced to feed the world population of over six billion (Drèze and Sen 1989), although if the global population were in the future to grow to ten billion or more, this would become more problematic. Meanwhile, increases in land security and food surpluses turn out not to increase birthrates but to reduce them, once it is apparent that large families are no longer required for labor or for security in later life (Ryberg 1997). Hence aid that promotes development can contribute to population being stabilized, where population growth would otherwise continue unabated (Carter 2004).

Much more plausibly, hunger is due to poverty and underdevelopment, and undernourishment not to absence of food but to lack of access to it. Even famines are known to have often occurred in regions where food is available for sale but unaffordable by the poor, regions that are actually exporting food to places where it will fetch a better price. Indeed, Amartya Sen has argued, hunger is widely related to inequalities (often extreme ones) within a society; another factor is environmental degradation, which in the forms of deforestation and desertification widely threatens rural people's livelihood (Drèze and Sen 1989). Jean Drèze and Sen further argue that a lack of democracy is a cause of famines; no twentieth-century famines have taken place under democracies, at least in peacetime, perhaps because democracies cannot conceal dangers of famine and are able to take steps to prevent actual famines beginning.

The role of the international economic system and international institutions such as the World Bank and the International Monetary Fund with regard to the occurrence of hunger is much debated. Granted that the characteristic cause of hunger is poverty, Thomas Pogge has argued that the support of developed countries and their citizens for this system and these institutions amounts to causing poverty and starvation, in breach not only of a possible positive duty to assist but also of a much clearer negative duty not to generate avoidable misery (Pogge 2007). To this causal and ethical view, Gerald Gaus has responded that the global economy is in fact benefiting the poor. Thus life-expectancy in the developing world increased from forty-one years in 1950 to sixty-one in 1998, and the number of people starving has decreased from 45 percent in 1951 to its current much lower average. He admits that the actual number of those starving has increased, but attributes this to an increasing world population rather than to the global economy. The prospects are of continuing improvement, particularly if population can be stabilized, and this underlying improvement is due to globalization, the global economy, and the increased wealth they bring (Gaus 2003). But even if Gaus's analysis is accepted, Pogge's case would not be entirely undermined: if the current system harms those who, rather than benefiting, are still starving, particularly if modifications of the system could alleviate their starvation, and if the presumed benefits of unalleviated globalization would take several decades to emerge, during which millions more would avoidably starve.

One of the United Nations Millennium Development Goals is to reduce by half the proportion of people who suffer from hunger by 2015. Without new effort and international agreements and investment, perhaps of the kind suggested by Pogge, not even this goal will be achieved.

Yet not all hunger is ascribable to the global economy or capitalism. There was hunger in subsistence economies before the rise of capitalism, and hunger can also be found under other systems. Famine in Tibet in the years following 1959 was partly due to the Chinese government's neglect of sophisticated traditional ecological knowledge and insistence that, contrary to what was climatically possible, wheat be grown in place of barley (Government of Tibet in Exile; Bradshaw 2007) In this case, the poor had access to land, but were prohibited on the strength of authoritarian theory from farming it intelligently. Nor is Tibet the only place in the world where respect for traditional ecological knowledge is vital if people of the future are to be able to feed themselves.

THEORIES OF OBLIGATION

While Pogge grounds obligations not to generate avoidable misery in human rights (2002), other ethicists who adopt similar conclusions appeal to utilitarianism (Ryberg 1997), or to Kantianism (O'Neill 1986). Obligations to remedy hunger can also be justified on the basis of the social contract theory of ethics and society, but John Rawls, the leading contract theorist of recent times, avoided such conclusions

in *The Law of Peoples* (1999): He implausibly attributes malnutrition and underdevelopment to local factors and features. However, both Brian Barry (1973) and Charles Beitz (1979) have demonstrated that such obligations can be derived from global versions of Rawls's original position. Jesper Ryberg's well-argued appeal to utilitarianism (and thus to consequentialism) as the ground of these obligations demonstrates that consequentialism need give no support to Malthusian conclusions. The problem with Hardin's attempts to elucidate how agents in developed countries can make the greatest favorable difference lies not in his consequentialism but in his Malthusian causal theories and prognostications.

There are environmental philosophers committed to all these varieties of ethical theory. Tom Regan is a rights theorist, stressing the rights of nonhuman animals as well as humans, but neglects the difference that current agents can make among possible beings (both human and nonhuman) of future centuries and to their prospects for freedom from hunger. The inspiration behind Paul Taylor's biocentrism is Kantian (1986), but this basis generates problems for consistently deriving defensible priorities for interspecies relations, let alone for interhuman relations relevant to hunger and obligations to avert it.

Mark Rowlands (1998) represents contractarianism in its application to interspecies issues, but one could question the coherence of Rowlands's original position, in which the choosers are ignorant not only of their prospects for poverty or prosperity but also of which species they will belong to. Holmes Rolston (1996) adopts a much broader deontological value-theory, but his specific conclusions about priorities between feeding people and saving nature have been criticized for lacking a clear enough account of value priorities. These conclusions also fall into the trap of crediting Hardin's causal theories and lifeboat ethics, or at least the misguided view that refraining from feeding people may sometimes be necessary to save wild species—despite the evidence associating starvation with stress on ecosystems (Carter 2001, 2004, 2005).

Singer's sentientist utilitarianism takes more seriously the far-flung impacts of human action (2004). Meanwhile, Robin Attfield's broader biocentric consequentialism—which takes into account and seeks to prioritize the interests of current generations, future generations, and nonhuman species (in addition to the obligations recognized by Onora O'Neill, Pogge, Barry, and Ryberg)—includes in its purview obligations to prevent, where possible, anthropogenic hunger among nonhumans by seeking to avert the destruction of their habitats through deforestation, pollution, or global climate change, as well as to prevent human hunger (Attfield 1991, 1995, 1999, 2003b). This approach is consistent with the capabilities approach (Nussbaum and Sen 1993, Crocker 1996), modified so as to recognize nonhuman interests, an approach that regards hunger as lack of access or entitlement to food, and proposes related remedies.

SOLUTIONS

Is genetic engineering part of the solution? While the possibility cannot be denied, such approaches can, like aspects of the Green Revolution, make matters worse, as well as sometimes helping boost production and overall prosperity. It is true that we need to produce more food without using up more land, and that genetically modified (GM) foods seem to offer a way forward. But there are questions over their stability, whether their yields are sustainably greater, and whether they require increases rather than decreases of pesticides (Granger 2002). Besides, increasing food production is not our only problem. What the poor need is access to food through growing it themselves, whether in the countryside or in urban allotments, and to this GM foods are not obviously relevant. Arguably, what is needed is access to land (where necessary through land reform), followed by the application of individual or communal effort (including support for new farmers), and the tender loving care widely found among small farmers in the Third World enjoying land security (Stamp 1997; Attfield et al. 2004).

More obviously, the solution to hunger and malnutrition lies in development (Crocker 1996). To some environmentalists, development is the source of all evils. But when development is understood as the process of moving away from poverty, malnutrition, illiteracy, and high mortality and morbidity, and toward participation in overcoming these evils, its desirability is hard to challenge, at least when it is blended with sustainability—not only of an economic but also of social and environmental kinds. Concern for nonhuman nature should not distract environmental ethicists from concern to blend environmental concern with concern for interhuman justice and for flourishing human as well as nonhuman lives across the foreseeable future. That is why comprehensive ethical theories such as biocentric consequentialism are needed. Ethicists who cannot stomach consequentialism need to develop comprehensive nonconsequentialist theories, along the lines, for example, of those of James Sterba (1998). Alan Carter has suggested that no such theories are viable (2001, 2005), but Carter's multidimensional value-pluralism turns out to embody problems of its own (Attfield 2003a, 2005).

While development provides a deeper and longer-term solution than famine relief and food aid, more comprehensive solutions depend on the issue of debates such as that about globalization and global institutions. If theorists such as Pogge are even partially vindicated, then international institutions and the prevailing international

system of trade and finance contribute to the incidence of hunger, and agents in developed countries—including many readers of this entry—have obligations to work towards and campaign for the reform of these international institutions and this system. Unlike Carter, Pogge is not suggesting that the overthrow of state sovereignty, or of capitalism, is required before significant problems can be solved: An internationally agreed tax on certain resources, while it would not rectify all our problems, could, as he shows, suffice to eliminate global poverty, and therewith human hunger, and could do so in a much shorter time period than the forces of globalization possibly could, even on the most optimistic of scenarios (Pogge 2002).

Pogge's Global Resources Dividend comprises part of a sufficient condition for ending of global hunger. If Sen is right, the introduction in all states of a vigorous democracy would form another component of such a sufficient condition. Hence, on most theories of obligation, most of us have a duty to work toward one or the other. Fortunately this obligation is unlikely to clash with duties to mitigate and alleviate global climate change or to preserve nonhuman species (Carter 2004), and is itself part and parcel of promoting sustainable development.

HUNTING AND FISHING

This entry contains the following:

I. OVERVIEW

Hunting and fishing raise central concerns for environmental philosophy. Many argue that they are quintessential activities that allow people to participate in and be part of nonhuman nature. Many others argue that these activities constitute undue human interference with the natural world. However nature is valued, embracing or rejecting hunting and fishing will help express one's environmental ethic. Whatever else nature is—species populations, communities, and ecosystems—it consists of individual animals and fish that should or should not be caught, killed, dismembered, and/or eaten. Critical evaluations of hunting and fishing have helped define and shape the field of environmental ethics.

HISTORICAL AND CULTURAL BACKGROUND

There were 299 million U.S. citizens in 2006. Approximately 30 million fished and 12.5 million hunted. These numbers were eclipsed by the 71 million who engaged in wildlife watching, an activity that does not necessitate capturing and/or killing animals and fish (U.S. Fish and Wildlife Service 2006). Although these three categories are not mutually exclusive, far more Americans interact with wildlife as passive observers. Hunting has been on the decline in the United States. It peaked in the early 1950s, when approximately one-quarter of American men hunted, and has been declining sharply since at least 1980 (the sharpest drop occurred between 1980 and 1990—from 19.5 to 16.4 percent of American males) (Dizard 2003). The declining popularity of hunting is the latest chapter in a broader cultural story.

Total Wildlife-Related Recreation in the United States, 2006

Participants	87.5 million
Expenditures	$122.3 billion
Sportspersons	
Total participants*	33.9 million
Anglers	30.0 million
Hunters	12.5 million
Total days	737 million
Fishing	517 million
Hunting	220 million
Total expenditures	$76.6 billion
Fishing	42.2 billion
Hunting	22.9 billion
Unspecified	11.6 billion
Wildlife Watchers	
Total participants**	71.1 million
Around the home	67.8 million
Away from home	23.0 million
Total expenditures	$45.7 billion

* 8.5 million both fished and hunted.
** 19.7 million both wildlife watched around the home and away from home.

Table 1. CENGAGE LEARNING, GALE.

Although the arrival date of people in North America is debatable, there is considerable evidence that nearly one-quarter of the continental genera of terrestrial mammals weighing at least one hundred pounds (for example, the American mastodon, mammoth, American cheetah, and Florida cave bear) were hunted to extinction by Clovis people in a relatively short period approximately 13,000 to 11,000 years ago. This might have been the first instance of human hunting pressures that changed North American landscapes. The Clovis extinctions opened ecological niches that were soon filled by Eurasian species more commonly known to Europeans and later Euro-Americans. Contemporary species of bison, grizzly bear, gray wolf, and elk arrived in North America 13,000 to 11,000 years ago, replacing now-extinct species of those mammals. European colonists in the seventeenth

and eighteenth centuries encountered overabundant populations of animals and fish. The standard interpretation is that that overabundance was a result of what might be called Native American Indian conservation practices. This should be tempered with the contemporary understanding that what Europeans and later Euro-Americans identified as wilderness lands teeming with wildlife were more akin to "widowed lands" with rebounded animal populations after nearly 90 percent of the native peoples had died off by the middle of the eighteenth century, leaving landscapes widowed by people.

The majority of European colonists in North America did not hunt. Those colonists came from European countries where hunting was controlled and practiced largely by elite aristocracies. The relative unpopularity of hunting in North America can be attributed to the fact that firearms were not readily available until after the American Civil War and the ideological dictum that the proper life of a European colonist consisted of farming, which anchored European civilization to newly established agricultural fields. The lifestyle of the wandering hunter became a homespun romanticized ideal in the nineteenth century, spurred by real-life figures such as Daniel Boone, Kit Carson, and Davy Crockett as well as fictional characters such as James Fenimore Cooper's Natty Bumppo. Market hunters and fishers, however, were dominant in the nineteenth century. Blamed for decimating animal populations such as bison and Brant goose as well as fish populations such as brook trout, commercial hunting and fishing fell into disfavor by the end of the nineteenth century. By the early twentieth century a sport ideal was championed in which one hunted and fished to celebrate the frontier legacy, retreat from the city into nature, and cultivate outdoor virtues embodied in manly men such as President Theodore Roosevelt.

This sport hunting and fishing ideal has persisted into the twenty-first century. The declining popularity of hunting in countries such as the United States and Canada is a cause of alarm for hunting enthusiasts who fear that Bambi-inspired animal concern will supplant an important tradition. The vast majority of hunters in the United States are white Euro-American men, but the 1.5 percent of American women who hunted in 1990 increased to 2.7 percent in 2000 (Dizard 2003).

FORMS OF HUNTING AND FISHING

Classifying forms of hunting and fishing brings into focus some of the different reasons used to justify these activities. Such classification is fraught with difficulties. What exactly is hunting? Many hunters respond that hunting is more than the mere killing of animals. In *Meditations on Hunting,* José Ortega y Gasset said that death is essential but is not the purpose of hunting, as "one does not hunt in order to kill" but instead "one kills in order to have hunted" (Ortega y Gasset 1972, pp. 110–111).

Subsistence hunters claim to hunt to provide nutrition that cannot be grown. For many people this is the least problematic form of hunting. In contrast, one of the most criticized forms is trophy hunting to acquire prestigious evidence of a killed animal. Commercial or market hunters hunt to sell complete or dismembered animal carcasses for economic gain. Sport or recreational hunters usually eat what they kill, and their primary motivation seems to be pleasure or a primitive, primeval, or atavistic connection with nonhuman nature. So-called pest or varmint hunting, such as prairie dog hunts in the western sections of the United States, is practiced to control or eliminate unwanted animal populations, usually for indirect economic gain. Ecological or therapeutic hunters kill animals such as white-tailed deer to regulate populations that are perceived to have exceeded the carrying capacity of a specific area. Canned hunting occurs when a game animal is enclosed (canned) within a regulated space, such as a private hunting ranch, and typically is taken under a contract between a client and a game owner.

These are not sharply defined categories. Is a sport hunter who mounts the uneaten head of an elk also a trophy hunter? Is a subsistence hunter who sells animal carcasses to make ends meet also a commercial hunter? Is the killing of geese that make one's backyard unsightly a form of varmint hunting? Characterizing the way indigenous peoples hunt and fish also may defy categorization and lead some who oppose hunting and fishing to grant exemptions for indigenous hunting and fishing. Substitution terms for hunting raise problems. Ecological or therapeutic hunting sometimes is called culling, suggesting that unwanted animals are simply removed as opposed to violently killed. Many sport hunters claim to harvest animals, suggesting that killing animals is no different from growing agricultural crops.

The harvesting of fish—fish farming or aquaculture—may make some forms of fishing more like growing plant foodstuffs. As with hunting, people fish for subsistence, financial (market) gain, sport, and trophies. These forms also are not mutually exclusive. For example, many sport fishers (anglers) attempt to catch the biggest fish possible, thus securing a trophy fish. There is no hunting equivalent of catch and release fishing, although camera hunting has most of the elements of a hunt except the kill. However, similar to wounded animals that escape from hunters and die in the wild, many caught and released fish die from angling wounds.

ETHICAL CONTROVERSIES

Hunting and fishing are similar activities. With the possible exception of catch and release fishing and camera

hunting, both activities result in the death of wild fauna. However, far more people disapprove of hunting than fishing. Although some people consider fishing a form of underwater hunting, individual fish seem to have less value than individual animals for many people. This may be related to questions about the sentience of fish.

Most people who hunt animals in North America call themselves sport or recreational hunters. Brian Luke (1997) argued that sport hunters face a paradox: To hunt ethically, one must adopt a sport-hunting ethic that implies that hunting is immoral. Sport hunters must admit the paradoxical nature of hunting, renounce an ethical hunting code, or renounce hunting. A. Dionys de Leeuw (1996) argued that sport fishing also is ethically problematic and that the proper response to the "angler's challenge" should lead fishers to give up fishing.

These challenges to hunting and fishing stem from philosophical positions on the intrinsic or inherent value of individual animals and fish. The environmental ethicist J. Baird Callicott (1980) argued that animal ethicists concerned about individual animals fail to see that the protection of holistic environmental entities such as species and ecosystems necessitates the death of individual animals. The animal ethicist Tom Regan (1983) labeled Callicott's view "environmental fascism," in which individual animals are sacrificed for the greater good of the ecosystem, and claimed that animal rights and environmental ethics are like unmixable oil and water. This debate plays out at the practical level of hunting. Many animal advocates argue that hunting is immoral and that people should leave wildlife alone. Many environmentalists argue that subsistence and sport hunting are morally acceptable and that ecological hunting sometimes is required to protect nature.

Some animal ethics positions may permit forms of therapeutic hunting to relieve animal suffering. However, many animal advocates argue that the proper human response to wildlife is noninterference. Many hunters and fishers counter with the claim that some forms of hunting and fishing allow people to participate in wild nature. Further, if *Homo sapiens* is a naturally evolved species, these kinds of activities may be morally similar to natural nonhuman predation. Critics sometimes respond by denying that moral similarity (Moriarty and Woods 1997).

II. RECREATIONAL HUNTING

Recreational hunting is a popular outdoor activity in many countries. It is controversial because it involves the killing of animals and sometimes causes animals to suffer; its supporters argue that it is a legitimate activity that contributes to conservation. It is a paradigm case of the conflict between animal liberation and holistic ethics as identified by the environmental philosophers J. Baird Callicott (1980) and Mark Sagoff (1984).

Recreational hunting is thought to have begun 3,500 years ago (Anderson 1987) and until comparatively recently was restricted largely to the royal and aristocratic classes. In Assyria and other areas of western Asia, India, Africa (especially during the period of European imperialism), and parts of Europe it sometimes was conducted on a vast scale and often was referred to as "the Hunt" (MacKenzie 1988).

Recreational hunting may be defined as the pursuit for sport of wild animals; a successful hunt typically is defined as one that ends with the killing of one or more animals, though many recreational hunters are satisfied by stalking the game, experiencing the outdoors, and sharing comradeship with fellow hunters. It is concentrated in North America, Europe, northern Asia, southern and eastern Africa, Australia, and New Zealand. In 2006, 12.5 million American adults hunted (U.S. Fish and Wildlife Service 2006). That represented a slight drop from 13 million in 2001. Most people hunt on foot, using modern rifles; others prefer primitive "black powder" weapons, handguns, or bows. Sometimes dogs are used to locate or corner animals for the hunter to kill, trail wounded animals, or retrieve shot animals, especially birds in wetlands. In British fox

Recreational Hunters Aiming at Waterfowl. *Three hunters raise their guns at a flock of waterfowl near a pond. Most recreational hunters follow some code of ethics designed to give the animal a "fair chance."* **U.S. FISH AND WILDLIFE SERVICE.**

hunting, which has been illegal since 2004 but still is practiced, the dogs are the hunters, locating, chasing, cornering, and often killing the fox.

HUNTING ETHICS

Most recreational hunters observe legal requirements designed to maintain both ecological balance and stocks of game. They also follow hunting ethics, known as fair chase or walk and stalk designed to even the odds, to give the animal a fair chance. Fair chase requires the hunter to forgo pursuing game in a vehicle or on horseback, shooting over a bait (such as a tethered goat or carcass) or at waterholes, using spotlights to dazzle nocturnal animals, and the like. Only unconfined animals may be hunted; canned hunting, in which the game is confined to an enclosure or small park, is considered unethical by many people. Many hunters believe that telescopic sights and night vision aids are also unethical.

Green hunting involves fair chase but with a nonlethal climax such as a paintball shot or a dart gun that injects a tranquilizer so that the hunter can pose for a photograph with the animal. This is often part of a research program, allowing the animal to be studied, fitted with a microchip, or translocated.

The founder of Orion the Hunter's Institute, Jim Posewitz, wrote: "Fundamental to ethical hunting is the idea of fair chase. This concept addresses the balance between the hunter and the hunted. It is a balance that allows hunters to occasionally succeed while animals generally avoid being taken" (Posewitz 1995, p. 57).

According to the historian John MacKenzie,

> In [subsistence] hunting the end is all-important, the death and utilisation of the animal. The subsistence hunter is concerned with the ease with which his purpose can be achieved. The sportsman indulging in the Hunt is concerned with the difficulty. . . . In the Hunt the animal is most to be valued, and by extension the hunter who slays it, according to the fight it puts up. In securing its death he follows strict rules of procedure and endangers himself in the process. (MacKenzie 1988, pp. 10–11)

However, this sharp distinction between subsistence and recreational hunting is questionable. First, the

herbivores that are the main target of recreational hunters are not merely edible but regarded as gourmet treats. Many hunters regard it as an obligation to ensure that the animals they kill are utilized, not wasted. Second, often these herbivores must be controlled either because their natural predators have become locally extinct, as in most parts of the United States, or because they were introduced to areas where they never had predators, such as New Zealand. Thus, hunters are often de facto pest controllers. Third, even in traditional societies that depended for subsistence and safety on killing animals, there were often elaborate rules circumscribing hunting, for instance, rules related to religious requirements and rites of passage. Moreover, in those societies hunts often are viewed as fair contests between equals.

KILLING

Killing, not merely successful stalking, is seen by most writers as central to hunting; those writers would not count green hunting as hunting. For proponents of hunting such as the Spanish philosopher José Ortega y Gasset and the U.S. ecologist Paul Shepard (1973) the central meaning of hunting is killing, and killing is essential to "participation in the life cycle of nature" (King 1991, p. 80). The philosopher Ann Causey wrote, "The one element that stands out as truly essential to the authentic hunting experience is the kill" (Causey 1989, p. 332). Some ecofeminists see hunting as a prime example of patriarchal oppression of nature: a "necrophiliac" culture (Daly 1978).

Ortega y Gasset's position is complicated. In *Meditations on Hunting* he stated that "killing is not the exclusive purpose of hunting" (1985, p. 45). Nonetheless, it is essential to hunting:

> To the sportsman the death of the game is not what interests him; that is not his purpose. What interests him is everything that he had to do to achieve that death—that is, the hunt. . . . Death is essential because without it there is no authentic hunting: the killing of the animal is the natural end of the hunt and that goal of hunting itself, not of the hunter. . . . To sum up, one does not hunt in order to kill; on the contrary, one kills in order to have hunted. (1985, pp. 96–97)

Opponents of hunting often claim that it violates animals' right to life. The usual response by defenders of hunting is to deny that animals have that right. The hunting literature uses terms such as *respect* but not *rights,* though in one classic hunting memoir the novice hunter is admonished by his mentor: "And don't forget that an animal has a right to live, the same as you" (Waldeck 1940, p. 45). Of course, a rights-based objection to hunting also implies an objection to killing animals for food, in research, and so on.

SUFFERING

Inevitably, some hunted animals suffer. Even skilled hunters who make a high proportion of clean kills sometimes only wound, and the skills of recreational hunters vary. Hunters acknowledge animal suffering: The environmental philosopher and hunting defender Robert Loftin regarded it as "the most serious argument that can be advanced against sport hunting" (Loftin 1984, p. 146). Hunting codes thus require hunters to acquire and practice the skills necessary for a quick and painless kill and always to follow wounded animals. Those who oppose hunting on the grounds that it causes suffering also must oppose the suffering caused in meat production and research.

HUNTING AND CONSERVATION

There is considerable evidence that subsistence and commercial hunting have contributed to loss of biodiversity, including the extinction of some species. However, in the history of environmental ethics there have been advocates of respect for the natural order who were recreational hunters. Aldo Leopold wrote, "[T]he man who does not like to see, hunt, photograph, or otherwise outwit birds or animals is hardly normal. He is supercivilized, and I for one do not know how to deal with him. . . . There is value in any experience that reminds us of our dependency on the soil-plant-animal-man food chain, and of the fundamental organization of the biota" (Leopold 1949, p. 227).

Others, such as Ortega y Gasset, saw hunting as a way for humans to reconnect with nature and participate in the land community. The ecologist Erik K. Fritzell wrote, "When I hunt I am immersed mentally, physically and even spiritually in an age-old predatory relationship among animals. I am participating in a common ecological process" (Fritzell 2004). Causey stated: "[T]he drive in sport hunting is to be a link in the chain of nature, connected as predator to prey"; the hunter "regards his prey with admiration, reverence and respect" (Causey 1989, pp. 332–333).

HUNTING AND CHARACTER

Traditionally, hunting has been seen as promoting virtue. The Greek mercenary and historian Xenophon (c. 431–c. 355 B.C.E.) wrote of "the health which will thereby accrue to the physical frame, the quickening of the eye and ear, the defiance of old age, and last, but not least, the warlike training which it ensures" (Xenophon, *Cynegeticus*).

However, hunting sometimes is seen as sadistic and cruel and is associated with serious crime against humans. According to the Fund for Animals, "Children raised in a hunting culture, sometimes wearing hunting garb and employing hunting tactics, like [the Jonesboro massacre murderers] Mitchell Johnson and Andrew Golden, have been killing other children with hunting weapons at a

stunning rate. . . . Now the question must be asked: Is the hunting industry's program for recruiting children into hunting also contributing to our national epidemic of children killing children?'' (Fund for Animals 2000).

In contrast, the German social psychologist and psychoanalyst Erich Fromm stated: ''The idea that hunting produces pleasure in torture is an unsubstantiated and most implausible statement. Hunters as a rule do not enjoy the suffering of the animal, and in fact a sadist who enjoys torture would make a poor hunter'' (Fromm 1973, p. 131).

III. ECOLOGICAL HUNTING (CULLING)

Ecological hunting, or culling, is the use of lethal means to remove animals or birds from a population to improve the quality of that population or prevent environmental degradation. Culling has been used for hundreds of years in the belief that it can improve future harvests of game animals by maintaining the carrying capacity of the animals' range, allowing larger numbers of animals to be harvested sustainably, or by improving the quality of trophy animals.

Those goals can require very different culling strategies. To maximize the number of animals that can be harvested sustainably, game managers need to maximize the number of offspring that survive each year. At the highest population densities, average individual welfare is reduced and fewer offspring survive, so to maximize annual harvests the population must be maintained at a lower level, where its rate of growth is highest. That requires an emphasis on culling younger males to maximize the number of breeding females on the range. Management for quality trophy animals, by contrast, usually requires a culling strategy designed to maximize the number of larger, older males on the range. This requires an emphasis on culling both females and young males because mature males are generally heavier and consume more resources.

PURPOSE AND RESULTS

Contemporary environmentalists tend to emphasize the importance of culling to protect the health or integrity of ecosystems and preserve endangered species. Species introduced by human beings sometimes threaten native plant species. Goats introduced to San Clemente Island off the California coast in 1875 thrived in the absence of predators, but by the 1970s they had degraded the island's vegetation dramatically. Indigenous species also can transform their ecosystems significantly, however, especially when their natural predators have become extinct or their prehistoric ranges have been altered significantly by human settlement patterns. In the American Southwest, for instance, deer populations are believed to have soared after wolves and mountain lions were removed by humans interested in increasing deer harvests, and in parts of Africa numerous plant and bird species became threatened with extinction as the elephant habitat was splintered into small, isolated game parks.

REACTIONS AND CRITICISMS

Proponents of holistic environmental ethics generally support culling to defend endangered ecosystems and species whether the threatened species' members are sentient or not. Insofar as an ecocentric ethic would give

ecosystem integrity or health top priority and a holistic ethic would give this and/or species' continued existence top priority, consideration of the conscious experiences of members of culled species must take a back seat to preserving the threatened species and/or ecosystem.

Proponents of individualist sentience-oriented views such as utilitarianism and animal rights find culling more problematic because individualist views claim that only the lives or experiences of sentient individuals have intrinsic value. Therefore, if the culling is aimed at preserving species whose members are not sentient or at preserving ecosystems (which are not sentient even if some of the organisms they support are), an individualist would give top priority to the lives of the sentient animals targeted for culling. Accordingly, culling of goats on San Clemente Island and culling of elephants in African national parks have encountered strong resistance from animal rights groups.

A utilitarian perspective, which attributes intrinsic value to the experiences of all individuals capable of conscious suffering or enjoyment, could endorse culling insofar as it maintains the carrying capacity of a herd's range and thus maximizes the aggregate happiness of animals in future generations. That is, if allowing overpopulation causes suffering through starvation, disease, and conflict over scarce resources, reducing carrying capacity and limiting the number of animals that can live on the range in future generations, the suffering caused by culling (especially if it is done humanely) could be more than outweighed by the reduction of suffering from the stresses of overpopulation and the number of additional satisfactory future lives that are made possible by the culling.

A rights view, in contrast, could rule out culling altogether because rights often are characterized as trump cards against such aggregative, utilitarian arguments. To justify culling various individuals because the culling will reduce the suffering of others and maximize happiness across future generations, rights theorists argue, fails to respect them as individuals with rights.

A further complication within individualist views is introduced by the fact that various animals with similar population dynamics may have very different cognitive capacities. If one considers that these different cognitive capacities qualify the individuals for varying degrees of ethical respect, culling may be more difficult to justify in species such as elephants than it is in deer. Both are ungulates, and ungulates protected from predation have a general tendency to overpopulate and degrade the carrying capacity of their ranges. However, elephants are celebrated for cognitive capacities that deer are not thought to have, such as elaborate memory for events from many years before, sophisticated problem-solving abilities, and perhaps an auditory communication system that rivals that of humans in complexity. Individualists who hold that those cognitive capacities qualify their possessors for special kinds of respectful treatment, as individualists commonly claim in the case of normal human beings, may find it more difficult to justify culling elephants than to justify culling deer.

Birth control technologies and trapping with transfer to understocked ranges are nonlethal alternatives to culling, but both are far more expensive and can have untoward side effects. For example, as few as 15 percent of translocated deer survive for one year; reversible birth control techniques usually require repeated administration to a large percentage of the female population, which can disrupt their lives; and Kruger National Park in South Africa terminated experimental treatment of female elephants with estrogen after they exhibited false estrus, which led bulls to harass the cows so much that several of their calves died.

IV. ANGLING

Angling is fishing using a hook and line. The more general term *fishing* refers to any form of hunting in which the prey is fish rather than land animals. The hook was developed from the more primitive gorge, a pointed object that is embedded in bait and sticks in a fish's gullet when the bait is swallowed. The hook can be baited with live animals (worms, minnows, even rats), bait produced by humans (bread, dough), or materials such as wool, feathers, and hair to produce an artificial lure. Snagging fish with a hook generally is not considered a form of angling, and when it occurs in angling, it is called *foul*

hooking and considered an unfortunate accident. The term *angling* has been used to distinguish more sporting forms of fishing such as fly fishing from bait fishing.

Angling can be pursued with the primary goal of securing fish as food. When the food is an essential part of the diet, it is referred to as subsistence angling, and there are also forms of commercial angling. Angling can be pursued for its own sake, in which case one can speak of sport angling, though the catch may be eaten. Perhaps the earliest depiction of sport angling dates back to 1400 B.C.E. in Egypt, and angling as a pastime is found in cultures around the world, both ancient and modern.

THE LITERATURE OF ANGLING

Beginning with the *Treatyse of Fyshinge with an Angle* (1496) and achieving an early high point with Izaak Walton's *The Compleat Angler* (1653), a major literature has developed around the sport of angling. That literature is dedicated to techniques and evocative accounts of angling, often including reflections on the meaning of angling for its devotees. A theme running through much of the literature is a concern to justify and recommend the sport as contributing to the health of both body and soul. Walton wrote, "God never did make a more calm, quiet, innocent recreation than angling" (Walton 1653, Part I, Ch. 5), and it did not occur to him to defend the angler against the charge of cruelty. As Arnold Gingrich noted in *The Fishing in Print* (1974), as early as 1577 a list of virtues of the angler was codified, including faith, hope, love, patience, humility, fortitude, knowledge, liberality, and prayer. However, by the eighteenth century the charge of barbarism and cruelty was being raised against anglers.

ETHICAL ISSUES

Angling raises ethical questions. From perspectives such as animal rights theory and some forms of biocentric egalitarianism, any angling that does not provide necessary nourishment is immoral and all sport angling inflicts pain and represents a failure to respect the inherent value of fish. In contrast to those lines of thought, in some approaches to environmental ethics human involvement in the ecological processes of life and death is valued. From this perspective responsible angling may be contrasted favorably with less interactive and more touristic ways of experiencing the natural world.

Even if angling is considered morally permissible, ethical issues arise within the practice. Fish that are to be eaten must be killed, and quick and humane killing of fish is part of some angling traditions, especially in Great Britain, where salmon anglers carry a short weighted club called a priest for administering "the last rites." Similarly, anglers often are admonished to avoid tackle that is too light and thus prolongs the fight unnecessarily.

Some angling practices can be harmful to the environment: Angling can damage fish populations, the use of lead as a weight has polluted the environment and has been outlawed in some places, discarded fishing line can be lethal to wildlife, and hatchery fish stocked for anglers can have a harmful effect on wild and native fish. Anglers have introduced exotic species of game fish, sometimes with devastating results to ecosystem integrity, but anglers are also the most ardent defenders of endangered populations of wild and native fish and of water quality. Like hunters, anglers have played an important role in the development of conservation and wilderness protection.

The practice of catch and release angling is a twentieth-century, originally American strategy for protecting endangered populations of wild and native fish. Contrasting the value of fish as food with their value for sport, in 1939 Lee Wulff wrote, "Gamefish are too valuable to be caught only once" (Wulff 1939, p. xv), signaling a revolution in angling ethics. Releasing much or all of one's catch is a form of resource conservation. Some anglers consider catch and release angling to be morally superior even when keeping some fish to eat would not damage the fishery. In opposition to that development, the Irish philosopher A. A. Luce argued that although catching fish for food is defensible, "To hook trout and put them back into the water . . . is to inflict pain, however small the amount, unnecessarily, and it therefore comes under the definition of cruelty" (Luce 1993, p. 179). Many writers have responded to this argument by insisting that fish do not feel pain the way humans do, do not suffer, or are neurophysiologically incapable of feeling pain at all. Scientific study of the issue is inconclusive (compare the publications of James D. Rose with those of Michael K. Stoskopf).

As the practice of catch and release has spread, it has generated internal ethical problems. Where angling pressure is great, guides report that fish are weakened from being caught repeatedly and their mouths become disfigured from being hooked repeatedly. When the fish are harmed, the practice becomes questionable, and anglers have begun to ask whether it is time to restrict angling to catching a few fish to eat.

V. COMMERCIAL FISHING

Commercial fishing is an ancient profession. In 1883 the biologist Thomas Huxley suggested that the great sea fisheries are inexhaustible. For decades Huxley appeared to be right. Between the 1950s and the 1990s the global fish harvest increased 400 percent, but in the first decade of the twenty-first century the picture changed.

THREATS TO THE FISH POPULATION

Naturally fluctuating populations and the inherent difficulty of gathering data from the oceans make it hard to get an accurate worldwide assessment of fish. In the Eastern Indian Ocean and the Western Central Pacific harvests of some species still are increasing. In the North Eastern Atlantic, Southwestern Atlantic, and Eastern Central Pacific marine harvests are generally in decline. The overall trend in wild fish harvests is cause for concern. Total global harvest of both inland and marine capture fish peaked at around 95 million metric tons per year in the late 1990s (Food and Agriculture Organization of the United Nations 2006). By some estimates larger predatory fish declined by 90 percent in the second half of the twentieth century. The percentage of generally longer-lived and more slowly reproducing bottom fish is going down. Spawning stock of Western North Atlantic cod, a fish once so plentiful that mariners claimed one could scoop them out of the ocean in buckets, dropped from 1.6 million metric tons in 1962 to 22,000 metric tons at the closure of the fishery in 1992. Cascading ecological effects threaten all marine species. Marine mammals such as whales and sea lions found at the top of the food chain are particularly at risk.

Threats to the health of marine ecosystems include overfishing, land and marine-based pollution (including oil, aquaculture waste, and nutrification), and competition from species not previously found in the area. Global climate change poses further threats, such as ocean acidification, changes in the range of particular species, and habitat destruction from increasing temperatures and more violent storms.

FISHING METHODS

The impact of commercial fishing on a specific ecosystem varies not only with the amount of fish harvested but also with the fishing technique used. Fishing methods range from the most environmentally sensitive, such as dive-caught and hand-gathered, to the most destructive, such as poisoning, explosives, and bottom trawling (Monterey Bay Aquarium 2007).

Trawling involves dragging a cone-shaped net through the water at selected depths. In bottom trawling the heavy, reinforced trawl net, sometimes with a rake on its lower lip to disturb the sediments, is dragged across the ocean floor. Purse seining involves surrounding fish schools with a long net. Once the fish are surrounded, the bottom of the net is drawn tight and the purse is winched slowly back onto the ship. Drift (or gill) netting involves hanging a net vertically in the water column to entangle moving fish. A set net is a type of gill net anchored to the shore and managed by one or two fishers from a small skiff. Long-lining involves putting lines of baited hooks in the ocean to soak before returning later to bring up the catch. Longlines can be suspended vertically in the water column, suspended horizontally at any depth, or placed on the ocean floor. Trolling involves dragging baited hooks through the water to catch fish feeding in the water column. Crabbers and lobster catchers put baited pots on the sea floor that they later winch onto their ships.

BYCATCH

One of the most ethically problematic aspects of most commercial fishing is bycatch, or the catching of nontarget species. Overall, fisheries bycatch is estimated to account for approximately 25 percent of the total harvest. However, because most boats in the worldwide fishing fleet do not have an observer from a regulatory agency on board, bycatch rates are hard to gauge accurately.

Bycatch mortality varies significantly by fishing method. In bottom trawling almost all the captured fish (both target and nontarget) suffocate in the net or when emptied onto the boat's deck. Trolling and rod and reel fishing generally give bycatch a better chance of survival. Lines typically are winched in as soon as a fish takes a hook, and nontarget species often can be released. Bycatch from purse seining depends on the target species. Seining for tuna can result in dolphin mortality because dolphins often swim near tuna. Seining for salmon typically involves little

Fish Seized from Two Chinese Ships, 2007. *The fish, seen at the port of Abidjan, in the Ivory Coast, were taken from two ships intercepted using "bottom trawling," a commercial fishing technique which is against national fishing laws and known to be severely environmentally destructive. Ivorian fishing groups spoke about the threat Chinese fishing fleets presented to aquatic flora and fauna from "exploitation and abusive practices."* **KAMBOU SIA/AFP/GETTY IMAGES.**

bycatch. In addition to nontarget fish, seabirds, turtles, octopuses, whales, and sea lions regularly fall victim to fishers. Some regulatory authorities, such as the Alaska Department of Fish and Game, permit a certain amount of bycatch to be retained for sale, with the remainder returned to the sea with minimum injury. Whatever method is used, fish brought up from great depths usually die when their stomachs are expelled through their mouths as a result of the change in pressure.

A number of devices and techniques have been developed by fishers to reduce bycatch. Turtle excluder devices (TEDs) can be attached to shrimp trawling nets to prevent sea turtles from drowning. Longline hooks can be deployed at night when birds are less active or between streamer lines so that circling birds avoid the baited hooks as they disappear under the water. Acoustic pingers can help scare off marine mammals such as whales and seals from potentially hazardous encounters with fishing gear (U.S. National Oceanic and Atmospheric Administration 2008).

ECONOMIC EFFECTS AND REGULATORY SYSTEMS

Different fishing methods sustain local economies to different degrees. Trolling is often a small-scale operation performed by fishers from local towns and villages. Bottom trawling involves much heavier and more expensive equipment. In the Bering Sea and Gulf of Alaska trawlers tend to be multimillion-dollar vehicles owned by large corporations. Some of those boats process fish in the local communities, providing a boost to their economies. Others are large enough to process and freeze the fish on board. These big boats often do not dock for many weeks.

Regulatory systems for fisheries run from the global to the local (OceanLaw 2008). In 1994 the United Nations Convention on the Law of the Seas came into effect, establishing Exclusive Economic Zones (EEZs) stretching two hundred miles from a nation's shore. In these zones a nation has sovereign rights to explore and exploit marine resources subject to the requirement that sustainable catch limits be determined and enforced by national law. The principle of maximum utilization mandated by the convention also requires that a state that is unable to harvest the entire allowable catch permit other countries to fish within its EEZ. Outside these zones the oceans are declared the "high seas," and nations under any flag can fish those waters subject to the principle of maximum sustained yield. States with adjacent EEZs and states targeting fish on the high seas that migrate into EEZs are instructed by the convention to "seek, either directly or through appropriate sub regional or regional organizations, to agree upon the measures necessary for the conservation of these stocks in the adjacent areas." Transnational organizations such as the European Community have established their own regulations for

FISH FARMING

Fish farming sometimes is presented as a way to compensate for declining wild fish harvests. Nearly one-third of the seafood eaten worldwide is farmed, and the proportion is rising. Ocean-farmed fish live in net pens close to shore. They are fed a carefully managed diet by aquaculture technicians. Tides and ocean currents continually flush the pens. At harvest time the fish do not need to be caught but are lifted out of the water and taken for processing. Because the timing of the harvest can be regulated carefully, it is easier to bring farmed fish to market in an efficient way and without the skin blemishes sometimes caused by wild capture fishing methods.

Opponents of maritime fish farming cite a number of environmental problems. The close proximity of the fish to one another results in a much higher incidence of disease. Antibiotics fed to farmed fish create new strains of bacteria that are harmful to wild native populations. The fish feces that fall beneath the net pens cause local nutrification problems. Fish escaping from damaged pens compete for food and habitat space with native fish. Sometimes native and farmed fish hybridize, altering the purity of the native genetic stock. If the farmed fish is a predatory species, wild fish have to be caught and converted into feed for the penned fish, raising questions about whether the farming saves the wild resource. In the case of tropical shrimp farming many miles of mangrove forests have been cleared to create space for the pens. Farmed fish and shrimp also tend to be less healthy to eat than their wild-caught cousins.

Fish that are farmed inland are less environmentally destructive. Tilapia, trout, and catfish can be raised in freshwater ponds that pose little or no threat to native fish populations. In some areas fish are ranched. Those fish are hatched in captivity and then, after a certain period of growth, allowed to swim free in the ocean for later capture. Unlike fish farming, fish ranching preserves the jobs of fishers.

member states. There are numerous bilateral and multilateral agreements as well as individual national laws to protect fish populations.

UTILIZATION AND CONSERVATION

Arriving at the right balance between optimum utilization and conservation presents significant management challenges. Fish species live most of their lives out of sight of resource managers. Some species are migratory. Proposed multilateral agreements often clash with traditional use patterns. Enforcement is difficult. The principle of maximum sustained yield that generally governs the use of marine resources at the international level may not coincide with the maintenance of biodiversity.

When agreements have been reached to conserve fish stocks, national governments have adopted a range of measures to reduce harvests. Some fisheries have become limited-entry, requiring boat owners to possess one of a fixed number of permits in order to fish. Banning of certain fishing gear, such as drift nets over 2.5 kilometers in the European Community, has reduced catch and bycatch. Seasonal restrictions, size limits, sex restrictions, and quotas are in use. Some governments have offered buy-back programs in which fishers receive a settlement in exchange for retiring their boats or permits. The establishment of a number of marine reserves or sanctuaries in which all fishing is banned has proved to be an effective method for protecting fish populations. Current marine reserves cover far less than 1 percent of the oceans, compared with about 4 percent of the terrestrial surface of the earth that is protected currently. Conventions against pollution, ocean dumping, and offshore drilling are also beneficial to fish populations.

In some cases conservation measures put in place in the last two decades have been effective in starting to restore populations. Increasing trends in catches are occurring in the highly regulated Northwest Atlantic and Northeast Pacific. Striped bass and North Atlantic swordfish are making a small comeback. Kelp beds off Los Angeles began rebounding after discharges into the ocean were reduced. Canada reopened its Atlantic cod fishery to limited catch. Increased management and enforcement regimes will be essential if these positive signs are to be replicated throughout world fisheries.

HURRICANE KATRINA

Hurricane Katrina was one of the deadliest and most costly storms in U.S. history. The destruction caused by Hurricane Katrina carries valuable lessons about the relationship between humans and nature.

Katrina formed over the Bahamas on August 23, 2005, over the remains of Tropical Depression 10. The system was upgraded to tropical-storm status on the morning of August 24 and became a hurricane only two hours before its first landfall between Hallandale Beach and North Miami Beach, Florida, on the morning of August 25.

The storm weakened as it passed over land, but it rapidly intensified after entering the Gulf of Mexico, growing from a Category 3 to a Category 5 storm in just nine hours. This rapid growth was due to the storm's movement over the "unusually warm" waters of the Loop Current, which increased wind speeds. Katrina attained Category 5 status (the most intense class of hurricanes) on the morning of August 28 and reached its peak strength at 1:00 p.m. U.S. CDT that day, with maximum sustained winds of 175 mph (280 km/h) and a minimum central pressure of 902 mbar. The pressure measurement made Katrina the fourth most intense Atlantic hurricane on record at the time, a record surpassed later that season by hurricanes Rita and Wilma.

Katrina made its second landfall at 6:10 a.m. CDT on August 29 as a Category 3 hurricane with sustained winds of 125 mph (205 km/h) near Buras-Triumph, Louisiana. At landfall hurricane-force winds extended outward 120 miles (190 km) from the center, and the storm's central pressure was 920 mbar. After moving over southeastern Louisiana and Breton Sound, it made its third landfall near the Louisiana-Mississippi border with 120-mph (195-km/h) sustained winds, still at Category 3 intensity. Katrina maintained this potency well into Mississippi, finally losing hurricane strength more than 150 miles (240 km) inland near Meridian, Mississippi.

The storm surge caused severe damage along the Gulf Coast. In Louisiana nearly every levee in the New Orleans area was breached as Hurricane Katrina passed to the east, subsequently flooding 80 percent of the city and many areas of neighboring parishes for weeks. In the aftermath of the storm, communication failures, poor federal response, and extensive levee failures combined to become one of the most devastating and costly disasters in the nation's history. Media coverage highlighted the vulnerability of the poor and predominantly black population of New Orleans, leading some commentators to characterize the aftermath of Katrina as an instance of racially aggravated environmental injustice.

Many analysts have interpreted Katrina and its aftermath as less a natural than an artificial disaster. New Orleans has always had an uneasy relationship with nature. Situated precariously between the Mississippi River, Lake Pontchartrain, and the Gulf of Mexico, the topography of New Orleans resembles a bowl. More than 80 percent of the city lies below sea level; the areas nearest the river (including the high-rent French Quarter and Garden District) are the highest in elevation, but the geographical center of the city is about five feet below sea level. Levee construction along the Mississippi River for the purpose of flood control has been going on since the French settled the region during the first years of the eighteenth century. Today levee construction and maintenance is federally mandated and charged to the Army Corps of Engineers. Efforts to contain the river have disrupted the wetlands ecosystem in its lower reaches and have aggravated New Orleans's elevation problem: The region's soil compacts in a process called subsidence, and without new soil from periodic river floods, the city's elevation decreases, making it even more vulnerable and increasing the risk of lost property and life during heavy rainfalls or storm surges or both—as happened in the case of Katrina.

Further, wetlands in the Gulf of Mexico provide a barrier to incoming storms and hurricanes, blunting their impact and their destructive potential. They function like a sponge, absorbing rain and wind. But containing the river sends further into the Gulf the millions of tons of sediment that would normally be deposited as floodplain silt, thus creating the potential for another environmental debacle—a Gulf of Mexico (hypoxic) Dead Zone.

The environmental risks in the area are compounded by oil and gas industry construction: Canals dug for offshore pipelines lead to saltwater intrusion, killing the soil-holding freshwater marsh grasses. The Mississippi River Delta region has lost more than 1 million acres of marshland since 1900. Each year the region continues to lose an area of about 24 square miles, an area about the size of Manhattan. Restoration of these wetlands could dramatically increase natural resilience and protect against future destruction of life and property.

I

INDIA AND SOUTH ASIA

India is the world's seventh-largest country and the second most populous, with more than 1.13 billion people. As a result of its size and population density, environmental ethics in India often focuses on reconciling social and environmental justice. India has diverse, long-standing traditions for accommodating people with place. However, these traditions were disrupted by five hundred years of colonial rule, and are currently being challenged by globalization. There are also indigenous sources of environmental degradation, resulting in issues such as deforestation and groundwater pollution.

More than 80 percent of India's people are Hindu. It is also the fourth most populous Muslim nation (13.4%), and includes smaller populations of Christians (2.3%), Sikhs (1.9%), Buddhists (0.8%), and Jains (0.4%). Tribal groups (called Adivasis) constitute 8.1 percent of the population. India recognizes fifteen official languages.

Geologically, India rests on the Indian Plate, which collided with the Eurasian Plate roughly fifty million years ago to form the Himalaya Mountains and the high Tibetan Plateau. Several of the world's great rivers originate in the Himalayas, including the Ganges, Brahmaputra, Yamuna, and Narmada rivers. They have been extensively dammed to retain water from the summer monsoon. Although these projects provide electricity and irrigation for industrial agriculture, they have been controversial among environmentalists (see Roy's "The Greater Common Good," 1999).

Sri Lanka, an island lying to the south of the Indian landmass, possesses a high level of flora and fauna diversity. Because 80 percent of Sri Lankans are Buddhist, environmental awareness is often expressed in terms of Buddhist spirituality.

RELIGIOUS AND CULTURAL INFLUENCES ON ENVIRONMENTAL ATTITUDES

The many diverse religious traditions of South Asia include strong elements of environmental awareness. Hinduism includes a vast range of religious practices that cannot be summarized briefly. The term *Hindu* is Persian in origin, and referred to Vedic peoples who lived beyond the Indus River. Shiva, Brahma, and Vishnu are held to be manifestations of one god, who is unnamable. Major religious texts include the *Vedas* and *Upanishads*. Most Hindus believe that the individual souls of all beings are identical to the universal soul, *ātman*. Because of its doctrine of reincarnation, some argue that Hinduism celebrates the interconnections between humans and nonhuman animals. Scholar O. P. Dwivedi has pointed out (in "Dharmic Ecology"), "Among the various incarnations of God are a fish, a tortoise, a boar, and a dwarf. His fifth incarnation was as a man-lion. As Rāma, God was closely associated with monkeys, and as Krsna, he was surrounded by cattle" (2000, pp. 6–7). Scientist and environmental activist Anil Agarwal, however, has expressed doubt (2000) about the environmental friendliness of Hinduism, arguing that Hinduism is highly individualistic in its concern for the welfare of one's soul.

One Hindu sect that is celebrated for its environmental awareness is the Bishnois, founded by Guru Maharaj Jambaji (born 1451) in the arid region of Rajasthan after a severe drought. He laid down twenty-nine

Hindu Devotees Offer Prayers During the Gangasagar Mela, 2006. *Thousands in India gather on Sagar Island, at the confluence of the River Ganges and the Bay of Bengal, to celebrate the main bathing day of Gangasagar Mela. The water has a deep religious significance for the gathered Hindus. India, with the second-largest population in the world, is over 80 percent Hindu. The religion has a profound impact on the environmental ethics of the country.* **GETTY IMAGES.**

principles (*Bishnoi* means "twenty-nine"). Central among these are bans on cutting green trees and killing any animal or bird. Three hundred years later, the Maharaja of Jodhpur ordered his men to fell green trees in Bishnoi villages to burn lime for the construction of his new palace. A Bishnoi woman, Amrita Devi, confronted the Maharaja's agents, arguing that the trees were sacred. She famously said that even one tree is worth the price of one's head. The Maharaja's agents severed Amrita Devi's head with their axes. More killing followed, until 363 people had died. Horrified at hearing the news of these deaths, the Maharaja decreed that no further tree cutting would be allowed on Bishnoi land. Amrita Devi remains a heroine of environmentalists in India to this day.

Another aspect of Hindu environmental awareness has recently been explored by the distinguished ecologist Madhav Gadgil. In "The Ecological Significance of Caste," Gadgil and his colleague K. C. Malhotra "document that castes more directly dependent on natural resources had so organized their mode of subsistence as to avoid excessive overlap with other castes in their demands for various resources" (1994, p. 27). That is, some subcastes fish, some graze, some are hunter-gatherers, in order to segment access to different parts of the ecosystem and reduce conflict. The authors observe, "One may then view the Indian society as being analogous to a biological community made up of a number of 'cultural species' or endogamous caste groups" (p. 30). British colonialism put far greater pressure on resources, privatizing the biological commons, causing "considerable impoverishment, and often complete collapse of the natural resource base" (p. 37).

Another dimension of Gadgil's research has revealed important elements of environmental practice among India's diverse indigenous peoples, the Adivasis. Despite colonialism, "Present-day India still abounds in many forms of nature worship," especially in the form of sacred groves. These groves of mixed vegetation, sometimes as large as twenty hectares, are often associated with tribal (Adivasi) groups. "All forms of vegetation in such a sacred grove, including shrubs and climbers are under protection of the reigning deity of that grove . . ." ("The Sacred Uses of Nature," p. 82). Sacred groves preserve entire intact ecosystems, as opposed to the also common practice of preserving individual trees, such as the medicinally important neem tree.

Jainism, whose most prominent spiritual leader was Vardhamāna Mahāẁira (c. 599–527 BCE), espouses the most thoroughgoing commitment to *ahimsā* (nonviolence)

toward all life forms. All Jains, clergy and laity alike, practice a vegetarian diet. Sidewalks are swept in front of Jain priests to avoid accidentally stepping on insects. Jains often support animal and bird hospitals. (See Chapple 2002.)

Buddhist environmental awareness is also indigenous to India. The Buddha (c. 563–483 BCE) was born in a sacred grove of sal trees dedicated to the goddess Lumbini in what is today Southern Nepal. His teachings included the idea of dependent origination: there is no enduring substance; every individual being is dependent on other beings. At a popular level, the *Jataka Stories* are a collection of early Buddhist tales depicting the Buddha's relationships in previous lives to non-human animals.

Asoka the Great (r. 273–232 BCE), military leader of the great Mauryan Empire, converted to Buddhism out of remorse for the carnage caused by his military exploits. Known for encouraging compassionate treatment of animals and the environment, he abolished animal sacrifice, built hospitals for animals, cultivated medicinal plants, and encouraged forest preservation. Asoka's influence might be said to live on today in Sri Lanka, in the Buddhist-Gandhian development organization Sarvodaya, founded in 1958 by A. T. Ariyaratne. Its programs provide "sustainable empowerment of people through self-help and collective support, to non-violence and peace" (http://www.sarvodaya.org).

THE ENVIRONMENTAL LEGACY OF COLONIALISM

The colonization of India by Portugal and Great Britain began with the arrival of Vasco da Gama in 1498. In 1600 Queen Elizabeth I established the East India Company, first for the purpose of trade with India, but later as the instrument of colonial rule. It was abolished in 1858 when Great Britain established direct rule over its colony. The British Utilitarians James Mill and his son John Stuart Mill administered India for the Company from 1830 until 1858 and established the foundations for resource control. (See Majeed, *Ungoverned Imaginings,* and Curtin, *Chinnagounder's Challenge.*) For an excellent, detailed account of the ways the British gained control over Indian forest resources, see Ramachandra Guha's book *The Unquiet Woods*.

No survey of the background for Indian environmental ethics, however brief, would be complete without mention of Mohandas "Mahatma" Gandhi (1869–1948). Gandhi's campaign for *swaraj* (freedom) against British colonialism was guided by the principle of thoroughgoing ahimsa (nonviolence) of body and mind, even in regard to "noxious insects."

Ramachandra Guha has argued in "Mahatma Gandhi and the Environmental Movement" that Gandhi's principal focus was on justice for human beings rather than the environment. Nevertheless, his teachings established an ideal for simple, sustainable living, which, as Vinay Lal has argued (in "Too Deep for Deep Ecology"), included an "ecological vision of life" (p. 183). In turn, he and his disciples, Mira Behn and Sarala Behn, have influenced the Chipko Movement through Vimla and Sunderlal Bahaguna, as well as the protests against the damming of the Narmada River by Medha Patkar and the Narmada Bachao Andolan.

Contemporary attitudes toward the environment are affected by India's worst tragedy of the industrial age, the Bhopal disaster. On December 3, 1984, forty tons of methyl isocyanate was released from a Union Carbide fertilizer plant in the city Bhopal. Although figures are disputed, it is likely that more than 20,000 people have died from exposure to the gas, and perhaps more than 500,000 have been affected by the disaster. Many still suffer from respiratory problems, cancer, blindness, and birth defects. Union Carbide has been widely criticized for its failure to properly compensate victims. Given the legacies of colonialism and industrial exploitation of the poor, it is not surprising that contemporary corporate globalization has been met with widespread skepticism and protest in India.

ENVIRONMENTAL ETHICS

Environmental ethics in India, then, must be understood in the context of centuries-old traditions of non-harm toward nature. Yet, during this period of four and a half centuries, India also suffered from colonial oppression, which was focused on extracting natural capital. Not surprisingly, writers on environmental ethics in India stress the deep connections between social and environmental justice. As Gandhi said, "There are people in the world so hungry, that God cannot appear to them except in the form of bread."

In *Varieties of Environmentalism*, Ramachandra Guha and Juan Martinez-Alier distinguish *ecosystem people,* people who depend heavily on local resources, from *omnivores,* or those who have the power to access resources globally. The environmentalism of the poor is based on the resistance of ecosystem people to attempts by omnivores to access their resources. These nature-based resistance movements have a distinctive vocabulary of protest, including the action designed to disrupt economic life and the *dharna.* or sit-down strike, designed to stop work on large dams. Another form of protest is the *bhook hartal*, or hunger strike, carried out in public by charismatic leaders such as Chipko's Sunderlal Bahuguna and Medha Patkar of the Narmada Bachao Andolan.

Chipko began in 1973 in the northern Indian state of Uttarakhand. Heavy monsoon rains in 1970 had

alerted villages to flooding caused by deforestation. Government logging contracts to private companies caused protest. Chandi Prasad Bhatt suggested the term *Chipko,* meaning "to hug," recalling the efforts of the Bishnois to protect trees in the fifteenth century. Although many of the best-known Chipko leaders have been men, authors such as Vandana Shiva (see *Staying Alive,* 1988) have argued that the core of the protest was women who were left at home to deal with flooding after men had left in pursuit of work. As is commonly the case in the wake of widespread ecological disruption, Chipko women bore the brunt of reduced access to fuel-wood and fodder. It is mainly in this sense that Chipko is a woman's and, to some extent, feminist movement. In the following years, Chipko spread across India and became a broadly based movement campaigning for ecologically responsible village development.

Another celebrated environmental movement, the Narmada Bachao Andolan (Save the Narmada Movement), began in protest against the plans of the government and the World Bank to build 30 large, 135 medium, and 3,000 small dams on the Narmada River. (Gandhi's protégé and India's first prime minister, Jawaharal Nehru, strongly advocated construction of large dams to support rapid industrialization after independence in 1947.) The Narmada was the last of India's major rivers to be dammed. Opponents have stressed the ecological and human cost of displacing 300,000 poor and tribal people. The river valley is also studded with religious monuments. Protest leader Patkar engaged in a twenty-one-day fast in 1991 that brought her close to death. For her efforts she and Baba Amte won the Right Livelihood Award later that year.

Chipko and the Narmada Bachao Andolan have also inspired many recent environmental movements. India was one of the original test sites for the Green Revolution, which brought industrial agriculture, heavy use of pesticides and herbicides, as well as plant monoculture focused on cash crops. Today, there are widespread concerns over the Gene Revolution, which uses genetically modified seeds. Important questions have arisen over questions of who owns intellectual property, as seed and pharmaceutical companies patent product lines that began with investigation of indigenous knowledge of nature. (See Shiva 1991; Curtin 1999.)

The critical roles of women (see the work of Bina Agarwal, Vandana Shiva, and Deane Curtin) in environmental protection are also demonstrated in the Self Employed Women's Association (SEWA), a trade union founded in 1972 by Elaben Bhatt (http://www.sewa.org). Ninety-four percent of female laborers in India are in the informal work force, whose labor is rarely visible to economic measurement. SEWA embraces Gandhian principles of "satya (truth), ahimsa (non-violence), sarvadharma (integrating all faiths, all people) and khadi (propagation of local employment and self reliance)." Its work emphasizes the difficulty of separating women's interests from environmental welfare, but its more explicitly environmental campaigns include campaigns for forest workers, for safe water access, and for safe food.

On other fronts, large plantations of quick-growing and water-hungry eucalyptus trees, used for paper pulp, have been criticized for their reckless use of water at the expense of the poor. Environmental activists have recently targeted the Coca-Cola Company for lowering water tables due to extensive well digging.

For up-to-date information on environmental issues in India, one might consult the Centre for Science and the Environment, founded in 1980 by Anil Agarwal (http://www.cseindia.org). It publishes a magazine and online journal *Down to Earth,* edited by the renowned environmentalist Sunita Narain (http://www.downtoearth.org.in).

INDIGENOUS ECOLOGICAL KNOWLEDGE

SEE *Traditional Ecological Knowledge.*

INDUSTRIAL AGRICULTURE

SEE *Factory Farms.*

INDUSTRIAL ECOLOGY

Industrial ecology (IE) can be generally defined as the multidisciplinary study of industrial and economic systems and their linkages with fundamental natural systems. More expansive definitions identify IE as a major mechanism by which humanity can rationally understand and approach sustainability. Among the critical elements of the IE framework are an emphasis on systems; on enhancing energy and material efficiency; on accepting continuing economic, technological, and cultural evolution; and on transdisciplinary frameworks integrating engineering, physical sciences, and social sciences. Robert Socolow in his 1994 article summarizes IE themes as including a focus on long term and systemic phenomenon rather than ad hoc issues; a focus on the intersection of human and natural systems rather than just one or the other; a concern about the resiliency of human and natural systems rather than single outcomes; and a reliance on technocratic tools and methodologies such as life cycle assessment and mass flow analyses.

Industrial ecology was introduced in a seminal 1989 article by Robert Frosch and Nicholas Gallopoulos, which suggested that industrial systems could be more efficient if modeled after natural ecosystems. This was followed in 1995 by the first IE engineering textbook by Thomas Graedel and Brad Allenby. The years since the publication of that book have marked the continuing institutionalization of the field, including a significant expansion of the literature, and the establishment of a journal of record (*Journal of Industrial Ecology*), and a society (the International Society for Industrial Ecology).

Unlike traditional environmentalism, IE was developed primarily by the industrial and technological communities. Conceptually, the growing gap between the complex, systems-based nature of regional and global environmental perturbations, and the inability of reductionist and incremental regulatory approaches to address them adequately, demanded new approaches. Increasing regulatory costs and responsibilities also encouraged industry to explore new, more systemic ways of managing these issues. Accordingly, certain sectors, particularly the electronics industry in the United States, began to develop a set of practices based on IE principles. Contrary to the common approaches at the time, these practices focused not on end-of-pipe management of wastes, but on product design and lifecycle techniques intended to reduce environmental impacts across technology systems. These were generally derived from, and compatible with, existing technocratic practices and tools, especially design methodologies.

Reflecting these origins, much of the early industrial ecology literature tended toward a technocratic, data-driven, engineering approach to environmental implications of manufacturing processes and manufactured products, particularly those aspects that can be addressed by superior design (such as life cycle energy consumption, reduced use of toxics, and enhanced recyclability). In this, IE differs from a number of other similar areas of interest, such as "natural capitalism" and "sustainability," in that it has focused less on normative postures and activism, and more on understanding the physical, built, and economic systems that interact with natural systems to produce environmental perturbations. In keeping with its engineering background, it is also more problem focused, and less broadly philosophic. Whether this should continue to be the case is a subject of ongoing debate within the IE community.

ETHICAL CONSIDERATIONS

IE raises a number of interesting ethical questions. To begin with, because it is a young field, and rests at an intersection of economic, environmental, and technological discourses, even its appropriate definition is contested from different ontological perspectives. The careful reader will have noted that the first definition of IE provided above is a relatively objective formulation, while alternative definitions refer, sometimes directly, to normative constructs such as "sustainability" (indeed, following Graedel and Allenby [1995], IE is sometimes called "the science of sustainability"). Thus, whether IE is, should be, or can be a relatively objective "science," or whether it should be intentionally structured to support environmental activism, is an active dialog within the IE community. The continuing exploration of this question of ontological value makes IE not only more challenging as a field of practice, but also a fertile case study for those interested in environmental politics, ideological conflicts in the scientific discourse, and the philosophy of science generally.

The complexity of the integrated economic/environmental systems that are the subject matter of IE raises additional questions. To begin with, the role of the researcher in defining appropriate topics for study, and therefore highlighting selected issues for technocratic and public audiences, is more important where systems are so complex, allowing for enhanced subjectivity in highly conflictual contexts. Within the IE framework, complexity is also problematic: Not only are characteristics such as discontinuities, temporal and spatial scale effects, and emergent behavior common in many IE analyses, but because IE deals with systems that integrate human and natural components, complexity may be cultural or ideological, not just physical. This makes determining the appropriate boundaries of IE studies, as well as that of the field itself, difficult, especially with regard to the role, and degree of inclusion, of social sciences (or indeed, of the humanities). The latent dichotomy between the social sciences and the physical sciences/engineering is reinforced because of the environmental origins of the IE field, which are difficult to outgrow. IE efforts to address sustainability thus tend to emphasize environmental, and downplay social and cultural, issues. Concomitantly, IE also tends to be less sophisticated in its handling of social and cultural questions than technological and environmental issues. All of this unavoidably complicates IE methodologies; the need for transdisciplinary methods and skills arises from the nature of the systems at issue, but maintaining high levels of intellectual rigor in each discipline while performing integrated analyses remains challenging.

A final question is whether *industrial ecology* should be taken as analogy, as mandate, or simply as suggestive. While most practitioners accept that biological systems, characterized by complex flows and transformations of energy and materials, offer an interesting source of learning and potential models, some go beyond this and treat biology not as metaphor, but as design mandate. Whether this reification of ecology as zeitgeist, replacing the "universe as mechanism" metaphor of the Enlightenment, can remain valid in an age of synthetic biology and technological convergence, and the implications for IE if it cannot, remain open questions.

INTERGENERATIONAL JUSTICE

Intergenerational justice—or justice between generations—refers to the set of obligations the members of one generation may owe to people of other generations, past or future. By contrast, *intragenerational justice* involves obligations that members of one generation owe to one another. Although some have argued that there can be obligations to past generations, most accounts of intergenerational justice focus on present obligations to future generations. For example, if people who are alive now have an obligation to preserve the living ecosystems of the earth and to

Rows Upon Rows of Taxis at Beijing's New Airport Terminal, 2008. *Just prior to the 2008 summer Olympics, Beijing opened a new airport terminal to help meet the demand of increasing numbers of tourists. 2007 saw an increase to 185 million passenger trips across China, and the projected number for 2008 was 210 million passenger trips. By the end of 2020, China expects to add nearly 100 new airports across the country. Some would consider this increase in carbon omissions a severe violation of intergenerational justice.* **LIU JIN/AFP/GETTY IMAGES.**

conserve resources for the benefit of people who will live in the future, then such a conception of future-directed intergenerational justice will be a crucial part of environmental ethics and politics.

THEORIES OF JUSTICE

A theory of justice is an incomplete theory of morality, since not all moral obligations are obligations of justice. The obligations of justice are a special group of moral obligations that are connected to the rights and interests of others. For this reason, it is usually considered appropriate to enforce obligations of justice using law or social policy—the coercive powers of the state. On this common view, it is inappropriate to use force or law to compel people to be kind or generous, or to promote other high moral values. But obligations of justice are obligations to others, and when they are violated these others become victims of injustice. Because people have both a general right and an obligation to protect others from injustice, it is permissible to use the coercive powers of the state to insure that people will not behave unjustly. In this sense, the requirements of justice are a relatively small, high-priority subset of the broader requirements of morality.

Political philosophers sometimes distinguish between two broad categories of justice: retributive and distributive. *Retributive justice* seeks to understand and formulate appropriate and just forms of punishment—or retribution—for crimes. This kind of justice pertains chiefly to the criminal-law system and is often applied in the prosecution of people or corporations that violate environmental laws. By contrast, theories of *distributive justice* extend beyond the criminal-justice system to encompass all aspects of the social order; they seek to establish standards for the fair and equitable distribution of goods, services, and rights in society as a whole, to understand what obligations and duties members of a society can fairly and reasonably expect of one another. Theories of intergenerational justice discuss the degree to which future generations have rights and interests that can justly and fairly govern and/or limit the actions of the present generation—or, seen from another perspective, whether canons of fairness and justice imply duties and obligations that the present generation has toward future generations. When accounts of intergenerational justice consider the fairness of resource distribution

between generations, they are centrally concerned with distributive, not retributive justice.

Environmental ethicists often wish to argue for environmental policies and laws. But if the only obligations that can be enforced by law are obligations of justice, then such arguments must be based on a theory of justice. One plausible way to support such policies is to show that they are requirements of intergenerational justice, based on our present obligations to conserve resources and protect the environment for the benefit of future generations.

ENVIRONMENTAL JUSTICE AND JUSTICE BETWEEN GENERATIONS

Many questions of environmental ethics and environmental policy pose fundamental questions of intergenerational justice. For example, it might be more convenient for people living in the present to enjoy the unfettered use of automobiles and jet planes for their convenience and pleasure in getting from place to place. But the carbon emissions from these conveyances are partly responsible for climate changes that could drastically reduce the quality of life—or even the very possibility of life—for people living fifty or a hundred years from now. Does the present generation have an obligation to curb the consumption of carbon-based fuels in order to protect the interests of future generations, even though the interests and convenience of the present generation might be better served by unrestricted use of fossil fuels? If environmental laws can govern or restrict the behavior of individuals within the present society for the benefit of all (intragenerational justice)—say, by mandating recycling of waste or limiting toxic emissions from factories—can such laws also enforce sacrifices on the part of the present generation to protect the interests of future generations? These are the types of questions theorists of intergenerational justice attempt to address.

FOUR CONCEPTIONS OF ENVIRONMENTAL JUSTICE

Because many theorists hold that obligations of justice are the only moral obligations that can justifiably be enforced by law, considerations of justice are crucially important for environmental ethics, and more broadly for environmental philosophy. If the only obligations that can be enforced by law are obligations of justice, then environmental policy arguments must have their foundation in a theory of justice. There are at least four different ways to approach this task:

1. First, one might argue that environmental offenders violate the rights of ecosystems or species, and that these ecosystems or species are the victims who must be protected by appropriate environmental policies. But ecosystems and species lack conscious interests. While the possession of conscious interests is not usually regarded as necessary for the possession of value, or of moral significance, many philosophers (for example Feinberg 1974) have urged that the possession of conscious interests is necessary for the possession of rights. Those who accept Feinberg's view are likely to find this first strategy unworkable.
2. A second approach presupposes that our obligations to protect the environment are obligations to animals—to nonhuman individual right-bearers within the biotic community. Since animals—at least so called "higher" animals do possess conscious interests, it is plausible to attribute rights to them. Many philosophers who are skeptical about the rights of species and ecosystems have argued that animals do possess some rights, including at least basic rights to humane treatment and to a life-sustaining environment (see Nussbaum 2006, and Feinberg 1974).
3. A third approach involves arguing that obligations to preserve and protect the environment are obligations to other existing human beings. Present-day people are the most obvious bearers of rights, and many environmental obligations can indeed be understood as requirements of intragenerational environmental justice (Shrader-Frechette 2007).
4. The fourth approach is to make the claim that the duty to protect the environment is, at least in part, an obligation of justice based on the rights and interests not only of people alive now but also of generations to come. This is the intergenerational standard of environmental justice.

Thus one might see a theory of intergenerational justice as one component of a broader theory of environmental justice, and as a crucial component of a broader theory of environmental values and policy.

RIGHTS, IDENTITY, AND SKEPTICISM ABOUT INTERGENERATIONAL JUSTICE

Skepticism and the Social Contract Some theorists have argued that there can be no obligations to future generations, and that the concept of justice can only apply between people who presently exist. That is, they have urged *skepticism* about intergenerational justice. For example, simple social-contract conceptions of justice such as those advocated by Thomas Hobbes (1588–1679) in his work *Leviathan* (1668/1994) and more recently by David Gauthier (1986) hold that justice is founded on principles that people who live together in the same community would agree to accept as binding, as long as they could be assured that others would abide by the same principles. In the absence of such restraining principles, it might be

advantageous for individuals to coerce others or to seize their possessions. But in such circumstances people would be insecure, at constant risk of the depredation of others. So individuals voluntarily agree to a social contract that places some limits on the freedom of action of individuals to ensure the security of all. According to the simple contractarian view, only those principles individual contractors would voluntarily accept as mutually advantageous can be enforced by the state, and such principles are thus the only requirements of justice.

Although contemporaries might gather together to negotiate a contract for mutual advantage, such negotiation is impossible between people who live at different times. Those living now might take actions that will advance or undermine the interests of future generations, but those living in the future cannot either reward us if we help them or punish us if our actions harm them. This limitation has sometimes been advanced as grounds for skepticism about intergenerational justice: Because distant generations cannot negotiate a contract with their forebears for mutual advantage, they cannot be bound by principles of justice in regard to us, nor can we in regard to them. Future persons could, however, be the objects of contemporary promises and contracts; present-day persons might make promises or contracts among themselves in which they accept obligations to future people. In that case contemporaries would have obligations to one another with respect to the interests of future generations. But promises must be made to someone, and contracts are reciprocal agreements. Because future persons do not now exist, they cannot be contractual partners, nor can we incur obligations to them. Accordingly, Wilfred Beckerman and Joanna Pasek (2001) and David Gauthier (1986) have argued that there can be no direct obligations of intergenerational justice.

Critics of this view argue that its adherents have adopted the wrong conception of justice. The choices we make now will influence the lives of people in later generations in a variety of ways, beneficial or detrimental: For example, we might deplete resources that will be desperately needed decades hence, thus harming future generations and making them the victims of present wastefulness. In such a case it would be reasonable to argue that the resulting intergenerational distribution is not fair to those who are deprived and thus has violated their rights. Simple contractarian theories of justice would seem to be seriously inadequate if they cannot account for such actions as violations of obligations of justice. For this and other reasons, recent contractarian theorists like John Rawls (1971) have urged that the principles of justice must include representation for the interests of future generations.

Justice and Rights Some scholars, including Beckerman and Pasek (2001), have argued against the idea of intergenerational justice on the grounds that future persons cannot have rights. This view is supported with two arguments that must be addressed by any account of intergenerational justice. The first such argument is metaphysical: Future persons are merely possible persons who do not yet exist—hence they cannot have anything at all, including rights. On this view, therefore, present obligations to them cannot be based on their rights.

This argument may be regarded as questionable because it conflates different senses in which future persons might be regarded as "possible persons." Future persons are not like fictional characters who have never existed and never will, or like the inhabitants of alternate possible worlds. While our present actions cannot advance or set back the interests of fictional characters, they will certainly influence the lives of people who will exist after we have died. In addition, critics can argue that Beckerman and Pasek's argument conflates possession of a right with possession of a property or a physical object. Rights are not properties but moral relationships—they bind people through moral and/or legal obligations. Such relationships can hold between present and future individuals even when there is no single time at which both exist. The status of people who will (or may) exist but do not now exist is quite different from the status of fictional characters who never have existed and never will exist and whose interests cannot be advanced or set back by our present actions; the former are potential bearers of rights, whereas the latter are not.

Another closely related skeptical argument is usually called the "nonidentity problem" and is associated with the work of Derek Parfit (1984). According to Parfit present actions do not simply influence future events, but they also determine which future persons will come into existence. Because even minor events will have ever broader implications over time, present actions and policies will result in the existence of a global population that is entirely different from the one that would have existed if the policy had been different. On this view obligations of justice and rights must be associated with specific claimants with determinate identities. But if the very existence of future people will vary with present actions, those yet-unborn individuals cannot be determinate claimants; present choices and actions cannot violate their rights or harm them or be unjust to them. How can one be harmed by an action without which one would not have existed at all?

A possible counterargument would point out that the features that make people eligible for rights are general and often do not refer to the specific identity of the rights bearer. The obligation not to roll boulders down a mountain, for example, is based on the rights of *anyone* who might be down below. The obligation not to shoot

arrows into a dark forest where children might be playing is based on the right of anyone who might be there to be protected from the harm such a reckless action might cause. Even if it turns out that there is no one on the path below, or no one playing in the dark forest, it does not follow that there is no obligation to avoid these reckless actions, as long as there might be some such potential victim.

If contemporaries have rights-based obligations to future generations, they would be obligations to anyone who might suffer the ill consequences of our present choices. These need not be obligations to specific individual right-bearers whose identities could be known in advance. If it turned out that there were no future persons at all, then there would be no one whose rights would have been violated by reckless choices made by those who lived earlier. But it would in no way follow that it is permissible to act in a way that is heedless of the interests of possible future persons who might be harmed by them; if such people were indeed to come into existence in the future, and if they were to suffer such harms, it would make perfect sense to say that their rights had been violated by the wrongful earlier actions (Reimann 2007).

ALTERNATIVE CONCEPTIONS OF INTERGENERATIONAL JUSTICE

One way to develop a conception of intergenerational justice would be to consider how the core concepts of the major theories of justice apply to this issue. For example, we might ask whether present policies are likely to result in a *fair* intergenerational distribution of burdens and benefits. A requirement of intergenerational fairness might at least rule out an unnecessary and rapacious consumption of resources that would deprive later generations of the ability to meet basic needs. Accordingly, one might also ask whether present actions constitute *harms* to future generations. In a similar vein actions can be deemed intragenerationally unjust if they result in excessive benefits for a powerful minority at the expense of a weak majority. Unless such actions are required by other provisions of justice (for example, respect for property rights) they would be judged unjustified and unjust.

Various conceptions of justice have different implications for the standing of future generations. The most common theories of justice fall into three broad categories: libertarian, liberal, and communitarian.

Libertarianism Libertarian theories distinguish between negative and positive rights. Negative rights are claims against the interference of others, whereas positive rights include claims to goods or services, or to the positive actions of others. The right not to be assaulted, for example, is a negative right, whereas the right to education or the right not to suffer deprivation of basic needs is a positive right. If future generations have rights (for example, the right that we not destroy resources they will need or a right to a life-sustaining environment), then these would be positive rights. Libertarian theories (Nozick 1974, Beckerman and Pasek 2001) hold that only negative rights imply requirements of justice. But the obligation to protect the environment seems to be based on positive, not negative rights. Most libertarian theorists accept this view and argue that justice does not justify restricting the liberties of those now alive for the sake of future generations, nor does it justify intragenerational measures designed to protect the environment. Some, however, believe that free market forces and the present protection of negative rights will adequately protect the environment and the interests of future persons (Gauthier 1986).

Liberalism In popular discourse the term *liberal* is usually counterposed to *conservative,* but among political theorists and philosophers the term has a different and quite specific meaning. Like libertarians, liberal political theorists also hold that justice requires the protection of negative rights. But liberal theorists of justice also include some positive rights that they consider basic to equity and well-being.

John Rawls's *Theory of Justice* (1971) is widely regarded as the touchstone for contemporary liberal accounts of justice. Like Gauther (1986) and Hobbes (1698/1994), Rawls develops an account of justice as a social contract. But unlike these other theorists, Rawls urges that a fair social contract must reflect the interests of future generations as well as present contracting parties, and he insists on special restrictions to insure that the social contract will embody principles of fairness, not the arbitrary influence of power or special interests. Rawls argues that the circumstances in which a fair social contract is chosen must exclude inappropriate influences. Just as an ordinary contract is invalid when it is imposed by force, so, according to Rawls, a social contract is invalid if it fails to incorporate the reasonable expectations and interests of all the parties. Hence, Rawls argues, the circumstances of the contract must exclude any information that would allow the contracting parties to skew the principles of justice to privilege their own particular interests or those of their group.

Rawls contends that justice should be based on the principles that rational individuals would choose from what he calls the original position (OP). The OP is designed to ensure that principles will be fair and will protect the rights and interests of everyone to whom they apply. As a thought experiment Rawls asks us to consider a hypothetical convention in which people are required to select principles of justice that will govern social cooperation from one generation to the next, over the life of a

society. In order to ensure that the principles chosen will be fair, Rawls suggests that participants must choose principles under the constraint of a veil of ignorance that deprives participants of any special knowledge about themselves that would enable them to distinguish their interests from those of other people in society. Thus parties to the original position do not know whether they are black or white or male of female or Christian or Jewish or Muslim or agnostic. They are thus prohibited from selecting principles of justice that would arbitrarily (and unfairly) help some people to gain an advantage over others.

Rawls also specifies that parties to the original position do not know to which generation they belong. They must, however, decide on the intergenerational rate of saving—how much each generation should save for subsequent generations. He argues that each generation should save at the rate at which they would like the previous generation to have saved. This will be, he implies, the same rate the children of the present generation would want their parents to adopt. Rawls argues that, although the members of the present generation have no obligation to impoverish themselves in order to make their descendants rich, there is a fundamental obligation to ensure that later generations will inherit just institutions and adequate economic and environmental resources.

Thus, on a Rawlsian view, many important environmental policies can be understood as necessary requirements of intergenerational justice. Rawls argues that intergenerational saving is necessary only when a society is relatively poor and is not yet in a position to guarantee that rights will be respected and basic needs met. Once just institutions are in place and basic needs are secure, there is no further obligation to save for later generations. Thus, on Rawls's view, the problem of intergenerational justice is temporary, and intergenerational saving is no longer necessary after the problem has been solved.

Although Rawls's account is among the best-developed liberal theories of intergenerational justice, it has drawn a wide array of criticisms. Rawls seems to assume that later generations will be better off than earlier generations even though problems of environmental destruction and resource depletion cast serious doubt on this assumption. Furthermore, Rawls does not adequately address the problem of population growth: If the population is increasing, then earlier generations cannot simply maintain an existing stock of capital resources because the subsequent, more populous generations would then suffer from a reduced per capita standard of living. Population growth brings with it increasing strain on resources and the environmental dangers of urban sprawl. The omission of this crucial factor compromises the usefulness of Rawls's work as a practicable theory of intergenerational justice. Nevertheless, some liberal theorists believe that some variant of Rawls's can address these issues (Wolf 2008). To accomplish this, one would need to generalize the Rawlsian view to accommodate changes in population size and corresponding changes in the resource and capital base needed to address people's needs and to secure justice.

Communitarianism Communitarianism developed as a critique of liberal theories of justice. The term *communitarian* is difficult to define because many different theories have been associated with the term (Sandel 1982, Walzer 1983, de-Shalit 1995). Most communitarian critics of liberalism have argued that liberal and libertarian theories place too much emphasis on individual rights and overlook the significance of nonindividual, nonrights-based sources of social value. Whereas liberal and libertarian theories often hold that public institutions should be neutral with respect to the diverse social and cultural values of individuals or communities, communitarians argue that institutions should promote such community values. These theorists emphasize the degree to which communities bind individuals together through a commitment to common values and ideals. Liberal and libertarian theories, on this view, underestimate or even ignore the value of the moral and social cohesiveness that can arise only in a community of like-minded fellow citizens (Buchanan 1989).

Communitarians believe that many of the most important obligations arise out of the roles people play in communities or in families. Instead of viewing political association as merely an instrumental good, communitarians hold that community membership is valuable in its own right and that political participation is good for its own sake, not merely as a means of rendering institutions more responsive to particular interests. Communitarians argue that obligations to future generations arise as an inherent part of the sense of human connectedness that is fostered by participation in a social or political community. Avner de-Shalit (1995) holds that the commitment to future generations is based on our understanding that we and they are members of a transgenerational community. Recognition of our role in this community requires the acceptance of obligations that extend to the next generation of community members.

But, as de-Shalit recognizes, we may not regard the members of *distant* future generations as members of our community. Thus, he argues, our obligations to remote future generations cannot derive from a communitarian view. He holds, rather, that such obligations are an aspect of "humanity," not of justice, because, as he writes, "justice is concerned with principles of ownership or the control of resources, while humanity is concerned with people's well-being." (de-Shalit 1995, p. 63) On this view

intergenerational justice has a sharply limited scope, extending only as far as the boundary of one's community, and does not necessarily take into account any negative effects present actions and policies may have on those who live in other communities or those who will live in the distant future.

Critics regard this limitation as an objection to de-Shalit's communitarian view, and perhaps to communitarian theories in general. If our obligations of justice extend only to members of our community, and distant peoples are not members of our community, this would imply that we do not violate the obligations of justice if our institutions or actions victimize others who are very distant in time or space. When institutions provide disproportionate benefits to some people at the expense of others—even those in the distant future or in far-flung parts of the world—it seems sensible to ask whether these institutions are fair. This question seems to invite a more comprehensive theory of justice than the one de-Shalit has developed, one that can span distant generations and local communities. But such a theory could still be called communitarian only if one's view of ''community'' encompasses humanity as a whole.

COSMOPOLITAN INTERGENERATIONAL JUSTICE AND ENVIRONMENTAL PROTECTION

Although most accounts of intergenerational justice apply to the policies of nation-states, many important environmental problems are global. For example, among contemporary environmental concerns, global climate change is the result of the environmentally damaging behavior of many individuals and corporations around the world. Environmental regulation of the open sea or the global planet's atmosphere requires international cooperation and regulations that fairly distribute the burdens and benefits of cooperation and protect the rights of all nations.

Recent philosophical work on international justice has focused attention on the concept of human rights and on the requirements (and limits) of international distributive justice. Notably, Rawls (1999) and Nussbaum (2006) develop contemporary theories that aim to provide the foundation for an account of internationally enforceable human rights, and Pogge (2002) argues for principles of international distributive justice. However, only a small portion of this work has addressed the intergenerational environmental implications of international agreements and the ways in which requirements of intergenerational justice might inform deliberations about just international policies.

Many of the norms and principles that have been employed to evaluate international institutions and agreements are applicable across generations. For example, in international negotiations aimed at achieving global regulation of greenhouse gas emissions, great weight has been given to considerations of fairness in the distribution of burdens and benefits. In these negotiations the representatives of many third world governments have argued that, because the developed nations of the global north have benefited disproportionately from industrialization during the twentieth century and generate most of the problematic emissions, they should bear more of the costs of addressing the problem.

Global climate change is among the central environmental problems of the twenty-first century, and contemporary theorists have sought to address the problem of climate within the framework of environmental ethics and intergenerational justice. Since the problem of climate is essentially global and intergenerational, and because the policy alternatives are necessarily international, contributions to this problem necessarily involve principles of cosmopolitan intergenerational justice. The Kyoto Protocol, an international climate agreement ratified by many states in 2001, is the most comprehensive climate treaty in effect. The Kyoto agreement sets greenhouse gas emission targets for participating nations, and created a market whereby nations could purchase emission credits from other nations, or could gain credits by exporting so called ''clean technologies'' to developing nations. Critics have argued that the treaty accomplishes too little (Gardiner 2004a, 2004b) and that the environmental problems involved in climate and global environmental change will require a more comprehensive arrangement, which will be difficult to achieve given the constraints of international negotiation. Others theorists have urged that the achievement of a global policy governing greenhouse gas emissions is a high priority requirement, and that failure to achieve such an agreement will violate requirements of both international and intergenerational justice (Shue 1993, 1999; Jamieson 2002).

IS INTERGENERATIONAL JUSTICE ANTHROPOCENTRIC?

Some environmental ethicists have criticized the notion that protecting the environment is chiefly a matter of looking out for human interests. Against this anthropocentric notion these critics oppose the nonanthropocentric argument that the ethics of environmentalism should be based on the intrinsic value of the protected resources or organisms, not merely on their instrumental value to humans—in other words, they view nature as an end itself, not merely as a means to human ends. But perhaps anthropocentric and nonanthropocentric ethical precepts do not conflict but dovetail insofar as they point to

similar kinds of obligations toward the natural world. To the extent that proposed environmental regulations can be shown to benefit both people and nature viewed as an end in itself, then such laws clearly protect the interests of both future generations of people and future ecosystems. Bryan Norton calls this "the convergence hypothesis" because it argues that anthropocentric and nonanthropocentric reasons converge to justify the same actions and policies (Norton 2005). If important environmental obligations are viewed as requirements of intergenerational justice, there is no inherent disparagement or denial of other, nonanthropocentric, justifications for the same obligations. If concern for the environment is founded mainly on nonanthropocentric values, then intergenerational arguments for environmental protections might be viewed as incomplete but not necessarily mistaken.

In practical political contexts there are good strategic reasons for framing environmental obligations in anthropocentric terms, even if such arguments seem to slight the intrinsic value of nature. In public-policy debates it is often prudent to tailor rhetoric to the broadest possible political base, minimizing any potentially controversial justifications. In this sense the anthropocentric justifications of intergenerational justice can help to achieve the ends sought by nonanthropocentrists even in eschewing the latter's principles for practical political reasons; environmental laws that are never passed or implemented do not benefit advocates on either side of that philosophical divide.

INTERGOVERNMENTAL PANEL ON CLIMATE CHANGE

The United Nations Environment Programme (UNEP) and the World Meteorological Organization (WMO) convened the Intergovernmental Panel on Climate Change (IPCC) in 1988 to comprehensively review the scientific and technical peer-reviewed literature on global climate change (GCC). The IPCC does not conduct original scientific research. Any country that is a member

of the UNEP and the WMO can be a member of IPCC. Scientists participating in the IPCC are chosen by their respective governments; there are about a thousand who participate. Because the IPCC represents the world's foremost collection of experts on climate change, nations' governments rely on IPCC reports to guide their GCC policy decisions, including those pertaining to the most important international agreements: the United Nations Framework Convention on Climate Change (UNFCCC) and the Kyoto Protocol. Every five years or so the IPCC issues detailed reports on, for example, ''The Scientific and Physical Basis for Climate Change,'' ''Impacts, Adaptation, and Vulnerability of Climate Change,'' and ''Mitigation of Climate Change.'' In addition, a shorter synthesis report also is published by IPCC that is intended for policy makers; the 2007 ''Fourth Assessment Report'' (AR4) is an example. All of the reports include analyses of possible future development paths relating to social, economic, technological, and energy growth and projections of future greenhouse gas emissions.

Although the IPCC's mission is to synthesize existing scientific and socioeconomic literature in as unbiased a manner as possible, its methods of reviewing and synthesizing the literature raises many ethical issues that often are ignored or underestimated. The examination of the ethical issues posed by IPCC's procedures and reports is important because it prompts a consideration of such matters in subsequent reports; if the issues are not identified, then the IPCC has no mandate to conduct ethical analyses of its work (Brown 2006, 2008).

SCIENTIFIC SYNTHESIS

Even though the IPCC's assessment reports persuasively document the realities of global climate change and attribute a significant amount of change to human activities, it is possible that the impacts of global climate change could be even more dire than the reports indicate. For instance, in the AR4 the IPCC decided to limit its projections of temperature changes to those that fell within a 90 percent confidence level and, therefore, discounted a small but potentially significant risk of greater temperature increases than those projected. These potentially greater increases would disproportionately affect regions in high latitudes and aggravate climate change problems for future generations. In addition, the IPCC decided not to report that there is a possibility—albeit of a lower order of probability—of an even more rapid dynamic melting of the Greenland and Antarctic ice sheets, thereby downplaying the serious and irreversible damages that would ensue in that case, most notably a sea-level rise of approximately thirteen to twenty feet. Finally, the IPCC decided to exclude nonlinear events that might result in higher or more rapid increases in temperature or sea level rise.

SOCIOECONOMIC SYNTHESIS

The various economic models used by the IPCC contain hidden ethical assumptions: for example—that public policy should maximize overall global welfare even if achieving this imposes serious harm on some people, that benefits accruing to future generations from actions to mitigate GCC should be discounted relative to the costs imposed on present generations, and that discount rates for future benefits should be based on how people value benefits to them and not on how costs or benefits are distributed to those most vulnerable to GCC impacts. All of these assumptions are ethically contestable because they discount or undermine principles of distributive justice by relying on cost-benefit analyses as the preferred rational basis for prescriptive guidance for GCC policies and decision-making; and they are not made explicit by the IPCC in its methodology or reports. Further, normative principles stated in the UNFCCC create a preference for energy efficiency and conservation, equity for developing and vulnerable countries, and the right to sustainable development. Although IPCC considers energy efficiency and conservation as options that can be employed to address GCC, it has not fully assessed their potential to provide equity for developing and vulnerable nations and to promote sustainable development.

PROCEDURAL JUSTICE

Procedural justice seeks to ensure that people who will be affected by policies are represented in policy-making deliberations. The IPCC reports rely almost exclusively on peer-reviewed and technical papers published by highly educated and often narrowly trained specialists, disproportionately from northern, developed nations. Typically, the governments who use the reports accept this form of ''expert'' opinion as the only legitimate form of knowledge that can be justified in the reports. Many people living in areas at high risk from GCC, such as indigenous peoples, children, and the disenfranchised poor often are not included in IPCC data-gathering procedures or policy or decision-making processes; nor is their consent sought for such decisions. For instance, when assessing GCC impacts on forestry the IPCC typically consults land managers and professional foresters, with little input from nonstate, nonexpert, nontechnical yet highly knowledgeable victims.

FUTURE WORK

There is no question that IPCC is the most highly respected and authoritative body on scientific and technological

aspects of GCC. At the same time, the way it handles scientific uncertainty, uses hidden assumptions in its socio-economic analyses, and limits full participation of groups most affected by GCC, creates ethical difficulties. Future work should better analyze the ethical issues embedded in dealing with each of these areas.

INTERNATIONAL SOCIETY FOR ENVIRONMENTAL ETHICS

The International Society for Environmental Ethics (ISEE) was founded in Boston in December 1990, at the Eastern Division meeting of the American Philosophical Association. The founding officers were President Holmes Rolston III (Colorado State University), Vice President Eric Katz (New Jersey Institute of Technology), Secretary Laura Westra (University of Windsor), and Treasurer Peter Miller (University of Winnipeg). In 2007, the ISEE had approximately 350 members, of which 76 were from twenty-six foreign countries. The ISEE has regional representatives from Africa, Australia and New Zealand, China, Taiwan, Eastern Europe, Western Europe, Mexico and Central America, South America, Canada, Pakistan and South Asia, and the United Kingdom, in addition to the United States.

The constitution, as revised in 2007, specifies the following activities of the ISEE:

- sponsor and support philosophical, educational, and scientific conferences, seminars, and workshops, solely or in cooperation with local, national, or international professional associations, meetings, and academic institutions;
- coordinate its activities with similar activities of Environmental Philosophy, Incorporated, the publisher of the journal *Environmental Ethics* (in continuous publication since 1979);
- publicize and where appropriate make available materials and media suitable for the teaching of environmental ethics and environmental philosophy;
- publish an *International Society for Environmental Ethics Newsletter* which shall communicate to the members events of interest and significance in the field of environmental ethics and environmental philosophy;
- make particular effort to relate environmental philosophy and ethics to a variety of other disciplines in ways promoting the objectives stated above;
- endeavor to publicize courses and classes in environmental ethics, environmental philosophy, and related courses, including those in biological conservation, and to facilitate exchange of information among those who teach them;

- promote undergraduate and graduate education in environmental ethics and environmental philosophy;
- run an electronic list and a web site in order to facilitate the transmission of information in the field of environmental ethics and philosophy;
- make particular effort to be global in scope of concern and membership.

The ISEE newsletter has been published quarterly since 1990. It features general announcements, news, and discussions about issues in environmental ethics and policy. In addition, the newsletter lists conferences and calls for papers, and it lists web sites, articles, and books dealing with environmental issues.

The articles and books listed in all volumes of the newsletter were collected into a comprehensive bibliography, which also lists publications in the journal *Environmental Ethics* and five additional environmental ethics journals. With over 12,000 entries, this collection is the largest bibliography of environmental ethics publications in the world. The bibliography, which receives about 15,000 hits a month, can be accessed at the ISEE web site.

ISEE regularly sponsors meetings at the Pacific, Central, and Eastern Division meetings of the American Philosophical Association. In addition, it co-sponsors an annual conference with the International Association for Environmental Philosophy each June. The ISEE also sponsors occasional sessions at meetings of American Association for the Advancement of Science, the Society for Conservation Biology, the American Institute of Biological Science, and the Society of American Foresters, among other professional and scholarly organizations. It has participated abroad at conferences of the Mind Association and Aristotelian Society in the United Kingdom, the Canadian Association of Learned Societies, and the Australasian Association for Philosophy, and it has been represented at the World Congresses of Philosophy in Moscow (1993) and Boston (1998).

ISEE was an official observer non-governmental organization at the United Nations Conference on Environment and Development in Rio de Janeiro in June 1992.

Over the years, several hundred papers representing research in environmental ethics and philosophy have been presented at these conferences, many of which have subsequently been published.

ISEE maintains an active listserv, whereby any member can contact other members on the ISEE-L list immediately by e-mail. The ISEE web site contains a wealth of information for scholars, teachers, students, and others interested in environmental ethics. In addition to the archive of newsletters, the listserv and the bibliography, the web site assists teachers of environmental ethics with its collection of course syllabi and with lists of leading textbooks and articles in the field. The ISEE web site also lists graduate programs in environmental ethics, related scholarly and public associations and publications, and funding opportunities, and it summarizes theses and dissertations completed in the field.

The ISEE web site is the best source of information about the International Society for Environmental Ethics, and the best avenue of approach for those who might be interested in joining the society. Questions to and comments for the members of the society are best circulated through the listserv.

Ernest Partridge

INTRINSIC AND INSTRUMENTAL VALUE

The distinction between intrinsic and instrumental value has been central to environmental ethics since its inception as a distinct area of study in philosophy, to the point that some authors believe that the search for intrinsic value in nature is the most fundamental quest of environmental ethics. In fact, this dichotomy is so fundamental that it is possible to create a taxonomy of rival schools of environmental ethics by reference to it, including those that consider the distinction and its various permutations to be less important than most others do. Although some environmental philosophers prefer the terms *inherent* to *intrinsic* and *worth* to *value*, the term *intrinsic value* has now become standard in the field.

THE ORIGIN AND SIGNIFICANCE OF THE DICHOTOMY

The opposition between intrinsic and instrumental value is not an invention of environmental ethics; such a distinction has surfaced in various guises throughout the history of philosophy. Traditionally the opposition between instrumental value and intrinsic value has been posed in this form: How can means, or a sequence of means, relate to an end, to something that is not itself the means to

another end (cf. Plato's *Republic*, Book 2. and Aristotle's *Nicomachean Ethics*, Book 1, for early discussions of the distinction)? If there are instrumental values that are means to ends, then there must be ends that have, by contrast, intrinsic value—ends that are not means to other ends but are ends in themselves. If an infinite regress of means is irrational, then sequence of means must stop at some point—at the end in itself. This is the familiar, classic argument that Richard Routley and Val Routley (1980) employed in some of the earliest papers in the field.

In environmental ethics, however, attributing intrinsic value to the entities of the natural world (or the discovery that these entities have such value) is a first step toward endowing them with moral status. This ethical regeneration of nature arose in the wake of the fierce denunciation of the anthropocentric nature of European and North American culture in a seminal article by Lynn White Jr. in 1967, published in *Science.* White attributed the contemporary environmental crisis to an anthropocentrism that, he argued, lies at the root of Christianity. In his view the triumph of Christianity over paganism was "the greatest psychic revolution in the history of our culture" (White 1967, p. 1204).

Two worlds were in conflict: On the one hand, there was the fundamentally animist world of Greco-Roman antiquity, in which people believed that all natural entities are guided by a tutelary deity or spirit, so that someone intending to intervene in the course of nature would need to gain the favor and win the graces of the presiding spirits; on the other hand, there was the monotheist world of Christianity, in which a de-deified nature could be exploited in indifference to the feelings of the now exorcised natural spirits and demigods. This disenchanted world, reduced to a state of passive inertia, could be subjected to technoscientific manipulation in the service of humanity's interests. In the Christian cosmogony nature lost its intrinsic value and was reduced to pure instrumental value—a mere tool in the hands of human masters. From the perspective of modern neoclassical economics, nature is a pool of interchangeable raw materials for human use and consumption; if humans exhaust one natural resource, such as great whales, other resources can be substituted with no loss of value.

In contrast, a nonanthropocentric environmental ethic—the cornerstone of which is the theory of the intrinsic value of nature—is a radical departure from this representation of a human-nature relationship in which humans are first and everything else a bad last. Environmental philosophers initially seized on Aldo Leopold's *A Sand County Almanac* as a possible point of departure; in Leopold's words, "men are only fellow-voyagers with other creatures in the odyssey of evolution," an implication he drew from the Darwinian worldview (1949, p. 109). A suitably modified theory of descent and the phylogenetic-tree image might undermine the prevailing anthropocentrism and foster greater receptivity to the possibility that some nonhuman natural entities and/or nature as a whole might have intrinsic value.

If humans are seen as members of a biotic community, coevolved with other members, the boundaries of the ethical community might extend to encompass the entire biotic community. Indeed, some philosophers think that environmental ethics owes its uniqueness to its openness to the possibility that nonhuman beings and the abiotic components of the natural world have moral status. One clear route to conceiving of such entities as objects of moral consideration is either to reveal that they have previously unnoticed intrinsic value or to confer intrinsic value on them as we might confer the right to vote on previously disenfranchised citizens. Encouraging environmental conservation and preservation as means to human prosperity and well-being would make environmental ethics a mere complication of human-to-human ethics. If environmental ethics is a distinct form of ethics, it demands taking the nonhuman environment into direct consideration because of an intrinsic value that, once acknowledged, places it beyond the realm of a mere natural resource for human exploitation. By analogy one might oppose slavery because it is economically backward; the prosperity and well-being of slave owners might be served by emancipation, but that is an argument based on criteria of efficiency or self-interest, not ethics. An ethical antislavery argument would require a recognition of the intrinsic human value of the slaves, not merely their instrumental value—or lack of it—to the slave masters.

THE BASIS FOR MORAL OBLIGATION

An environmental ethic must first determine a defensible criterion for intrinsic value and then apply it in judging which natural beings possess intrinsic value and to what degree. A second task is the anchoring of moral obligations and human responsibility to the environment in a recognition of intrinsic value in nature. Since the late 1970s three major approaches to these tasks have emerged in the work of Paul W. Taylor, Holmes Rolston III, and J. Baird Callicott.

According to Paul W. Taylor, all living individual (wild) organisms—whether they are animal, vegetable, or unicellular organisms—have intrinsic value because they are teleological centers of life (1981). In the effort to realize their shared goals of living, flourishing, and reproducing, they have developed complex adaptive strategies that are the means in the service of their ends. Therefore a multitude of self-valuing, goal-seeking individuals exists in nature, independently of any human valuation of them. According to Taylor, the affirmation of an

"inherent worth" in the nonhuman world is sufficient to generate prescriptive or prohibitive norms that do not center on human beings; among the first is the rule of noninterference, which prohibits the hindrance of the development and the prosperity of these life forms.

Holmes Rolston III (1994) agrees with Taylor's criterion for intrinsic value but harbors doubts that such a "biocentric ethic" is suitable for developing measures to protect not just individual living organisms but also species and entire ecosystems, which include abiotic elements. As for species, they are the ends that individual organisms strive to attain. An organism's developmental trajectory ends in a fully developed specimen of its species, and what it reproduces are more specimens of that species. Ecosystems are the theater of the evolutionary play and thus are productive of all the diverse forms of life, each of which has intrinsic value. Rolston describes with an abundance of detail the evolution of life on earth as it was made intelligible by Darwin while drawing attention to the formidable creativity of the evolutionary process so that it commands our respect and admiration. It is for this purpose that Rolston invites his readers to consider more carefully the scope and diversity of the living world and to ponder its wonders of organization, self-regulation, and functional integration. Seen from this angle, asserting that a natural being possesses no value independently of human consciousness appears parochial and narcissistic because many such beings have long had their own genetically embedded agendas that they strive to realize.

But a natural being is itself only part of a whole; it is a member of a species that is adapted, through the evolutionary process, to the ecological niche that it inhabits. And the ecosystem that it inhabits is itself closely connected to a network of ecosystems hierarchically structured in successive levels of integration. That being so, although natural beings individually construct their intrinsic value, this value is transferable, passing successively from individual natural beings to the species, and from there to all the interrelated and hierarchically structured ecosystems in which the species function.

J. Baird Callicott (1986) follows another course. He attempts to construct an environmental ethic that is just as inclusive, but in the framework of a subjectivist theory of value that carefully distinguishes between the site that has a value and the source of all values. An ethic of anthropogenic values that views any valuation as the result of human conscience is not necessarily anthropocentric because it does not reduce all values—except the value of human beings—to the status of instrumental values. This theory joins forces with the Leopold land ethic. Callicott argues that *value* is first and foremost a verb, and a noun only derivatively, and that *instrumental* and *intrinsic* are, therefore, adverbs, not adjectives. Something has value, in other words, only if it is valued by a conscious being capable of intentionality. There are two basic ways in which intentionally conscious beings value: instrumentally and intrinsically.

All conscious beings value aspects of their worlds instrumentally—as bats, for instance, value caves for the shelter they provide. But, as Rolston effectively points out, all conscious beings value themselves intrinsically. By a kind of metaphorical extension, Rolston argues that even nonconscious organisms like plants value themselves intrinsically, to the extent that they vigorously compete with other plants for sunlight, water, and nutrients. Therefore, Callicott argues, despite his protestations to the contrary, Rolston's outlook is also a subjectivist theory of intrinsic value. Organisms have intrinsic value because they value themselves. Human beings and perhaps some other robustly conscious animals are capable of ascribing intrinsic value not only to themselves but also to other entities. Although it is logically possible to value anything intrinsically, people normally do so only for good reasons. In addition to providing a cogent analysis of intrinsic value, part of the work of environmental philosophers, according to Callicott, is to provide people with good reasons to value the natural environment intrinsically. Leopold's *A Sand County Almanac* is perhaps the most effective effort so far to provide such reasons. More recent works, such as E. O. Wilson's *The Diversity of Life* also do that kind of work well.

CRITIQUES AND CONTROVERSIES

There is reason to wonder, however, whether the foregoing discussion is based on a misunderstanding. There are two possibilities: (1) Environmental ethicists genuinely aim to guide policies by subjecting them to rational standards, in which case their failure to achieve this objective so far should encourage them to consider what it is in their way of expressing and dealing with problems that has prevented them from succeeding and how they can adapt their discursive strategy to the realities of politics; (2) or the theorists of environmental ethics choose to indulge their metaphysical wrangles over the intrinsic value of natural entities in oblivion to the practical implications of their work.

This criticism was first formulated by Bryan G. Norton (2005) and was the starting point of what has become a dominant school of thought in environmental ethics: environmental pragmatism. Norton observes that the debate between anthropocentrists and nonanthropocentrists is futile insofar as the major concept of "human interests" (or human utility), on which the whole discussion turns, is left undefined. In fact, Norton argues, satisfying human interests does not necessarily involve the irreversible

destruction of the object of desire; he makes a distinction between a utility that is satisfied by the immediate consumption of natural goods and a utility that implies the conservation of the useful object, conservation being a prerequisite for the continued satisfaction of human interests. Norton insists that programs for the protection of the environment are perfectly justifiable on the basis of a sufficiently broad and long-range interpretation of anthropocentric instrumental values—broad enough to transcend the traditional division of human values into only two categories: instrumental and intrinsic. That dichotomy, in his view, fails to express the whole range of values that human beings actually attribute to nature. Rather than force all the diverse values into the straitjacket of a binary theory of value, Norton proposes a plurality of human values situated on a continuum ranging from the consumptive and self-oriented to nonconsumptive concerns such as aesthetics and spirituality. He also explores a new type of value, "transformative value": a nonconsumptive valuing of nature that can transform unself-critical preferences into expresssions of higher ideals.

Some scholars dispute Norton's assumption that the idea of intrinsic value is politically ineffective. To the contrary, intrinsic value has become the war cry of many advocates of the protection of nature, including members of Greenpeace, the Wilderness Society, and Earth First! Judging from the example of the preamble to the International Convention on Biological Diversity, the belief in the existence of intrinsic values in nature is playing an increasingly important role in the development of environmental attitudes and policies worldwide.

INVASIVE SPECIES

The global distribution of plants and animals has evolved over many millions of years, having been influenced by oceanic and mountain barriers (Elton 1958). Although such geographic isolation led to major speciation, species still dispersed where geographical barriers permitted, either to avoid deteriorating home ranges or to take advantage of potentially new resources (Stenseth and Lidicker 1992). However, since early humans started to migrate, natural barriers to plant and animal dispersal have been broken down and species have been translocated ("introduced") deliberately or accidentally to new ecosystems. The rate at which these introductions occur has increased significantly over recent decades as a result of increased globalization of travel and trade.

When released from their native predators, competitors, and diseases, some species become well established and abundant and have a significant impact on natural environments, agriculture, and human health and infrastructure. Often these invasive species or invasive alien species (IAS) have to be managed (i.e., killed), but in dealing with a sentient species conflict can arise between those wanting to protect the indigenous species and ecosystems threatened by the IAS and those wanting to protect individuals of the IAS.

Those conflicts have led to debate between proponents of individual-based ethics and proponents of ecocentric ethics.

CONSEQUENCES OF INVASIVE ALIEN SPECIES

Internationally, biological invasions pose the second biggest threat to biodiversity loss after habitat destruction; in the United States, with more than 50,000 IAS, damage and losses to agriculture, forestry, fisheries, and other human enterprises are estimated to cost $120 billion per year (Pimentel, Zuniga, and Morrison 2005). Internationally, about 80 percent of endangered species are threatened through competition or predation by IAS; island biotas are especially vulnerable.

With continuing globalization and the resultant increase in travel and trade, national borders are being increasingly challenged by new biological invaders. Although the most effective way to prevent potential IAS from establishing themselves is to prevent their introduction, that outcome often is not achieved because of commercial imperatives. Both international and national legislation and policy are established to facilitate trade, with most policy (e.g., World Trade Organization) including a presumption of safety and requiring proof that the introduction of a species poses a significant risk (Simberloff 2005). However, there is often insufficient evidence of harm to defend a case against such a nonprecautionary policy. As an exception, New Zealand's Biosecurity Act of 1993 was the first national law that did not presuppose innocence. Conflicts can arise when precautionary trade tariffs or restrictions are seen as disguised protectionism. Policy makers appear to fail to recognize that the benefits of an introduction often accrue to only a few whereas the wider society has to bear the substantial cost if an introduced species becomes invasive.

ETHICAL ISSUES

Because some IAS threaten indigenous species, communities, and ecosystems or cause significant economic losses, action to mitigate their impacts results in a reduction in their abundance or their eradication. However, especially when IAS are sentient, there is never universal agreement on whether control is necessary or, when it is, how it should be implemented. The extent to which an introduced species is characterized as good or bad is a value judgment, and such judgments often lead to conflicts. Philosophers such as Mark Sagoff (2005) suggest that an invasive species policy based on aesthetic, ethical, or spiritual values might be legitimate, but when based on nebulous concepts of biodiversity, harm, and impact, that policy can be challenged.

Mitigating the impacts of IAS often requires the use of lethal trapping, shooting, or poisoning, but when used against sentient species, such actions often are considered unethical. There are two major philosophical positions:

An Invasive Species in New Zealand. *The Common Brushtail Possum (*Trichosurus vulpecula*) was introduced into New Zealand from Australia in the 1800s to establish a fur trade. It is now New Zealand's most invasive mammal species, modifying native forest ecosystems and spreading Bovine Tuberculosis to livestock.* **© TOBIAS BERNHARD/OXFORD SCIENTIFIC IMAGES/ PHOTOLIBRARY.**

one focusing on individuals (animal rights and animal liberation) and the other on communities and ecosystems (holistic eco- or biocentric ethics). Those holding a strict animal rights position (Regan 1983) argue that sentient animals have a "right to life," and so individuals of an endangered species are no more or less worthy of moral concern than are nonendangered species such as an IAS. Animal liberationists argue that the interests of sentient animals should be given equal moral consideration and their capacity to suffer must be considered. Anything less would be speciesist.

These conflicting positions do little to support effective management, especially when many thousands of sentient IAS have to be culled to protect nonsentient species (e.g., goats culled to protect vegetation) or only a few sentient individuals (e.g., thousands of rats killed to protect a few individuals of a threatened bird species). Because these individual-based ethics often do not provide clear guidance on what is morally acceptable, especially when ecosystems clearly are being degraded, those concerned about communities and ecosystems argue for an ecocentric ethic that recognizes ecosystems and communities as moral subjects that have intrinsic value (Callicott 1980). However, proponents of ecocentric ethics fail to support effective environmental management because they do not deal adequately with the multiple

values that pervade environmental issues. Bryan G. Norton (1995) suggested an alternative pragmatic, pluralistic, and policy-based approach that recognizes that humans value things in different ways, that those values may be context- or site-dependent, and that differing values often are in conflict. Although not providing a unified ethic, this approach provides a process for dealing with the reality of managing natural environments in the face of uncertainty and in the presence of multiple values.

Often the ethical debate confuses the why (justifying control) with the how (what methods can be used to cull animals). In relation to the how, most people accept the idea that minimizing harm is good, and utilitarian theory provides an effective framework for doing this. However, in most cases the benefits cannot be quantified easily, and so this approach is essentially a harm minimization approach. Thus, control methods that cause the least harm should be used whenever possible. As Peter Singer (1997) suggested, because humans have created a bad situation and must deal with that reality, the way forward is to seek the least bad way out.

The most invasive species on earth is *Homo sapiens,* but even though humans threaten more native species, communities, and ecosystems than do any other IAS, they do not act to minimize this harm as they would for other IAS. Thus, the question arises: Are people therefore speciesist?

ISLAM

Islam is an Arabic term, literally meaning "submission"—that is, to the will of Allah. A monotheistic religion having arisen in the Arabian Peninsula during the early seventh century, in the twenty-first century Islam counts some 1.3 billion individuals worldwide who identify with the tradition on some level. The largest concentration of Muslims today is found in the South Asian countries of Pakistan, India, and Bangladesh (about 350 million, or a third of the world total), and the country with the largest Muslim population is Indonesia (about 200 million). By contrast, about 25 percent of Muslims live in the Middle East, and Arabs today constitute only about 15 percent of the world's Muslim population.

FOUNDATIONS

According to Islamic tradition, a pious merchant from the west Arabian town of Mecca, Muhammad son of Abdallah, began in the year 610 to receive divine revelations during the course of a mountain retreat. These revelations, transmitted from God to Muhammad via the angel Gabriel, continued over the course of the next twenty-three years until Muhammad's death in 632. Collectively, this body of divine revelation is known as the Qur'an ("recitation").

The Quranic text is divided into two periods of revelation, each thematically somewhat distinct. The first period corresponds to Muhammad's early prophetic career in his hometown of Mecca, where his message attracted a growing number of followers, especially from the more marginalized segments of society, while increasingly alienating most of Mecca's elites. This led the latter to begin persecuting Muhammad and his followers, who eventually accepted an invitation from the inhabitants of Yathrib, a town to the north, to settle there. Yathrib, which became known as Madinat al-nabi (The city of the prophet), or Medina for short, served thereafter as a power base from which Muhammad and his followers the Muslims (literally, "the submitters") could launch raids against the caravans of their Meccan enemies. Generally speaking, the earlier, Meccan revelations emphasize such themes as the oneness of God (contradicting the largely polytheistic culture of Arab religion at the time), and the accountability of humans before God's justice. The later, Medinan revelations are often more concerned with how human societies should be ordered.

ISLAMIC VIEWS OF HUMANS AND NATURE

The Qur'an states that Allah is the all-powerful creator of the universe and all it contains, and that the proper role of humans is that of *khalifa* (2:30, 6:165), a term generally understood in this context as meaning a steward or vice-regent. Creation is said to be good, and all aspects of it are miraculous signs (*ayat*) proving the existence of God. All of creation, moreover, is said to praise God, though humans may not perceive it (17:44). Nonhuman species are said to constitute "communities" similar to those of humans (6:38). In fact, humans are distinct only in that they possess a conscious will (*taqwa*), making them morally answerable to God for their actions. Islam is described as the religion of *fitra*, "the very nature of things," and all created beings are said to be originally "muslim," in that their nature is to submit to God's will, but many humans err by choosing not to do this. Accordingly, it may be said that of all created beings, humans alone have a potentially problematic relationship with Allah.

While the Qur'an explicitly states that the Earth was created for all beings and not just for humans (55:10), it is also stated that certain species (particularly domestic animals) were created to serve humans (16:5–8). Given that Islam accords the special status of *khalifa* to humans, it could be said to be an anthropocentric religion, though Muslims often prefer to call their faith "theocentric." Because creation belongs to God, humans are not to engage in activities that cause it harm (2:205, 7:85). Wastefulness and excess consumption are likewise condemned (7:31).

According to the hadiths (Muslim oral traditions), which, being far more voluminous than the Qur'an, actually serve as a more frequent basis for Islamic norms, the Prophet possessed what might be termed a kind of "environmental consciousness" that was perhaps characteristic of the Arabs in general as they had to survive in a marginal environment providing limited natural resources. The Prophet instructed Muslims to respect plants and animals, to conserve water, and to set aside certain

"No Hunting Area," Kfar, Lebanon. *A young cowherd manages his cows in the "no hunting area" in the village of Kfar Zabad. A pre-Islamic system of environmental protection, born over 1500 years ago in the Arabian desert, is being revived with great success. The community based system, called hima, means that a local population, rather than distant Beirut authorities, decides how to manage its ecosystem, and reap the benefits.* **HASSAN AMMAR/AFP/GETTY IMAGES.**

lands as preserves (*hima* and *harim*). Among Muhammad's best-known sayings cited by contemporary Muslim environmentalists are "The entire earth is a mosque" and "Live in this world as if you will live in it forever, and live for the next world as if you will die tomorrow."

It is often argued by Muslim environmentalists today that the sharia (body of religious laws), if applied to the letter, contains adequate restrictions to ensure a use of natural resources that is both sustainable and just. Resources such as water, air, and wildlife are deemed to be common property, and the utilization of resources is supposed to be determined by the following principles, among others: 1) nonvital needs are subordinated to vital needs; 2) the needs of the poor take precedence over the needs of the rich; and 3) one may not cause harm in order to obtain a benefit. As in any human society, however, these principles remain ideals and often have not been followed in practice.

Classical Islamic philosophy, which thrived from the ninth through the eleventh centuries, was derived to a large extent from Greek philosophy and incorporated much of the Greeks' views of nature. Islamic philosophers coined the Arabic term *tabi'a* to represent the Latin and Greek equivalents *natura* and *physis*, and equated the divine will with Aristotle's first cause. The Islamic philosophers largely followed the Greek model of the cosmos, which they understood to be spherical in shape and bounded by the stellar field. The planets, the sun, and the moon occupy the middle layers, with the Earth constituting the center. The heavenly world (*al-'alam al-a'la*), though made up of ether in contrast to the lower world (*al-'alam al-asfal*) which is comprised of the four elements, shares with it the qualities of heat, cold, moistness, and dryness and acts upon the lower world accordingly. The Earth's geography was most often understood in terms of the pre-Islamic Iranian divisions of seven concentric climes (*keshvar*s), although the fourfold division of the Greeks and the ninefold version of the Indians were also known.

The Islamic philosophers affirm the position of humans near the top within the hierarchy of created beings, below angels but above other animals, plants, and minerals. Humans are the mediators between the heavenly and earthly realms and a major channel for divine grace. The human body, furthermore, is perceived as a microcosm of the universe, with specific parts of the body being identified with parts of the zodiac and thus subject to their influences.

Muslim mystics, known as Sufis, have tended to interpret Quranic references to the oneness of God (*tawhid*) as indicating an underlying unity to all reality. The Andalusian mystic Muhyi al-din ibn 'Arabi (1165–1240) described creation in terms of "unity of being" (*wahdat al-wujud*), an idea that won wide popularity among Sufis, especially in South Asia where his work remains highly influential. Many mainstream Muslims have found this belief to verge dangerously close to pantheism, however; the eighteenth-century Indian Sufi teacher Shah Waliullah (1703–1762) preferred the term "unity of witness" (*wahdat al-shuhud*) as more clearly maintaining the distinction between creator and creation.

The Sufi notion of the "complete man" (*insan al-kamil*), also elaborated by Ibn 'Arabi, expands the conception of the human being as microcosm of the universe. For Sufis, cultivation of the individual is analogous to cultivation of the cosmos as a whole; thus, one's personal spiritual development can affect the entire world.

To Sufis such as Jalal al-din Rumi (1207–1273), not just animals and plants but the entire universe of creation is alive. "Earth and water and fire are his slaves," he writes in the *Masnavi-yi ma'navi*; "With you and me they are dead, but with God they are alive" (1.838). Nature also speaks, though only the mystics realize this: "The speech of water, the speech of the earth, and the speech of mud are apprehended by the sense of them that have hearts" (1.3279). The conversations of nature are indicative of affective relationships: "You yourself know what words the sun, in the sign of Aries, speaks to the plants and the date palms / You yourself, too, know what the limpid water is saying to the sweet herbs and the sapling" (6.1068–69). Moreover, the Sufis often employ the symbolism of love (*'ishq*) to describe the relationship of mutual attraction between the creator and his creation. Yunus Emre, a thirteenth-century Turkish poet, composed the famous line, "We love all creation for the sake of its creator."

Many Sufi tales, such as those found in the works of Rumi, Farid al-Din Attar (c. 1142–1220), and others, include animal characters, though these are almost always stand-ins for human characteristics associated with particular species. Nonhuman animals are seen as occupying a level below humans and the "animal soul" of the philosophers is equated by the Sufis with the "lower self" (*nafs*), or one's own baser instincts that, along the path of spiritual development, one strives to overcome.

CONTEMPORARY ISLAMIC ENVIRONMENTAL THOUGHT

While the preceding observations could indicate a basis for environmental ethics in the Islamic tradition, to project present-day environmental understanding onto any pre-modern society would be inappropriate. Among Muslims, as is the case with all human societies, environmentalist discourse today is in many respects distinctly contemporary and is emerging in response to particularly modern problems and ways of thinking. Despite the presence of some apparent attention to environmental protection in the classical Islamic texts, in general it

would seem that Muslim societies historically caused no more or less damage to the environment than others. These same societies today share the problems common to all developing countries, including severe and in most cases worsening environmental degradation.

Islamic environmentalist thinking as such emerged only toward the end of the twentieth century. Moreover, it has come largely as a defensive or apologetic response to Western environmentalist critiques, and remains unknown to the majority of Muslims who are far more preoccupied with issues such as international and domestic politics, social justice, and gender roles. On the other hand, because environmental problems in countries where Muslims live have become so severe, a certain awareness of these problems is on the rise.

The Muslim probably having the best claim to be the first contemporary Islamic environmental ethicist is the Iranian-American philosopher Seyyed Hossein Nasr, who attributes his environmental awakening to walks in Walden Woods during the 1950s. His identification of human mistreatment of the environment as arising from a crisis in values slightly predates Lynn White Jr.'s famous 1967 essay "The Historical Roots of Our Ecologic Crisis." Contrasting the Islamic tradition to White's portrayal of the Christian West, Nasr argued in a number of works that Islamic science never lost its reverence for the sacredness of nature, and his attribution of Muslims' loss of environmental consciousness to pernicious Western influence has been taken up by many if not most subsequent Muslim environmentalist writers. It may be noted that Nasr, like most Islamic environmentalists, lives in the West and writes in English, largely for a non-Muslim audience, though some Islamic environmentalist works have begun to appear in Muslim countries and languages, including translations of earlier works published in the West.

Perhaps the first explicit attempt to articulate an Islamic position on environmental protection was a short tract commissioned by the World Conservation Union (IUCN) in 1983 and written by a group of Islamic legal scholars then based in Jeddah, Saudi Arabia. The resulting text was published in English, French, and Arabic, but very poorly circulated. One of the authors, the Iraqi-born Mawil Izzi Dien, went on to write a number of articles on Islam and the environment as well as the first full-length book on the subject, which he published in 2000. Izzi Dien has been engaged in attempting to establish a Centre for Islam and Ecology at the University of Lampeter, Wales.

A major watershed in the emergence of Islamic environmentalist discourse was the conference on Islam and ecology organized by Mary Evelyn Tucker and John Grim at Harvard University in 1998. Some forty Muslim scholars, politicians, and activists from around the world participated, and the resulting volume of papers, published as *Islam and Ecology: A Bestowed Trust* in 2003, is the largest single collection of writings on Islam and the environment as of 2007. Similar conferences have since been held in Muslim countries, including Saudi Arabia and Iran, and a growing number of scholarly and popular articles on Islam and the environment are appearing worldwide.

CONTEMPORARY MUSLIM ENVIRONMENTALIST MOVEMENTS

It should be noted that while increasing numbers of Muslims worldwide are engaging in environmental activism, their activism is more often motivated first by environmental concern than by religious belief. Thus much of this activism seems more "Western" than "Islamic," and many Muslim activists are only marginally religious or not at all. In the case of activists who are also believers, in most cases it would appear that the individuals involved first become committed to the environmental cause, then subsequently seek to understand and justify it in terms of their Islamic faith.

Similarly, while most governments of Muslim countries now have departments devoted to environmental protection, they are typically staffed by Western-trained scientists and policy-makers who often do not share many of the values of the broader society. The environmental programs initiated by such government organizations, which often focus more on the interests of tourism or local elites than on genuine environmental needs of the population (such as clean water, garbage collection, and so on), are frequently seen as ineffective or even illegitimate.

Moreover, in all Muslim countries, as elsewhere in the world, environmental concerns are almost invariably subordinated to the demands of development. Economic constraints limit the implementation of environmental protection programs and up-to-date technologies, and corruption and cronyism often privilege industrial and commercial interests at the expense of the environment. Finally, policies imposed by external organizations such as the International Monetary Fund (IMF) and the World Bank often lead to an increase in environmentally destructive activities and unsustainable projects which disproportionately hurt the poor.

Nevertheless, a small number of Muslim environmentalist organizations have proven effective, some of them promoting explicitly Islamic values. The most significant such organization is the Islamic Foundation for Ecology and Environmental Sciences (IFEES), established in Birmingham, England, by Fazlun Khalid. Since the early 1990s IFEES has conducted environmental education campaigns based on Islamic principles throughout the Muslim world. Among its successes are persuading the Muslim fisherman of Zanzibar to cease fishing with dynamite, and

getting religious schools in Indonesian villages to add environmental issues to their curriculum.

One Muslim country where suspicion of environmentalism as an alien Western ideology is largely absent is the Islamic Republic of Iran, where environmentalists have sought government approval by articulating their message and justifying their activities by using Islamic language. The Iranian government, for its part, has adopted strongly environmentalist rhetoric, though its environmental policies are often not put into action. One area in which Iranian government policies have been effective has been human population control. Beginning in the late 1980s an official policy of family planning was adopted, providing for women's health clinics and free contraceptives across the country, with the result that by the year 2000 Iran's fertility rate had dropped to only 1.8 births per woman, lower than that of many Western nations. This success story stands in contrast to most of the rest of the Muslim world, where population control is largely seen as Western propaganda and incompatible with traditional preference for large families. Recently, however, Indonesia has seen some success in implementing family planning programs as well.

While environmental awareness and familiarity with Islamic principles concerning proper attitudes toward nature remain extremely marginal throughout the Muslim world, this is slowly changing as Muslims increasingly suffer from the effects of severe environmental degradation and seek appropriate responses from within their own religious and cultural traditions.

ISRAEL AND THE MIDDLE EAST

Respect for individual human life and the protection and promotion of health for all are among the core ethical values of Judaism, Christianity, and Islam. These core values imply the prevention of the environmental destruction, depletion, and contamination that jeopardize life, fertility, and reproduction for future generations. (World Congress of Imams and Rabbis for Peace 2008; Hessel 1998, Izzi Dien 1990). In all three a concern for equity in particular requires protection of the weak—a concept that merges with the environmental principle that protection of all from toxic exposures comes from protecting the most vulnerable from the effects of these exposures (Abumoghli 2006).

A HERITAGE OF REGIONAL CONFLICT

Can respect for life and health and a sense for conservation of environment overcome the region's endemic fanaticism and chronic incitement to terror and hate—which have led it to squander life and much of its capital, resources, and energy? Nearly one million people are estimated to have died in battle during the Iran-Iraq war (1980–1988); according to the Human Rights Watch Web site (1993), the genocidal campaigns of chemical warfare against the Kurds in Iraq under Saddam Hussein's rule are estimated to have claimed more than 150,000 lives, and 151,000 deaths are estimated to have followed the U.S. invasion of Iraq in 2003 (Brownstein and Brownstein 2008).

In the Darfur region of Sudan, desertification triggered a conflict between herders and farmers that served as the pretext for genocide (estimated 400,000 deaths) and ecocide (Richter et al. 2007). Its perpetrators were protected and supported by an outside enabler—China, coveting Darfur's oil reserves. On a much smaller scale, Israel and the Palestinian Authority, locked together in a tiny landmass, face choices between win-win strategies or

zero-sum strategies for protecting the land's carrying capacity and the health of its ecosystems. According to Israeli-Palestinian ProCon Web site (2007), some 4,400 Palestinians—nearly all young males—and more than 1,000 Israelis—from all ages and groups and both sexes—have been killed since September 2000, when the terror attacks of the second Intifada were initiated.

History tells us what happens in the region when there is war, conquest, exploitation, and depletion of environmental resources. In first-century Roman Judea (with a population of less than one million), Jewish farmers were able to feed their families and sell surplus yields of barley, grapes, figs, olives, and pomegranates. But Roman overtaxation of homestead farmers in the Judean hills—and throughout the Mediterranean area—triggered a slow but inexorable chain reaction of overcultivation, followed by loss of soil fertility, abandonment of terraced farmsteads, breakdown of hillside terracing, erosion, further loss of fertility, mass flight to the cities, cutting down of hillside forests to supply wood for building in the cities, and then urban poverty, unrest, riots, and hunger. The Judean hills west of Jerusalem have never fully recovered their fertility, although the rich silt that washed down to coastal areas from the depleted hills became the basis for agriculture in later centuries (Sperber 1974, 1991).

This three-to-four-century scenario of depletion and hardship occurred in a traditionally poor agrarian and mostly autarchic society forced to extract too much from its environment. In Jesus' time, most of the population of Roman Palestine was desperately poor, living on the edge of subsistence. The land's carrying capacity was determined by what it could grow. Today 7 million Israelis and 3 million Palestinians live west of the Jordan River; the once-agricultural coastal areas are now covered by cities, suburbs, highways, factories, military bases, and airports. Less than 3 percent of the Israeli economy is now based on agriculture. The economies of the Gaza Strip and the West Bank are still mainly agricultural. Nevertheless, the carrying capacity of Israel and the Palestine Authority's societies is determined only partly by agricultural yields and far more by their participation in the global economy, which requires access to energy, capital, the information economy, markets, trade, and the capacity for governance, civil society, stability, and social cohesion (Richter 2006). Political instability, war, emigration, and brain drains can disrupt, destroy, and deplete a society's human and natural capital. During the summer of 2006, missile, artillery, and air attacks from terror groups in Gaza and Lebanon—and the ensuing counterattacks—produced loss of life and limb, oil and sewage spills, forest fires and smoke, asbestos contamination, and an array of public health emergencies associated with the breakdown of everyday community-support services. Stepped-up terror attacks and bigger wars, with or without nuclear weapons, will bring much worse.

Israel, the Palestinian Authority, and Jordan, although separated politically, belong to a common ecosystem sharing the same water, air, arable land, and, to a considerable degree, pollutants and exposures to toxic substances (Abumoghli 2006, Richter 2007).

The dispersion of air pollutants and the flow of toxins in streams, subterranean aquifers, and sewers obey the physical laws of energy, gravity, and hydrodynamics, not politics. Global climate change, with its risks of coastal flooding and spread of desertification, along with the progression northward of vector-borne diseases by mosquitoes from tropical areas, pose an emerging region-wide risk.

Israel's population is much wealthier and healthier than those of its nearest Arab neighbors—and its tiny size obscures the fact that its ecological footprint per capita, along with Saudia Arabia, is greater than that of its neighbors, though smaller than that of major Western countries (see Table 1).

These differences pose the question: Can wealth and health be generated and sustained across the Middle East without producing enduring damage to the region's carrying capacity? So far, most of the time, governments of all the countries in the region have been too preoccupied with military threats and, by and large, have, until recently, regarded environmental concerns as an impediment to development or a distraction—except when pressured by advocacy groups—or by what appear to be sudden shortfalls, such as the current water crisis.

WATER RESOURCES AND WATER QUALITY

There always has been a water crisis in the Middle East. Population growth has always expanded to the limits of the scarcest available resource, which has usually been water. The Egyptians and Sumerians built elaborate irrigation systems based on the waters of the Nile and the Tigris-Euphrates. Later, the Nabateans who inhabited Israel's desert—the Negev—and Jordan, built gigantic networks of cisterns and irrigation canals to catch rainfall and runoff from flash floods in the Negev desert. Aqueducts built during the reign of Herod (ruled 37–4 BCE) brought water to the Second Temple—but Jerusalem's inhabitants collected rainwater in cisterns (Isseroff 2001).

Today Israel obtains nearly half its water from the National Water Carrier connected to a rapidly sinking Sea of Galilee and the rest from wells that tap into aquifers in the coastal area. These wells, many of which are now contaminated, are recharged by waters coming off the mountain watershed of upstream sources in the Sea of Galilee and back into Syria, Lebanon, and Jordan.

Ecological Footprint (Global hectares per person, in 2003 gha)

Country	Total population (millions)	Ecological footprint	Cropland	Grazing land	Forest: timber, pulp and paper	Forest: fuel wood	Fishing ground	Co2 Fossil fuels	Nuclear	Built-up land	Water withdrawals per person (1000m^3/year)2
Iran	68.9	2.4	0.52	0.13	0.04	0.00	0.08	1.52	0.00	0.09	1071
Iraq	25.2	0.9	0.10	0.02	0.00	0.00	0.00	0.75	0.00	0.00	1742
Israel	6.4	4.6	0.88	0.12	0.29	0.00	0.37	2.88	0.00	0.07	325
Jordan	5.5	1.8	0.49	0.07	0.08	0.01	0.20	0.82	0.00	0.09	190

SOURCE: From Richter, Elihu. (2006). "Toxic Exposure in a Shared Ecosystem." *Bridges Magazine* 2 (6). Available from http://www.bridgesmagazine.org/nindex.php?page=issues.12.4.

Table 1. *The ecological footprint measures the estimated impact of human activities on the environment in terms of the surface area required to produce everything that an individual or population consumes (transport, accommodation, food, etc.) and to absorb the resulting waste. It is expressed in hectares (ha) per person per year.* **CENGAGE LEARNING, GALE.**

Most Israelis—but not Palestinians or Jordanians—currently have enough water to drink, wash, cook, and dispose their sewage, and the disparities represent major asymmetries in power, economic development, governance, management, and maintenance as well as exploiting of latest technology, for example, desalination.

Contrary to widespread belief, problems with regional availability of adequate and safe water are a consequence rather than cause of the conflict. The water shortages have resulted from regional mismanagement, waste, poor conservation policies, conflict, and zero-sum policies rather than region-wide resource deficiency, as can be seen in the bar graph on water supply and consumption for the countries (see Figure 1).

Ever-expanding demand clearly requires desalination, more conservation, recycling, recovery, reuse of waste effluent, and domestic harvesting of water, the latter as in Roman times—and tradeoffs between water-rich and water-poor countries. Contamination of large aquifers with small amounts of toxins spoils their waters for drinking, washing, and domestic cooking; there is a clear need for zero-permissible emission standards for toxins from industrial and agricultural sources (Marei 2006, Isseroff 2001).

Supply and Demand of Water in the Middle East, 2000

Figure 1. **CENGAGE LEARNING, GALE.**

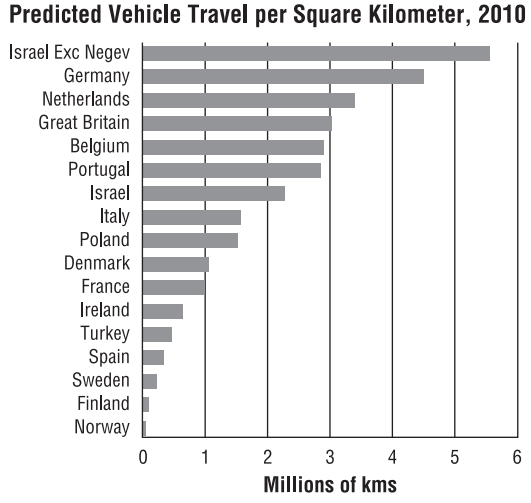
AGRICULTURE AND PESTICIDES

Agriculture is still the major source of livelihood for about half of the population in Jordan and the areas governed by the Palestinian Authority. Only a small percentage of Israelis work in agriculture. Israel is heavily dependent on irrigation, herbicides, insecticides, and fungicides, although figs, spices, and olives thrive in arid areas. The health, developmental, and ecotoxic risks

arising from overuse of organochlorines (endocrine disrupters that bioconcentrate in the food chain) and organophosphates (the major effect of which is neurotoxicity) are well known, as are intergenerational effects through in-utero exposures. Yet there is hard evidence to support strategies for increasing crop yield with less pesticide use from both Egypt and Israel. But an ethical commitment to life and its protection often requires use of pesticides to suppress epidemics of parasitic diseases transmitted by mosquito vectors which currently depend on pesticides (Richter et al. 1997).

TRANSPORT AND URBAN SPRAWL

The heaviest contributor to the region's ecological footprint comes from the enormous growth in roads, motor-vehicle transport, and urban sprawl. The scenario of "predict and provide"—which has led to more roads, more vehicles, more congestion, and, in turn, more road building, urban sprawl, and air pollution—is not only destructive to biblical sites but also has regionwide environmental and public health impacts, including increasing risks for respiratory disease and cancer in infants, schoolchildren, and older adults. Pollutants go from the tailpipes of well-off suburbanites to the windpipes of urban poor. Despite its relatively low rate of car ownership per capita compared to European countries, Israel is heavily congested with motor vehicles (see Figure 2).



SOURCE: Figure 1 from Fletcher, Elaine (2003). "Transport in the Middle East." *The Earthscan Reader on World Transport Policy and Practice*.

Figure 2. CENGAGE LEARNING, GALE.

Bus, truck, and taxi diesel emissions of particulates, polycyclic aromatic hydrocarbons, and other volatile organic compounds (VOCs) contribute disproportionately to health-related air pollution risks in Israel, although regional vehicle traffic and industrial emissions produce only a miniscule contribution to worldwide $C0_2$ emissions.

The recent growth of rail travel—as well as bicycle use—although an extremely important trend, still accounts for well under 10 percent of all intercity travel in Israel. Runoff of sludge, contamination of aquifers, loss of surface earth for filtration, loss of green spaces, and leakage from gasoline storage tanks into groundwater are the results of massive road construction from 1993 to 2008. Sludge from oil refineries is the major solid waste component of toxic waste.

INDUSTRIAL POLLUTION AND WORKER HEALTH

Protecting the most exploited, exposed, and vulnerable—especially workers in industry and agriculture, including women of childbearing age—is a key ethical priority. In the Haifa Bay area—Israel's industrial powerhouse—worker exposures and industrial point-source stack emissions of metals, gases, and solvents probably account for the region's excessive incidence of morbidity and mortality from cancer and cardiorespiratory disease. Since the 1980s there have been epidemics involving workers, adjacent community populations, and others. The causes are diverse: exposures to asbestos; mercury releases into the work environment and seawater from a mercury cell chlor-alkali plant; massive contamination of fields and aquifers with nickel and cadmium from a battery factory; multiple exposures and releases from armament factories; release of bromines; exposures to solvents, pesticides, and volatile gases in pesticide-manufacturing plants; massive contamination of ground, air, and water in the vicinity of the national toxic-waste dump; and ionizing radiation from a nuclear reactor. Toxic effluent from "clean" factories that manufacture silicon chips and other components for high-tech products present new risks.

INCITEMENT: THE MOST TOXIC ENVIRONMENTAL EXPOSURE?

There is a need to recognize that the significance and importance of all the foregoing "traditional" exposures is dwarfed by state-sponsored incitement and hate language, which leads directly to terror, violence, and war and their ecotoxic effects, and diverts energy, capital, and resources away from sustainable development and environmental protection. Such incitement and hate language is the software that leads to the use of the hardware—the guns, rockets and missiles, and weapons of mass destruction, which kill, maim, and destroy. As with other toxic

exposures, it is the children who are the most vulnerable and in whom the effects are most long lasting. Children exposed to incitement and hate language become programmed to act on its messages as they grow up, thereby ensuring the intergenerational perpetuation of violence through the generations. Therefore, people have to apply public health models of surveillance to identify and ban the use of hate language and incitement to prevent its toxic effects to this and coming generations.

ETHICS AND THE WILL TO ACT

The precepts of environmental ethics presuppose the will to act. They are based on the principle that the quality of life (and life itself) requires clean air, water, food, and policies for sustainable development. In the region there are existential pressures to promote live-and-let-live policies in keeping with core principles promoting life, equity, and cooperation through the preservation and protection of health and environmental and social capital. There have been examples of translating this principle into cooperative action. But there is no assurance that win-win scenarios to protect life and the environment will prevail over the cults of hatred, violence, and death. So far, regional and outside powerbrokers have not firmly and unequivocally supported a commitment to ethical values of life and respect for life, and environment, but sometimes seem to prefer the panacea of injecting of huge amounts of financial and military aid. In choosing respect for all life over death, the region's leaders need to develop strong national and regional frameworks based on regional cooperation and effective, coherent, and sustainable environmental policies.

Israel and its Arab neighbors lag behind Europe and North America in environmental philosophy, legislation, and regulation, which remain skeletal and inadequate for the scale and complexity of modern environmental problems. Cost-benefit analysis (rather than cost-effectiveness) and short-term gain rather than long-term impacts remain the guiding motifs. The most notable shortcoming is the failure to develop and enforce substitution strategies and emission standards at the source. The potential for change rests on meshing the protection of the environment and the promotion of public health with the geostrategic advantages to be gained from reduced dependence on fossil fuels and cooperation in protection of vulnerable populations. Several key strategic interventions would advance sustainability, carrying capacity, and public health:

1. Implement zero-emission strategies for controlling industrial and mobile emissions to air, land, and water at the source through substitution strategies, substitute technologies, recovery of emissions, and incineration-recovery technologies (''waste to energy'').
2. Arrest and reverse ''predict-and-provide'' policies by freezing all new road construction.
3. Stop urban sprawl and suburbanization to protect green spaces.
4. Promote energy-efficient rail and integrated transport systems to reduce dependence on private automobiles.
5. Protect vulnerable neglected populations, notably those in work environments, from toxic exposures.
6. Promote ''green building codes'' with proper insulation, proper siting of buildings, and proper roofing, with a possibility of rainwater harvesting.
7. Maximize use of the region's most important renewable-energy source—solar power—and reduce dependence on oil.
8. Promote research and development on increasing crop yield with less pesticide use.
9. Bury power lines and use more fiber-optic technology to reduce exposures to electromagnetic fields.

J

JACKSON, WES
1936–

Wesley Jackson, agricultural scientist, founder of the Land Institute, and proponent of perennial polyculture, was born on June 15, 1936, and grew up just outside Topeka, Kansas. Jackson pursued a variety of options for environmental activism during his career, developing one of the first environmental-studies texts, founding an alternative school, and developing an agricultural-research institution. His most significant contribution to environmental thought was the plant-breeding research at his institute, where he attempted to apply the idea of biomimicry (or nature as model) to science and agriculture.

Jackson earned his Ph.D. in plant genetics at North Carolina State University in 1967 and then moved to Kansas Wesleyan University to teach. While there, he transformed an introductory biology course into one titled Man and the Environment, and in 1971 he edited a textbook based on that course. Though he was raising student awareness of environmental issues, he was not satisfied with his impact.

In 1974 he took a sabbatical and, as part of the back-to-the-land movement, moved to a plot of land in Salina, Kansas. Eventually he and his then-wife Dana founded the Land Institute to create an ideal learning environment and to explore appropriate technology. He also explored environmental ethics. In 1976 he presented a paper called "Toward an Ecological Ethic," in which he lightheartedly suggested that Aldo Leopold would be the most important thinker in an ecological Bible. Yet in the end it was not in philosophy, but in the practical application of ideas, where Jackson's work proved most significant.

The foundations of his later work were presented in the 1978 article "Soil Loss and the Search for a Permanent Agriculture," published in *The Land Report*, the journal of the Land Institute. Soil erosion provided an immediate spur for Jackson to consider how the split between humanity and nature might be addressed. In this he followed in a line of agricultural conservationists who see preservation of soil and the wise use of it as important for human health. He suggested that a more sustainable agriculture would rely on the imitation of key aspects of natural systems. In nature, multiple plant species grow in a field, and the soil is not disrupted each year for planting. Hence, a more sustainable agriculture might also follow those traits.

He further developed his ideas about perennial polyculture and science in his books *New Roots for Agriculture* (1985 [1980]) and *Altars of Unhewn Stone: Science and the Earth* (1987). The Land Institute slowly transformed from a school into a research institute. In his work Jackson sought to develop an agriculture suited to his region, and so he studied the prairie ecosystems of the Great Plains as models. In his emphasis on using nature as a model, he was a pioneer in the field of biomimicry.

Jackson assigned practical and philosophical value to functions at the ecosystem level. Early on, a sense of holism motivated his proposal, but eventually he drew on the work of J. Stan Rowe and Arnold Schultz to argue more specifically that emergent properties on higher levels of organization require identification and respect. Jackson was less interested in valuing the ecosystem in itself than he was in preserving properties of the ecosystem. He believed that plants can be grown more efficiently when humans make use of the properties of the ecosystem.

Jackson looked at two key ecosystem-level properties, one being polyculture and the other being perennialism, which his research staff focused more on as years passed. Agriculture that uses perennials can protect a host of soil microorganisms and the interactions between them, which annual plowing disrupts. The Land Institute saw roots and what occurs in the soil as important, as shown by its logo. Their research assumed that what evolved did so because it developed a useful function in an ecosystem, and thus all aspects of an ecosystem can be worthy of study and preservation. In *The Land Report* through articles by himself and others, and perhaps more so through the photographs of Terry Evans, Jackson promoted an ethic of respect for the prairie (which had few champions when he began his work).

Mainstream agricultural research since World War II promoted reductionism in what it studied and valued, focusing on plants in relative isolation and on chemicals that could be applied to those plants. Little value was assigned to interactions between plants and soil, or to interactions among plants. Little value was assigned to farmers or to the knowledge that farmers developed. The knowledge developed by scientists was privileged, as was the goal of increasing production per acre, and the realization of this goal continually put more and more farmers out of work.

Jackson's work developed in response to these trends. He valued systems, not just parts in isolation. So when he used nature as a model, it was originally on the ecosystem level. Even when he focused more exclusively on perennialism, he did so in part to preserve soil interactions. He sought to respect farmers by having the Land Institute develop a presence in Matfield Green (a small town near Salina), and he made the case for protecting rural communities in his book *Becoming Native to this Place* (1994). Though farmers rarely contributed to his research, he hoped that farmers' knowledge could eventually play a role in a future sustainable agriculture, with farmers breeding species appropriate to their particular places.

Along with focusing on the practicalities of agriculture, Jackson also sculpted an epistemology different from that of most research. He did not believe that laboratory experiments were an effective means of gaining knowledge about nature, since results in the field were so different from results in experiments. For Jackson, reductionist experimental knowledge was of questionable utility and validity. Along with his frequent collaborator Wendell Berry, Jackson promoted a worldview cognizant of human ignorance, arguing that what humans do not know is much greater and more significant than what humans do know. He hoped that humans could find ways to benefit from natural processes, even if they did not understand how those processes functioned. He sought an agriculture that, as he phrased it, relied more on nature's wisdom and design, and less on human cleverness.

JAINISM

Jainism, which originated prior to 500 BCE in northeastern India, supports key ideas and practices that accord well with environmental ethics. Its cosmology states that soul (*jiva*) is found even in plants and the elements, and its rules of behavior advocate avoiding harm to all beings. Its monastic and lay leaders have advocated personal and societal life patterns that protect life in its myriad forms.

The oldest extant Jain text, the *Acaranga Sutra* (ca. 300 BCE), proclaims that "a wise person should not act sinfully towards the earth, nor cause others to act so, nor allow others to act so" (1:1.3; anon. 1968, p. 5), that one "should not kill, nor cause others to kill, nor consent to the killing of others" (1:3.2; anon. 1968, p. 31), and that "all breathing, existing, living, sentient beings should not be slain, nor treated with violence, nor abused, nor tormented, nor driven away. This is the pure, unchangeable, eternal law" (1:4.1; anon. 1968, p. 36). These passages outline the fundamental rule to be obeyed by all Jains: the observance of nonviolence (*ahimsa*). This exhortation extends not merely to behavior toward other humans but, as noted,

also to behavior toward the earth itself, toward the elements (water, fire, and air), and toward plants and animals. This earliest text outlines several techniques for avoiding violence to living beings, including not wearing clothing produced in ways that unduly harm mobile living beings, such as fur or silk garments; not consuming meat, fish, or eggs; and not moving about excessively during the rainy season (this last practice helps one to avoid stepping on the many insects that proliferate when it rains).

Jains remember twenty-four great religious leaders, of whom the most recent was Mahavira Vardhamana. Early Jain textual and archaeological materials indicate that Mahavira Vardhamana most likely lived in the fifth century BCE and taught a fivefold discipline of nonviolence, truthfulness, not stealing, sexual restraint, and nonpossession. He was preceded by Parsvanath, a Tirthankar (enlightened ascetic) who lived around 800 BCE. Later texts extol these twenty-four great teachers' accomplishments, especially the *Adipurana* of Jinasena (ninth century), which tells detailed stories about Rsibha, the first Tirthankar, and his son Bharata, the first world ruler. Like his successors, this first teacher, as an expression of his deep commitment to nonviolence, eventually renounced all clothing and entered death in old age by refusing food.

Jain literature and philosophy parallels that of the other two great ancient traditions: Brahmanic Hinduism and Buddhism. All three traditions concern themselves with making sense of the human condition. For Hinduism, adherence to one's dharma (duty), observance of ritual, and prayerful reflection and meditation constitute the good life. Buddhists seek to understand the root causes of human suffering and to follow an eightfold path of ethical behavior and meditation. Jainism emphasizes the role of ethics in advancing along a fourteenfold path toward total liberation. All three traditions include detailed assessments of karma, particularly in the Samkhya texts of Hinduism, the Abhidharma texts of Buddhism, and the extensive commentaries on Umasvati's *Tattvartha Sutra* (ca. 400) in Jainism, along with the *Karmagranthas*, the *Pancasamgraha*, and the *Karmaprakrti*. These texts make clear that action (*karma*) taken in the present will leave a residue or seed (*samskara*, *vasana*, *bija*) that will bear fruit (*phala*) at some future time. Consequently, ethics must be assiduously observed to assure a propitious outcome to human endeavors.

Jain philosophy accords particularly well with thinking about the state of the material world. According to Jainism, as poetically expressed by Mahavira and encapsulated in the aphorisms of Umasvati, life forms pervade the universe. From time without beginning, masses of living entities, known as *jivas*, have operated reciprocally with matter (*dravya*, *karma*) through movement (*dharma*) in time (*kala*). The *Acaranga Sutra* warns that life is to be found even in the particles of the earth itself, and that to avoid accruing harmful karma that will ripen inauspiciously, monks and nuns must shun any abuse to living creatures, including plants and the soil itself. Water must be strained to avoid ingesting small bugs, and food must be eaten before sunset so as to avoid inadvertently harming anything. In some traditions, various unusual observances can be found for protecting the status of one's karma. For instance, in the Sthanakvasi Svetambara branch of Jainism, monks and nuns generally wear a mouth covering (*muhpatti*) to avoid harm to the air and the beings living in the air through breathing or speaking too forcefully. The covering also prevents one from inhaling bugs. Even laypeople wear the *muhpatti* on special occasions, such as during temple visits, during particular holidays, or just to increase one's awareness while at home. All Jains espouse vegetarianism. Although they acknowledge that harm is done by taking the lives of plants, this is seen as necessary for survival. Periodic fasting is universally observed by all Jains, the most notable being the fast of Parysan, which occurs a few weeks before the fall equinox. Fasting ensures that no life forms have been injured or killed to support one's own life.

Jains have developed a scrupulous regimen for deciding what livelihoods are most conducive to the observance of nonviolence. As early as the *Acaranga Sutra*, lists were developed prohibiting Jains from participating in specific occupations that kill or injure animals (*Acaranga Sutra* 1:1.6; anon. 1968, p. 12). Consequently, Jains will not participate in butchery, livestock rearing, or agricultural practices that abuse animals. This concern results in the shunning of perhaps less obvious forms of violence as well: "dealing in charcoal, selling timber, driving oxcarts, dealing in ivory, manufacturing or selling alcohol, dealing in poisons or weapons, burning fields, draining water, breeding destructive animals" (Jaini 1979, p. 172). Six professions are approved: government, writing, farming, education, commerce, and crafts. The most preferred occupation for Jains is commerce. By some estimates, Jains constitute the single wealthiest group within India today—a result in large part of generations of conscious choice of profession.

Jains have developed a profound ethical awareness and conscience in their worldview, which sees life forms as passing through a cycle of birth after birth and regards every human being as having spent time as an almost unimaginable array of other life forms, including animals and bacteria (referred to by Jains as *nigoda*). Knowing that they were once sheep or goats or cows, they take special care to protect all animals. Even kindling fire becomes problematic for observant Jains, on account of the physical pain created by the friction of generating a flame. Jain monks and nuns never light or extinguish lamps or cook food. Lay Jains often avoid overusing

electricity, with some families eschewing air conditioning not for lack of wealth but out of concern not to steal from other life forms for the sake of one's own physical comfort.

Jains adhere to nonviolence to purify their own souls. Jainism does not escape anthropocentrism and in fact lauds human birth as a necessary prerequisite for the liberation of the soul. The ultimate goal, omniscience (*kevala*), exists beyond the concerns of birth, life, death, and rebirth. Jainism does not advocate love of nature in the sense that it might be practiced in New England, but preaches self-restraint and caution around nature. If one harms a being, that harm will return to hurt oneself. Jain literature, such as the story of Yashodhara, does not celebrate the beauty of plants and animals, but rather serves as a cautionary tale, warning its reader not to succumb to the violence and lust that runs rampant in nature (Chapple 2006, pp. 241–249).

Various Jains in the past several decades have taken leadership roles in calling attention to problems of pollution and environmental degradation. In 1949 Acarya Tulsi, a confidant and adviser to Mahatma Gandhi, promulgated a list of twelve vows, starting with a vow not to commit violence in any form, and ending with "I will do my best to avoid contributing to pollution" (Kumar and Prakash 1997, p. 71). L. M. Singhvi, a member of Parliament who also served on India's Supreme Court, published *The Jain Declaration on Nature*, which lists the core teachings (nonviolence, interdependence, the doctrine of manifold aspects, equanimity, and compassion) that constitute the foundation for a Jain ecological ethics. He reiterates that in Jain cosmology, life pervades the world, appearing as "earth-bodies, water-bodies, fire-bodies, air-bodies, vegetable-bodies, and mobile bodies ranging from bacteria, insects, worms, birds and larger animals to human beings, infernal beings, and celestial beings." Singhvi asserts that by applying the five traditional vows and practicing kindness to animals, vegetarianism, avoidance of waste, and charity, one can find "a viable route plan for humanity's common pilgrimage for holistic environmental protection, peace, and harmony" (Chapple 2002, p. 222).

The traditional worldview developed by the Jain community over the course of several centuries could not directly anticipate the environmental crises of the twenty-first century. It does, however, provide conceptual resources that might be marshaled and applied to specific problems as they arise. The complexity of environmental issues requires approaching each situation from a variety of perspectives. The Jain philosophy of many-sidedness (*anekanta*) can be instructive in this regard. John Cort has pointed out that one of the Jain environmental initiatives in India, planting trees to reforest the mountain that houses the renowned Satrunjaya temple complex, has prevented shepherds from grazing their sheep on lands once accessible in common (Chapple 2002, p. 89). Environmental justice, though perhaps enhanced by vegetarianism and kindness to animals and monastic communities that leave a negligible footprint on the earth's resources, requires a level of social and economic analysis broader than the simple observance of a moral code. Interpreting and applying the principles and practices of Jainism to the environmental problems of the early twenty-first century presents new challenges to this ancient faith.

Jains are well poised to make strategic business decisions to help protect the environment. In India they are well known for their ownership of major newspapers, steel companies, mining concerns, and insurance companies. As knowledge comes to light regarding the potentially devastating effects that global climate change will have on India, Jains hold positions of leadership and can provide an important voice for change. As the Himalayan glaciers continue to melt, some have estimated that by 2050 the Ganges River will go dry for a few months each year. Jain industrialists and jurists may support legislation that can slow the progress of global climate change. Relief agencies will need continued support from Jains as flooding and heat spikes create a need for emergency food and shelter. Jain engineering firms might also help design and implement water-catchment systems to compensate for lost river water. Jains are well positioned and hopefully will respond to the challenges posed by climate change.

JAMIESON, DALE
1947–

Dale Jamieson was born in Sioux City, Iowa, on October 21, 1947, and received a doctorate in philosophy from the University of North Carolina in 1976. He is currently a professor of environmental studies and philosophy, an affiliated professor of law, and the director of environmental studies at New York University. He is the author of *Morality's Progress* (2002) and *Ethics and the Environment: An Introduction* (2008), the editor of *A Companion to Environmental Philosophy* (2001) and *Singer and His Critics* (1999), and the coeditor of *Reflecting on Nature* (1994) with Lori Gruen and *Readings in Animal Cognition* (1996) with Marc Bekoff.

Jamieson approaches environmental philosophy from a perspective that is "philosophically naturalist, morally consequentialist, and metaethically constructivist" (Jamieson 2002, p. vii). His contributions to the discipline have been so broad and deep as to defy easy summary, but the following aims to give a sense of some of the most prominent work.

First, Jamieson has published extensively on the ethics of the treatment and study of nonhuman animals, especially on cognitive ethology, animal cognition, and animal experimentation. In general, he defends an animal welfare approach that is based on a utilitarian ethic that places substantial value on individual liberty for both humans and animals. Perhaps his most famous essay in this area is "Against Zoos" (1986), which has been widely anthologized. In it he argues for two claims: Although there is something to be said for the usual defenses of zoos—for example, that they educate people about animals and assist in preserving endangered species—these defenses provide reasons for different types of zoos, and these reasons are in tension with each other; and, despite their positive aspects, all things considered zoos ought to be abolished because they deny liberty to individual animals, cause significant suffering in other respects, and "teach us a false … [and also 'dangerous'] … sense of our place in the world" (Jamieson 1986, p. 175).

Second, Jamieson has written a number of influential articles that critically examine, and reject, key environmental concepts such as ecosystem health and sustainability. In general, he believes that people should be wary of attempts to articulate environmental concerns through the invention of new quasi-scientific terms because "the environmental problems we face are not fundamentally scientific problems … but [problems] in our institutions of governance, our systems of value, and our ways of knowing" (Jamieson 2002, p. 224). Instead, they should seek positive visions of ways to relate to animals and nature that have been absent from the Western tradition to this point.

Third, Jamieson has worked to undermine a number of important schisms in environmental philosophy, such as those between animal advocates and environmentalists (Jamieson 1998), between metaphysical realists and subjectivists (Jamieson 2003), and between those concerned with environmental justice between humans and those concerned with the human relationship to nature (Jamieson 1994).

Finally, Jamieson has been a pioneer of work on the ethical aspects of climate change. His many articles on the topic include the early paper "Ethics, Public Policy and Global Warming" (1992), which assails contemporary economics as a useful paradigm for understanding climate change; "Adaptation, Mitigation, and Justice" (2005), which argues that both adaptation and mitigation need to be addressed in a serious climate policy; "Ethics and Intentional Climate Change" (1996), which explores the moral constraints that should be imposed on any attempt to "geoengineer" the climate; and "When Utilitarians Should Be Virtue Theorists" (2007), which argues that, in order to confront the looming environmental crisis, utilitarians should embrace an uncompromising set of green virtues.

In addition to his substantial research effort, Jamieson has made major contributions to the development of the field. He coedited an early reader on the topic (Gruen and Jamieson 1994) and helped the discipline come of age with his monumental *A Companion to Environmental Philosophy* (2001). More generally, Jamieson has spent many decades acting as an effective bridge between

mainstream academic philosophy and environmental issues, not only playing a significant role in encouraging the younger philosophers in the field but also explaining and defending the usefulness and integrity of applied ethics in general to a sometimes skeptical wider audience. On this topic, his essay "Is Applied Ethics Worth Doing?" (1988) is widely regarded as a classic.

JAPAN

Encompassing some 3,000 islands in the Pacific Ocean in East Asia, Japan is one of the great economic success stories of the post–World War II era. Although it ranks tenth in the world in population (127,433,494 as estimated in 2007), it is the world's third-largest economy (behind the United States and China) by one measure (purchasing power parity) and the second-largest (behind the United States) by other yardsticks (real gross domestic product [GDP] and nominal GDP). Japan's economic might is all the more remarkable considering the starting point—the country was in economic ruins after its defeat in World War II but applied its collective energy and entrepreneurial ingenuity in achieving a spectacular recovery: near-miraculous annual growth rates of an average of 10 percent in the 1950s and 1960s, 5 percent in the 1970s, with declining but steady rates of growth since then. Home to the world's largest automaker—Toyota—and one of the world's most powerful media and electronics conglomerates—Sony—Japan has led the way among industrial powers in confronting the tradeoffs between economic growth and environmental protection. Toyota and Honda were among the first auto companies to offer hybrid vehicles, and their fleets of cars rank among the highest in fuel efficiency and the lowest in emissions. Japan hosted the 1997 conference that promulgated the Kyoto Protocols on climate change (to which it is a signatory).

JAPANESE RELIGION AND NATURE

Japanese attitudes toward nature and the environment have deep roots in the religious traditions that have shaped the country's cultural ethos. Japan's indigenous religion, Shinto, is a form of animistic nature worship, in which the divine "kami" (deities, spirits, or gods) are believed to reside in animals, trees, rice fields, and certain human beings. Viewed from a contemporary perspective, Shinto might be called an ecoholistic religion because not only sentient beings but also whole mountains and the land itself are the objects of worship. Every village once had its own Shinto shrines, many of which still exist today. Buddhism, Taoism, and Confucianism found their way into this religious context but were transformed and melded into native Japanese traditions.

Buddhism thrived in the Nara and Heian era (710–1180). The Buddhist monks Kukai (774–835) and Saicho (767–822) propounded the belief that "mountain, river, grass, and trees have attained Buddhahood." This thesis is different from the sentient/nonsentient dualism of original Buddhism and expresses the ecological continuity of beings. In the Kamakura era, Zen Buddhism thrived, represented by Dōgen Zenji (1200–1253) (Callicott 1994).

After a period of civil war, Japan was united. Thus began the Edo Era (1603–1867). Edo (today's Tokyo) was densely populated (roughly 1 million people resided there in the seventeenth century) and because the ruling class itself was not wealthy, the difference between rich and poor was small. Meat eating and land development were illegal. Edo society retained and even enriched the natural environment by its symbiotic human/nature interactions.

When Jesuit missionaries visited Japan, some major local rulers accepted Christianity, but later the missionaries were exiled, and Japan became a closed country with the exception of the admission of occasional foreign traders. The principal ideological opponent of Christianity was Hukan Fabian (1565–1621), the author of *Refuting Deus*. By then Buddhism had become the national religion; every family had both Shinto and Buddhist altars in its house. Further, Confucianism was adopted as a governmental ideology, and its implicitly ecological world view thus complemented the combined Buddhism and Shinto traditions of Japan.

Japanese Confucianism was founded by Kaibara Ekken and developed and practiced by Ogyu Sorai (1666-1728) and Ninomiya Sontoku. For Japanese Confucians, "heaven" ("heaven-earth-nature" or *ten-chi-sizen*) was a symbol of the natural environment. Although the social ethics of these thinkers was similar to today's European and North American utilitarianism, their environmental views were ecoholistic, giving serious consideration to nature's welfare or well-being. Sorai's ethicopolitical outlook respected heaven and the happiness of people; hence human happiness was embedded in an ecological worldview. Sorai's motto was "happiness of people and world peace."

When Japan was forced to open it economy and culture to Europe and North America in the 1850s, the goal of "rich country, strong army," based on European Enlightenment ideals, became the guiding spirit of the age. Japan's national independence became an overriding concern of public policy. Yet the leading philosophers such as Nakamura Keiu were originally Confucians. Keiu combined his own belief in a Confucian heaven with a Christian God. Uchimura Kanzo (1861–1930), a leading Christian thinker, argued for an agriculture-based (instead of industry-based) state, "small-countryism" and "non-warism," positions that ran against the tide of industrialization and imperialism. Contrary to other Enlightenment thinkers, they accepted utilitarianism in the social and ethical spheres while retaining a traditional Confucian view of nature.

Although Japan began to evolve into a capitalist-industrial society under the influence and pressure of the United States and European powers, the culture remained steeped in traditional Shinto, Confucian, and Buddhist thinking while critically evaluating and absorbing European ideas. Out of this confluence original Japanese philosophies have emerged. The so-called Kyoto School, led by Nishida Kitaro (1870–1945), created a nondualistic philosophy based on Zen Buddhism. Some of the members of this school argued against European and North American modernism. Their philosophies were mainly concerned with religion, aesthetics, and culture. Today the Kyoto School is reviving, but it has not yet given much attention to the global ecological crisis, despite the influence on global environmentalist thought by Nishida's friend Daisetz Teitaro Suzuki (1870–1966).

ENVIRONMENTAL CONCERNS SINCE WORLD WAR II

Japan's defeat in World War II drastically shifted people's attitudes and values toward modern anthropocentric concerns. Under the guidance of the occupation authority, traditional thought was suppressed and channeled toward European and North American modernism. Modern democratic values eclipsed traditional morals. The attack against traditional thought—now denigrated as the ideology of a feudal, class society—prevailed and become institutionalized.

Japan's economic success—attained through aggressive industrialization—brought with it domestic environmental degradation and, indeed, some environmental calamities that were subsequently ameliorated. The most notorious was Minamata disease, a neurological syndrome caused by severe mercury poisoning. It was caused by the methyl mercury in the effluent from the Chisso chemical factory from 1932 to 1968; this effluence bioaccumulated in the marine life of Japan's Minamata Bay and the Shiranui Sea. Those eating seafood from these waters were the principal victims; their misfortunes made the dangers of heavy-metals pollution well known to medical science.

More subtly destructive was the introduction of the rich lifestyle of affluent societies, which displaced the traditional symbiotic way of life. Mass consumption and mass abandonment replaced traditional recycling systems. Indeed, the industrialization of densely populated Asian countries, following the models of European and North American modernism, is a major force in the contemporary global ecological crisis.

Those Japanese thinkers who are disciples of European and North American modernism have paid scant attention to the contemporary environmental crisis. However, if Japanese thinkers honestly confront the global environmental crisis, criticize the modernism (including industrialization) that produced it, and revive the traditional philosophies with their rich heritage of environmental

Victim of Mercury Poisoning, Minamata, Japan. *A woman holds a victim of "Minamata Disease," or mercury poisoning, in Japan in 1973. Many of the victims of the disease suffer from physical deformities, such as the malformed hand of the girl shown. Between 1932 and 1968, Chisso Corporation, originally a Japanese fertilizer and carbicle company, dumped an estimated 27 tonnes of mercury compounds into Minamata Bay.* **AP IMAGES.**

ethics, then a distinctive environmental philosophy can emerge in Japan (Callicott 1994).

Since the 1960s Japan has seen the emergence of various green civil movements, sometimes spurred by overseas aid programs focused on environmental quality. Books concerning green movements in other parts of the world (such as Vandana Shiva's [2005]) are being translated and introduced to the Japanese public. In academic circles various research projects on the environment have arisen, including the founding of the Society for Studies on Entropy, a group that brings together physicists, economists, and environmentalists to discuss the nature of living systems, technology, and sustainable modes of economic growth (1994–2003).

JEFFERS, ROBINSON
1887–1962

Robinson Jeffers, born in Pittsburgh, Pennsylvania, on January 10, 1887, was a regional poet. His work is rooted in California, but it speaks of larger themes, such as the cycles of life, the cruelty of humans, the dance of death and renewal, and the ways in which culture and civilization can blind people to the beauty of the world. Jeffers published over fifteen volumes of poetry in his lifetime. He wrote epic narrative and lyrical poetry. He laid a foundation for bioregionalists and environmentalists concerned with place and human obligations to nature.

In September of 1914, Jeffers and his wife Una moved to Carmel, California. There, under the influence of the Big Sur coast and its people, Jeffers found his voice. His collection *Californians* (1916) described the Big Sur region and explored ideas about the decline and future of Western civilization. By 1919 Jeffers and his family had moved two miles south of Carmel to live on the windswept, rocky coast. Jeffers learned the craft of stonemasonry. With local granite, he built Tor House for his family residence and Hawk Tower, a four-story tower overlooking the Pacific. Jeffers wrote poetry in the morning. In the afternoon, he worked with stone and tended to the trees he had planted, a grove of over two thousand eucalyptus, cypress, and pine trees. His poetry and his life grew out of his attachment to this place along the Big Sur coast. It was a landscape of rock, stormy skies, kelp, sea lions, and intense, passionate people. Jeffers remarked that his poems grew like a plant out of particular places—a canyon; a promontory; a relationship of rock, water, wood, and grass.

Jeffers's poetry not merely described these places, but plunged into symbolic and metaphorical depth. The West was the place of the Pacific Ocean, but also of the end of

Robinson Jeffers, 1934. *Robinson Jeffers was an early twentieth-century poet known for his symbolic and metaphorical depictions of the natural world. Jeffers also developed the concept of "inhumanism," seeing the nonhuman as significant.* **COURTESY OF THE BANCROFT LIBRARY, UNIVERSITY OF CALIFORNIA, BERKELEY.**

western migration and the end of human civilization. In such collections of poetry as *Tamar and Other Poems* (1924), *Roan Stallion, Tamar, and Other Poems* (1925), *The Women at Point Sur* (1927), and *Give Your Heart to the Hawks and Other Poems* (1933), Jeffers developed themes that would remain consistent throughout his work. He believed that poetry should be of beauty and of larger things; poetry was a way to deepen our awareness of the nature of the world—the flux, the beauty, the cycle of death and rebirth. His long, epic narratives are laden with violence, murder, and incest. These narratives are indebted to Greek tragedy and are based on stories and people from the Big Sur region. The characters are rough, violent, passionate, and driven to destruction. Jeffers despaired of human cruelty and self-centeredness. For Jeffers, it was civilization that blinded people to the beauty and divine nature of the world. His poetry is a reminder and a tribute to the natural world. His lines are filled with hawks, water, rocks, cypress trees, pelicans, and horses. His poetry brings attention to the natural world and asks that people participate in it.

Jeffers developed the concept of inhumanism, in contrast to the idea of humanism. Inhumanism represents a shift from seeing humans as significant to seeing the nonhuman as significant. Inhumanism is a move away from egocentrism to an acknowledgment of the divine beauty of the world. People must overcome self-centeredness to keep their integrity and appreciate nature. In "The Answer," Jeffers writes,

For Jeffers, we must move away from an
obsession with self to love things greater than ourselves. To do otherwise is to suffer pain and confusion.

Loren Eiseley, in the foreword to *Not Man Apart* (1965), shows how Jeffers, his poetry, and the Big Sur coast are all connected. Eiseley writes, "The sea-beaten coast, the fierce freedom of its hunting hawks, possessed and spoke through [Jeffers]. It was one of the most uncanny and complete relationships between a man and his natural background that I know in literature" (p. 23). The rocky, windy coast of Big Sur carved Jeffers and his poetry.

JUDAISM

Judaism's teachings, including those on environmental matters, derive their authority from being found in,

traced to, or implied by the Torah. In Hebrew, *torah* means "instruction." As a proper name, it refers primarily to the laws divinely revealed in the Pentateuch (the first five books of the Bible). Secondarily, it refers to the Hebrew Bible and its teachings as a whole. These include, above all, belief in an all-powerful, all-knowing God who has created the world (Gen. 1:1–2:4), revealed a definitive set of laws for the Jewish people (Ex. 20:1–23:33, 25:1–31:17; Lev. 1:1–7:38, 11:1–24:9, 25:1–26:2, 27:1–34; Num. 27:8–11, 28:1–30:17, 34:50–35:34, 36:7–9; Deut. 4:15–19, 5:6–18,12:1–26:19), and promised to reward obedience to those laws with communal prosperity and punish disobedience with political, social, and environmental ruin (Lev. 26:2–45; Deut. 11:10–17, 28:1–69, 29:9–30:20). Except for laws that spell out some minimum standards of moral decency which are meant to be appropriate for any political society (Gen. 9:3–7; Sacks 1990, 66), the Torah's laws are not directly intended for non-Jews, though they do invite prudent emulation (Deut. 4:6–7).

Central to the Torah's laws are the institutions of the Sabbatical and Jubilee Years (Sacks 1990, 94–114). Their general purpose is to protect and foster community life in the Promised Land (ancient Israel) insofar as its flourishing depends on each patriarchal family's ancestral farm. The Sabbatical laws (Ex. 21:2–6, 23:10–11; Lev. 25:1–7; Deut. 15:1–3, 24:19–22, 31:10–13) stipulate that every seventh year farms must lie fallow. Meanwhile spontaneous vegetation must be left unharvested and unfenced for any passers-by (including animals) to consume. Also, all debts must be forgiven. Finally, heads of families nation-wide must assemble to hear a public reading of the laws. The Jubilee laws (Lev. 25:8–55, with Ex. 21:2–6 and Deut. 15:12–18) add that farms can never be sold, only leased. All leases expire every fiftieth year, when each farm reverts to its ancestral owners. Simultaneously, all slaves must be freed, with one-on-one economic assistance to prevent their relapse into slavery. As for the theological and political importance of these laws, the prophet Jeremiah laments (Jer. 34:13–22) that it was neglect of the Sabbatical and Jubilee Years which brought God's punishment in the form of the Babylonian conquest and the resulting exile of the Jewish people from their land in 586 BCE.

Preparing for Sukkot. *An Ultra Orthodox Jew inspects willow branches for Sukkot, the fall harvest celebration when pious Jews thank God for the rains that irrigate farms, forests, oases, and rivers. Responding to critiques of being anti-environmental, several Revisionist proposals have been suggested in an effort to "green" Judaism.* **DAVID SILVERMAN/GETTY IMAGES.**

THE ORAL LAW

Judaism's post-biblical legal and related writings are called the "Oral Torah" (or "Oral Law"). These extend the Pentateuch's "Written Law" to the circumstances of Jewish life in exile. Foremost among such writings are the Mishnah (a legal code compiled around 200 CE), the Talmud (containing the Mishnah with wide-ranging legal and homiletical controversy and commentary, called Gemara, compiled around 500 CE), and Midrash (contemporaneous compilations of brief homilies, or mini-sermons, loosely geared to biblical texts). There are also ongoing Teshuvot ("responses" by authorities in the Oral Law to specific legal inquiries), Bible translations (from Hebrew into vernacular languages) and, eventually, detailed biblical, legal, ethical, and theological commentaries. Also authoritative is Moses Maimonides' *Mishneh Torah* ("recapitulation of Torah," circa 1170–1180 CE), a codified digest of the Talmud whose invisible backdrop is Platonic-Aristotelian philosophy. The Oral Law's purely legal component is called Halakhah ("walking," i.e., rulings reached step-by-step). The Halakhah's original formulators were the Pharisees ("separatists," i.e., innovators), who also instituted synagogue worship, personal prayers, and ritual blessings to be recited over mundane activities such as eating. Its subsequent authorities are called Rabbis ("teachers" of the Oral Law).

Nowadays Jews are divided into Orthodox and non-Orthodox denominations, according to how strictly they adhere to the Oral Law. Demographically, most Jews are non-Orthodox—Reform Jews considering themselves only loosely or voluntarily bound to the Oral Law, Conservative Jews adhering somewhat more strictly. These differences show up in Judaism's discussions of environmental matters as follows. How well, it is asked, does the Oral Law address the unprecedented legal and moral issues posed by the environmental crisis of the twentieth and twenty-first centuries—the massive pollution of the air, water, and land as a side effect of the steadily accumulating advances of modern technology, with the resulting threats to the flourishing of plant, animal, and

human life? Orthodox scholars find the Oral Law adequately equipped with precedents for meeting today's crisis. Among other things, they note its prohibitions against wanton or needless destruction (called by the Rabbis *bal tashchit*, "Don't destroy!") and against causing animals pain (called *tsa'ar ba'alei chayyim*, "animal suffering"), as well as to its Sabbatical and Jubilee provisions. In contrast, various non-Orthodox scholars have proposed radically revising—or *greening*—Judaism with a view to letting it speak to the crisis more directly. Their proposals have resulted in a variety of syncretistic arguments—innovative syntheses of Jewish and environmentalist views—shaped partly by traditional Jewish teachings, partly by how the religious implications of the crisis happen to be understood (or perhaps misunderstood) by prominent green authors, notably the historian Lynn T. White Jr. (1967).

WHITE, LEOPOLD, AND TOYNBEE VERSUS THE BIBLE

In "The Historical Roots of our Ecologic Crisis" (1967), White alleged that the source of the contemporary environmental crisis was Genesis 1:28—where God tells the first humans to "fill the earth and master it; and exercise dominion over the fish of the sea, the birds of the sky, and all the living things that creep on the earth." White's allegation echoed similar allegations by the forest ecologist Aldo Leopold, who protested against what he called "our Abrahamic concept of land"—by which he meant regarding the land "as a commodity belonging to us"—and who commented sarcastically that "Abraham knew exactly what the land was for: it was to drip milk and honey into Abraham's mouth" (Leopold 1949, viii, 204f.). White's and Leopold's allegations resonated further in the historian Arnold Toynbee (1972), who called for a return to pagan nature-worship, on the supposition that it would protect us against the environmental deterioration accompanying modern industrialization and commercialization, which the Bible (he asserted) had inspired. Neither White nor Leopold nor Toynbee, however, adduced much more than a biblical verse or two, cited out of context, to substantiate their far-reaching, if historically dubious, claims.

Nor did they examine other, more direct sources for the modern view of the relation between human beings and their natural environment. In particular, they overlooked the detailed arguments for the environmentally invasive project to "conquer nature . . . for the relief of man's estate" and make human beings "like masters and owners of nature" which are found in the writings of the philosophical founders of modern technology, Francis Bacon and René Descartes, respectively (Yaffe 2001, 66 nn. 28–29, 70 n. 73). Bacon, for example, in his rhetorical appeal to the early chapters of Genesis to underwrite that project (Bacon 1963, 296–297), bypasses Genesis 1:28 altogether. He refers instead to the biblical description of the neediness of human beings after they had been expelled from the Garden of Eden for having acquired "knowledge of good and evil" (Gen. 2:9, 17, 3:1–7a) and could no longer look to God to supply their wants but had to rely entirely on their own initiative and industriousness (Gen. 3:7b, 17–19, 23). Here Bacon mentions, as precursors to his own project, figures of an "active" bent—Cain, the first tiller of the ground (Gen. 4:2, 17), and Cain's offspring, including the inventors of the musical and metalworking arts and the builders of the Tower of Babel (Gen. 4:21–22, 11:3–5)—whose very inventiveness the Bible criticizes as evidence of their ongoing rebellion against God (Gen. 4:10–14, 23–24, 11:5–9), as Bacon duly notes. For Bacon, the project to bring about "the limitless scientific mastery of nature and the technologizing of human life," being of strictly human origin, is not to be identified with the way of life mandated by the divine command set forth in Genesis 1:28, with which it is in direct competition (Kennington 2004, 5–6, 70, with 123–144 on Bacon's thoroughgoing influence on Descartes).

THE ENVIRONMENTAL CREDENTIALS OF JUDAISM

Jewish environmental ethics—as distinct from Judaism's traditional theological and ethical discussions—emerged once contemporary scholars saw a pressing need to defend Jewish texts and practices against the unsupported allegations by White and the others. In their various counterarguments, Orthodox and non-Orthodox scholars alike consider three interrelated questions—historical, ethical, and philosophical. Historically, they ask, what is Judaism's ecological track record? Ethically, they add, how should Jews as Jews face the crisis here and now? And, they wonder philosophically, does contemporary environmentalism fit, or fail to fit, with traditional Jewish piety? These questions are not easily separated. Moreover, they are often followed out all too incompletely, intermittently, and haltingly. Nor is there strict unanimity of answers. Also, as already stated, Orthodox and non-Orthodox scholars differ on whether their task is simply to recount Judaism's traditional teachings with an eye to today's environmental concerns, or to revise (or green) those teachings. Last but not least, the allegations by White and the others force scholars who would defend Judaism's ecological heritage to construe it in terms of "nature," a notion for which there is no exact equivalent in the Torah. As a result, Jewish green responses to White and the others often fall short in addressing the full issue at stake.

The shortcomings have to do with how the Torah's silence about "nature" and science correlates with its articulateness about "creation" and law. Generally speaking, either living things and their habitats are "natural" (that is, self-originating, self-maintaining, and scientifically intelligible in their own terms) or they are "created" (that is, originated, arranged, and provided for by a divine Creator). By assuming the second of these two incompatible alternatives, the Torah implicitly excludes the first (Maimonides 1963, 281–360). Its reticence about "nature" cannot be ascribed simply to a lack of scientific sophistication or an excess of mythological imagination, however, since the Torah, by its own lights, is neither "science" nor "myth"—biblical Hebrew lacks terms for these as well—but revealed law. The Torah's presenting things as created (rather than "natural") is tailored to its practical interest in the extra-human or supra-human support for law-abidingness. It spells out that support in a manner that is intelligible and persuasive to its immediate adherents. Thus, for example, its account of day two of the first week of creation, when God is said to separate the primordial watery chaos into "waters above" and "waters below" and to maintain that separation henceforth (Gen. 1:2, 6–8), is meant as a straightforward description of God's ongoing separating activity, and not, say, as a poetic description of a "natural" separation on the part of the waters themselves. The straightforward implication is that God could in principle abandon or otherwise modify his activity whenever appropriate for disciplinary or instructional purposes. Such purposes are evident, for example, in God's allowing the "waters above" to collapse into the "waters below" during Noah's flood (Gen. 6:17–8:19), and subsequently—in keeping with a post-flood covenant whereby God vows never to allow that collapse again and stipulates in return that human beings must henceforth govern their behavior by written law (Gen. 8:20–9:17)—in God's promising to provide seasonable rain as a reward for obeying the Sabbatical and Jubilee laws in particular and threatening to withhold the rain as a punishment for disregarding those laws (Lev. 26:3–5, 18–20; Deut. 11:10–17). In short, from the Torah's viewpoint, the stability and flourishing of human beings and their larger environment depend on the will of their Creator as revealed for the sake of fostering adherence to law, rather than on "nature." The conceptual and other shortcomings that show up in Jewish environmental ethics are, generally speaking, traceable to its following White and Leopold and Toynbee uncritically in ignoring the likelihood that the differences between the Torah, with its theological supposition that the earth and its inhabitants are creatures of God, and Baconian science, with its philosophical supposition that they are to be mastered by human beings, are, at bottom, irreconcilable (Spinoza 2004, 67–101).

THE ECOLOGICAL TRACK RECORD OF JUDAISM

Be that as it may, the main historical counterargument against White and the others (Ehrenfeld and Bentley 2001) is that Genesis 1:28 does not give humans unrestricted sway over nature, but only caretaking authority, or stewardship. Much theological support is found for this view. Biblically speaking, all the land—or earth (*arets* in Hebrew means both)—belongs to God (Ex. 9:29; Lev. 25:23; Deut. 10:14; Ps. 24:1). God is said to govern the earth providentially so as to reward law-abidingness and punish rebelliousness (Kay 2001; Allen 2001), especially by supplying or withholding rain in the manner already mentioned. *Sukkot*, the fall harvest festival, is also a water festival (Schaffer 2001), whose ritually displayed plant species—willow branches, date-palm fronds, myrtle twigs, citrons—celebrate ancient Israel's divinely-bestowed water abundance in its four ecologically distinct regions: riverine wetlands (willow), desert oases (palm), forested highlands (myrtle), and cultivated farmlands (citron). In addition, post-biblical Midrashim criticize the very notion that humans should be masters over all other creatures (Cohen 2001, 74ff.), since although they resemble angels in being created in God's image, they also resemble beasts in being procreated and mortal—and thereby susceptible to lawlessness.

Halakhic evidence for Judaism's environmental conscientiousness is also considerable. Deuteronomy 20:19–20's prohibition against destroying fruit trees for siegeworks during wartime serves as precedent for the Oral Law's *bal tashchit* prescriptions (Cohen 2001, 77ff.; Schwartz 2001). Ambiguity about whether the Torah's concern here is—in today's parlance—biocentric (that is, for the trees) or anthropocentric (that is, for their human beneficiaries) permeates Talmudic rulings as well. For example, according to the Mishnah (*Baba Kamma* 8:6), destroying any fruit tree is punishable by a fine. The tree's owner is exempt, however, on the presumption that no one willingly destroys one's own property needlessly. Here the Mishnah surrounds a biocentric principle (saving a tree for its own sake) with an anthropocentric restriction (accommodating the needs of its owner). Nor is this all. The Gemara (*Baba Kamma* 91b–92a) adds that the owner's need must be specific—the tree's unprofitability, say, or its inconvenience to others. Here the Gemara trims the aforementioned restriction (the owner's putative need) so as not to obstruct the basic principle (the tree's presumptive right to exist and flourish as a living creature). As in the foregoing, a continual need to reconcile anthropocentric and biocentric (or, as we shall see, zoocentric) considerations also guides post-Talmudic case-law deliberations in this and other matters—including questions of *tsa'ar ba'alei chayyim*, about which more shortly.

The evidence just cited shows that the allegations by White and Leopold and Toynbee are ill-informed about biblical and post-biblical Jewish law. Nevertheless it does not dispose of those allegations altogether. This would require showing, in addition, that the meaning of Genesis 1:28 is absorbed without remainder into the Torah's legal and moral prescriptions. On the contrary, in its immediate context Genesis 1:28 invites its reader to consider, if only for a moment, the possibility of a way of life which is not only completely free of legal restraints and oriented to the unimpeded human domination of the earth but, even so, backed by God's blessing (Sacks 2001, 153ff.)—as White and the others surmise—although or because the Torah goes on to replace the foregoing possibility with that of life under a divinely revealed law that is, in turn, both ethically and ecologically enlightened (Kass 2001, 384, 409). Here, perhaps, White and Leopold and Toynbee share some moral and intellectual high-ground with the Torah after all. That is, despite their unfounded resentment and unscholarly presumptions about the Torah, White and the others may have a viable, if one-sided, insight into the human-all-too-human starting-point that prompts its environmental teachings—namely, unrestricted human freedom and the environmental and other risks that would and do arise from it. Current defenders of Judaism's ecological track record would do well to explore this high-ground more fully.

FACING THE CONTEMPORARY CRISIS

Three noteworthy proposals would revise traditional Jewish teachings so as to incorporate contemporary environmental activism. Another noteworthy proposal would adjust contemporary environmental activism so as to incorporate traditional Jewish teachings. In addition, several Jewish activist organizations and projects are worth noting.

One revisionist proposal (Artson 2001, 161, 171) would extend the putative sacredness of Israel's environment to the entire earth. Israel's environment is sacred, it is argued, as the original location for obeying the Mitzvot (divine "commandments"). Because the Mitzvot remain binding on Jews in the Galut ("Exile"), that is, in post-biblical circumstances anywhere on the earth, it follows that the latter's environment must to that extent be sacred too. Meanwhile Israel's exclusivity is preserved, on the premise that the ultimate purpose of the Mitzvot is to live piously in the Land of Israel. This argument manifestly privileges *aliyah* ("ascent" or immigration to Israel). A difficulty with its premise, however, is that it discounts the intrinsic value of Mitzvot whose evident purpose is simple moral decency, regardless of location (Ex. 23:1–9; Lev. 19:13–18; Deut. 15:1–18, 22:6–7).

Another revisionist proposal (Troster 2001) would amalgamate Gaia worship with Judaism, on the premise that the earth ("Gaia") is God's creature. A difficulty here is the Torah's uncompromising prohibition of creature-worship (Ex. 20:3–6; Deut. 5:7–10 with 4:15–19; Wyschogrod 2001).

A third revisionist proposal (Benstein 2001) would offset the Mishnah's warning against being distracted from Torah study while looking at trees and fields (*Pirkei Avot* 3:7; Schwarzschild 2001), by supplementing the two traditional categories of Mitzvot—ethical obligations to fellow humans and ritual obligations to God—with a third category: obligations to one's natural environment. Fitting scientific ecology neatly into this new category, however, would depend on whether or not the aforementioned tension between "nature" and "creation" is resolvable within the purview of Jewish law (Jonas 2001).

A non-revisionist proposal (Rosenblum 2001) would educate environmental activists generally in the ecological benefits of the Sabbatical and Jubilee Years: Resting farms every seven years would reverse the soil-depleting effects of steady planting. Remitting debts would relieve economic pressures on poor farmers to exhaust their land's resources. Explicating the laws in public forums would foster communal environmental awareness. Returning farms to their original land-grant owners every half-century would forestall absentee land-accumulators who might abuse the land with impunity. Finally, freeing indentured servants and offering one-on-one economic assistance might keep them out of the impoverished underclasses, who are especially hard on the environment. If these policies seem utopian and unlikely to be implemented, they nevertheless provide a lodestar for activists and a measuring-stick for their successes.

Among Jewish activist organizations is COEJL (Coalition on the Environment and Jewish Life), an umbrella group that facilitates green projects in Jewish communities both locally, with activities such as nature-walks and guest-speakers, and nationally, with campaigns to purchase energy-efficient light-bulbs, and green political advocacy in general. Teva Learning Center (*teva* is the post-biblical Hebrew word for "nature") supplies green educational materials, teacher-training, and recreational opportunities for Jewish schools, camps, and youth groups. Shomrei Adamah ("Guardians of the Earth") is a popular label for Jewish green programs in various localities. Finally, the Heschel Center for Environmental Learning and Leadership is an educational and policy think-tank located in Israel. (For a longer list of organizations, see Waskow 2000, I:290–92.)

CONTEMPORARY ENVIRONMENTALISM AND JEWISH PIETY

The foregoing defenses against White and Leopold and Toynbee result in a philosophical quandary. On the one hand, revisionist proposals for greening Judaism risk forfeiting traditional Jewish teachings that are otherwise indispensable. On the other hand, traditionalist attempts to read Genesis 1:28 exclusively as a mission-statement for environmental stewardship ignore its surface connotation as a permission-slip (subsequently withdrawn) for environmental recklessness. This quandary is intellectually humbling, but not hopeless. Given that our present crisis is no mere academic exercise, we need not expect our philosophical reflections simply to underwrite this or that ecologically friendly view, whether traditional or revisionist, which we may have favored before we started thinking about it. The tension between environmental ethics and Jewish piety—between an independent-minded search for clarity about our ecological predicament, and reverent devotion to the teachings of the Torah—is perhaps unbridgeable. But one may come to grips with it by being either a philosophical inquirer open to Judaism's ecological insights, or a piously observant Jew open to those of philosophy.

Consider, in this regard, current controversies over animals' welfare. Prodded to some extent by White and Leopold and Toynbee, advocates of animal rights and vegetarianism wonder about Judaism's notion of *tsa'ar ba'alei chayyim*. At issue here is not whether Jewish teachings promote animals' welfare, but whether they do so as far as they might. Certainly the Torah prohibits, for example, working animals on the Sabbath (Ex. 20:10, 23:12; Deut. 5:14), overburdening draft-animals (Ex. 23:5), and muzzling oxen treading edible grain (Deut. 25:4). And the Talmud goes on to forbid, for example, dismembering live animals, hunting animals for sport, and leaving animals hungry while humans eat (Bleich 2001, 333–38). But, it is asked, what about possible cruelties inflicted when using animals in laboratory experiments or even slaughtering animals for meat (Levy 2001)? Would espousing animal rights not make Jewish teachings more up-to-date and consistent? As in cases of *bal tashchit*, however, there is a need to reconcile, in this case, animals' welfare with that of human beings. As for animal experimentation, Orthodox and non-Orthodox scholars alike would reply that humans need ongoing scientific medical research. Besides, Jewish teachings are designed to ennoble character (Bleich 2001, 349–52), not just regulate behavior. Hence pious Jews are expected to recognize, and refrain from, inflicting or endorsing cruelty and unbearable suffering anywhere, even or especially in laboratories (Bleich 2001, 344–49). As for animal slaughtering, rules for *kashrut* (dietary certification) specify butchering methods aimed at—and effective in—minimizing if not eliminating animals' pain (Bleich 2001, 338–44). Also, even though vegetarianism is permissible halakhically (Bleich 2001, 371–83), meat eating in conformity with *kashrut* restrictions remains desirable for theological reasons. On reflection, kosher land-animals, fish, and birds turn out to be "pure" (or "clean"; the Hebrew *tahor* means both) in the ecological sense that each as a species inhabits its own generic environment-sector—land, water, or air—as designated at the time of creation (Lev. 11 with Gen. 1; Kass 2001, 386–93, 397–403), none mimics in its motility genera outside its own, each has a "clean" or clearly delineated shape, and none is carnivorous (except that kosher fish may eat other kosher fish; Kass 2001, 408f. n. 29). Piously and self-consciously restricting meat-eating choices to these—following proper ritual slaughtering and after reciting appropriate blessings—reminds Jews versed in the Torah of the diverse and mind-engaging character of creation itself, therefore, and of Jews' long-standing obligations to its Creator.

K

KOREA, NORTH AND SOUTH

The history of post–World War II Korea is a tale of two countries—or, more accurately, one country split in two. The two parts of this divided nation share a name (informally South Korea and North Korea, formally the Republic of Korea and the Democratic People's Republic of Korea, respectively), a landmass, a language, and a culture, but are bitterly divided by ideology, economic circumstances, and geopolitical pressures.

A Japanese colony until the end of World War II, Korea was divided into two administrative zones at the war's end: the Soviet Union occupied the territory north of the 38th parallel, and the United States was in charge of the area to the south. With the collapse of postwar reunification talks, the northern zone declared itself the Korean Democratic People's Republic on May 1, 1948. On June 25, 1950, North Korean troops invaded the southern zone with Soviet and Chinese backing, seeking to unify the country under a communist regime. United Nations troops, under U.S. leadership, fought off the invaders, and the war ended in a standoff in 1953, with the country indefinitely divided.

Since then the capitalist economy of South Korea has registered spectacular rates of growth, skyrocketing from a per capita gross domestic product (GDP) of $100 in 1963 to $10,000 in 1995; its economy now ranks tenth in the world as measured by nominal GDP. North Korea, meanwhile, has stagnated under its planned, centralized communist economy; it is one of the poorest countries in the world, ranking 156th in total GDP with a per capita GDP of roughly $1,000. Beginning in the 1990s, the country's ideologically rigid leadership began to make grudging initiatives in the direction of limited free-market experiments, especially in its tentative economic exchanges with South Korea.

SOUTH KOREAN ENVIRONMENTALISM

South Korea's transformation from a traditional agricultural society into a modern industrial economic powerhouse began in the 1960s. Until the 1970s and mid-1980s, pollution was the main environmental issue, and antipollution movements took the form of victim demands for damage compensation or farmers' and fishermen's protests concerning the siting of industrial facilities. Civil protests against industrial and urban pollution were not taken seriously, however, because of the government's headlong pursuit of economic development.

The Korean Pollution Research Institute (PRI, *Gonghae-Yonguhoe*), established in 1982 by progressive Christian clergymen, made determined efforts to support victims of pollution, to research various environmental problems, and to educate the public about such issues. The majority of the group's supporters were intellectuals and antigovernment activists under the leadership of Yeol Choi. The PRI allied itself with the nationalist-democratic movement, a merger that has led many analysts to view the PRI's environmentalism as part of the left. Yeol Choi later became copresident of the Korean Antipollution Movement Association (KAPMA, *Kongchuryon*), founded in 1988. Its ideology remained broadly leftist, demanding environmental justice combined with criticism of the monopolizing capitalist power.

But South Korean environmentalism was not monopolized by leftist activism. Quite apart from KAPMA and other environmental movements, the national forestation policy, a public campaign for tree planting, and the effort to preserve greenbelts in urban and suburban areas were initiated by the government as early as the 1950s and carried out from then through the time of President Park Chung-hee's regime (1961–1979) effectively enough to secure a comparatively solid ecological foundation for agricultural productivity and sound rural landscape at least in the southern part of the peninsula.

Notable ideological changes of the environmental movement began to occur in South Korea in the late 1980s, namely from leftist activism to a moderate professionalism, and from the radical antipollution movement to a realistic ecological conservationism. While KAPMA regarded huge industrial corporations and political rulers in South Korea as the main violators of ecological balance, Citizens' Coalition for Economic Justice (CCEJ, *Kyungshilyon*), YMCA, and YWCA, for example, criticized the radical strategy of the former antipollution activists.

The South Korean government began, though late, to keep pace with increasing public consciousness that the natural environment must not be sacrificed in pursuit of economic development and that economic value should be harmonized with environmental value through the legal and political systems. As the 1990s began, increasing pollution and environmental degradation were brought under control with higher efficiency on the basis of advanced scientific research and green technologies. The government's earlier repressive attitude toward antipollution activists changed to that of a more responsive as well as responsible and reasonable policy maker. The Ministry of Environment was inaugurated in January 1994, replacing the former National Environment Agency. New laws were enacted in the early 1990s to complement the existing legal measures for environmental policy, including the Environmental Conservation Law, the Fundamental Law for Environmental Policy, the Air Pollution Control Act, the Water Pollution Prevention Act, the Conciliation Law for Environmental Pollution Conflict, and others.

But a variety of hot-button environmental issues continued to arise in South Korea during the 1990s and after 2000. They took in general the form of civil protest against the government's development plans. But the real controversy arose often out of the conflicts between civil interest groups. In some cases, they became nationwide struggles, involving public opinion as well as the political and legal systems, to preserve ecologically valuable resources or endangered rare species of flora and fauna.

Protesters who tried to preserve wide mud flat regions along the west coast of the Korea Peninsula couldn't stop the Shihwa Lake project in Kyunggi Province and the Saemangeum Mud Flat project in Cholla Province. But central and local governments had to cancel the Dong River Dam project in Kangwon Province and the Buan Radioactive Waste Depot project in Cholla Province because of tenacious protests and legal battles to defend the natural landscape and ecological living conditions of the human and biotic inhabitants throughout a wide range of related areas. Protesters rallied against the Cheonseong-Keumjeong Mountain Tunnel project and express railway construction in Kyungsang Province to preserve the habitat of the Korean clawed salamander (*Onychodactylus fischeri*). Only following intervention by the South Korean president and the Supreme Court was tunnel construction able to continue after it waited three years for the final legal decision.

Other notable developments have fostered increased attention to environmental issues in South Korea: the sandy wind blowing every spring from Mongolia and China, the reduction of habitat areas for migratory birds, fish, and marine animals that inhabit or stop on and around the peninsula, and international projects for the protection and preservation of flora and fauna on the peninsula and in the Demilitarized Zone (DMZ) that separates the two Koreas. The United Nations Conference on Environment and Development (UNCED) in 1992 also motivated the Korean people to pay more attention to global environmental issues than they had before. A major contributor to the growing public awareness of environmental problems has been the bimonthly magazine *Green Criticism* (*Noksaek Pyongron*), founded in October 1991 by Jongchul Kim, a poet and professor of English literature. This magazine provides the public with copious information and critical essays on environmentalism, Deep Ecology, critiques of modern civilization, and thoughts on alternative ways of living and their practicability.

The ethical significance of the issues that arose in the 1990s stimulated academic research and philosophical discussions about the most fundamental themes of environmental ethics and the ecological sustainability of human civilization. The Korean Society for the Study of Environmental Philosophy was founded in 1995 and has published its journal, *Environmental Philosophy (Hwankyung Cheolhak)*, since 2002. Scholars and theologians have awakened anew to the ecological wisdom of the religious traditions of Asia (especially, Buddhism, Daoism, and worship of spirits) and in native Korean ideas of nature (e.g., Ch'i-ecology, worship of mountains, and cosmology of heaven-earth-human).

Noteworthy private institutions for the promotion of green culture include the Canaan Farming School (founded by Young-Gi Kim, presbyter, 1962), the Toji (Earth)

Foundation of Culture (founded by Kyung-ree Park, novelist, 1999), the Korea Green Foundation (founded by Yeol Choi, agriculturist, 2002), Green University (founded by Hoeick Chang, professor emeritus, physicist, 2003), and the World Life-Culture Forum (initiated by Jiha Kim, poet, 2003).

GROWING CONSCIOUSNESS IN NORTH KOREA

Since its founding, North Korea has been governed by one-ruler dictatorship, first Kim Il-sung till 1994, then his son Kim Jong-il, with the support of one political party system. It may be assumed that all of North Korean environmental policy has been directed or supported by the same centralized governing structure. The dominant environmental issue in the years before and after the Korean War was forestation policy. It aimed to restore the forest resources that were exploited during the Japanese colonization (1910–1945), and was carried out so effectively that timber production in the 1970s quadrupled that of the late 1940s. But North Korea has had to cope with other environmental issues since the 1950s, in particular, industrial pollution that began in the late 1950s; and the adverse effects of the agricultural development policies introduced in 1976 by Kim Il-sung.

North Korea's industrial development, which had begun earlier than in South Korea, was effective enough that its industry made up 74 percent of the whole national economy in the early 1970s, while it made up only 34 percent in 1956. This process of development must have raised problems of industry pollution and public health. Kim Il-sung himself emphasized continuously in his official speeches beginning in 1972 the seriousness of water, air, and land pollution caused by toxic materials that were emitted from factories and in the urban areas. Material evidence suggests that he didn't stop to promote administrative and legal measures against every kind of pollution. The Land Law, enacted in 1977, contains regulations for environmental protection both in industrial sites and in urban and rural areas. The Pollution Research Institute (later renamed Research Institute for Environmental Protection) was founded also in 1977. Three years later the People's Health Protection Law was enacted following the will of the Supreme People's Assembly to mobilize all the possible antipollution measures.

The Environmental Protection Law, enacted in 1986, introduced environmental protectionism as North Korea's state ideology together with socialism and communism.

An amendment to North Korea's National Constitution in 1992 gave priority to environmental protection over the growth of economic production. Many other new laws and enforcement regulations for environmental protection were continuously enacted almost every year until 1998. But the environmental situation in North Korea worsened during the 1990s as repeated floods and droughts brought disastrous famine, destruction of water supply facilities, a drop in agricultural productivity, and the spread of waterborne epidemics.

Analysts believe that ecological collapse must be, if not the primary, at least one of the main reasons for North Korea's agricultural collapse, economic stagnation, and failure to increase its energy supply in the 1990s, and that the primary reason for the ecological collapse was a false agricultural policy. Kim Il-sung, whose political goal was to realize a self-sufficient national economy, had introduced his Terraced Farm Policy (*Darakbat Campaign*) in 1976 to raise agricultural productivity. But this policy was executed so excessively that after ten years every hill and grassland in the provinces had been converted to plow lands, while the transformation of mountain tops and the devastation of forests had caused other forms of geographic and climate calamities, including earth erosion, aridity, a decrease of fertility, drying up of streams and groundwater, and diminished ecological habitats for flora and fauna species.

Fortunately, North Koreans have learned from their experiences. Since 1998 they have introduced new plans for securing water resources and new policies for environmental protection. A new long-term plan for forestation was started in 2000. The Floodgate Law, the National Land Planning Law, and the River Act were enacted for environmental protection, and systematic reservation plans for the preservation of biotic species were introduced in 2003. North Koreans are enlarging various cooperative measures and possibilities of exchange plans with South Korea not only for industry, agriculture, and energy supply but also in agriculture, forestation, and environmental conservation.

L

LAND ETHIC

Aldo Leopold's land ethic is perhaps the most prominent American articulation of an environmental ethic. Leopold's "The Land Ethic" was published posthumously as the capstone essay in *A Sand County Almanac, and Sketches Here and There* (1949). In the view of most readers the substance of his ethic was stated when he asserted that an interaction with nature "is right when it tends to preserve the integrity, stability, and beauty of the biotic community" and "is wrong when it tends otherwise" (Leopold 1949, pp. 224–225). Leopold's ethic has drawn wide attention and conflicting responses, particularly after critical study of it gained momentum in the 1980s. According to one exponent, J. Baird Callicott, Leopold's ethic has been the "most popular among professional conservationists and least popular among professional philosophers" (Callicott 1999, p. 59). Whether lauded or challenged, Leopold's land ethic has cast a long shadow; it would not be an exaggeration to claim that it is the central pillar of contemporary environmental philosophy.

Leopold's land ethic rests on an understanding that humans exist within an integrated community of life that also includes other animals, plants, rocks, soils, and waters. Particularly in his later years Leopold referred to this assemblage as the "biotic community" or, more simply, "the land." Humans are "plain members and citizens" of this biotic community, Leopold contended (Leopold 1949, p. 204), and therefore have a moral obligation to act consistently with the long-term welfare of that community. That welfare is linked to the ways a community functions ecologically; to its capacity, under human use, to remain fertile and productive over the long term.

Leopold devoted considerable effort to understanding how the biotic community functions and needs to function if it is to retain its productive capacity. Late in life he synthesized his conclusions into a normative concept of ecological functioning that he termed "land health." Leopold viewed land health as an appropriate and much-needed goal for all conservation efforts. Just before his death he encouraged colleagues in the conservation movement to embrace it as their goal. With his land ethic Leopold transformed land health from a communal goal into an ethical norm to guide individual behavior. As Leopold explained, the land ethic "reflects a conviction of individual responsibility for the health of the land" (Leopold 1949, p. 221). He restated that point a few paragraphs later by naming the elements of land health: Human actions are morally right when they uphold the "integrity, stability, and beauty" of the biotic community (pp. 224–225).

Leopold's ethic has given respectability to ethical stances that extend moral value beyond human communities (tribe, nation, global village) to cover collections and assemblies of living things such as species and ecosystems. It also has encouraged ethicists to take science seriously as they frame their ethical norms. Leopold summarized the complexity of nature in terms of the ways landscapes function ecologically rather than, for instance, in terms of their physical or biological composition. By making normative use of the modes of functioning of nature, Leopold invited others to embrace ethical stances that respect nature in functional terms. Leopold's ethic emerged out of a lifelong effort to motivate people, particularly private landowners, to live on land in ways that are sustainable. His land ethic, he hoped, would yield practical

Aldo Leopold, Seated Near a Shack, circa 1940. *"The Land Ethic" is possibly Aldo Leopold's most famous writing, and is one of the most prominent works of U.S. environmental ethical literature. Leopold's background as a wildlife scientist and manager lent itself to the development of his environmental ethic.* **COURTESY OF THE ALDO LEOPOLD FOUNDATION ARCHIVES.**

conservation benefits in terms of improved land-use practices. He implicitly encouraged later conservation advocates to integrate philosophical ideas with on-the-ground conservation labors and evaluate alternative perspectives on the basis of practical consequences.

During his lifetime Leopold (1887–1948) was best known as a wildlife scientist and manager. His professional knowledge extended to multiple-use forestry, grassland management, and the challenges of soil erosion. He disclaimed expertise in agricultural sciences even though farmers and farm organizations regularly sought his professional advice and his academic appointment at the University of Wisconsin was in the Department of Agricultural Economics.

Leopold's early writings on wilderness preservation drew considerable attention, as did his accumulated evidence that wildlife conservation was in many settings best promoted by improving wildlife habitats rather than by imposing tighter limits on hunting, creating additional game preserves, and employing artificial propagation. The frequently quoted essay "Thinking Like a Mountain" in *A Sand County Almanac* has prompted many readers to assume that Leopold was comparatively late in recognizing the ecological roles of predators. However, a broader study of his writings suggests that by the mid-1920s Leopold was aware of the functional benefits of predators. A working forester at the time, however, Leopold also recognized that livestock grazers had a practical need to control predators. Further, he understood that predator control could help private landowners enhance crops of wild game on their lands and that game cropping, even with predator control, could improve alternative land uses. Nonetheless, by the mid-1920s Leopold criticized excessive predator control and pushed for measures to protect predators.

CRUCIAL ISSUES IN THE LAND ETHIC

Critical secondary writing on Leopold's land ethic has tended to dwell chiefly on five overlapping issues:

1. What is the origin of the moral norm in Leopold's ethic?
2. How well does Leopold's concern for the land community as such fit with moral concerns for its human and nonhuman parts?
3. What is the substantive force or content of the land ethic; that is, what did Leopold mean by preserving the biotic community's "integrity, stability, and beauty"?
4. How did Leopold imagine that his ethic might gain traction over time, building on earlier extensions of communal norms?
5. Is Leopold's ethic now largely irrelevant or in need of material revision because of changes in the ways ecologists understand the functioning of nature?

Leopold understood ethics as a body of normative ideals that constrain individuals in daily life as they pursue their self-interest. Individuals are prone to do what is expedient for them personally, he asserted. Applicable ethical schemes require them to broaden their selfish concerns to take account of the welfare of other community members and the "community as such" (Leopold 1949, p. 204). Rarely did Leopold discuss the ethical implications of direct interactions between two or more individuals. Instead, he concentrated on what he saw as the clash between the welfare (expediency) of the individual and the welfare of the surrounding community. He discussed this clash in many other writings, particularly those dealing with conservation economics. In light of this framing of the conservation predicament, the size, composition, and functioning of the relevant moral community were of vital importance for Leopold.

When discussing ethics, Leopold showed special interest in how relevant moral communities expand in size and composition over time, beginning with early peoples. He perceived a slow, long-term expansion in such communities. In several writings he wondered whether this long-term evolution could and would continue, expanding the moral community to include the land as an integrated whole.

Also influential in Leopold's ethical thinking was his conviction that humans are limited beings. As he expressed it, there is much that humans do not know and probably never will know. Humans also have limits on their ability to reason and the expressive capacities of their languages. Even trained scientists, Leopold asserted, know little about the functioning of the land, a reality that exacerbates the challenge of defining land health. Because of these limits, Leopold concluded, it makes sense for people to rely on sentiments and intuitions as well as known facts and reason. It makes sense for them to act humbly and draw lessons from the behaviors of species that have thrived far longer than has *Homo sapiens*.

Leopold viewed his ethic as more than a rule of conduct governing behavior. It was a proposal for a wide-ranging shift in the ways people conceive of and interact with nature, from being separate and apart to being full-fledged community members. His land ethic, Leopold explained, requires "an internal change in our intellectual emphasis, loyalties, affections, and convictions" (Leopold 1949, p. 210). It requires changes in what people want, what they value, and what they deem beautiful.

ORIGIN OF LEOPOLD'S ETHIC

Philosophers studying Leopold's ethic have paid close attention to its moral grounding and to the way it compares with leading approaches to interpersonal ethics. Did Leopold's emphatic concern for the welfare of the biotic community arise out of a belief in the intrinsic moral value of that community apart from the instrumental values that attach to its parts? Is his land ethic, that is, both nonanthropocentric and holistic? Alternatively, did Leopold focus his ethic on the functioning of the community not because the community itself is morally considerable but because the lasting health of the community is instrumentally essential to long-term human welfare? Also, is Leopold's ethic best understood, as it is formally expressed, as a deontological claim, admonishing humans to fulfill their moral duties, or is it better interpreted chiefly as the distillation of pragmatic thinking and experimentation aimed at long-term conservation?

Callicott has asserted that Leopold's ethic is best understood as a claim that the land community as such has intrinsic value and that humans are duty-bound to respect it by fostering its ecological functioning. Thus, Callicott sees Leopold's land ethic as nonanthropocentric and both holistic, extending moral value beyond humans to the land community, and deontological. In supporting his interpretation Callicott has emphasized that Leopold distinguished between conduct that is expedient and conduct that is ethical.

A contrary interpretation was staked out by the philosopher Bryan Norton, also beginning in the 1980s. Norton has viewed Leopold's ethic chiefly as an outgrowth of pragmatic efforts to promote land conservation. Leopold's aim, Norton contends, was to craft an ethic that would prompt people to live in ways that foster long-term human welfare. Leopold's ethic thus remains within the standard anthropocentric ethical paradigm and is best analogized not to Kantian or other deontological perspectives but to the pragmatic moral reasoning of William James, Charles Sanders Peirce, and John Dewey. In Norton's interpretation the land community for Leopold does not possess moral value as such; his ethic thus is neither deontological nor holistic. Instead, the community is simply the soundest practical focus for conservation efforts designed to promote long-term human flourishing. Norton interprets Leopold's distinctions between expediency and ethics as referring only to conflicts about satisfying short-term human preferences at the expense of long-term human well-being. In the long term and taking all humankind into account, expediency and ethics come together.

Both Callicott and Norton have endeavored to promote nature conservation. As they did so, their conflict over interpretations of Leopold quickly turned into a broader dispute about the best way to frame a contemporary environmental ethic. As Leopold scholars, however, they seemed largely to agree on central elements of Leopold's thought. Both read Leopold to include future generations within the relevant moral community. Both conclude that Leopold equated long-term human welfare with the long-term welfare of the biotic community as a whole, thus eliminating conflict between humans and nature. Both believe that Leopold was influenced strongly by Darwinian theories of ethical evolution and, behind them, theories of moral sentiments and virtue-based reasoning.

Few scholars have challenged Leopold's readiness to extend moral value to future generations, a problematic step for many philosophers. In addition, little has been said about his unusual perspective on human welfare. Leopold described human welfare holistically, as a unified totality, not in terms of the summed welfare of individual humans. In addition, Leopold spoke of human welfare after humans embraced the kind of ecological awakening that he deemed essential. Such humans would forgo superfluous wants and would be satisfied by the aesthetic and spiritual benefits of living in a whole and healthy biotic community.

MORAL VALUE OF THE PARTS OF THE COMMUNITY

In a controversial 1980 essay, "Animal Liberation: A Triangular Affair" (Callicott 1989), Callicott asserted that Leopold's concern for community welfare trumped the moral duties that humans owe to other community

members as individuals, duties that Leopold also recognized. His essay drew strong responses, leading to an important clarification of Leopold's ethical vision.

For several decades academic philosophers ignored Leopold's ethic chiefly on the ground that moral considerability could never attach, as Leopold seemed to propose, to an intangible aggregate such as the land community. Even ethicists who could take that step found Callicott's interpretation of Leopold troubling. To elevate the whole over the parts was to make the parts morally subordinate. By implication, it seemed morally permissible, if not obligatory, to reduce species populations, humans included, when lower numbers are needed to uphold the healthy functioning of the community. This was the charge of ecofascism: In the name of protecting the land community, humans could and indeed should be killed.

Callicott responded with a refined interpretation of Leopold's land ethic. That ethic, Callicott contended in *In Defense of the Land Ethic,* was not intended to displace existing standards of interpersonal ethics. Instead, it was to be added to them. Leopold's holistic stance, in fact, did justify lethal methods to reduce populations of nonhuman species but certainly not the killing of people. With this reasoning Callicott undercut the charge that Leopold's holism is a form of fascism. Yet as he recognized, he left Leopold's ethic unable to provide clear guidance when the claims of morally worthy individuals call for actions that clash with moral respect for the land community. Thus, to implement Leopold's ethic it became necessary to generate a second-order rule that would integrate the land ethic with existing interpersonal standards.

In several of his writings Leopold commented on the "biotic rights" of parts of nature to continued existence. He applied the term, however, only to species and rare natural communities, not to individual organisms. In the practical work of conservation, efforts to preserve such collective wholes are unlikely to collide with efforts to sustain land health. Accordingly, Leopold's respect for the biotic rights of species and rare communities seems not to conflict with the moral primacy of community health.

SUBSTANCE OF THE LAND ETHIC

Nearly all discussions of the land ethic quote Leopold's famous summation of it. Few commentators, though, have attempted to figure out what Leopold meant when speaking of the "integrity, stability, and beauty" of the land. The word *stability* in particular has been problematic. The term seems to endorse a view of healthy nature as static or unchanging that contemporary ecologists reject. The word *integrity* also has created difficulties. The term typically refers to the totality of species and perhaps also to the full range of biological assemblies that existed in a particular landscape before humans arrived or, more arbitrarily, before humans of European descent arrived. When integrity is defined in this way, people can preserve it only by leaving land untouched and undoing prior human changes, a practical impossibility in places where people live and work. Commentators rarely have taken Leopold's reference to beauty seriously. Beauty, it is assumed, is too vague and subjective a concept to provide objective guidance.

In his writings on Leopold, Callicott examined late twentieth-century writings in ecology to figure out which of several contemporary meanings of stability (and, to a lesser extent, integrity) make the most sense when applied to Leopold's ethic. In a more recent study, *Aldo Leopold's Odyssey* (2006), Julianne Newton (now Warren) attempted to identify with precision the meanings Leopold personally attached to those key words rather than beginning with definitions composed by others. Newton's conclusion is that the substance of Leopold's land ethic cannot be understood without grasping what Leopold meant by land health. His key words, she concludes, were intended to incorporate into his ethic the full body of his writings about land sickness and health. Leopold's writing on land health in turn built on his lengthy effort to construct, from studies of differing landscapes, a "common concept" of how land in general works.

The key attribute of healthy land for Leopold, according to Newton, was apparently stability, by which Leopold meant not a community with an unchanging biological membership but a biotic system that possesses and retains an ability to cycle nutrients over and over at high levels of efficiency without significant loss. "Land is stable," Leopold explained in "Biotic Land-Use" (circa 1942), "when its food chains are so organized as to be able to circulate the same food an indefinite number of times" (Leopold 1999, p. 205). Similarly, integrity for Leopold apparently referred to the suite of species required in a landscape for that landscape to retain its stability. Leopold preferred that positions in nutrient chains be filled by native species but defined health in a way that allows exotics to substitute for native species and permits significant simplifications in community membership as long as nutrient flows remain lengthy and efficient. Beauty for Leopold apparently was an attribute of lands that retained their health, particularly lands that displayed their native integrity.

In this interpretation—that Leopold's key words linked his land ethic to his ideal of land health—insights on Leopold's ethic and its practical implications are best obtained by studying the symptoms of land sickness as he explained them, Leopold's more extended comments on land health, and the illustrations he used in "The Land Ethic" and elsewhere of lands that retain their health despite long human use. Also useful for this purpose are

Leopold's observations that natural communities over evolutionary time tend to increase in biological composition and in their ability to cycle nutrients efficiently without loss. The best land uses, Leopold suggested, are ones that do not impede these apparent evolutionary trends.

EVOLUTION OF A LAND ETHIC

Writing on Leopold's ethic also has paid attention to Leopold's many comments on how ethics emerge over time within moral communities. Most visibly in "The Land Ethic," Leopold drew on the writings of Charles Darwin describing the evolutionary forces that seemingly push communities, over time, to expand the reach of their ethical ideals. Leopold defined an ethic as "the tendency of interdependent individuals or groups to evolve modes of co-operation" (Leopold 1949, p. 202). With little conscious thought, he believed, members of a moral community gradually expand the size and composition of their community, pushed by invisible evolutionary forces. The key to the continued expansion of ethics, then, is to broaden the moral community beyond humans to include the parts of nature with which humans are interdependent. Such an expansion, Leopold believed, is an evolutionary possibility as well as an ecological necessity.

Drawing on the conclusions of anthropologists and historians, several commentators have cast serious doubt on Leopold's evolutionary theories and the conclusions he drew from them. Early peoples often included nonhuman life within their moral calculations. The expansion of ethics to include more people—different tribes, races, ethnic and religious groups, and the like—apparently was accompanied by a contraction in the moral value attributed to wild species. Leopold's errors as anthropologist, however, have not prompted commentators to call his ethic into question given that its moral force rests on different grounds. History aside, Leopold's speculations are vulnerable to claims that evolutionary processes at work in the past have been weakened or displaced by social welfare programs. People who degrade their home landscape may have the ability to remain in place and thrive—to survive in evolutionary terms—as a result of benefits supplied by distant governments; they are not forced to leave or to change their inappropriate land uses.

IS LEOPOLD'S ETHIC OUT OF DATE?

Callicott has been the most prominent commentator who has questioned the validity of Leopold's ethic because of changes in ecological thought since his day. Callicott's concerns are shared by many others, who view Leopold's ethic as a throwback to an earlier, discredited era of ecological understanding.

In his criticism Callicott assumed that Leopold shared the ecological ideas that dominated his day. Like his contemporaries, Leopold viewed natural systems as organized into coherent, persistent communities that retain their composition and functioning until disturbed by external, often anthropogenic, forces. Callicott has undertaken to revise Leopold's ethic to make it more dynamic: that is, to incorporate into it overt reference to the ongoing changes in nature and to the ability of people, without violating the ethics, to alter land at relatively slow spatial and temporal scales.

In her detailed study of Leopold's science and scientific influences Newton implicitly challenged the view that Leopold's science is out of date. She presents Leopold's scientific understandings as peculiar to him, not the same as those of his contemporaries. In her view Leopold and his contemporaries were far more aware of the dynamism of nature than standard historical accounts suggest. Further, Leopold's ethic did not focus chiefly on the biological composition of a community: the part of nature that ecologists see as most dynamic. Instead it focused on the ecological functioning of the community, particularly its ability to cycle nutrients efficiently, an aspect of community functioning that is less prone to change. Thus, contemporary emphases on dynamic changes in community composition may not pose the problems for the land ethic that Callicott discusses.

LANDSCAPE ARCHITECTURE, DESIGN, AND PRESERVATION

Landscape architecture is a diverse but holistic discipline that has emerged since the 1850s as a leading profession in advocating sustainable land-use practices. Landscape architects focus their work on the intersection of human need, environmental sustainability, and aesthetics. Human need is broadly conceived to include practical matters of function, economic need, safety, mental and physical health, and less easily quantified needs such as comfort, engagement with social groups, and self-worth. Care for the natural environment considers how to integrate these human needs into natural systems so as to reduce environmental damage and allow systems to operate more closely to their natural pattern. All of this is done within the framework of creating pleasing landscapes, since those that are appreciated are more often cared for and protected.

As practitioners of a diverse discipline, landscape architects work at different scales and types. Projects can be as small as a walled courtyard or as large as a regional plan. The purposes of these projects may be as diverse as recreation, resource conservation, education, and housing. The field includes such subfields as planting design, natural-resource planning, site planning, heritage-landscape preservation, garden design, urban design, land-use planning, disturbed-land reclamation, wildlife planning, and environmental art. All of this work, no matter its size or scope, is linked by the underlying philosophies of stewardship for land, care for the natural systems that form it, and concern for the people who inhabit it.

EARLY EXAMPLES

These attitudes have evolved over a long period of time because landscape architecture, as an activity rather than as a specialized profession, has been part of human experience since prehistoric times. In the distant past, people learned about natural systems from intimate day-to-day contact. The simple technologies of prehistoric times limited people's ability to modify their environments. Gradually they began to make substantial changes to landscapes. They dammed rivers, channeled water to places it did not go naturally, leveled hills, and planted trees in areas distant from where they naturally occurred. Such activities created environmental problems. In ancient Greece (ca. 1200–323 BCE) and the Cambodian kingdom of Angkor (ninth to fifteenth centuries), for example, the harvesting of wood for agricultural land clearing, construction, and fuel led to extensive deforestation, which intensified local soil erosion.

With the emergence of the Renaissance in Europe, advances in science led to new knowledge about natural systems, as well as to changes in attitudes toward the environment. Medieval fear and awe of nature was replaced by an ever increasing sense that humans could, and should, alter it. Leonardo da Vinci, often cited as the epitome of the Renaissance mind, engineered a large-scale scheme to drain natural wetlands of the Chiana Valley in central Italy. He also advocated rerouting the Arno River to improve the geophysical setting for Florence. In the Renaissance such dreams at times outpaced technology—the Arno was not rerouted, but the marshy Chiana Valley was drained, and thereby transformed into one of the most productive agricultural regions of Tuscany.

Much post-Renaissance environmental thinking was framed within the philosophical perspective referred to today as the Enlightenment. This system emphasized rational thought and science as the basis for human decision making, as well as the importance of individual creativity in solving human problems. The Enlightenment, which influenced Europeanized parts of the world into the twentieth century, served as a critical philosophical system during formative periods of both the profession of landscape architecture and the environmental movement. Both fields came to appreciate natural complexity through Enlightenment philosophy. In the nineteenth century another philosophy, Romanticism, also began to influence human perceptions of nature. Romanticism emphasized emotional, sensory experience of the environment. Taken together, the two philosophies were behind many of the developments in landscape architecture and environmentalism that occurred in the eighteenth and nineteenth centuries.

EIGHTEENTH CENTURY

Developments in the eighteenth century illustrate the influences of both these philosophies. Rationality in economic thought led to an increasing focus on land as private capital and a resource for private, rather than communal, benefit. One resulting process in Great Britain was enclosure, a process that consolidated small feudal land holdings into monolithic estates and thus drove many tenant farmers from the land. Even more extreme were the large plantations of the American South, in which both

The Medieval Town of Cortona, in Tuscany, Italy. *Small towns such as Cortona evidence the delightful way that natural landscape and human-made architecture can complement one another. The town overlooks the Chiana Valley, which was drained during the Renaissance and is now one of the most agriculturally productive regions of Tuscany.* **© GILLIAN PRICE/ALAMY.**

land and people were exploited as the right of the landowning class. The Industrial Revolution, with its emphasis on science and engineering innovation, also reflected Enlightenment thought. In part as a reaction to industrialization, Romanticism countered with a view that idealized nature. A design approach variously known as the Landscape Gardening School, the Natural Style, the English Style, or the Picturesque evolved from Romantic philosophy and the arts that it influenced. These styles emphasized naturalistic appearance, but not natural processes or preservation of environmental resources.

NINETEENTH CENTURY

With the advent of the nineteenth century, the threads of thought and action began to emerge that eventually led to environmental problems or more recent decades, as well as approaches to their solutions. It is important to note that people were often fully aware of the environmental changes that their activities caused, but continued them out of economic need while experimenting with remedies. For example, owners of southern plantations were conscious, at least by the first decades of the 1800s, that their land clearing and tilling activities caused soil erosion. Planters often reported in agricultural journals both successful and unsuccessful experiments that they carried out to control erosion on their land. In other instances, the public expressed concern about potential environmental impacts from proposed projects. As a case in point, when construction of the Erie Canal was announced in the 1830s, a New York citizens' group raised the issue of possible pollution of Lake Erie with salt water from the Atlantic Ocean. In the middle of the century, thinking about the environment was influenced by Romanticism and other philosophies, especially Transcendentalism, as found in Ralph Waldo Emerson's *Nature* (1836).

Since the early part of the nineteenth century, observers, especially those in America, had noted the rapid pace of environmental change. Before 1820 the botanical explorer and horticulturist François André Michaux observed extensive deforestation in the American East. At around the same time, the painter George Catlin, surveying the drastic

Bridalveil Fall in Yosemite National Park. *Bridalveil Fall is an outstanding example of a waterfall issuing from a hanging valley far above the Yosemite Valley floor. The natural beauty of Yosemite served as a convincing argument for landscape preservation in the mid-1800s, when it became the first large-scale landscape set aside for public use.* **© J.A. THOMAS/U.S. GEOLOGICAL SURVEY.**

changes in the American West, especially the decimation of buffalo herds, made the farsighted proposal of establishing what he called a "nation's park" to preserve "Nature's works" (Catlin 1926 [1840], vol. 1, pp. 292–293). In fact, the first officially created park, though not a true national park, came less than ten years after he wrote, with the establishment of Hot Springs Reservation (now Hot Springs National Park) in Arkansas.

A different type of appreciation of the environment, focused on the negative effects of human activity, appeared in George Perkins Marsh's *Man and Nature, or Physical Geography as Modified by Human Action* (1864). Marsh's book gave those who had long expressed concern for the natural world, including many early landscape architects, ammunition to support their arguments.

Loss of natural features and systems was often framed in terms of beautiful scenery—a convincing argument in an age when Romantic thought dominated. Horace W. S. Cleveland and Frederick Law Olmsted Sr., both of whom emerged after the Civil War as leaders in landscape architecture, were early advocates of the preservation of beautiful and environmentally significant areas. In the 1850s Cleveland argued for preserving the Middlesex Fells landscape outside of Boston, and later for preserving Minnehaha Falls in Minnesota. In the 1860s Olmsted proposed placing Yosemite Valley under public control for its protection. Yosemite became the first large-scale landscape set aside for public use, but not by the federal government. Instead, it was the state of California, presaging its late-twentieth-century role in progressive environmental legislation, that made Yosemite Valley the first state park in the nation in 1864 (it later became a national park). Within a decade the federal government followed the lead of California. Based in part on the glowing descriptions of Ferdinand V. Hayden and accompanying painter Thomas Moran, over two million acres in the Yellowstone area became the first named national park. The awe inspired by western mountain landscapes led Canada to establish Banff as its first national park in 1885. Landscapes in the East were also deemed worthy of preservation. Niagara Falls became the first cross-border park—an effort that also involved Olmsted.

In the decades after the American Civil War (1861-1865), a number of national organizations formed to advocate active restoration and protection of environments or specific natural features. Among the first was the Arbor Day Foundation, founded by the scientific agriculturist J. Sterling Morton. Alarmed by deforestation in his home state of Nebraska and elsewhere, Morton promoted planting seedlings across the nation. The Audubon Society made protecting birds and their habitats its mission. Founded in 1886 by the appropriately named George Bird Grinnell (and incorporated as a national organization in 1905), the society first focused on reducing slaughter of plumage species. Later it employed conservation wardens, set up sanctuaries, and educated the public. John Muir and others formed the Sierra Club in 1892 to further preservation of California landscapes, especially Yosemite. The group quickly evolved into an advocate for more national parks. Its objectives, as well as differences in philosophies among founders of the group, became clarified when San Francisco revealed plans to dam and flood the scenic Hetch Hetchy Valley near Yosemite Valley. In this struggle, the old emphasis on scenic beauty worked against Hetch Hetchy, which would have been considered spectacular if it were not outshone by Yosemite Valley. O'Shaughnessy Dam was completed in 1923, and the valley was flooded, and remains so today. In the 1980s the U.S. Department of the Interior began considering removing the dam and restoring the valley—a cause that the Sierra Club continues to promote more than eighty years after it lost its first major environmental battle. The arguments that became part of the public debate over Hetch Hetchy, arguments between the value of natural systems in their own right and their value only as resources for human use, continue today.

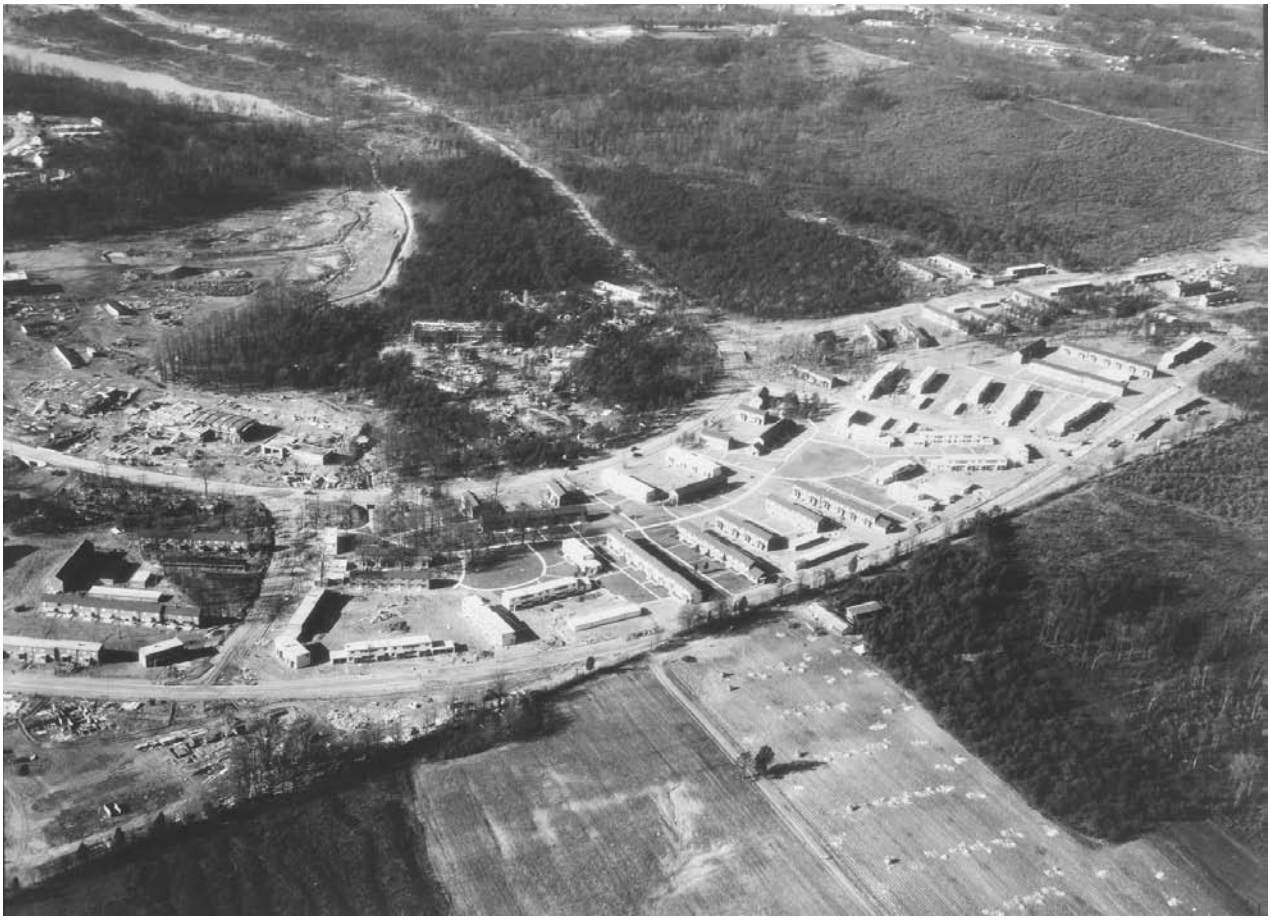
As influential as these private groups have been, it was through federal action that the largest tracks of land have been preserved, although not for purely environmental purposes. National forests were first established in 1891. Termed reserves, the forests were created to manage consumption with planned harvesting and replanting, rather than to keep trees inviolate. Under Gifford Pinchot, the first chief of the U.S. Forest Service, the service and the forests themselves became institutions professionally run on the basis of current scientific principles. Pinchot advocated wise use for a sustained yield, but did not believe that complete protection, even of outstanding natural areas, was required. This attitude led to much disagreement with Muir and others in the preservation movement.

EARLY TWENTIETH CENTURY

Federal action intensified in the twentieth century. The National Park Service, set up in 1916 with Stephen Mather as its first director, managed existing and future parks. The fledgling service hired its first landscape architect, Charles Punchard, in 1919. In language composed by Frederick Law Olmsted Jr., son of the famous nineteenth-century landscape architect and an inheritor of his firm, legislation establishing the parks set out their rationale as being "to conserve the scenery and natural ... objects and the wildlife therein ... by such means as will leave them unimpaired for the enjoyment of future generations" (as quoted in Albright 1985, p. 36). Unfortunately, just what constituted leaving parks unimpaired meant different things to different groups. Hence, the varied stakeholders in park activities have rarely agreed on the proper direction of park management.

Many landscape architects of the early twentieth century were just as active in environmental causes and issues as had been their nineteenth-century predecessors. Their activities affected all areas of practice, but had special influence on planting design, urban planning, and regional planning. Use of native plants had been a part of landscape architecture since Ossian Simonds proposed use of prairie plants in his projects, such as Graceland Cemetery in Chicago. Others expanded on native plants in designs by suggesting natural groupings for disturbed lands. Frank Waugh, of the University of Massachusetts and later the U.S. Forest Service, advocated study of native plant arrangements and their use in roadside plantings—ideas that he articulated in his classic work *The Natural Style in Landscape Gardening* (1917). Others as well focused on use of native plants, including Beatrix Jones Farrand, who devoted her estate home at Reef Point in Bar Harbor, Maine, to the cultivation of New England natives. Jens Jensen not only valued plants native to the prairie states, but also proposed their use in similar settings in the natural landscapes of Wisconsin, Illinois, Iowa, and Indiana. His designs for parks of the West Side of Chicago typically included miniature versions of regional landscape features: wide, slowly moving streams, which he referred to as prairie lagoons; rockscapes that mimicked the limestone outcroppings found in glaciated regions of Illinois; and large open prairielike spaces fringed with tree species typically found at the fringes of real prairies.

Even in their practice of urban planning, landscape architects of the early twentieth century achieved impressive examples of environmental preservation. This was done largely in the planning of park systems, but also occurred in the design of individual subdivisions. For example, Frederick Law Olmsted Jr. protected the Rock Creek riparian area in Washington, D.C., as part of the park system proposed by the Senate Park Commission of 1900. Walter Burley Griffin designed the Rock Crest subdivision in Mason City, Iowa, to preserve the creek that ran through it by placing house sites on high ground surrounding it and making the stream corridor a wooded backyard for each house.



Aerial View of Greenbelt, Maryland, 1937. *As the economy of the United States and the world declined in the 1930s, many landscape architects took jobs in government programs to plan, design, and oversee work as diverse as park building, community design, water-control construction, and soil stabilization. The city of Greenbelt was a planned community, modeled after English garden cities of the 19th century.* **THE LIBRARY OF CONGRESS.**

Landscape architects can rightly be considered full participants in the environmental progressive movement of the early twentieth century. This is especially true of those who focused on regional and resource planning. Warren Manning, Clarence Stein, John Nolen, and Frederick Law Olmsted Jr. provided leadership in this effort. Manning's plan for Harrisburg, Pennsylvania, proposed that a minimum of 5 percent of the natural landscape within the city be set aside for protection, a high figure for the early twentieth century. Stein, a cofounder of the Regional Planning Association of America, worked to establish the Appalachian Trail as the first modern multistate footpath. Nolen, although today best known as an inspiration to new urbanists, believed that plans should conform to natural topography, and that land use should fit natural capacities, as he outlined in his 1908 plan for San Diego. Olmsted balanced his more common work in city planning with interest in national parks. Through his firm he worked on a number of environmentally sensitive sites, including Acadia National Park in Maine, Everglades National Park in Florida, and Redwoods National Park in California.

MID-TWENTIETH CENTURY

As much as had been achieved in the early 1900s, it took the twin disasters of the crash of 1929 and the Dust Bowl of the early 1930s to really bring environmental concerns and sustainable-landscape treatments to the forefront of public thought and professional practice. As the economy of the United States and the world declined in the 1930s, many landscape architects, unable to continue private employment, took jobs in government programs to plan, design, and oversee work as diverse as park building, community design, water-control construction, and soil stabilization. For example, landscape architects designed many of the state-park sites and facilities constructed by Civilian Conservation Corps workers. They were also active in the Green

Cities program of the Resettlement Administration, which planned and built model low-cost communities, like Greenbelt, Maryland.

The Dust Bowl, a massive wind-erosion event that crippled the Great Plains for several years, made the general public aware of the effects of environmental damage. A number of concerns voiced earlier, such as that concerning soil erosion, became the basis of new governmental programs. Hugh Hammond Bennett had attempted to point out the potentially drastic consequences of soil erosion, but it took the Dust Bowl to make his arguments graphic. As a result, the Soil Conservation Service, now the National Resources Conservation Service, formed during the 1930s to educate the public on proper soil-preservation strategies. Although staffed largely by soil scientists, the service employed some landscape architects in the planning of some soil-control demonstration sites, particularly near cities.

Environmental concerns took a backseat to military and political survival during the 1940s. World War II and its aftermath caused serious environmental damage in both Europe and Asia. After the war, resource degradation continued as people struggled merely to live. In the United States, which escaped direct war damage, environmental problems resulted from industrial production in munitions production, mining, and other support activities. In some cases, efforts that had started to support the war continued for peacetime use with little consideration about the air, soil, and water pollution that they caused.

As prosperity returned in the 1950s, people began to examine conditions in the environment and take initial steps to lessen damage. The Nature Conservancy was one of the first new organizations to form after the war as a result of these concerns. In 1955 it began the mission for which it is best known, land acquisition, with the purchase of sixty acres (now over seven hundred acres) for the Mianus River Gorge Preserve in Bedford, New York. Other organizations quickly emerged or expanded. This was also a period in which books extolled the value of the environment or warned about the damage being done to it. Marjory Stoneman Douglas championed preserving the Everglades in her classic volume *The Everglades: River of Grass* (1947). She went on to battle wetland destruction by developers and the U.S. Army Corps of Engineers, eventually founding Friends of the Everglades. Aldo Leopold, a noted wildlife expert, scientifically studied nature and emoted about it. He ultimately presented his observations in *A Sand County Almanac* (1949). Although published after death, he was able through its words to communicate what he referred to as a "land ethic," a social and political conscience intended to influence any human intervention in natural landscapes. In *Silent Spring* (1962), Rachel Carson chronicled the damage done through modern pollution, especially from pesticides, using affecting imagery to make her point about the causes of declining bird populations.

LATE TWENTIETH AND EARLY TWENTY-FIRST CENTURIES

Several pivotal events occurred in the 1960s. In middecade Congress passed the Wilderness Act, which permanently protected over 9 million acres of significant land from development. Among other pieces of environmental legislation, in 1966 the Endangered Species Preservation Act passed, and then two years later came the Wild and Scenic Rivers Act. But a milestone of U.S. and world environmental policy came in 1969 with passage of the National Environmental Policy Act. This law prescribed a formal process that considers the environmental consequences of any activity receiving federal funding, including public review. This process was codified in required environmental impact statements, many of which were written by landscape architects in consultation with scientists.

The landscape architects Philip Lewis and Ian McHarg brought scientific analysis of landscape capabilities to the discipline by developing the overlay method to study natural and human systems—an approach today done digitally through Geographical Information Systems (GIS). In his seminal work *Design with Nature* (1969), McHarg articulated both a study method and an application of that process to sound land planning, as his firm had done in the Plan for the Valleys in Baltimore County, Maryland. The methods that he outlined in the book and taught at the University of Pennsylvania became the standard by which landscape architects evaluated sites.

As the century progressed, new issues emerged to challenge the profession. Worldwide growth of tourism required consideration of the environmental impacts of both large numbers of visitors and massive tourist facilities on delicate ecosystems. In this discussion, questions of landscape management were central: How could the carrying capacity of an area be determined? Which means of access would protect the ecology? How could sites be used to educate the public on the value of natural systems? Out of these issues there were developed important design guidelines, such as the use of boardwalks for access in sensitive areas.

Such significant philosophical and administrative questions were at one level of the practice of landscape architecture. At other levels, more direct, practical concerns were addressed, such as how to house people in environmentally sensitive and sustainable communities. Village Homes in Davis, California, begun in 1974, demonstrated that sound land-use planning, including retention of onsite runoff and planting of productive species, could be coupled with socially sensitive community building. Village

A Prairie Crossing Home in Grayslake, Illinois. *The Prairie Crossing is a nationally recognized conservation community, planned by Peter Walker and William Johnson. The community contains 359 single family homes, and was built on such ecofriendly principles as environmental protection, healthy living (including all organic farming), and energy conservation.*
© KIM KARPELES/ALAMY.

Homes became a model of innovative sustainable community design. Other developments took different approaches. Planning at the Woodlands, Texas, aimed at preserving a vital water recharge area for an aquifer that served Houston. As planned by Wallace, McHarg, Roberts, and Todd, a Philadelphia firm of landscape architects and planners, housing occupied less sensitive areas, ponds were created to let water soak into the soil above the aquifer, and numerous pine woods were preserved to retard runoff. Prairie Crossing in Grayslake, Illinois, planned by Peter Walker and William Johnson, represented a different approach to community planning. There buildable sites were clustered tighter than is typical to preserve more land for open space, which includes protected farm land, river corridors, and wildlife habitat.

On a smaller scale, an extensive array of design strategies are now being used to make sites more sustainable and thereby reduce environmental damage. Techniques include xeriscaping (the use of native and adaptable plants to reduce water and other resource consumption), construction of retention and detention ponds to prevent or limit the amount of runoff that leaves a site (as an aid in flood control downstream), energy conservation through site design (including proper building orientation and shading of structures), use of recycled or renewable materials (such as shredded tires to make playground surfaces), and construction of wetlands to purify contaminated water. Landscape architects take seriously the charge to act locally, making sound decisions for a sustainable environment at every scale of work.

Landscape architecture continues in the forefront of efforts in the early twenty-first century to create a more sustainable future for the world. Its practice affects every aspect of sustainability and goes beyond theory and general principles to apply both philosophy and science to real world situations used by people daily. Every action in the landscape—from the most mundane, such as shrub clearing, to the large-scale, such as the construction of a new town—has significant consequences for the local environment. When these local outcomes become aggregated, serious global environmental change can occur. The overriding goal of landscape architecture is, in the words of Robert L. Thayer, to create places "where human communities, resource uses, and the carrying capacity of surrounding ecosystems can all be perpetually maintained" (1994, p. 235).

LANDSCAPE PAINTERS AND ENVIRONMENTAL PHOTOGRAPHY

Landscape painting, which began in the late Middle Ages, has played an important role in environmental thought and environmental philosophy, especially in the first eight decades of the nineteenth century in the United States. Although the type of painting that promoted nature preservation ceased to be mainstream art by the end of the nineteenth century, landscape photography, after 1860, began to play a comparable role and has continued to do so to this day.

VIEWS OF NATURE IN THE MIDDLE AGES

In the Middle Ages educated people were taught that nature was not beautiful, for the theology that pervaded the culture of the time saw nature as competing with and detracting from the love of God. For example, Petrarch (1304–1374), while climbing a moutain in 1336 and taking pleasure in the view, reprimanded himself for "admiring earthly things" (Clark 1976, p. 10). Realistic depictions of nature were rare. Images of earthly or natural objects were intended to be symbolic rather than representational. This focus was a characteristic form of thought of the time—"symbolic thinking"—according to which images were associated with biblical stories (Huizinga 1924). The landscape painting of the Middle Ages was essentially a "landscape of symbols" (Clark 1976, chap. 1, pp. 1–31). Mountains, for example, symbolized the wrath of God at the time of the Flood of Noah.

The darkness in depictions of forests reflected a general fear of nature and its estrangement from God, who was otherworldly. In the centuries that followed, the understory of forests gradually brightened with light, signifying the presence of God in nature. By the nineteenth century, the conflict between God and nature was broken. It was possible to love God while loving nature in what otherwise appeared to be realistic, secular painting.

EARLY MODERN VIEWS OF NATURE

As the Middle Ages waned, symbolic thinking was displaced by representational thinking as the primary mode of thought. In the early modern period representation was especially important in the rise of science, but its role was no less important in painting. A central feature of modern painting was the development of perspective, which led to the realistic depiction of spatial relations. In addition, artists began to try to accurately represent the details of nature, which gradually led them to incorporate the science of natural history into their work—especially biology, botany, and geology.

Painters developed close ties with the science of natural history because they were attending to the same properties of natural objects: secondary properties (color, taste, smell, texture, and sound), in terms of the distinction developed by Galileo Galilei and René-Descartes between primary and secondary qualities. Biologists, botanists, and geologists used these properties to classify the objects of their scientific interest. Painters rendered these properties in their artistic work. Writers followed suit, making use of additional secondary properties in their poetry and prose.

Although the transition from the "landscape of symbols" to the "landscape of fact" (Clark 1976) can be presented as a general development among nearly all European artists, American painters of the nineteenth century identified three artists as especially important: Titian (c. 1485–1576), Salvator Rosa (1615–1673), and Claude Lorrain (1600–1682). Titian was considered the first painter to use landscape as background. The human figures, however, were large and the central feature of the paintings. The landscapes themselves were simply generic background decoration. Rosa introduced the sublime into painting in terms of jagged, broken geological features and stormy, tempestuous skies. A weathered stump of a tree in the lower left corner of painters became a tradition among the artists that followed after him. The sublime was an aesthetic appreciation of nature involving the transformation of properties of God into properties of nature. Mountains symbolizing the wrath of God came to be regarded as terrifying but breathtaking natural phenomena (Nicolson 1963). Claude pioneered picturesque beauty in painting.

Initially, the sublime was viewed as the opposite of the beautiful and the primary aesthetic attribute of nature. The sublime was big, the beautiful small; the sublime rough, the beautiful smooth; the sublime terrifying, the beautiful pleasant. The dichotomy between the sublime and the beautiful was established by the philosopher Edmund Burke (1729–1797) in his book *A Philosophical Enquiry into the Origin of Our Ideas of the Sublime and the Beautiful* (1757). William Gilpin (1724–1804), a writer,

Italian Landscape, 1640, by Claude Lorrain. *Claude Lorrain was an early landscape painter whose techniques had a significant influence on nineteenth-century American painters. He is considered the pioneer of the "picturesque," an aesthetic category that seemed to combine both the sublime and the beautiful in landscape painting. Prior to this historical period, landscapes alone were not considered to be an appropriate subject matter for serious painting.* **THE ART ARCHIVE/TATE GALLERY LONDON.**

artist, and clergyman, attacked Burke's distinction in a series of books analyzing the aesthetic elements of natural scenery, particularly river valleys, arguing that nature also could be beautiful as well as sublime—that is, picturesque. Claude's paintings were the model of picturesque beauty, which combines elements of both the sublime and the beautiful (Hussey 1927): some roughness without being frightening; some harmony without being formal.

The scenic elements of Claude paintings are harmonious rather than chaotic. The human figures are small, but the paintings include ruins or castles to provide a humanizing element. In the nineteenth century the paintings of Rosa (epitomizing the sublime) and Claude (epitomizing the picturesque) served as alternative formulaic styles for American landscape painters.

The admiration for the painting of natural scenery gradually led to an aesthetic appreciation of landscapes similar to those depicted in picturesque painting. People became fascinated with particular landscapes during travel, and it slowly dawned on them that the scenery reminded them of Claude paintings. The transition proved to be a difficult one. In order to facilitate the development of a taste for natural scenery, people used "Claude glasses," a mirror surrounded by a small picture frame, which, when standing with one's back to the natural scene, permitted the traveler to rearview the natural scene much like a framed painting. The glass of the mirror was stained to match the golden brown of the varnish Claude used on his paintings so as to enhance the picturesque aesthetic effect.

VIEWS OF NATURE DURING THE NINETEENTH CENTURY

Although he was not a landscape painter, the writer Henry David Thoreau (1817–1862) articulated a view of nature that emerged out of two traditions that were central to landscape painting: the science of natural history and picturesque travel. Thoreau was considered an important amateur naturalist. In addition, his early writing attempts were heavily influenced by Gilpin. Thoreau began writing *A Week on the Concord and Merrimack Rivers* (1849) shortly after reading twelve of Gilpin's picturesque travel books.

American painting started with a strong focus on portrait painting because it was the most reliable way for artists to receive payment for their work. The first major American landscape painter was Thomas Cole (1801–1848), who is considered the founder of the Hudson River School, a group of artists in New York and New England who became known for the painting of natural scenes, especially in the Adirondacks and the Catskills. Cole focused on landscape painting in large part because he had little ability as a portrait painter. Cole was troubled throughout his career about the type of paintings that would sell. He preferred to paint ideal or composed paintings in which the scene depicted arose from the artist's imagination. Cole believed that the depiction of a real landscape was merely imitation and therefore could not be appreciated for the creativity of the artist, only for the artist's technical skills in painting. Unfortunately, from Cole's perspective, Americans preferred paintings of real places and often wanted to know where they could go to compare his paintings with actual locations in nature. He lamented that, because of the poor tastes of the American people, he was never able to become the great artist he should have been (Novak 1969). On occasion he did paint real places: For example, *The Oxbow (The Connecticut River near Northampton)* (1836) is the kind of painting for which he is best remembered and which served as the inspiration for the rest of the Hudson River School. *The Oxbow* was admired especially because it replaced the formulaic tumultuous sky of Salvator Rosa with a representation of a recognizable meteorological front. Cole was most interested in his religious paintings, but his place in history is based primarily on his work as a landscape painter.

Most members of the Hudson River School did not share Cole's preference for "composed" paintings. After Cole's death, Asher Durand (1796–1886), as the editor of *The Crayon,* a newsletter for artists, became the leader of the Hudson River School. In an editorial in *The Crayon,* he argued for the accurate depiction of real places in landscape painting:

> Let it be remembered that the subject of the picture, the material object or objects from which it is constructed, are the essential parts of it. If you have no love for them, you can have no genuine feeling for the picture which represents them. You may have a kind of admiration for the masterly treatment, and remarkable qualities, but that does not constitute love of Art—it is only an intellectual perception of power.... We *love* Nature and Beauty—we admire the artist who renders them in his works. (Durand 1855)

Durand also emphasized the relationship of landscape painting and nature poetry with one of his most famous paintings, *Kindred Spirits* (1849), which depicts Thomas Cole and William Cullen Bryant (1794–1878), an American Romantic poet. Bryant himself called attention to this connection with a two-volume illustrated book, *Picturesque America* (1872), filled with pen-and-ink drawings documenting the beauty of the United States.

Frederick Church, Cole's only student, became interested in the role of painting in the science of natural history after reading *The Cosmos* (1850) by Alexander von Humboldt (1769–1859), in which Humboldt lamented that he had not taken an artist with him to visually document his scientific studies in South America. A year later Church traveled to South America and retraced Humboldt's steps in order to paint the natural history of the region. Most of Church's paintings were "composed"—that is, not actual places—but he presented them as scientific summaries of the South American landscape. One of Church's currently most famous paintings, *Heart of the Andes* (1859), did not depict a real place but rather was a summary of the typical features of the landscape, with special attention to scientific detail. Art critics recommended that viewers consider portions of the painting separately, much as travelers do in viewing natural scenes. For example, one part of the painting shows a peasant praying before a cross by a road. Another part of the painting depicts a tree precariously growing on a bank that is being undercut by a stream below. The first says something about the religiosity of the region. The second presents a freeze-frame in dynamic natural history: The bank will continue to erode, and the tree will eventually fall into the river.

Church encouraged a fellow artist, Martin Heade, to travel to South America, where he painted studies of hummingbirds. These paintings—for example, *Brazilian Hummingbirds* (1865) and *Magnolia Grandiflora* (ca. 1880)—show that major artists were also influenced by the scientific illustration of eighteenth- and nineteenth-century biologists, botanists, and geologists. Because photography was very primitive until the second half of the nineteenth century, and even then produced only black-and-white images, scientists took art lessons as part of their scientific training and, as a result, developed the same aesthetic sensibilities as landscape painters. Even ideal or "composed" paintings by mainstream artists often

Heart of the Andes, *1859, Frederick Edwin Church.* *One of Church's most famous paintings, this scene does not represent an actual geographical location, but is rather a summary of various features the artist encountered while traveling through South America. Church was the only student of American painter Thomas Cole, the founder of the Hudson River School.*

produced reliable scientific information because the artist usually used plants, animals, and geological features typical of the region where they painted.

A characteristic feature of nineteenth-century American landscape painting was the presence of intense, bright light. John I. H. Baur (1954) linked all of this painting together, coining the term *Luminism*. The light performs two functions. First, it introduces a religious dimension into seemingly secular paintings. This light might, for example, be a beam coming out of the sky, characteristically accenting a waterfall or a radiant glow brightening the understory of a forest. Second, the light starkly intensifies the materiality of the natural objects represented in the paintings. The result is a presentation of a natural world that is both material and spiritual. (Compare Thomas Cole's *The Pilgrim of the Cross at the End of His Journey* [1844-1845], in which an area of bright light depicts the border between heaven and earth, and Albert Bierstadt's *Sierra Nevada Morning* [1870], in which the same lighting techniques produce a similar effect.)

The Luminists were guided by a belief that all nature is beautiful, as encapsulated in an oft-quoted remark by John Constable (1776–1837): ''No, madam, there is nothing ugly; *I never saw an ugly thing in my life:* for let the form of an object be what it may—light, shade, and perspective will always make it beautiful'' (Leslie 1951, p. 280). In a similar vein, Ralph Waldo Emerson (1803–1882) wrote, ''There is no object so foul that intense light will not make beautiful. . . . Even the corpse has its own beauty'' (Emerson 1836), and John Muir (1838–1914) wrote, ''none of Nature's landscapes are ugly so long as they are wild'' (Muir 1901, p. 4).

This position—that everything natural can be viewed as beautiful—has been named by Allen Carlson (Carlson 1984) as ''positive aesthetics.'' Carlson argues there that ''Art is created, while nature is discovered'' and that creativity is in the standards created by humans to describe nature but not in nature itself; there is no creativity in nature (Carlson 1984, p. 31). Eugene Hargrove has argued, to the contrary, that creativity is in nature and it is the same as the creativity attributed to God in the late Middle Ages, when the properties of God symbolically manifested in nature were transferred to nature itself in the concept of the sublime. The result is indifferent rather than artistic creativity (Hargrove 1996 [1989]).

ENVIRONMENTAL PHOTOGRAPHY

Luminist painting ceased to be cutting-edge, mainstream art in the 1880s, when it began to be displaced first by impressionism, then postimpressionism and cubism, and ultimately by abstract expressionism. With impressionism artists no longer painted objects lit by strong light and instead painted the light itself in such a way that the objects dropped out of consideration. With postimpressionism and cubism artists gradually abandoned linear perspective and with it the realistic depiction of material objects. With abstract expressionism the quest for accurate representation of nature, begun in the late Middle Ages, was completely abandoned. These new forms of painting severed the link between "art and nature" and instead sought a link between "art and self," making so-called modern art irrelevant environmentally. However, the tradition of representational art continued with the rapid emergence of photography, which quickly elevated itself to an art form in its own right.

Photography began with Louis Daguerre's invention, in France in 1839, of the daguerreotype, which remained the primary form of photography until 1859. Because daguerreotypes required long exposures, did not produce the detail needed for landscape photographs, and were not reproducible through print media, they were mostly limited to portraiture. The glass-plate process developed in the 1850s made landscape photography as we know it today possible and profitable, because multiple copies of each photograph could be easily produced. The technology was fully perfected by 1860, in time to produce chillingly detailed documents of the death tolls on Civil War battlefields in the United States. Shortly thereafter, however, it was put to more pleasant use in nature photography. The poor quality of daguerreotype photography can be strikingly seen in J. D. Hutton's photography of the Great Falls of the Missouri during the W. F. Reynolds's expedition of 1858–1859 (Naef and Wood 1975, p. 29), which is misidentified as a falls on the Yellowstone River. Although Hutton was attempting to reproduce a sketch of the falls made by Meriwether Lewis, the result is so poor that the photograph requires significant explanation to make it intelligible as a nature scene.

In addition to mammoth glass-plate cameras, stereoscopic cameras were also developed at this time, providing smaller three-dimensional views of nature with stunning effect. Nevertheless, the larger photographs, which were more like landscape paintings, proved to be more popular and commercially successful.

The importance of western American nature photography was firmly established internationally with the submission of photographs of Yosemite to the 1867 Paris International Exposition, where they won a bronze medal. Although the photographs were submitted under the name Thomas Houseworth (1828–1915), they are believed to have been made by C. L. Weed (1823–1903) or C. E. Watkins (1829–1916), photographers who worked for Houseworth's company. Weed and Watkins began photographing Yosemite in 1859 and 1861, respectively. Watkins competed with Weed, often photographing the same scenes previously photographed by Weed in order to prove his superiority as a photographer. Eadweard Muybridge (1830–1904) joined the competition, also photographing the same locations. This competition helped call attention to landscape photography as an art form and to Yosemite as a place of spectacular national importance.

Government-sponsored geological surveys also advanced landscape photography in the 1860s. The California State Geological Survey, which came to be a model for other state geological surveys, hired Watkins as a photographer in connection with the survey of Yosemite Valley that was to become a state park as a gift of the federal government. Clarence King, who later became the first head of the U.S. Geological Survey, happened to be in California looking for "the Cotopoxi of the West," a mountain that would be as aesthetically spectacular as an active volcano painted by Church in South America. King joined the California survey and was given the task of surveying Yosemite. There he worked with Watkins and learned the value of landscape photography in geological work. In 1867, when King became the head of the Fortieth Parallel Survey, he immediately hired Timothy O'Sullivan as a photographer. O'Sullivan's work was considered so spectacular and so useful in gaining additional congressional appropriations, that F. V. Hayden's survey of the territories and John Wesley Powell's survey of the Colorado River quickly followed his example. W. H. Jackson (1843–1942) became especially well known for his photographs of Yellowstone and Colorado while working for Hayden.

There was considerable interaction between artists and photographers during this period, especially on the geological surveys. Thomas Moran (1837–1926), most famous for his two paintings of the Great Falls of the Yellowstone, worked with Jackson and sometimes stood in his photographs for scale (see Naef and Wood 1975, p. 222). Bierstadt used a Watkins photograph of the Grizzly Giant in the Mariposa Grove in the creation of his famous painting of the same tree (c. 1864) (Naef and Wood 1975, p. 62). The aesthetic perspectives and goals of the artists and the photographers were the same.

Landscape painting and photography had a tremendous impact on nature preservation in the nineteenth century. Landscape paintings and photographs played a central role in the creation of Yosemite, a California state park, and, a few years later, Yellowstone National Park.

Uinta Mountains, Utah. *This photograph was taken by Timothy O'Sullivan in 1869 while working for the Fortieth Parallel, or King, Survey. The glass-plate process, which replaced daguerreotypes in the 1850s, made landscape photography both possible and profitable.* **PHOTO BY T.H. O'SULLIVAN/U.S. GEOLOGICAL SURVEY.**

Nearly all of the places painted and photographed by major artists and photographers during that time period are now national parks or national monuments. Frederick Law Olmsted (1822–1903) acknowledged this connection in his report on Yosemite Valley to the California legislature in which he recommended that half of the commissioners for the park be "students of natural science and landscape artists" (Olmsted 1952). A few years later, when landscape photography was better established, he would have most certainly added "landscape photographers."

The creation of these images of then-remote areas permitted the general public to learn about and care about these places, and congressional action to preserve these places quickly followed. In admiring the aesthetic qualities of the paintings and photographs, people were also admiring the aesthetic qualities of the places that the images represented, and their aesthetic enjoyment, as G. E. Moore (1873–1958) put it in another context in *Principia Ethica* (1903), depended on a true belief that the aesthetic qualities depicted continued to exist in the original (Hargrove 1996 [1989]). Just as images of natural objects in the Middle Ages, in terms of symbolic thinking, produced a religious, otherworldly aesthetic experience, the images of natural objects in the modern period, in terms of representational thinking, produced an aesthetic experience of the world as it actually existed a desire to preserve it in a natural state.

The link between images and natural places still plays a critical role in the environmental movement politically, for it makes it possible for people to become committed to protecting places that they may never visit. Without this representational link, the environmental

Yellowstone National Park, Wyoming. *Taken by W.H. Jackson in 1872 while working for the Hayden geological survey, Jackson became especially famous for his photographs of Yellowstone—such as this image of Old Faithful Geyser—and Colorado.* **U.S. GEOLOGICAL SURVEY.**

movement would have been a local rather than a national and international movement. The original impact of nineteenth-century landscape painting and photography is still appreciated in the work of Ansel Adams (1902–1984), who stands at the end of a tradition started by Weed, Watkins, and Muybridge. The impact, however, is pervasive, for the general public is surrounded by images in photographs and motion pictures that follow the principles and perspectives of nineteenth-century painting and photography. When tourists move back and forth at a scenic view while taking a photograph, they are intuitively employing the compositional techniques developed by those artists and photographers.

LAST MAN ARGUMENTS

The *last man argument* was devised by Richard Sylvan (before 1983 Sylvan went by the name Richard Routley) and was first published in Routley's article "Is There a Need for a New, an Environmental, Ethic?" (1973). It is a thought experiment designed to show that the prevailing principles of the dominant European and North American tradition are unable to provide a satisfactory basis for an environmental ethic. An adequate ethic of concern for the nonhuman world must therefore have very different foundations.

The shared core assumptions of European and North American ethics (which Sylvan calls a "super ethic") include a *freedom principle,* according to which agents are permitted to act as they please provided that they do not (1) harm others (understood usually, though not always, as other *persons*) or (2) harm themselves irreparably. Sylvan labeled this anthropocentric principle *basic human chauvinism*, because it affirms that moral deliberation and choice involve only human interests and concerns. The last man thought experiment was devised to refute this core principle and thus expose the inadequacy of traditional European and North American ethics as a foundation for an environmental ethic.

Most scholars argue that ethical principles must be universal and therefore applicable not just to actual situations but to all possible situations. It is for this reason that thought experiments are important intuition pumps and play a central role in testing ethical principles. The last man thought experiment is as follows: "The last man (or person) surviving the collapse of the world system lays about him, eliminating, as far as he can, every living thing, animal or plant (but painlessly if you like, as at the best abattoirs). What he does is quite permissible according to basic [human] chauvinism, but on environmental grounds what he does is wrong" (Routley 1973, pp. 207–208).

Because he is the last human survivor, there are no other human interests to be considered, and the chauvinistic liberty principle therefore provides no grounds for moral condemnation of his actions. Nevertheless, it is clear to an environmentally enlightened conscience that the actions of the last man are morally dreadful. If you share Sylvan's intuition that these terminal actions are

morally reprehensible, and if there are no anthropocentric considerations to support this intuition, then there must be some nonanthropocentric considerations or values that explain the evil of the acts. (The last man argument is formulated at greater length in Routley and Routley (1980), which Sylvan (then Routley) authored jointly with his then-partner, who later took the name Val Plumwood.)

Holmes Rolston (1975) has set out a parallel "African butterfly" argument in support of nonanthropocentric environmental values. Gratuitous acts of "speciescide" carried out by unscrupulous butterfly collectors, like the actions of Sylvan's last man, are reprehensible to the environmentally enlightened conscience. Robin Attfield (1981) and Mary Anne Warren (1983) have also presented variants of the argument.

A thought experiment that anticipates some aspects of Sylvan's argument was proposed by G. E. Moore in a famous attempt to establish the objective value of beauty.

> Let us imagine one world exceedingly beautiful. Imagine it as beautiful as you can; put into it whatever on this earth you most admire—mountains, rivers, the sea; trees, and sunsets, stars and moon. Imagine these all combined in the most exquisite proportions, so that no one thing jars against another, but each contributes to increase the beauty of the whole. And then imagine the ugliest world you can possibly conceive. Imagine it simply one heap of filth, containing everything that is most disgusting to us, for whatever reason, and the whole, as far as may be, without one redeeming feature.... The only thing we are not entitled to imagine is that any human being ever has or ever, by any possibility, *can*, live in either, can ever see and enjoy the beauty of the one or hate the foulness of the other. Well, even so, supposing them quite apart from any possible contemplation by human beings; still, is it irrational to hold that it is better that the beautiful world should exist, than the one which is ugly? (1903, pp. 83–84)

Moore's intuition is that the beautiful world is objectively better than the heap of filth—and he suggests that this is so quite independently of whether any evaluators exist to contemplate the worlds in question. Nevertheless, according to David Hume (1740), we must be cautious about inferences, however appealing, that draw evaluative conclusions from descriptive premises.

Value intuitions depend crucially on the nature of evaluators. It is not difficult—given our aversion to dung—to share Moore's intuition. This preference, however, is shaped by our biological constitution. It is far from clear that our preference would be shared by, say, a dung beetle or a blowfly. Rather than establishing the objective value of beauty, Moore has established the existence of deep-seated intersubjective aesthetic intuitions shared by humans—and the difficulty of thinking like a blowfly.

Sylvan's argument similarly fails to establish secure objective grounds for nonanthropocentric values. Like other famous thought experiments, however—such as brains in vats (Brueckner 2004) and "trolley" problems (Thomson 1976)—it helps us to regiment our intuitions. The powerful visceral impact of the last man thought experiment reveals a widespread though perhaps not universal biophilia—an affinity for rich, diverse, complex, and beautiful biological systems. The use of cyanide and explosives for fishing on coral reefs, rather than sustainable practices, and the clear-felling and burning of old-growth forests, generate a similarly powerful visceral repugnance that is also widely shared but is also, alas, not universal. The last man thought experiment helps us to understand that the depletion of biodiversity impoverishes not just the biosphere but also the requirements for the sort of human life to which we are adapted and to which many of us aspire.

LEOPOLD, ALDO

1887–1948

Aldo Leopold was born on January 11, 1887, in Burlington, Iowa, and became one of the most prominent environmental philosophers of the twentieth century. In his childhood he was an avid naturalist, ornithologist, hiker, and hunter. After finishing a master's degree in forestry at the Yale Forest School in 1909, he joined the U.S. Forest Service. Until 1924 Leopold worked exclusively in the Southwest, and from 1924 to 1928 he worked for the Forest Products Laboratory in Madison, Wisconsin. From 1928 to 1932 he conducted game management research for the Sporting Arms and Ammunitions Manufacturers' Institute, and in 1933 he accepted a position as professor of game management at the University of Wisconsin–Madison. He died in Wisconsin on April 21, 1948.

Leopold was among the founders of the field of wildlife management; his *Game Management,* the first text in that field, was published in 1933. He helped create the first designated wilderness area in the United States in 1924 and cofounded the Wilderness Society in 1935. Although he wrote over three hundred articles, he is best known for his posthumously published book *A Sand County Almanac* (1949).

Aldo Leopold, circa 1943. *Aldo Leopold is one of the most prominent environmental philosophers of the twentieth century. He is well known for his work with the U.S. Forest Service, and his famous essay, "The Land Ethic."* **COURTESY OF THE ALDO LEOPOLD FOUNDATION ARCHIVES.**

A SAND COUNTY ALMANAC

The last and most philosophical essay in the *Almanac* is "The Land Ethic." In that essay Leopold argued that human ethics can, must, and should evolve and that the sense of community on which human ethics is based must expand to include the land itself (i.e., all living and nonliving components of the environment). He went on to say that humans must transform themselves from ecological conquerors to ecological citizens and that changes in a nation's environmental policies must be preceded by similar philosophical changes in that nation's populace. Leopold held that land is a structured ecological mechanism that is replete with energy circuits, capable of being healthy or unhealthy, and vulnerable to sudden anthropogenic disturbances; purely economic, instrumental approaches to land use are ethically impoverished and unsustainable. The essay culminates with the well-known claim that land usage "is right when it tends to preserve the integrity, stability, and beauty of the biotic community. It is wrong when it tends otherwise" (Leopold 1949, pp. 224–225). The land ethic stands as the first systematically holistic ethic in environmental philosophy. However strong people's concern for individual members of the land community may be, concern for the land community itself should be much stronger.

As a whole the *Almanac* is difficult to characterize, partly because of Leopold's efforts to meet common expectations of what "nature books" should be like: personal and narrative, with analytical and theoretical comments tolerated only when "worked into a framework of actual field experience" (Ribbens 1987, p. 93). The overarching theme is an evolutionary and ecological worldview. Part I conveys it indirectly through personal and experiential narrative, Part II conveys it more directly and didactically, and Part III explores its normative implications. One of the most striking blends of personal narrative and philosophical commentary occurs in "Thinking Like a Mountain," a personal, confessional essay in which Leopold not only acknowledges his predator-eradicating past but credits it as a source of sudden and unexpected moral insight. The essay marks a humble approach to the difficulties of making progress on an unfamiliar moral frontier.

It is difficult to determine the ultimate motivation for Leopold's environmental philosophy. Is the land ethic fundamentally prudential and anthropocentric? If that is

not the case, is it possible to commend it, as Leopold often does, on grounds of seemingly antithetical enlightened self-interest?

INTERPRETATIONS OF LEOPOLD'S LAND ETHIC

Answering these questions has been a challenge for Leopold scholars. J. Baird Callicott characterized Leopold's land ethic as subjectively deontological but objectively prudential (Callicott 1987, p. 214). Bryan Norton interpreted Leopold as a pragmatist and a value pluralist who embraced "a standard of long-term survival as a noneconomic basis for evaluating a culture's practices and institutions" (Norton 2005, p. 75). Roderick Nash described Leopold as "a battle-scarred veteran of conservation policy wars" who appealed to enlightened self-interest only because it "was the best way to sell his philosophy in the 1930s and 1940s" (Nash 1987, p. 81). Julianne Lutz Newton and Curt Meine denied the presence of an ultimate motivation. Leopold simply encouraged people to evaluate their treatment of land "in both moral and prudential terms" (Newton 2006, p. 320) and "tried to strike a balance between the reality of economic necessity and the truth that standard economic definitions of 'necessity' did not suffice in conservation" (Meine 1988, p. 503). When it came to conservation, Leopold believed that "a profit motive was not enough. Nor, for that matter, was a sentimental motive" (Meine 1988, p. 503).

The scientific foundations of the Leopold land ethic are a source of both strength and vulnerability. Science is regarded as objective and credible, but it is also fallible and dynamic. Ecology no longer conceives biotic communities as stable over time or as exhibiting robust integrity. The Leopold land ethic may be undermined by the so-called shifting paradigm in contemporary ecology and the replacement of the notion of the balance of nature with that of the flux of nature. In that case contemporary environmental ethicists face the question: Can the land ethic be updated in light of the contemporary flux paradigm in ecology?

LIFE: RESPECT/ REVERENCE

Albert Schweitzer (1875–1965) attempted to combine a systematic nature philosophy with a sense of mystical devotion to the phenomenon of life. Through his reverence for life ethic he sought to create a biocentric worldview that was informed by biological individualism. However, his argument was not developed formally in his written works.

Distracted by his fight against nuclear weapon research and testing after 1945 as well as his medical mission in French Equatorial Africa, Schweitzer made partial drafts but never completed the last two volumes of his *Philosophy of Civilization*. He hoped that his life's work would provide the needed clarity and the definitive example for his philosophy. However, unanswered questions have prevented his work from having a wider influence in environmental thought. It has been concluded by many that Schweitzer could not overcome the inherent problems in trying to reconcile a focus on biological individualism with ecocentric aims. Reverence for life has not been seen in academic circles as a practical ethic or a consistent philosophy.

SCHWEITZER'S ETHICAL MYSTICISM

More recent scholarship has revealed greater sophistication in Schweitzer's thought. Schweitzer intended his concept of ethical mysticism to serve as a balance between his argument for the respect due to all living beings and the need to set this against the reality to take other life to

survive. This tension is also at the heart of the conflict between animal rights activism and holistic environmental concerns. Resource managers, for example, often must destroy individuals within a managed population or eliminate invasive exotics entirely for the greater good.

Yet Schweitzer indicated that it is necessary to protect all life that comes within the reach of a moral agent. However, moral agents cannot live up to this standard fully because they must eat and alter their environment to live. The key for Schweitzer was to atone actively for the taking of life through devotional service to all "Life" by promoting a greater good. This creates a deepening and lifelong devotion to ethical duty. Schweitzer became an exemplar of this ethic through his fifty-year medical mission in Africa.

Schweitzer's inspiration came from the Lutheran theology of the Cross. Schweitzer was an ordained Lutheran minister and believed that all would-be disciples of Christ are called upon to follow Jesus's example of self-sacrificing love (*kenosis*) through compassionate missions to eliminate suffering wherever it is found. However, Schweitzer did not see reverence for life as an exclusively Christian ethic. He was a student of world religions and believed that all faiths contain the seeds of ethical mysticism, though he did not find all faiths equally satisfactory in terms of the ethical traditions they promoted.

In a article titled "The Ethics of Reverence for Life" Schweitzer presented the admonition "I see that evil is what annihilates, hampers, or hinders life … goodness, by the same token, is the saving or helping of life, the enabling of whatever life I can to attain its highest development" (Schweitzer 2002 [1936], p. 129). This argument was derived from German philosopher Arthur Schopenhauer's concept of the will-to-live. For Schopenhauer the will is not intention or desire but refers to the etiological changes in bodies through time. An acorn, for example, contains all the potential manifestations of an oak tree, yet these forms become actualized only over time. The will is the cause for the movement from potentiality into actuality. All bodies possess a will-to-live that gives an organism the instincts and dispositions necessary for the expression of its potential. For Schweitzer, helping all life reach its highest possible development of its will-to-live in light of the needs of others is the basic good in the reverence for life ethic.

APPLICATIONS AND REFINEMENTS

Schweitzer refused to lay down rules for every possible situation in which conflicts between saving life and taking life arise because that would externalize morality in a codified object, leaving it vulnerable to egotistical rationalization, depreciating negotiations, and superficial conviction. However, his life and work show that he recognized that it is necessary to take life to save other life. His practice as a physician, for example, required him to kill countless pathogenic bacteria and parasites to save the life of human and nonhuman patients. In this way he sought to widen and deepen public acceptance of reverence for life and recruit additional moral agents in the promotion of a greater good.

This position is not inconsistent or contradictory. An analogy with pacifism illustrates the underlying dynamics. A pacifist is confronted by a skeptic with the following dilemma: either kill the men who are threatening his or her neighbors or allow them to be killed. The pacifist replies, "I am not concerned primarily with what to do about these dilemmas when they arise; I am concerned with preventing them from arising to begin with through disarmament, institutions to secure world peace, and distributive justice to redress social wrongs." Similarly, the reverence for life ethic seeks ends that secure the best and highest good for all Life.

Schweitzer set out to offer a "path in the thicket" for a civilization that had lost its way (Schweitzer 1949, p. 185). He had come to see the ethical traditions of Kantianism and utilitarianism as morally bankrupt. In their place he sought to weave together several complementary strands of thought at the core of his reverence for life ethic. From Charles Darwin he took the shared evolutionary heritage with all life and the evidence for a social instinct; from David Hume, Arthur Schopenhauer, and Adam Smith, a philosophical basis for sympathy; and from the religious traditions of mysticism, a substantive and personal connection to ethical duty directed to the here and now. In the decades that followed, others moved to establish a life-centered philosophy with greater prescriptive clarity, with or without direct reference to Schweitzer. They include Kenneth E. Goodpaster, Paul W. Taylor (1986), Peter G. Brown, and David K. Goodin.

LIMITS TO GROWTH

The 1950s and 1960s were a time of growing awareness of environmental problems, with lethal smog in major cities, warnings that growing air pollution in New York would make the city uninhabitable, the Cuyahoga River catching fire, and predictions of imminent mass starvation and environmental catastrophe from unchecked population growth. Recognizing a crisis situation, the developed nations began to take important steps to address these issues; the United States, for example, created the Environmental Protection Agency, extended the Clean Air Act, and passed the National Environmental Policy Act, Clean Water Act, and Endangered Species Act, all between 1970 and 1973.

EARLY WARNINGS ABOUT GROWTH

In this atmosphere Donella Meadows and her coauthors published *Limits to Growth* (1972), a report on the results of a computer-systems model of the interactions between the human economy and the planetary ecosystem that sustains and contains it. Focusing on population growth, resource depletion, industrialization, pollution, and food production, and assuming exponential growth but finite resources, the model showed that existing trends would lead to resource exhaustion in the coming decades, with potentially catastrophic consequences by the middle of the coming century and perhaps sooner. The report advised that avoidance of this outcome required rapid stabilization of human populations, resource, use and waste emissions. The oil crisis of 1973 initially seemed to confirm some of these conclusions.

The Meadows report was certainly not alone it its conclusions. In *The Entropy Law and the Economic Process* (1971), Nicholas Georgescu-Roegen argued that our economic system, like all physical systems, is subject to the laws of thermodynamics. The laws of thermodynamics (matter-energy cannot be created or destroyed, useful energy dissipates, and disorder increases) limit the physical size of the economy on a finite planet. The increase in entropy entailed by economic production requires compensating inputs of low-entropy energy, and the economy systematically converts low-entropy resources into high-entropy waste, providing human welfare in the process. The economy has access to two sources of low entropy to maintain this process: finite stocks of fossil fuels and other natural resources that we can use as fast as we choose and the finite flow of solar energy, which arrives at a rate beyond our control. As finite stocks become exhausted, the size of the economy will be limited by the flow of solar energy. Eventually, all the material building blocks of our economy must become so dispersed that the fixed flow of solar energy will be inadequate to recycle them, and the economy must collapse. Economic growth can only speed our doom.

Herman Daly also recognized the limits to growth, but he more optimistically argued that a no-growth, steady state economy could be sustained indefinitely. However, the raw materials that serve as the inputs into economic production also serve as the structural building blocks of ecosystems. Structure generates function. Along with other valuable services, ecosystems provide irreplaceable life-support functions that are essential to human survival. Both the extraction of ecosystem structure for economic production and the emissions of waste (known together as throughput) degrade ecosystem services. Long before the threshold of collapse, the diminishing marginal benefits of increasing economic output are likely to fall below the rising marginal costs of ecological degradation, at which point continued economic growth—defined as a "quantitative increase in ... the rate of flow of matter and energy through the economy ... and the stock of human bodies and artifacts"—becomes uneconomic. Economic development—a "qualitative improvement in non-physical characteristics" (Daly 1987, p. 323)—remains possible, however. A sustainable economy cannot extract renewable natural resources faster than they can regenerate, extract nonrenewable resources faster than we can develop renewable substitutes, or spew waste emissions into the atmosphere faster than they can be absorbed. This position became known as strong sustainability. In Daly's view, the sustainable use and just distribution of resources takes precedence over their efficient (wealth-maximizing) allocation.

CORNUCOPIANS AND DOOMSDAYERS

Such claims of limits to growth were met with great skepticism, particularly by conventional economists, who branded their proponents as doomsdayers. Those skeptical of limits became known as cornucopians. From the perspective of the cornucopians, the doomsdayers ignored the capacity of human innovation in general and the free market in particular to adapt to scarcity. As resources become scarce, their prices increase, providing a market incentive to develop substitutes. Relative scarcity might exist, but not absolute scarcity. Almost two hundred years earlier, Thomas Robert Malthus predicted that geometric increases in human population must eventually outstrip linear increases in food production, leading to widespread starvation. Instead, by the time of the Meadows report, humanity was producing more food per capita than at any other time in history, and productivity was continuing to rise. William Stanley Jevons, a nineteenth-century English economist, warned that society must inevitably run out of coal and that "we must not dwell in such a fool's paradise as to imagine we can do without coal what we do with it" (Jevons 1865, p. 145). Both Malthus and Jevons had been proved wrong. In the words of Nobel laureate Robert

Solow, "If it is very easy to substitute other factors for natural resources, then there is, in principle, no problem. The world can, in effect, get along without natural resources" (Solow 1974, p. 11). We can adapt to scarcity simply by dematerializing the economy. Human ingenuity, the ultimate resource, would solve all problems (Simon 1996). The position that human-made capital could substitute for natural capital became known as *weak sustainability*.

The optimism of the cornucopians notwithstanding, wealthier societies made major investments in environmental protection; as a result, many measures of environmental quality began to improve, some dramatically. The doomsdayers claimed that society had acted appropriately on their recommendations. The cornucopians, in contrast, claimed that these outcomes were to be expected anyway. Economic growth, in fact, was not the cause of the problems the doomsdayers presented, but rather the solution. As societies became richer, birth rates declined, so economic growth was the solution to the population problem. A rising tide lifts all boats, in the view of the cornucopians, and in the presence of widespread poverty, growth is a moral imperative. In addition, pollution emissions formed an upside-down parabola when plotted against per capita gross national product (GNP)—poor countries have clean environments, but as they begin industrializing, pollution levels increase. However, as countries get rich enough, their citizens began to demand clean environments, a luxury good. A number of recent books by cornucopians argue that almost all environmental indicators are improving, that resource abundance continues to grow, and that limits-to-growth theorists have again been proved wrong (e.g., Simon 1996; Lomborg 2001).

The concerns of the doomsdayers have increased significantly: They argue that improvements are illusory, that wealthy nations have simply exported their most environmentally damaging industries to poorer nations, and that even if pollution levels taper off with growth, pollution will increase for decades to come. Population growth is slowing but is expected to stabilize at much higher levels than the planet can sustain. Increasing consumption to slow population growth is counterproductive.

CLIMATE CHANGE, RESOURCE DEPLETION, AND DISTRIBUTION

Climate change has convinced many that planetary waste-absorption capacity is the greatest constraint on growth, and some believe that we are already doomed to a catastrophically warmer planet. Diminishing fossil-fuel stocks and rising prices have convinced others that we have reached peak oil, the point at which increasing rates of use overwhelm declining rates of discovery and then begin a steady decline, threatening chaos in a system built on cheap energy. A third group is concerned with renewable-resource depletion and biodiversity loss; the concern is that these trends will result in the collapse of ecological life-support functions. Others believe that water shortages are the greatest threat, or population growth, or toxic wastes. Many believe that we are exceeding all of Daly's tenets for sustainability, overwhelming sources, sinks, and services simultaneously. Such systems thinkers believe we are well into overshoot, currently living off natural capital rather than its yield. They also recognize that we are dealing with complex, dynamically adaptive systems, in which precise prediction is essentially impossible. This is the position taken by the report *Limits to Growth: The 30-Year Update* (Meadows et al., 2004).

Topping off the doomsdayers' woes, distribution has become a major concern. *Limits to Growth* appeared at the end of a forty-five-year decline in both poverty rates and income inequality, which, with the exception of a brief interval in the 1990s, have climbed steadily since. Similar trends are occurring at the global level. In absolute terms the wealthiest nations have amassed far more additional wealth than the poorest—1 percent of gross domestic product (GDP) in the United States equals the GDP of the world's twenty-four poorest nations (Daly and Farley 2004). In relative terms, China, India, and a few other outliers appear to have grown faster than the wealthy nations but have simultaneously experienced unprecedented increases in domestic income inequality. Experiments with green accounting in China have shown that ecological damage and resource depletion accounts for up to one-third of GNP in some regions (Qiu 2007). Real incomes in sub-Saharan Africa, the region with the world's poorest countries, and in the poorest areas of Latin America have actually declined. To make matters worse, the environmental costs of growth, such as climate change, are likely to fall disproportionately on the poor. Growth has done little if anything to alleviate absolute poverty while exacerbating relative poverty.

Conventional economists nonetheless continue to play the role of optimists, their models frequently suggesting that the potential future costs of climate change, heavily discounted, are less than the current costs of mitigation, and that little should be done. The 2006 *Stern Review* on the economics of climate change is considered quite pessimistic and a call for action, but in reality it estimates that even if we do nothing about climate change, the economy will double or triple in size by 2050 (Stern et al., 2006). The report concludes that we should act to mitigate climate change, but under the report's assumptions, this would ironically require supposedly poorer generations to sacrifice for richer ones. The extreme of this cornucopian vision is presented by Thomas C. Schelling, a 2005 Nobel laureate in economics, and other economists who suggest that climate change will matter little because it primarily affects

agriculture, which is only a small percentage of GNP (Schelling 2007). Measured in dollars, any consumer good is apparently a perfect substitute for food.

Some argue not only that human wants and needs are satiable but also that, beyond a threshold already passed in the wealthy countries, increasing consumption makes us worse off. With our basic needs satisfied, it is primarily relative wealth that makes us better off, and increasing wealth for all helps no one. In addition to physical limits to growth, we have reached psychological limits, so continued economic growth is undesirable as well as impossible. The horn of plenty is overflowing. As scientists have reached near consensus on the danger of climate change, even some cornucopians and conventional economists are recognizing the need to act, and those who do not risk fading into irrelevance.

CONCLUSION

Arguments in the growth debate range from predictions of inevitable doom no matter what we do—through strong and then weak sustainability—to faith in inevitable sustainability as long as we trust in the market. In our complex ecological-economic system, with uncertain facts and a sample size of one, absolute proof for any position is impossible; uncertainty cannot be eliminated, and the past is a poor guide to the future. The decision whether to act on predictions of the doomsdayers or cornucopians must therefore be weighted by ethical considerations about future generations and risk. The worst-case scenario is acting on the beliefs of the cornucopians if the doomsdayers are correct. In contrast, suppose that we act on the beliefs of the doomsdayers and limit throughput; in that case, even if the cornucopians are correct, market forces will improve efficiency and provide substitutes, and no harm will have been done. If the neocornucopians are correct, the costs of addressing environmental problems are negligible or negative, so even if the chances of catastrophe are vanishingly small, we should act.

M

MARSH, GEORGE PERKINS
1801–1882

George Perkins Marsh, diplomat, public servant, polymath scholar, and pioneer conservationist, was born in Woodstock, Vermont, on March 15, 1801, and died in Vallombrosa, Italy. Lawyer, congressman (1843–1849), U.S. envoy to the Ottoman Empire (1850–1854) and to Italy for an unparalleled twenty-one years (1861–1882), he was an intimate of the best-known scholars of his age on both sides of the Atlantic. A Dartmouth College graduate, Marsh was largely self-taught, notably in mastering twenty languages. Reputed in his own day as an authority on English language and literature, Marsh's enduring fame stems from his insightful study of human impacts on the environment. His classic *Man and Nature* revealed the menace of environmental misuse, explained its causes, and prescribed essential reforms. It linked the collapse of the Roman Empire with the soil exhaustion and erosion attendant on deforestation and exploitative agriculture, warning that similar pressures threatened the new world with the fate of the old. "The Earth is fast becoming an unfit home for its noblest inhabitant, and another era of equal human crime and human improvidence . . . would reduce it to such a condition of impoverished productiveness, of shattered surface, of climatic excess, as to threaten the depravation, barbarism, and perhaps even extinction of the species." Continuously in print since its publication in 1864, *Man and Nature* inaugurated much of today's ethical stance toward nature.

In linking culture with nature, science with history, *Man and Nature* was the most influential text of its time next to Charles Darwin's *On the Origin of Species*. With Darwin, Marsh challenged traditional belief in preordained harmony between humanity and the rest of creation. Many before Marsh had noted various specific facets of environmental impact; none had seen or traced the combined effects of human action. Moreover, such influence had previously been assumed largely benign; damage was thought trivial or short-lived. Marsh was the first to see that human impacts were not only enormous and fearsome, but potentially cataclysmic and irreversible.

The long-held general belief was that mankind's God-given mission was to fructify the earth, and the bounty that followed forest clearing, swamp draining, and cultivation attested divine approval. Adverse side effects were easily dismissed, especially in the United States. Soils eroded or exhausted were simply vacated for new lands farther west; forests logged and burned seemed trifling by comparison with the wealth of timber beyond the horizon. Meanwhile, nature left alone would heal itself.

But this recuperative scenario accorded less and less with witnessed facts. A single lifetime saw vast tracts cleared, cultivated—and despoiled. Occupied nature did not heal itself; land once exploited and then abandoned remained for ages, if not forever, depleted. Greed was only partly to blame; much damage was unintended, often unseen. Men did not mean to derange nature; they were blind to the ruin they wrought. But myopia was not incurable. The harm done did not preclude dominion over nature, in Marsh's view; to the contrary, it mandated more alertly intensive governance. Awareness could prompt reform: technology deployed to break nature might also mend it. Ecological processes that revivified

George Perkins Marsh. *A scholar, diplomat, and author, Marsh became a world-renowned champion of environmental conservation and the first to study the potentially damaging impact of humans on the environment.* **NPS PHOTO.**

the environment could be protected and emulated by man as a coworker with nature. For all its dire portents, a pragmatic optimism pervaded *Man and Nature*. Marsh believed that men could learn to manage the environment for their own sake and for nature's good.

Appearing at the peak of Western resource optimism, *Man and Nature* refuted the myth of limitless plenty and spelled out needs for conservation. In forestry, hydrography, and pedology, Marsh's ecological insights and warnings became virtual gospel, animating watershed management and resource stewardship internationally. Floods and soil erosion during the Dust Bowl and other 1930s disasters rekindled its salience. A 1965 reprint of *Man and Nature* quickened the Earth Day crusade launched by followers of Rachel Carson and Aldo Leopold.

What is known—and feared—about anthropogenic impact has vastly expanded since Marsh's day; anxiety extends to realms and terrors undreamed of by him. Marsh's vision of a self-regulating equilibrium in nature, if left alone, became Frederic Clements's ecological paradigm of the early twentieth century. Although no longer scientifically credible, it continues to pervade popular conceptions of nature among the general public, including many environmentalists. Yet Marsh's appraisal of forest cover and erosion remains largely valid, his watershed control cautions still cogent, his call for stewardship ever more pertinent.

Following *Man and Nature*, Marsh continued to champion ecologically sustainable and socially desirable practices in forestry, irrigation (notably in the American west), and the establishment of parks and nature reserves. Traduced by some as a hard-nosed, resource-focused utilitarian pragmatist, against the aesthetic and ethical idealism of Henry David Thoreau and John Muir, Marsh, in fact, shared their concern for the preservation of wild nature.

Marsh believed social and environmental reform must go hand in hand. His deistic Calvinist-Enlightenment-transcendentalist faith stressed commitment to durable community, aligning respect for past with concern for future generations. To understand and care for nature required rooted residential attachments woefully lacking in pioneer America. Nevertheless, Marsh at first believed that enlightened self-interest would suffice to effect needed reforms. But the overwhelming might of amoral corporate capitalism persuaded him that governmental regulation was essential, lest America suffer the fate of ancient Mediterranean societies ruined by heedless environmental abuse.

MENDES, CHICO
1944–1988

Francisco Alves Mendes Filho, better known as Chico Mendes, was born on December 15, 1944, on the Porto Rico rubber estate in the town of Xapuri, state of Acre, in the southwestern part of the Brazilian Amazon rain forest. The son of a rubber tapper, he began tapping rubber at age nine, accompanying his father through the forest as was customary for children at that time. Unlike most of his contemporaries, when he was fifteen, Chico was taught to read.

RUBBER PRODUCTION IN BRAZIL

The exploitation of rubber (*Hevea brasiliensis*), which is native to the Amazon, peaked at the turn of the nineteenth to the twentieth century and was characterized by the contrast between large fortunes and unjust social relations. Poor farmers from the northeast were recruited to work in the Amazon and, once there, were imprisoned by a system of indentured servitude for generations. The high price of rubber; the absence of state oversight in the areas of health, education, transportation services, and labor regulations; and isolation contributed to the social injustice. British rubber cultivation in Asia and the later development of synthetic rubber excluded the Amazon rain forest from the international rubber market.

During World War II a blockade of Asian rubber plantations led the U.S. government to sign agreements with Brazil to reactivate the old rubber estates (*seringais*). These were not plantations but native rubber areas. Brazil maintained that protective policy until the end of the 1960s, allowing thousands of rubber-tapper families to remain in the forest after the price of the raw material fell. Discouraged by low prices and unable to prove title to the land, the native rubber areas were left in the hands of the rubber tappers, who developed a way of life that was based on the use of forest-related products, including rubber, Brazil nuts, fish, game animals, and fruits.

However, that system did not last long. At the outset of the 1970s Brazilian government policy encouraged major landowners from the south to buy land in the Amazon basin for farming and cattle raising. To set up the new farms, forests had to be cleared, and conflict with the rubber tappers became inevitable.

ACTIVISM AND CHANGE

At the age of twenty Chico Mendes taught rubber tappers to read and write. He supported initiatives to help families become economically independent, an action that risked repression by the military regime. In 1973 he gained support from the Christian Base Communities, a Catholic initiative that supported the defense of human rights. In conjunction with the church, starting in 1975, the first rural worker unions began to appear in Acre. Chico soon became their leader.

In 1976, in Brasiléia, a neighboring town to Xapuri, rubber tappers decided to resist deforestation, organizing the first publicly recognized movement to defend the Amazon rain forest. Known as "*empate*" (nonviolent obstruction of tree felling), the tactic soon spread, giving rise to strong resistance to new farms. Although it involved defending the forest, the struggle actually was for social rights and conservation of the forest as a way of life for thousands of families.

After attempting to prevent deforestation, the rubber tappers sought to secure acknowledgment of their rights to the land and their need to make a living from forest-based products. With the support of anthropologists and researchers, the First National Meeting of Rubber Tappers was organized in Brasília in 1985. That meeting produced both the National Rubber Tappers Council, which continues to represent those groups, and the concept of extractive reserves (territorial areas protected by public authority, oriented toward conservation and sustainable use of extractive resources, regulated by concession contracts in accordance with a management plan approved by the environmental agency).

The confrontation between these two ways of using the land worsened in Xapuri, and on December 22, 1988, Mendes was murdered on orders from Darli Alves, a fugitive from justice for crimes committed in the southern part of Brazil. International support stimulated by prizes for and documentaries on Mendes's work from 1986 to 1988 led to the trial and imprisonment of the murderers and forced changes in Brazilian Amazon rain forest policy. In 1990 the first extractive reserves were created in the region, including one named for Mendes, with over 800,000 hectares, putting an end to land disputes in Xapuri.

From 1990 to 2007, 81 conservation units were established for traditional communities, with over 21 million hectares, accounting for 4.3 percent of the Brazilian Amazon and benefiting more than 400,000 people. Mendes's main legacy is the state's recognition of the right of such communities to a type of agrarian reform that respects traditional use of natural resources and ensures access to public education, health care, and development.

The legacy of Chico Mendes extended beyond the social groups to which he was linked. As a result of conflicts related to access to and use of natural resources, the concept of agrarian reform and development has changed, leading to the implementation of an innovative public policy throughout the Amazon basin. A new paradigm has emerged in which local communities that depend on the use of natural resources become conservation allies. As a result of rubber-tapper movements, public policies began prioritizing a new form of development

that reconciles environmental protection with social justice. In the years after Mendes's murder that initiative came to be known as sustainable development.

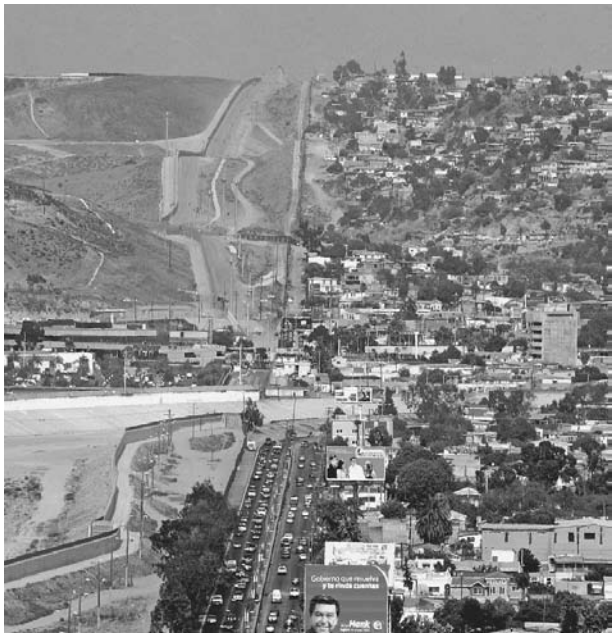
MEXICO AND CENTRAL AMERICA

Environmentalism in Mexico and Central America must be understood in the context of the environmental problems facing that region. Among those problems is a population explosion. Since 1940 Mexico has gone from 28 million to over 100 million inhabitants. Demographic pressures and the model of development (mostly state capitalism in Mexico) have led to a drop in support for conservancy programs and the deterioration of soils, waters, forests, and wildlife. Additionally, the expansion of urban centers has precluded the pursuit of a path to sustainable development. Between 1950 and 1990 Mexico City went from 2 million to 20 million inhabitants. Because of high population densities, unemployment, and a high concentration of industries, many cities in Mexico and Central America are overwhelmed by problems of transportation, air and water quality, garbage disposal, and human health.

ECONOMIC FACTORS

Environmental problems across the region have been accentuated since the transition to a free-market global economy in the late 1980s and early 1990s. The implementation of the North American Free Trade Agreement (NAFTA) in 1994 and the Central American Free Trade Agreement (CAFTA), which includes El Salvador, Guatemala, Nicaragua, Honduras, and Costa Rica, in 2006 has been particularly controversial. Balancing environmental responsibilities with the demands of economic growth has been a difficult challenge for national governments, regional and local nongovernmental organizations (NGOs), and the corporate community.

The emblematic illustration of this problem is the multinational factories constructed in cities along the Mexican-U.S. border that are called *maquiladoras.* Multinational corporations escaped environmental and occupational constraints elsewhere by moving to Mexico and other countries in Central America that have less stringent environmental laws and low labor costs. At the same time relatively attractive wages in combination with drought and unemployment in the central highlands of Mexico emptied villages as young people migrated to work in the *maquiladoras.* As a consequence of that migration, villages and towns grew around factories without water-treatment plants or sewage systems while the *maquiladoras* were dumping toxic waste into local rivers.



Maquiladoras *in Tijuana, Mexico.* *Multinational factories called* maquiladoras *can be found along the Mexican-U.S. border. Towns and factories on the Mexican side of the border grew up around factories without water-treatment plants or sewage systems while the* maquiladoras *dumped toxic waste into local rivers.* **LUIS ACOSTA/AFP/GETTY IMAGES.**

POLLUTION AND CLIMATE CHANGE

Other environmental problems in the region that grew more serious in the last decade of the twentieth century and first decade of the twenty-first include chemical pollution of soils, water, and air in large plantations devoted to export-oriented agriculture; desertification and increased demand for irrigation and drinking water; deforestation, which adds to the problem of water depletion (in spite of policies and regulations, indiscriminate felling and illegal timber trafficking are rampant); illegal trade in fauna and flora; and scarcity of agricultural products for domestic human consumption.

The peoples and environments of Mexico and Central America are affected by the impacts of global climate change. The region has been hit particularly hard by hurricanes since 1988. Seven of the ten most intense Atlantic hurricanes ever recorded have occurred since that time, including Mitch in 1998, the second deadliest on record.

LEGISLATIVE ACTIONS AND NONGOVERNMENTAL ORGANIZATIONS

What is an equitable burden for Latin Americans to assume in the international effort to remedy and limit global change? The current politics of hydrocarbon fuels illustrates the complexity of the problem. The projected economic growth in Latin America and the scarcity of energy in international and regional markets have created a demand for increased production and consumption of hydrocarbon fuels. However, regional and local environmental problems have created a demand for a smaller carbon footprint and a need to address the human and environmental dimensions of the use of hydrocarbon fuels.

Mexicans and Central Americans are aware of current and past ecological problems. The relatively new discipline of environmental history is rescuing from oblivion the contribution of past environmentalists and historical examples of balancing economic development and environmental protection. In this respect Miguel Angel de Quevedo stands out as the most prominent environmentalist of the late nineteenth and early twentieth centuries.

Latin American countries have passed many laws to protect the environment. For instance, in 1988 the Mexican legislature passed the General Law of Ecological Balance and Environmental Protection, an integrated response to the environmental problems of the country and those of Mexico City in particular. About that time the government created the Secretariat of Urban Development and Ecology (SEDUE). Environmental initiatives have driven the regional integration of Central American countries, as evidenced by the creation of institutions such as the Central American Commission on Environment and Development (CCAD) in 1989 and the Central American Alliance for Sustainable Development in 1994.

The philosophy of sustainable development began to emerge in the 1980s. At that time Mexico became an academic leader in Latin America on the theory and application of sustainable development. The Mexican philosopher Enrique Leff, who became the coordinator of the United Nations Environment Program office in Mexico, made many contributions in this area.

The 1990s witnessed the formation of more than a thousand environmental NGOs in Mexico. The unification and alliance of several of them gave birth to the *Partido Verde Ecologista de México* (Green Ecologist Party of Mexico). A milestone in the history of environmentalism in Mexico was the formation of the *Grupo de los Cien* (Group of 100) in 1985, led by the writer Homero Aridjis and founded when a hundred writers and artists published a declaration against pollution. Over the years the *Grupo de los Cien* has called attention to the widespread and unremitting destruction of the Mexican natural environment.

Among the various approaches to environmental concerns in Mexico and Central America the environmental-justice approach has called attention to inequity in the distribution of environmental burdens and risks. For instance, the relationship between public health and ecology has long been understood and its neglect denounced, particularly in regard to urban pollution and the hazards of the *maquiladora* sector near the border.

As North American transnational companies have razed forests and mountains in Central America, a growing number of Catholic clergy (cardinals, bishops, and priests) have come to see protection of the land and water as godly work. Church and community groups have pointed to studies that have found high levels of heavy metals in the soil and water near mines across the region. In spite of the jobs created by those companies, mining and logging are depleting the water table, drying up wells, and forcing formerly productive farming regions to import food. Catholic environmentalism in the region, with its challenges to the powerful and solidarity with the poor, resonates with liberation theology in the minds of many. However, Catholic clergypersons seem to be increasingly in tune with the Vatican's position on the environment. Official Catholic teaching on the environment is based on the belief that creation is a gift of God that must be protected, used responsibly, and shared equitably.

THE ENVIRONMENT AND SOCIAL JUSTICE

The integration of environmental problems and social justice issues is an achievement of environmentalist thinking and activism in Mexico and Central America. In fact, it could be argued that the intellectual tradition in Mexico since the nineteenth century has resisted the typically North American erasure of the human from environmental thinking. The inclusion of history and people in the representation of landscapes in different media and arts to a great extent has been a reaction to a perceived obsession among foreign travelers for representing Mexico and Central America as a wilderness deprived of human history and large urban centers. This vindication of the city is problematic as it also reflects a history of imperial domination by the urban over the rural.

The environmentalist positions taken by the Zapatista rebellion in 1994 in the state of Chiapas in southeastern

Mexico illustrates the complexity of the human-nature/urban-rural environmental thought characteristic of the region. Zapatista documents connect the call for environmental protection with the rights of rural citizens against the centralized authority of the government in Mexico City, political ecology (access to and control of natural resources), and environmental justice. The environmentalism of the Zapatistas also includes the spirituality and biocentrism of traditional indigenous values, which nurture not only Zapatista environmental philosophy but also its commitment to a political struggle without violence.

One response to the environmental crises produced by modernity has been the unearthing and reawakening of forgotten or repressed traditions. This cultural trend can be seen in the recovery of traditional environmental knowledge such as traditional agricultural techniques in Mesoamerica. Environmental and indigenous organizations have established alliances to promote sustainable agriculture and community autonomy in rural Mexico. However, this can lead, as in the case of the Nobel laureate poet and essayist Octavio Paz, to the deployment of poetry for purposes of exposing the legacy of political and ecological destruction over the course of the twentieth century. The connection between embracing environmental thinking and rejecting the legacy of violence associated with utopianism and millenarianism in the twentieth century should not be overlooked, particularly in the context of the civil wars that bled Central America in the 1980s. Mexican and Central American literature is an ideal site for observing this connection, as in the work of José Emilio Pacheco, Pablo Antonio Cuadra, and Ernesto Cardenal.

If the awareness of ecological problems and their many human dimensions among the public and government is not the issue, what is needed to address those problems in Mexico and Central America? The consensus is that in spite of the popularity of environmentalism, the region lacks a powerful environmental movement that would offer unified and strong political support for environmental justice and the protection of wildlife. The challenge has not been environmental awareness and progressive environmental policy and legislation; it has been the inability of governments to implement environmental policy and enforce environmental laws to protect ecosystems and the people who inhabit them.

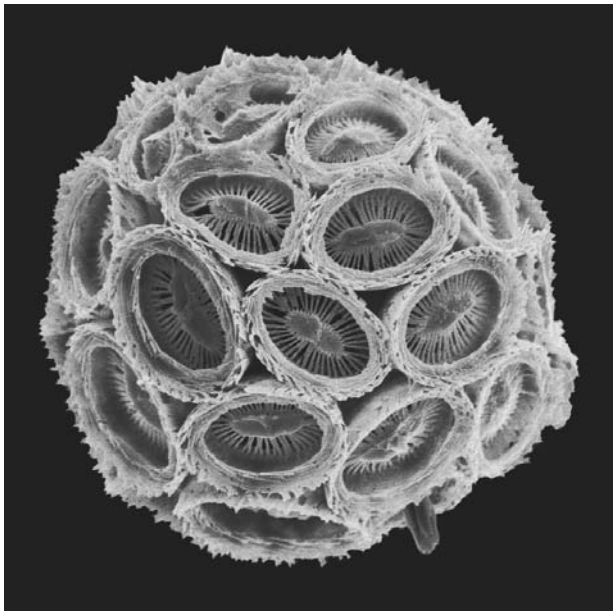
MICROBES

Microbes carry out the functions of life. These entities, too small to see with the naked eye, have the wherewithal to reproduce with sufficient variation to enable evolutionary processes to proceed continually by natural selection. Humans, as with all other large animals and plants, are made up of tens of trillions of cells, whose dimensions are generally in the range of 10 to 30 microns (thousandths of a millimeter). Indeed, each such cell is actually a colony of some 1 to 500 smaller cells, with a 1-micron diameter, called mitochondria and chloroplasts—cells the size of free-living bacteria. Each such cell collective may be regarded as a single ecosystem. Thus ecosystems may range in size from volumes of less than a microliter (a 0.1-millimeter-sided cube) to a system the size of the planet Earth. In addition to cellular life forms, there are also viruses. These entities, having diameters of 20 to 200 nanometers (thousandths of a micron), may also be included in the category of microbes because they carry within them the genes that enable their reproduction, although they are incapable of reproducing in the absence of other living microbial cells.

While life at the microbial level began some 3.5 to 4 billion years ago, ethics is a relatively new invention of humans, who began to use words with the intention of affecting the behavior of other humans within the last 0.1 to 0.2 million years or so. Biologically, ethics are used to enhance the survival and reproductive chances of individual humans and/or groups, societies, or nation-states. Microbes play a role in determining the qualities of the environments that we humans inhabit. The composition of the air we breathe is largely determined by free-living microbes and by chloroplasts, microbes that have become entrapped within the cells of higher plants. Thus if



Coccolithopore, a Microbial Plant. *Microbes, too small to see with the naked eye, play a relatively large role in the maintenance of ecosystems. The coccolithopore, an algal organism seen here with scanning electron micrograph takes carbon dioxide from the air and converts it into calcium carbonate plates.* **STEVE GSCHMEISSNER/SCIENCE PHOTO LIBRARY/PHOTO RESEARCHERS, INC.**

environmental ethics seeks to enhance the survival and reproductive chances of human beings and human civilization, microbes and the ecosystems in which they vitally function should be included within the purview of environmental ethics.

In 1772 Daniel Rutherford discovered the nitrogen cycle driven by bacteria. Bacteria transform the nitrogen in dead organisms to gaseous ammonia and elemental nitrogen as a byproduct of their own metabolic processes. Other bacteria convert these two gases to nitrogenous salts, such as ammonium nitrate, as a byproduct of their metabolic processes. These salts eventually become incorporated, initially, into the proteins of other microbes, and then, via an extensive food chain, into the proteins of higher organisms, upon whose deaths the nitrogen becomes gaseous once more. A similar cycle processes carbon. In the case of carbon, the fossil fuels we burn, the food we eat, and our bodies when we die are in part transformed into carbon dioxide, which is liberated into the atmosphere to become a greenhouse gas. Carbon dioxide in turn becomes food for algae (microbial plants) and plants, which convert this gaseous carbon dioxide into sugars and carbohydrates. The coccolithophore, one such alga, lives in the oceans and is instrumental in acquiring carbon dioxide from the air and converting it into calcium carbonate plates of considerable beauty. This chalk then sinks to the bottom of shallow seas, where it forms the limestone of many coastal cliffs and hills.

Such cycles normally operate in the absence of human intervention. Yet humans modify them for their own purposes. For example, Fritz Haber in 1908 developed a process for artificially producing ammonia from nitrogen. Ammonia later became used to generate fertilizers for increasing crop yields. As a result, when nitrogen-rich salts run off fertilized land, river waters become enriched, and wild plants flourish in them. Here our human ethics requires us to produce food to feed people at the expense of polluted rivers. Similarly, humans interfere in the carbon cycle by producing some 26 billion tons of carbon dioxide per year, in addition to the more than 700 billion tons produced by the respiration of other living organisms both on land and in the oceans. While this provides more carbon dioxide for plants and coccolithophores to thrive on, it is also held to be responsible for part or all of the 0.6-degree-centigrade increase in the temperature of the planet that has occurred over the last century. How to reconcile the requirements of human ethics with those of environmental ethics is a complex and thorny problem.

Many diseases of humans, animals, and plants have microbial causes. The human response to this is to generate cures based on the products of other microbes grown in fermenters. For example, antibiotics such as penicillin are produced by the fungus *Penicillium chrysogenum*. This approach to diseases, mostly caused by bacteria, was received with open arms in the 1940s, when penicillin became widely available. Unfortunately, the overuse of antibiotics has led to the evolution of microbes resistant to such treatments. An alternative approach to diseases caused by microbes (bacteria, viruses, protozoa, and helminths) is to prevent their occurrence with vaccines. This approach led to the elimination of smallpox in 1977 and is close to eliminating polio. As we are beset with new diseases (HIV/AIDS, SARS, the avian flu), new approaches to the generation of vaccines are yielding effective agents to combat such diseases.

At the small end of the scale of living organisms, microbes have a greater influence on the environment than any other type of organism, humans included. They may hold many of the keys to solving the environmental crises that face us.

MIDGLEY, MARY
1919–

The British philosopher Mary Midgley was born in Dulwich, East London, on September 13, 1919. She graduated from Oxford University in philosophy and ancient history in 1942 and worked as a civil servant and teacher during World War II. In 1950 she married and moved north to Newcastle, where she concentrated on reviewing books and bringing up a family. It was not until 1963 that she took up a lecturing position in the philosophy department at Newcastle University. After "retiring" in 1980, Midgley stayed in Newcastle, where she has continued to work as one of a rare breed: a freelance philosopher. She has published extensively in ethics and environmental philosophy and is an active social commentator on animal ethics, environmental issues, Gaia theory, and the role of science in society.

Animals and Why They Matter was published in 1983, at a time when ethical theory was still firmly entrenched behind human lines. She argued, alongside Peter Singer and a handful of other ethicists, that ethical obligations extend beyond our own species, carefully unraveling and exposing the intellectual confusions that lead to a denial of interspecies ethics and setting out the implications of cross-species ethical obligations for European and North American ethical thought. Unlike Singer's orthodox utilitarian approach to animal ethics, Midgley's is based on the more nuanced concept of human-animal "mixed communities." Her communitarian approach to animal ethics facilitates an otherwise elusive integration of animal ethics with the popular "land ethic" of Aldo Leopold, which is based on the concept of the "biotic community." Midgley's early focus on animals extended into a seminal discussion of our ethical relationships to the wider environment in the essay, "Duties concerning Islands."

A constant theme in Midgley's work is the attempt to uncover the often unnoticed intellectual frameworks or worldviews against which we live our lives, to show how these patterns of thinking affect how we live and act, and, above all, to open them up for critical scrutiny. In the context of environmental and social justice issues, the need for new mental models is, she argues, as crucial as the need for cleaner and more efficient technology. European and North American societies still struggle with corrosive forms of social atomism and individualism that militate against sustained effort to deal with collective human problems, such as hunger, on a global scale. And the dominant view of the environment as a set of resources for people, and of ourselves as detached managers of these resources, has arguably contributed to problems such as climate change and species extinction that now loom so large.

Drawing on Gaia theory as a key source, Midgley attempts to reconstruct our background worldview in a way that is not only more felicitous but that will afford profound understanding of our environmental problems—and inspire us to act. Earth, in her view, is not a lifeless jumble of commodities but an immense, living complexity of interrelated systems. She argues that we are not independent of this living whole but are deeply immersed in it. Once this simple truth is understood—emotionally as well as intellectually—then our reasons for taking care of the environment as an overriding priority become utterly and compellingly clear.

Midgley's work combines careful, detailed analysis with a constant return to wider questions about the place of humans and human activities—especially science—in the bigger scheme of things. This outlook has enabled her to show that apparently conflicting perspectives are, in fact, complementary aspects of a wider whole and that these positions can and should be reconciled. She has argued in this way against the polarization of animal welfare and environmental concerns. She reveals the close connections between reason and emotion through her exploration of the human mind in its evolutionary context, and she emphasizes the importance of imagination in reasoning processes. She argues, in works such as *Science and Poetry* and *The Myths We Live By,* against the supposed opposition between science and myth, science and spirituality. In all these cases she eschews the "intellectual tribalism" whereby one perspective or dimension of an issue is taken to be the whole story and is then ranged in battle against other perspectives. This mistake, she argues, can be noticed only when the wider context is brought into focus. Once this is done, it is possible to achieve bridge building and reconciliation, which in turn have tremendously constructive implications, both practical and theoretical.

The work of "bending thought around to look at itself" or "thinking about thinking," although difficult, is also intensely practical. Midgley's position reveals the potential of philosophy in general—and environmental philosophy in particular—as a practical activity that is both radical and necessary, affording us the much needed ability to rethink our economic social and political institutions when they become problematic—for example, by leading to ecological collapse. Her chief contribution to environmental philosophy is thus an approach concerned

not with cleverness and abstraction but with wisdom, with insight, and with change.

MILLENNIUM ECOSYSTEM ASSESSMENT

The Millennium Ecosystem Assessment (MA) documents how people are transforming their environment and how environmental transformation is affecting human well-being. As a scientific assessment the report is supposed to be free of ethical judgments. At the same time the intention of the MA is to inform the public and policy makers so that ethical judgments embedded in behavioral and policy decisions are scientifically informed.

The MA was initiated largely by biological scientists who, at the end of the last millennium, were already concerned about the effects of ecological transformations on humanity's future. The four-year study was carried out by some 1,300 environmental scientists, economists, and other social scientists from developed and developing countries who came into the assessment with a wide range of perspectives on issues such as the prospects for new sustainable technologies or the possibility of market solutions to environmental problems. The study frames people's relation to nature in mostly economic terms. Ecosystems are portrayed as natural capital from which ecosystem services flow in support of the human economy, whereas human activities modify and typically deplete nature's capital and thereby also affect the flow of services and future well-being.

KEY FINDINGS

The four main findings of the 2,500-page study, published in four volumes and titled *Ecosystems and Human Well-Being* (2005a), are as follows:

1. Over the past 50 years, humans have changed ecosystems more rapidly and extensively than in any comparable period of time in human history, largely to meet rapidly growing demands for food, fresh water, timber, fiber, and fuel. This has resulted in a substantial and largely irreversible loss in the diversity of life on Earth.
2. The changes that have been made to ecosystems have contributed to substantial net gains in human well-being and economic development, but these gains have been achieved at growing costs in the form of the degradation of many ecosystem services, increased risks of nonlinear changes, and the exacerbation of poverty for some groups of people. These problems, unless addressed, will substantially diminish the benefits that future generations obtain from ecosystems.
3. The degradation of ecosystem services could grow significantly worse during the first half of this century and is a barrier to achieving the Millennium Development Goals (adopted by the United Nations in 2000).
4. The challenge of reversing the degradation of ecosystems while meeting increasing demands for their services can be partially met under some scenarios that the MA has considered, but these involve significant changes in policies, institutions, and practices, that are not currently under way. Many options exist to conserve or enhance specific ecosystem services in ways that reduce negative trade-offs or that provide positive synergies with other ecosystem services (Millennium Ecosystem Assessment 2005b, Synthesis Volume, p. 1).

The assessment investigates five key stressors on global ecosystems—habitat change, climate change, invasive species, overexploitation, and pollution (including both toxics and nutrification)—across thirteen broad ecosystem types: forest (boreal, temperate, and tropical), dryland (temperate grassland, Mediterranean, tropical grassland/savanna, and desert), inland water, coastal, marine, island, mountain, and polar. For the five drivers across thirteen ecosystem types, there was only one combination, habitat change in temperate forests, where the impact of the driver was lessening. Thus, for sixty-four of sixty-five possibilities, stresses on ecosystems are increasing.

The MA investigated alternative policy options to decrease, or even reverse, stresses on ecosystems. The elimination of subsidies that encourage destructive practices such as land conversion and greenhouse gas release would be effective in reducing many kinds of ecosystem transformations. Reducing ecosystem stressors further, however, requires combinations of new economic incentives, behavioral changes, and technological innovations, the specific mechanisms and combinations of which will vary across ecosystems; as well as social, cultural, and political contexts. Integrating complex, context-specific policy responses across stressors, ecosystems, geographic scales, and political boundaries is difficult to even contemplate, let alone describe coherently for policy makers.

IMPACT ON ENVIRONMENTAL UNDERSTANDING, VALUES, AND POLICY DECISIONS

The findings of the MA have been widely cited in academic and popular literature. Material from the MA can be found in the readings of many college courses and textbooks. Numerous regional assessments around the world are amassing knowledge for subsequent global analysis. Nevertheless, the impact of the MA on environmental understanding, values, and policy decisions remains unclear. While the climate assessments of the Intergovernmental Panel on Climate Change (IPCC) have been crucial in shaping climate knowledge, eliciting fresh concerns for the future and focusing policy debates, the MA is much less focused, and so its impacts on people's values, corporate decisions, and public policy are harder to pinpoint.

ETHICAL AND PHILOSOPHICAL ISSUES WITHIN THE ASSESSMENT PROCESS

The choice of a scientific framework for the MA has ethical implications simply because different frameworks highlight, and hence differentially value, different aspects of a problem. The assessment's characterization of ecosystems as capital and their benefits as services evinces a utilitarian ethics and an economic worldview. Perhaps this economic framework accounts for the MA's favorable portrayal of the economic approach known as "payments for ecosystem services." Selecting scientists from developing countries concerned with improving the material well-being of the poor balances the more ecocentric views of scientists from the developed countries. Conventional economists avoid the term *overconsumption*, but the inclusion of ecological economists and sociologists in the work of the assessment has led to an extensive exploration of this issue. Hence even scientific assessments reflect underlying, implicit ethical predispositions and decisions, even if they are never explicitly formulated.

The MA is an example of a new approach to applying science to the complex interactions between social and natural systems. This approach, used most famously in the climate assessments of the IPCC, entails the use of several thousand scientists from a wide range of disciplines to address key policy questions to explore and summarize the findings of the latest scientific literature. Although the focus of the assessment is on the interaction between social and natural systems, natural scientists' portrayals of ecosystems rarely include people, and social scientists rarely include nature in their descriptions of social systems. Numerous other methodological problems had to be overcome, including recognizing and transcending disciplinary assumptions and language in achieving insights into the issues of natural capital and ecosystem services. One of the most important by-products of the MA was the training of numerous scientists to think and communicate across disciplinary boundaries and to identify critical questions for future research.

MINING

This entry contains the following:

I. OVERVIEW

Mining is one of the most controversial uses of land. The extraction of materials from the earth is an invasive, nonreversible process that often causes extensive environmental damage, but it is the only known method of acquiring sufficient supplies of many of the raw materials needed to support human well-being. According to U.S. Geological Survey statistics, 2004 world mining production included 14.6 million metric tons of copper, 2,430 metric tons of gold, and approximately 1,340 million metric tons of iron ore.

Mining can be done only in places where there is an economically viable deposit of a desired material. Mineral deposits are the result of complex earth processes that concentrate certain elements in specific locations. Nature determines the distribution of mineral deposits and thus the possible locations for mining; people can choose whether to mine deposits that have been discovered but cannot dictate where the deposits are situated. Mines are often a long distance from the markets that consume their products. From the earliest times flint, salt, gold, and other commodities were traded extensively, making mining the first global industry.

Three sectors dominate the mining industry: metals such as copper, gold, lead, zinc, iron, and nickel; energy minerals, including coal and uranium; and industrial minerals such as sand and gravel for construction, clays for ceramics, and salt for many industrial uses. Each sector uses a range of extraction techniques and faces environmental issues related to the nature of the ore deposits, their chemical composition, and the environmental context of any specific deposit.

HISTORY

The history of mining is linked closely to developments in metallurgy and mineral processing and influenced by political and economic circumstances. Copper, gold, and lead were used in the Middle East by 3500 BCE. Early mining focused on collecting nuggets of pure metal. The recognition of veins of metal-bearing minerals and improved smelting methods to separate metals from rock were the foundations for the Bronze Age and Iron Age. The Romans were the most noteworthy ancient miners; in an advance that allowed miners to reach depths of over 650 feet, they replaced some slave labor with mechanical devices to drain water from mines. Technical innovations were few until the fifteenth and sixteenth centuries, when two methods of removing silver from copper ore—liquation and mercury amalgamation—led to the exportation of silver from the New World to the Old World.

Widespread industrial use of coal started in the eighteenth century in Britain and the nineteenth century elsewhere. Coal often occurs in aerially extensive flat-lying beds, unlike the narrow, often steeply dipping metal-bearing veins that were the main source of most metals except iron until the twentieth century. Coal at the surface of the earth is amenable to large-scale open-pit mining. It is difficult to support the roof of underground coal seams when the coal has been removed; this, combined with the combustible nature of coal and the associated gases, makes underground coal mining particularly dangerous.

TECHNOLOGY AND SOCIAL ASPECTS

Many advances in mining have been tied to improved sources of power. People wielding picks, wedges, and crowbars were the main source of energy until recent times. Explosives were not employed in Europe until the seventeenth century; their use increased greatly after Alfred Nobel's 1863 invention of dynamite. The introduction of steam power in the 1700s was significant, particularly as it powered the Cornish pump, which could remove large volumes of water from deep mines. Steam power was replaced by compressed air in the late 1800s and by electricity in the early 1900s. Much of the industry has been mechanized by combining these forms of power with modern, efficient rock-cutting materials and the introduction of robotics. Mechanized mining has enabled the economic development of large-scale open-pit mines, particularly for coal, iron, and low-grade deposits of base metals.

Important advances in processing include the 1886 discovery of the cyanidation process, in which cyanide is used to dissolve gold from crushed rock; the development in the early 1900s of the flotation process to separate copper, lead, and zinc from finely ground sulfide ore; the adaptation in the 1980s of solvent extraction-electrowinning to process copper and zinc oxide ores by chemically leaching the metal out of crushed rock and then extracting it from solution by electrical methods instead of smelting the ore; and the introduction of bioleaching, which uses bacteria to extract metal from crushed rock. In situ leach mining is an approach that was developed in the 1980s. Instead of removing and crushing the rock and then extracting the metals, a dilute chemical solution

Mining for Coal, West Virginia. *Draglines, such as this one at a mine in Boone County, West Virginia, can weigh millions of pounds and are tall enough to loom over a 20-story building. They are used to expose mountaintop coal seams. Mining practices can cause severe environmental damage in terms of physical ground impact and possible contamination of water, air, and soil.* **PHOTO COURTESY VIVIAN STOCKMAN/WWW.OHVEC.ORG.**

is circulated through the ore deposit in the ground to leach out the metals. The metal-bearing solution then is collected through extraction wells and processed to obtain the metals. Modern processing methods are generally less environmentally hazardous than older techniques.

The societal aspects of mining have been as important as the technological advances. The Roman Empire structured mining operations throughout much of Europe from about 100 BCE to 500 CE; independent miners returned to the fore when the empire collapsed. Spanish monarchs controlled mining in Central and South America in the sixteenth century. The middle to late nineteenth century saw a great territorial expansion in mining when independent miners opened up the goldfields of the western United States, western Australia, and southern Africa. In the first decade of the twenty-first century it was estimated that thirteen million people were operating similar small-scale independent, or artisanal, mining enterprises, particularly in developing nations. Small-scale informal mining poses special environmental and social problems because it operates largely outside the rule of law.

Modern mining companies emerged around the start of the twentieth century, when capital costs rose to levels far beyond the resources of individual miners. Major multinational mining companies based in Australia, Brazil, Britain, Canada, Chile, China, South Africa, and the United States came to dominate the industry. The balance of power between states, corporations, and local communities is constantly in flux, with alternating periods of nationalization and privatization of resources and growing awareness in the formal mining sector of the importance of sustainable development, social license, and reliable governance.

ENVIRONMENTAL IMPACTS

The environmental impacts of traditional mining can be severe. The physical impacts include large surface pits, noise and vibration during operations, subsidence caused by underground workings, piles of unconsolidated waste material leading to unstable ground, dust pollution, and the influx of sediment into watercourses. Chemical contamination of surface and ground water, air, and soil, which may be long lasting, can be caused by acid mine drainage and the release of metals or the chemicals used to process ore. Little attention was paid to the environmental consequences of mining until the middle to late twentieth century, when social agitation and government regulation forced mining companies to address the issue.

Almost all the environmental impacts of mining can be mitigated, although at a price. Most modern mining companies budget for and implement environmental mitigation programs in all their projects; it is more challenging both legally and technically to remediate the effects of past mining activities and ongoing small-scale mining. It is also difficult to quantify the social impacts of mining and develop appropriate mitigation strategies. Though the benefits of mining are distributed throughout society, the social and environmental costs are concentrated in areas where mines are situated. Defining appropriate distributions of the costs and benefits of mining and determining how much society is willing to pay to mitigate the environmental and social impacts in return for a reliable supply of raw materials are major challenges facing governments, civil society, and the mining industry.

II. ACID MINE DRAINAGE

Mineral resource production is vital to modern industrialized societies. The environmental consequences of mineral production, however, have resulted in degradation and destruction of air, water, soil, land, and biological resources. Quantitative estimates are difficult to make, but tens to hundreds of thousands of mine sites in the United States and hundreds of thousands more worldwide probably have caused environmental damage (Custer 2003; Young and Ayres 1992). Environmental restoration is expensive, time-consuming, and a substantial challenge to scientists and engineers. The total costs to clean up mine sites in the United States are thought to run to a few hundred billion dollars (Mining, Minerals, and Sustainable Development 2002). One of the most injurious consequences of metal mining is the formation of acid mine drainage (AMD), a major contaminant to surface and ground waters.

AMD is acidic effluent water discharged from metal mines or mineral-processing wastes containing high concentrations of acidity, sulfate, and metals that are toxic to most forms of life except certain species of microbes (Nordstrom and Alpers 1999). When fresh rock containing pyrite, FeS_2, is exposed to air and water, a rapid reaction ensues, catalyzed by acidophilic bacteria. The general reaction is represented by

$$FeS_2 + \frac{15}{4} O_2 + \frac{7}{2} H_2O \rightarrow Fe(OH)_3 + 2H_2SO_4$$

in which pyrite is oxidized and dissolved, sulfuric acid is produced, and some form of ferric hydroxide is precipitated. The precipitated iron can be seen as orange-red to brown staining or coating on rocks and sediments in mined areas. Other coexisting minerals dissolve rapidly in sulfuric acid and contribute other metals (copper, zinc, cadmium, lead, cobalt, nickel, chromium, aluminum, and manganese) to the water. Such effluent from mine portals, adits, waste rock, and tailings piles typically has pH values of 2 to 4, although in extreme cases the pH can decrease to below 0 (Nordstrom et al., 1999). The high metal concentrations are a greater source of toxicity than is the low pH. In contrast, drinking water has pH values of 6 to 8, and most metals are insoluble in those conditions.

Acid Mine Drainage. *A journalist with Danish Public Broadcasting and Owen Stout of Cabin Creek, West Virginia, examine acid mine drainage at the base of Kayford Mountain, about an hour south of West Virginia. The contaminated water flows constantly from an abandoned deep mine. The West Virginia Department of Environmental Protection has known about the acid mine drainage for years. The tainted water flows into Cabin Creek, which makes its way to the Kanawha River, then flows into the Ohio River, and on to the Mississippi River.* **PHOTO COURTESY VIVIAN STOCKMAN/WWW.OHVEC.ORG.**

Accidental releases of impounded AMD have caused major devastation to some rivers; for example, the Aznalcollar impoundment in southern Spain broke and released about 7 million tons of acid slurry into the Guadiamar River, contaminating agricultural land, destroying aquatic biota, and threatening the largest European bird refuge, Doñana National Park (Grimalt and Macpherson 1999).

Acid rock drainage (ARD) is a more general term that refers to both AMD and acidic drainage that occurs naturally in mineralized areas where there has been no mining. Mineralized and unmined areas often produce acid waters with elevated concentrations of metals (Runnells et al. 1992). The geochemical process is the same, but mining greatly enhances the rate by exposing much more pyrite-bearing rock to air and water. One estimate from studies at Iron Mountain, California, indicates that mining increased the sulfide-weathering rate by at least two orders of magnitude (Alpers et al. 2007).

The large-scale and hydrogeochemical complexities of the contamination have hindered remediation efforts, although remediation has succeeded at several mine sites worldwide (Fernandez-Rubio 2004). The most common treatment for AMD is lime/limestone neutralization, an effective short-term solution. Because AMD can continue for hundreds to thousands of years, long-term, passive treatment is recommended. Research on wetlands treatment, water management, disposal practices, land reclamation, and phytoremediation holds promise for the long term. New mines can greatly reduce the environmental consequences of mining by incorporating environmental planning and monitoring into the mine plans

before mining begins. This approach also saves considerable amounts of money compared to the costs of environmental restoration after mining is finished and compared to legal costs when mining companies are sued for the damages they caused.

Foreign mining companies have taken advantage of the lack of regulatory authority in some underdeveloped poor countries and caused large-scale pollution of resources that destroy or harm the livelihood of native peoples. Mining companies have an ethical and economic obligation to minimize or prevent damage to air, water, soil, land, and biological resources and to prevent injuries to local communities as they exploit mineral resources for the needs of modern society.

III. MOUNTAINTOP REMOVAL

Mountaintop removal is a method of strip mining for coal in mountain regions. Its violent effect on nature and society has generated public controversy in the United States, where it has been practiced since the mid-1980s. Though mountaintop removal mining is done worldwide, its oldest and largest footprint appears in central Appalachia in an area predicted to be the size of the state of Delaware by 2012. The massive scale of mountaintop removal, its irreversible destruction of biologically diverse ecosystems, and its legacy of postbiotic landform complexes distinguish mountaintop removal from earlier forms of strip mining.

THE METHOD

Mountaintop removal involves stripping all vegetative cover and then blasting open a mountain to loosen the overburden, the name the coal industry uses for the communities of soil and resident life forms, defined as "material of any nature . . . that lies on top of a deposit of useful materials, ores or coal" (Squillace 1990, p. 138). Mountain ranges have been reduced by as much as 1,000 feet in Kentucky and West Virginia, where up to 2,000 metric tons of explosives are used daily. In the wake of blasting, a twenty-story-high excavator known as a dragline then scoops up the exploded materials and loads them into rock dump trucks, which deposit them in an adjacent hollow to form what is known as a valley fill. The U.S. Environmental Protection Agency (EPA) has predicted that by 2012 more than 2 million acres of the central Appalachian coalfields will have been exploded, mined, regraded, and revegetated in this manner. By the first decade of the twenty-first century more than 2,000 miles of headwaters, including intermittent and perennial mountain streams, had been damaged severely or buried beneath mine spoil (U.S. Environmental Protection Agency 2005). The coal industry defends mountaintop removal mining as the safest and most cost-effective way to meet the energy needs of a nation that produces more than half of its electricity in coal-fired utility plants.

HISTORICAL BACKDROP: LAND ACQUISITION, TECHNOLOGY, AND SOCIAL COMPACTS

The relationship between the coal industry and coalfield communities is characterized by what the anthropologist Marshall Sahlins has called negative reciprocity. In the extractive, nonrenewable coal economy the industry must take out more than it puts back to make a profit. In the twentieth century that negative reciprocity was codified and protected through "instruments of writing" (legal documents) that resolved disputes over land, labor, and resources in favor of the coal industry (Williams 2001).

Those instruments, which form de facto social compacts, include the Broad Form Deeds executed between the 1880s and the 1930s, the 1950 accord between the United Mineworkers and the Bituminous Coal Operators, and the 1977 Surface Mine Control and Reclamation Act (PL 95–87), also known as SMCRA.

The Broad Form Deeds transferred mineral rights to absentee landowners through negotiations that allowed farmers to continue traditional patterns of land use. Between the 1880s and the 1920s thousands of transactions were drawn up between land companies and coalfield residents, deeding mineral rights to the companies in exchange for clear title to the surface. By means of the Broad Form Deed residents gave land companies unfettered access to minerals and timber in exchange for the right to continue farming the land. Ninety percent of the land in that region is owned outright by absentee companies.

In the 1960s and 1970s strip mining was used increasingly throughout the region, with the externalities of acid runoff, deadened streams, and deforested and scarred landscapes. Despite opposition from local communities, strip mining was justified as the most efficient way to get at seams of coal that were too thin to retrieve through underground mining, and residents were held to unfettered access for absentee owners that had been guaranteed by the Broad Form Deeds decades earlier. The giant earthmoving machines used during that period were diminutive precursors of the contemporary draglines and rock dump trucks. The strip mining of the 1960s and 1970s, referred to as highwall, contour, or augur mining (and now as prelaw, that is, before SMCRA, mining), operated by cutting a wedge into the side of a mountain, simultaneously creating a wall perpendicular to a level bench. The bench supported a machine that drilled or cut away the coal from the wall. Refuse, or gob, consisting of mine dust, shale, clay, and poor-quality coal was disposed of in nearby hollows and impounded behind slag dams built of larger chunks of shale and rocks. Water that accumulated behind the impoundments increased the likelihood of severe flooding during heavy rains.

In the 1960s the Pittston Coal Company built a series of slag dams in the Middle Branch at the head of Buffalo Creek in Logan County, West Virginia. In 1972 the uppermost dam burst after a heavy rainfall. What witnesses described as a "wall of blackwater" (Erikson 1976)—132 million gallons—roared through the narrow seventeen-mile-long valley of Buffalo Creek, killing 125 people, injuring 1,100, and leaving 4,000 homeless in a matter of minutes.

That disaster precipitated the 1977 passage of the SMCRA. In addition to prescribing safety standards for surface mining and reclamation operations, SMCRA integrated provisions of the National Environmental Policy Act, the Clean Air Act, the Clean Water Act, and the Historic Preservation Act to facilitate citizen input regarding the propriety and legality of surface mining activities. Some citizen groups, such as Save Our Cumberland Mountains, opposed SMCRA, arguing that environmentally responsible strip mining is not possible (Stacks 1972). In a key provision of SMCRA, Section 515c(1), a coal company is exempt from the requirement to restore the land to its approximate original contour (AOC) if it can demonstrate that flat land will be of greater economic value for postmining development. Claiming that flat land can serve postmining developments such as industrial parks, prisons, shopping malls, airports, and golf courses, coal companies have petitioned for and been granted this exemption in nearly all mountaintop removal mining permits filed since the mid-1980s. In the aggregate the fine print in such agreements has provided the loopholes through which the coal industry has internalized its profits while externalizing its costs.

SOCIAL AND ECOLOGICAL COSTS

The offsite impacts, also referred to as negative externalities, of strip mining and coal-fired utilities plants include the pollution of air, water, and soils; forest decline as a result of acid rain (Ayers et al. 1998); and boom and bust economies at the sites of extraction, resulting in government subsidies during recurrent periods of unemployment and disasters such as mine explosions and flooding. Mountaintop removal mining adds several unprecedented negative externalities to this list.

Impacts on Coalfield Communities Beginning in the mid-1980s, preparations for mountaintop removal mining in the Appalachian Mountains took place out of public view and beyond the awareness of nearby communities. Local citizens first learned that something was changing when customary routes through the mountains were closed. Eventually the use of explosives began shaking their homes, cracking foundations, and destroying water sources, including spring-fed streams and wells. The blasting also precipitated blowouts of water that had accumulated in underground mines, sometimes with enough force to flatten buildings. Rivers grew shallow with siltation and the runoff from denuded slopes and during heavy rains made creeks overflow their banks and roar through the hollows, twisting road signs, ripping apart bridges, and carrying away vehicles, animals, and sometimes people, eleven of whom drowned in the floods of 2001 and 2002. Millions of gallons of blackwater are stored in hollows near coal preparation plants that tower above schools and homes. Black plumes, indicating discharges, in local streams and rivers are reported frequently. As a storekeeper in Stickney, West Virginia,

Aerial View of Mountaintop Removal, at Marthatown, West Virginia. *The mountaintop removal method of strip mining for coal, practiced in the U.S. since the mid-1980s, is largely controversial for the devastating effects the practice causes to an ecosystem. The states of West Virginia and Kentucky have declared states of emergency several times since 2000, due to the severe environmental pollution caused in their Appalachian regions by this form of mining.* **FLYOVER COURTESY SOUTHWINGS.ORG/PHOTO COURTESY OF VIVIAN STOCKMAN/WWW.OHVEC.ORG.**

put it: "We fear the river above more than the river below" (Hufford 1995, p. 543).

Since 2000 the governors of Kentucky and West Virginia have declared states of emergency in mountaintop removal counties almost annually. On October 11, 2000, a Massey Coal Company impoundment broke in Martin County, Kentucky, sending 300 million gallons of slurry into the Tug Fork River, thirty times more pollution than was released by the *Exxon Valdez*. The EPA called it the worst environmental disaster in the history of the southeastern United States.

Impacts on Biodiversity and Ecology The social and ecological impacts of mountaintop removal mining become clear when one considers that the coves and ridges it destroys support the world's most biologically diverse temperate-zone hardwood forest system. Although this forest is threatened by acid rain from fossil fuel combustion, mountaintop removal adds a further dimension to the ecological assault. In traditional strip mining the location of undisturbed forest above the disturbed mine site allowed for the revegetation of sites downslope with native species. In mountaintop removal disturbed ground upstream of everything else must be reclaimed with exotic species that will grow in nutrient-poor conditions (Edmunds and Loucks 1998).

Postbiotic landform complexes have been replacing an ecosystem that evolved over 300 million years into the world's most biologically diverse temperate zone hardwood system. This system of cove, ridge, and valley associations includes 40 canopy species, with another 40 in the understory, in addition to 1,200 species of botanicals.

Never glaciated, the climate-ameliorating coves sheltered the seed stock that reforested the eastern United States after the Ice Age. The ecologist E. Lucy Braun named this system the mixed mesophytic. Ecologists call it the mother forest. Human interactions with this forest over many generations have resulted in a rich store of knowledge about how to engage its biodiversity. The effects of destroying this region and replacing it with desert species that can survive in the nutrient-poor soils left by strip mining are incalculable. Some ecologists say that it could take 500 years or more to grow hardwoods in such a place; in that span of time the animating bond between collective memory and ecology that formed thousands of years before the European conquest of North America will have been broken.

ETHICS, PHILOSOPHY, POLITICS AND THE LAW

The controversy over mountaintop removal points out a number of contradictions in the system that is supposed to protect private property rights while safeguarding public goods such as air and water quality, soils and biodiversity, and the cultural heritage of a community's surroundings.

Lawsuits and Legislative Battles It was not until the mid-1990s that mountaintop removal mining drew national attention and citizens began organizing against it. After it made the headlines in major journals and newspapers and was featured on television networks, coalitions of local, state, regional, and national citizen groups began campaigning around this issue. In 1998 a West Virginia lawyer named Joe Lovett represented a group that included residents of Pigeon Roost Hollow, the West Virginia Highlands Conservancy, and the Ohio Valley Environmental Coalition. In a landmark case, *Bragg v. Robertson,* the group sued state and federal agencies for breaching a provision of the Clean Water Act that prohibit mining activities within 100 feet of a stream. In allowing mining companies to create valley fills by dumping mine spoil in streams, the plaintiffs argued, the government had failed to protect the stream buffer zone. In 1999 a federal judge ruled in favor of the plaintiffs, noting that valley fills violate the Clean Water Act. Two other judges later issued concurring rulings. The industry has appealed those rulings, and its lobbyists have been working to persuade federal legislators to revise the definition of fill material so that the U.S. Army Corps of Engineers may continue authorizing the dumping of mine waste into headwaters. A protracted battle has continued on the legislative and judicial fronts over the rights of coal companies to violate the stream buffer zone.

Politics: Technology's Subversion of Democracy The effort to overturn the stream buffer zone provision of the Clean Water Act ignores the function that political philosophers ascribe to substantive goods in a democratic polity. Hannah Arendt ascribes twin functions to the physical commons, which serves both to unite stakeholders while forming a buffer that preserves distinct positions (1958). The stream buffer zone functions in both ways. The coal industry, supported by the international banking system, invested its profits in a technology that displaced human workers and communities, and then argued that the laws protecting the commons of clean air and water had to be changed to accommodate the technology of giant earth-moving machinery. Shifting from citizens to engineers the authority to make environmental decisions, the coal industry and its supporters in state and national governments privatize the public goods that give citizens a voice in government. Destroying the headwaters, the coal industry destroys the political grounding of local, regional, and national publics. For local communities, the streams and their names are landmarks for navigating contemporary and historical space. The names for streams also form a set of mnemonic cues to the histories of mountain community life going back many generations. The streams are therefore vital resources for cultural identity and reproduction. Regions may be defined as the ecological limits of large watersheds, in which citizens share a biological stake in the quality of waters upstream. Protected by federal law, the headwaters also provide an anchorage in public life for every citizen in the United States, for whom the capacity to protect the health of headwaters is an indicator of viable democracy. The changing of laws to accommodate technology shifts decision-making authority to corporate engineers, diminishing the substantive commons, and dangerously weakening local, regional, and national democratic capacity.

Epistemological Errors Mountaintop removal mining epitomizes a fundamental error of Western epistemology—the Cartesian mind/body split. This is manifested as the separability of humans from their environments, and the location of human communities outside of ecological systems. Phenomenologists such as Martin Heidegger and Maurice Merleau Ponty, and pragmatists such as John Dewey have identified conceptual trailheads to the way out of this problem. Heidegger, in his *The Question Concerning Technology*, warns against an orientation to technology as a means of development that "challenges forth" a desired outcome rather than "bringing forth" what is already underway in existing relationships. In this regard, he mentions strip-mining and hydro-electric dams, which extract energy as something that can be stockpiled and which threaten to freeze the world (including human beings) into a set of "standing reserves" (Heidegger 1977). Sundering what Dewey calls "the bond that binds the living creature to his environment," (Dewey 1934,

p. 252), the fixed identity of the standing reserve prevents the "bringing forth" of that which is implicit in existing relationships between human and non-human nature. Such relationships would form the object of development in democracy as Dewey envisions it: "the creation of a freer and more human experience in which all share, to which all contribute." (1993, pp. 244–245).

Linking Social and Environmental Justice The federal policies that benefit the coal industry and maintain the status of coal as a source of more than half the electricity produced in the United States have turned the central Appalachian Mountains into a standing reserve of coal. This fixed identity blocks the development of potential alternatives. One term commonly used for the region, *the national sacrifice zone,* highlights the disadvantage at which residents are placed because they experience a disproportionate percentage of the negative externalities generated to meet national energy demands. The groups placed at such a disadvantage are often ethnic minorities who share the conditions of poverty and unemployment that are used to rationalize the concentration of undesirable forms of production and employment such as mineral extraction, petrochemical production, and low-paying factory and service industry jobs.

Some activist groups have used the concept of environmental justice to combat mountaintop removal. That concept highlights the interconnectedness of social and environmental issues in a region that has been neglected by mainstream environmental groups as well as government agencies. In 2003, for example, the Sierra Club mounted an environmental justice campaign against mountaintop removal, and a coalition of groups based in West Virginia, Tennessee, Kentucky, and southeastern Virginia has sponsored Mountain Justice Summer, an annual training camp for citizens interested in working on alternatives to mountaintop removal. Building relationships around the commons of headwaters and biodiversity among citizens from disjunct regions and sectors around the country, such efforts promise to engender and sustain the "genuine care for common experience" called for by Herbert Reid and Betsy Taylor (citing McDermott 1987, p. 91; see also Reid and Taylor, 2003) foundational to democratic capacity and mountaintop retention.

MOUNTAINS

Mountains are dominant features of our physical environment. Covering more than one-fourth of the earth's land surface, mountains occur on all continents and at all latitudes. They are found in 75 percent of the world's nations and provide a home for 10 percent of its human population. Mountains provide abundant natural resources and ecosystem services that support and sustain both mountain dwellers and lowland residents.

Mountains also are rich in cultural significance. Around the globe and throughout history, humans have responded to the evocative presence of mountains in diverse—and sometimes contradictory—ways. These responses have been shaped by the cultural conditions out of which they emerge and find expression in a dizzying array of beliefs and practices, myths and stories, philosophical ideas, and works of art. These socially constructed meanings frame the ways in which human beings perceive, understand, and relate to mountains and mountain environments.

PHYSICAL CHARACTERISTICS

The chief characteristics of mountains are verticality and slope, which together produce wide climatic variability and biological diversity over relatively short distances. For this reason, mountains often serve as ecological islands and refugia (areas where isolated populations of formerly widespread species still exist) that provide critical habitats for many species of rare, often endemic, flora and fauna.

Along with great diversity, mountains are notable for their high geomorphic energy and fragility. The same tectonic processes that build mountains (faulting, folding, thrusting, subduction, earthquakes, and volcanoes) also contribute to their fragility and instability. The presence of steep slopes covered with young, erosive soils further adds to the fragility of mountain environments and increases the potential for severe, long-lasting ecological disturbance.

The diversity and fragility of mountain environments is mirrored in the rich—and threatened—cultural diversity found among mountain communities throughout the world. Relative isolation and inaccessibility, as well as diverse ecosystems, have contributed to a great variety among mountain cultures; at the same time,'remoteness and isolation have marginalized these communities and contributed to extreme poverty in some mountain regions. Twentieth-century advances in communications and transportation technology have greatly increased accessibility to mountain regions, bringing both opportunities and challenges to traditional mountain cultures.

MOUNTAIN RESOURCES AND ECOSYSTEM SERVICES

Mountains provide a number of valuable natural resources and ecosystem services for both mountain communities and lowland populations. Many of the plants used as foods and medicines around the world come from mountain regions. The Andes, for example, are the source of more than 200 indigenous varieties of potatoes, and the Himalayas account for approximately 2,000 varieties of rice. The world's population uses medicines developed from plants that grow in mountain environments.

Mountain regions contain 28 percent of the world's forested areas. Besides providing a number of important resources, including timber, fiber, fuels, foods, and fodder for livestock, these forests contribute countless ecosystem services. They provide stability for steep mountain slopes, intercept precipitation, reduce soil erosion, protect water quality, moderate surface temperatures, and provide habitats for numerous forest-dwelling organisms. For many years their relative inaccessibility protected mountain forests and their subsistence-based communities. In recent years, however, growing demand for forest products and increased access to mountain regions have greatly accelerated the rate of deforestation in these areas.

Mountains shape hydrological processes in numerous ways. They influence precipitation patterns, store fresh water in snowfields and glaciers, and regulate the direction and flow of streams and rivers. Most of the major river systems of the world have their headwaters in mountain regions, and mountains provide 80 percent of the earth's surface water. More than one-half of the world's population depends directly upon mountains for the water they use to drink, grow crops, generate electricity, and support industrial processes.

MOUNTAINS AND MINING

Mountains also contain rich deposits of mineral resources, and the history of mining is intimately tied to the history of humanity's relations to mountains, because the tectonic forces responsible for creating most of the world's mountain ranges also provide the intense heat and pressure needed to produce ore deposits of economically valuable metals such as gold, silver, and copper. The discovery and extraction of mountain minerals, as well as key developments in metallurgical processes, have had a dramatic influence on the rise—and fall—of many great civilizations around the world. Gold from the

highlands of Nubia and the Sinai Peninsula supplied the great wealth of ancient Egypt. The mountains of southern Spain provided a rich source of tin, lead, silver, copper, iron, and gold for Phoenicians, Carthaginians and other early Mediterranean civilizations. Silver, lead, and gold from the Laurium mines in the mountains of Greece supported the rise of ancient Athens, while the rich gold and silver mines of Mount Pangaeus helped finance the rise of Macedonia under King Philip and Alexander the Great. For more than 400 years, the hills and mountains of Spain, Greece, Britain, Anatolia, Austria, and Transylvania supplied the gold, silver, lead, iron, and tin (a key ingredient in the production of bronze) that contributed to the great material wealth and military might of the Roman Empire.

During the Middle Ages, mountainous regions in Saxony and Bohemia became centers of metal mining in Europe. Between the tenth and twelfth centuries, major copper, silver, and lead mines were established in the Harz Mountains of Lower Saxony and the Erzgebirge (''Ore Mountains'') region near the headwaters of the Elbe River. In the centuries that followed, a variety of social, political, and economic factors contributed to the continued expansion of mining activities in Europe, as well as to significant advances in mining techniques and metallurgical processes. These developments culminated in a mining boom in Europe that began in approximately 1450; within the next hundred years, the production of silver in Germany increased fivefold, with much of this production coming from the Harz Mountains.

Rumors of golden cities of El Dorado and ''mountains that gushed silver'' fueled the imagination of fortune-seeking Europeans arriving in the Americas in the sixteenth century. Less than five years after Hernán Cortés conquered the Aztecs in 1521, Spanish mines were producing silver in several locations across Mexico. Within the next fifty years, major silver strikes in Guanajuato and Zacatecas resulted in the establishment of silver mines throughout the Sierra Madre that yielded tremendous wealth for the new colonial power.

With Francisco Pizarro's defeat of the Inca Atahuallpa in 1533, this pattern repeated itself in the Andes Mountains of Peru, Ecuador, and Bolivia. In 1545 Spanish colonists learned of the rich silver deposits lying beneath Cerro de Potosi in Bolivia, and within a year the Potosi mine was extracting silver from the 15,827-foot mountain. Soon, Cerro de Potosi became known as Cerro Rico (''rich mountain''), and the Spanish idiomatic expression, *valer un potosi* (''worth a potosi''—a fortune) appeared in Miguel de Cervantes' *Don Quixote.* Between 1556 and 1783, the mines of Potosi produced more than 45,000 tons of pure silver. It also is estimated that more than 8 million Indian miners died while working in the Potosi mines.

The discovery of precious metals and other minerals helped drive the westward expansion of the United States and the settlement of the country's western mountains. In 1848 gold was discovered at John Sutter's sawmill, and the California gold rush began in the foothills of the Sierra Nevada. This was followed by major gold strikes during the 1850s and 1860s in places such as Carson City, Nevada; Leadville, Silverton, and Telluride, Colorado; and Helena, Virginia City, and Butte, Montana. Although gold mining in Butte proved to be short-lived, the presence of vast silver and copper reserves earned the city its reputation as ''the richest hill on earth.'' In 1876 European American settlers discovered gold in the Black Hills of South Dakota, which resulted in the establishment of the Homestake Mine in 1877 and the removal of the Sioux Indians from their traditional homelands.

Since the 1990s mountaintop-removal mining has become an increasingly common method of extracting coal from the Appalachian Mountains of the eastern United States. In this process, forests, top soil, and overburden rock are removed from the mountaintops to expose seams of bituminous coal. The coal is then extracted and processed, while the overburden and waste rock are left in nearby valleys and hollows as valley fill. Waste water from processing methods is known as slurry and is impounded in storage pools on site. At current rates, the United States Environmental Protection Agency estimates that approximately 1.4 million acres in the Appalachian Mountains (primarily in West Virginia and eastern Kentucky) will have been mined using mountaintop removal methods by 2010. Although this process is lucrative for mining companies, critics cite a host of environmental and social problems associated with mountaintop-removal mining, including deforestation, habitat loss, surface and groundwater contamination, air pollution, mudslides, and flooding.

People have always looked to mountains as storehouses of valuable natural resources and potential wealth. Humans have used mountain minerals to make tools and weapons; establish currencies; decorate their bodies, artwork and buildings; supply energy; and drive industrial processes. However, the extraction, processing, and use of this mineral bounty have been accompanied by significant environmental and social costs. The tension between the benefits and costs of mineral development in mountain regions has profoundly influenced how humans understand their relationship with mountain environments and their role as agents of environmental change profoundly influenced how people relate to mountain environments and how they understand humanity's role as an agent of environmental change.

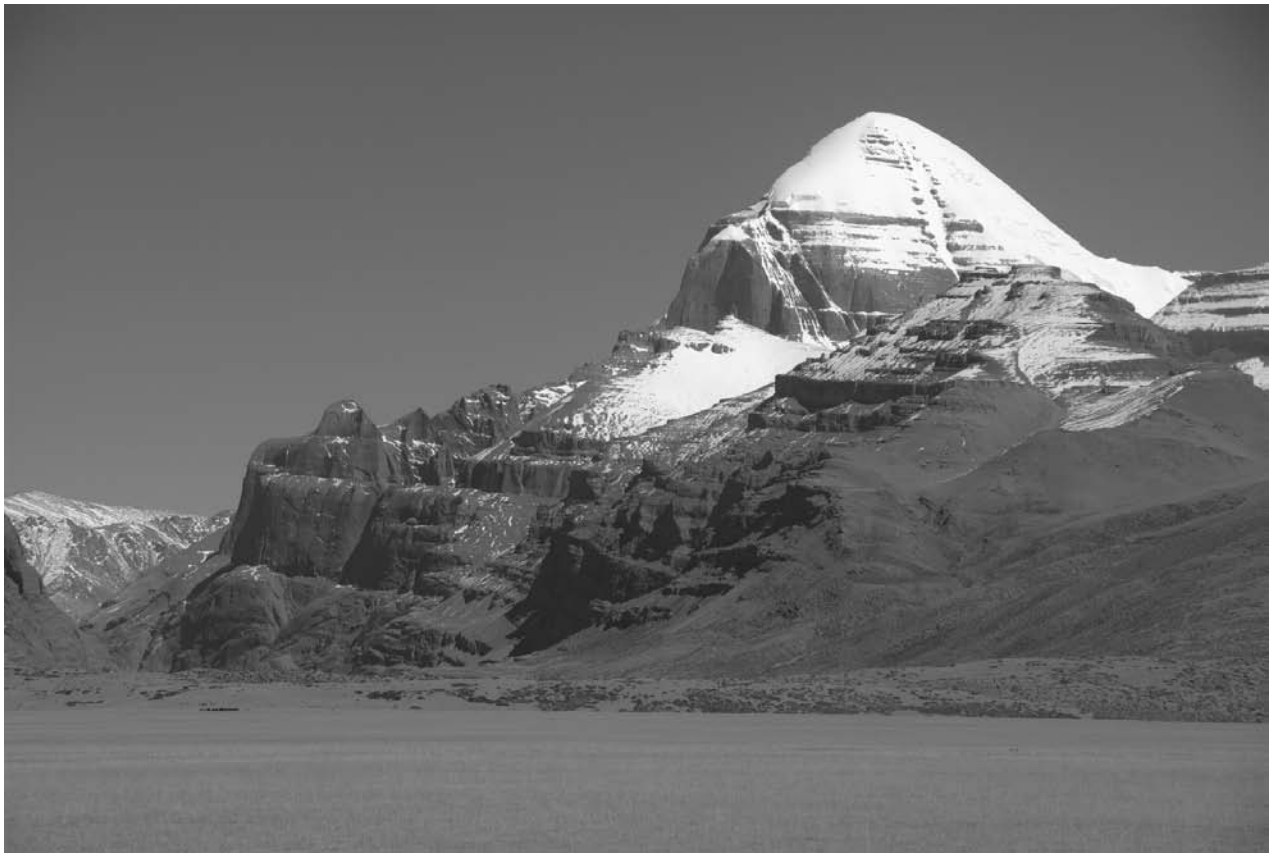
Mountaintop Removal. *The towering dragline, center, is dwarfed by the size of this mountaintop removal operation in Boone County, West Virginia, May 2003.* **FLYOVER COURTESY SOUTHWINGS.ORG/PHOTO COUTESY OF VIVIAN STOCKMAN/WWW.OHVEC.ORG.**

MOUNTAINS AND THE CULTURAL IMAGINATION

In addition to providing an abundant supply of the natural resources and ecosystem services needed to sustain human communities, mountains are extremely rich in cultural significance. Throughout history and across the globe, mountains have spoken to the human sense of the sacred, and the human response to this powerful address has manifested itself in countless forms of religious expression.

Sacred Mountains In many cultures throughout the world, mountain peaks are considered dwelling places of the gods. For the ancient Greeks, Mount Olympus was the home of Zeus and palace of the twelve major gods. For many Hindus, the god Shiva and his consort Parvati (daughter of the god Himalaya) reside on Mount Kailas in Tibet. Other imposing Himalayan peaks also are associated with the divine couple, including Shivling (India), Nanda Devi (India), and Annapurna One (Nepal). Among Tibetan Buddhists, Mount Kailas is the home of Demchog, the Buddha of Supreme Bliss. In Japan, Mount Fuji is the abode of the goddess Konohana Sakuya Hime; in Hawaii, the goddess Pele dwells atop the volcano Kilauea. All major Andean peaks are inhabited by mountain gods known as *apus,* with the supreme *apu* residing atop towering Mount Ausangate (Peru). Many of these sacred mountains serve as temples, shrines, altars, and pilgrimage sites, where devotees go to pray, do penance, and perform sacrifices. For the faithful these mountains serve as fountains of physical and spiritual blessings, bestowing—or withholding—a wide range of divine gifts, including rain, fertility, healing, wisdom, happiness, and success.

In other cultures the gods and their messengers may not live atop mountains, but the mountain heights serve as important meeting places where the divine and human realms intersect. In these cases mountains are sites of



Mount Kailas, Tibet. *Mount Kailas is a sacred site to both Buddhists and Hindus in western Tibet. In addition to their often symbolic importance, mountains provide many valuable natural resources and ecosystem services.*

divine revelation. For example, Moses went up Mount Sinai to receive the law and establish the covenant between Yahweh and the children of Israel. In a cave on Mount Hira, the Archangel Gabriel visited Muhammad and began the series of revelations that are recorded in the Koran. For the Plains Indians of North America, the tops of mountains and buttes serve as vision quest sites, where people seek out divine power, protection, and guidance through fasting and prayer.

Mountains also establish sacred geographies. Numerous mountains throughout the world act as the *axis mundi*, or world axis, that stands at the center of the universe, organizing space and uniting the various levels of existence. For Hindus and Buddhists the mythic mountains of Meru and Sumeru, respectively, are located at the center of the world, embodied in the physical form of Mount Kailas. For the Hopi Indians of the southwestern United States, the San Francisco Peaks are the location of the *sipapuni*, or center hole, from which the people emerged and through which they maintain contact with ancestors dwelling below. For the ancient Greeks a similar center hole or world navel (*omphalos*) was located on the slopes of Mount Parnassus, near the site of the famous temple of the oracle at Delphi. Other mountains stand not at the center but at the periphery of the world, holding up the heavens, ordering the landscape, and establishing boundaries. For the Navajo, Apache, and Pueblo Indians of the American Southwest, identifiable peaks mark the four cardinal directions that define and enclose their respective worlds.

The sacred power of mountains does not always manifest itself as divine; it also may take the form of the demonic. Mountains have often been experienced as terrifying and desolate places that inspire fear. For centuries the European Alps were considered a forbidding and dangerous place populated by witches, dragons, ogres, and demons. Mount Hekla, an active volcano in Iceland, was considered the entrance to hell. In many cultures throughout the world, mountains are places from which one's ancestors came and to which, upon death, they return.

Contemporary Mountain Meanings in Europe and North America As these examples and countless others suggest, mountains have held tremendous religious significance

MOUNTAIN TOURISM IN NEPAL

The environmental and social impacts of mountain tourism in the Himalayas are most evident in Nepal. Although closed to foreign visitors as recently as 1950, over the past several decades Nepal has promoted mass mountain tourism through private-sector initiatives with minimal regulation, monitoring, and control. As a result, nearly one million overseas tourists now visit Nepal each year. Most of these visitors participate in some form of mountain tourism, with approximately 25 percent engaging in mountaineering or trekking. The great majority of Nepal's mountain tourism activity is concentrated in the regions surrounding the Annapurna Conservation Area, Langtang National Park, and Sagarmatha National Park (Mount Everest), areas made famous through the writings of foreign mountaineers exploring Nepal in the 1950s and 1960s.

The tremendous influx of foreign tourists since the 1970s has had significant environmental impacts. Increased demand for fuelwood has resulted in dramatic losses in tree and shrub cover. This problem is especially acute in higher-elevation alpine zones, where the harvesting of slow-growing juniper shrubs for fuelwood has resulted in increased soil erosion and denuded landscapes. Other environmental problems associated with high-volume mountain tourism include degraded trails, contaminated water supplies, and large amounts of garbage. The severity of the latter problem has led some to dub Mount Everest the "highest dump on earth."

Mass tourism also has had tremendous social and economic effects on Nepal. On the positive side it generates revenues for tourism-related enterprises and creates employment opportunities. For the Sherpas of the Everest region and for the Gurung, Thakali, and Magar living near Annapurna, tourism revenues have invigorated local economies, raised the standard of living, and supported numerous infrastructure improvements and community-development projects. On the negative side, the influx of tourist money has inflated the costs of basic consumer goods and services and increased economic inequalities and social stratification in some local communities. Much of the revenue generated by tourism does not remain in local mountain communities; instead, it flows back to tourist-generating countries and Nepalese urban centers like Kathmandu. Most tourism jobs pay low wages and are subject to seasonal fluctuations. Negative social consequences associated with mass tourism include the deterioration of traditional values, loss of cultural practices and lifeways, and alienation caused by overwhelming numbers of foreign visitors. During peak seasons the number of nonresidents in the Everest region may be four times greater than the number of native Sherpa residents.

For the people of Nepal, mountain tourism has been, at best, a mixed blessing. Overcoming the host of environmental and social problems associated with mass tourism will require the development of sustainable and equitable policies and effective regulatory practices that conserve fragile mountain environments and benefit local communities.

throughout human history. In contemporary European and North American society, many traditional religious meanings of mountains have taken on secular form. No less powerful than their religious counterparts, these secularized mountain meanings contribute to a rich constellation of ideas and images that continue to inform contemporary understandings of, and relationships to, mountains. For example, the hulking and immovable presence of mountains continues to suggest stability and permanence in a rapidly changing world. Their lofty, snow-covered peaks bespeak purity, wildness, beauty, and transcendence, and they are looked upon by many with awe, wonder, and reverence. They may symbolize one's greatest struggles, trials, and challenges, as well as one's highest goals, vision, and aspirations. They are sought out as sources of inspiration, transformation, and recreation, where many go to test and renew themselves—physically, spiritually, and emotionally.

In Europe and North America, these various mountain meanings have become so well-established that it is tempting to take them as universal. The idea that mountains might evoke images of the demonic rather than divine, that they might represent negative qualities of hubris and unbridled ambition, or that they might be viewed as hideous and ugly deformities seems implausible to many contemporary Europeans and North Americans. Nevertheless, these negative mountain meanings were precisely those that prevailed among many Europeans as recently as the seventeenth century. In *Mountain Gloom and Mountain Glory: The Development of the Aesthetics of the Infinite* (1997 [1959]), Marjorie Hope Nicolson

ALPS

The Alps are a domain of great biological diversity, because of widely varying climate, exposure to sunlight, geology, morphology, hydrology; and also of cultural diversity, with widely varying language, religion, ethnic groups, history and politics. Yet, in any part of the Alps, patterns of life, economy, social and spatial organization are also similar in many respects.

As the main mountain range in Europe, the Alps were for centuries an obstacle to human communication and travel. They were viewed as a hostile terrain due to the imagined presence of negative supernatural forces, and the (often actual) presence of threatening natural or human forces. By the eighteenth century, however, the Alps had begun to attract artists and scientists, and became an example of an inhospitable environment victoriously challenged by humans. Its "sublime" character fascinated visitors, and this "delightful horror" contributed to the growing popularity of Alpinism and tourism. Humans, insignificant and weak, face alpine Nature, infinite and powerful, but they win the confrontation with it by means of mind and spirit (e.g., see Percy B. Shelley's ode *Mont Blanc* and George Gordon Byron's poetic drama *Manfred*, both written in 1816) (Marjorie Hope Nicolson 1959 [1997]).

Following industrialization, and the agricultural, industrial, and commercial development of cities and lowlands, there was a crisis in the Alpine economy and problems of migration and depopulation.

Nonetheless, transit across the Alps increased: Roads crossed the Alps in the early nineteenth century, then railways and tunnels, and finally highways. The traffic was concentrated along some valleys, promoting their economies, but also causing noise and air pollution. Since the late nineteenth century, alpine watercourses have been exploited for hydroelectric plants.

So the Alps were subject to opposing processes: on the one hand, intensive exploitation of transit corridors and tourist areas (with a seasonal overcoming of capacity limits), and on the other hand the depopulation of large areas which reverted to a wild state, where wild animals—predators included—reappeared, and ecological cycles broken for some time were reestablished. This "re-wilding" process is appreciated by ecologists because it favors biodiversity, but farmers, worried about cattle and crops, fight it: Therefore the authorities often allow the killing of wild animals, even members of protected species (wolves, bears).

Some alpine regions maintained a vital culture and economy and a well-balanced relationship with the natural environment without depopulation. This happened where, for instance, local population reached a critical mass, and alpine economy enjoyed comparative advantages in agriculture and manufacture of typically alpine products (e.g., cheese, wine, sausages, delicatessen, in Gruyère, Emmenthal, Val d'Aoste, Valtellina, Trentine, Tirol, and so on), in comparison with the standardized ones of the lowlands; or where demographic and social resistance flows from ideological and political factors (e.g., where ethnic minorities are located).

Around the turn of the twenty-first century, however, climate changes (temperature rise, snow precipitation decrease) hindered winter tourism, which faced growing difficulties. Winter sports development favors bigger and higher tourist resorts, which leads to investing in ski-plants at higher altitude and snowmaking, and penalizes the smaller, lower resorts. This causes a further concentration of development in fewer sites, but in these places there is overbuilding and pollution.

The bigger problems in the Alps thus derive from a paradox: To survive, economically and demographically, either societies open up to the outside, losing their cultural identities and destroying their environments, their two greatest assets; or they close in on themselves, separating from the mainstream of modernity, without suffering its hazards but also without enjoying its opportunities.

The possible solution is the protection of fundamental cultural and natural values through the rule of modernity's local processes. This is only possible if communities do not retire into themselves for an impossible self-defense, but produce a real identification with the land and control the present modifications and opportunities, which are ambivalent because they can have, according to local circumstances, positive or negative issues to communities themselves.

Guglielmo Scaramellini

notes that when seventeenth-century English poets wrote about mountains, they usually portrayed them as ugly and repellent deformities, dangerous to both body and soul. Poets such as John Donne, Andrew Marvell, and their peers drew their images of mountains less from personal experience than from a received literary tradition influenced by several factors: a biblical morality in which mountains symbolized sinful pride; Roman poetry that portrayed mountains as aloof, inhospitable, and hostile; classical notions of beauty emphasizing symmetry, regularity, and proportion; and allegorical and abstract treatments of mountains found in the works of authors such as Augustine and Dante Alighieri. All of these sources contributed to the negative view of mountains that pervades much of seventeenth-century English poetry.

At the close of the century, however, important developments in theology, philosophy, astronomy, and geology were beginning to alter how Europeans conceived of their place in the cosmos and their relationship to the natural world. Although Thomas Burnet's *Sacred Theory of the Earth* (1965 [1684]) still described a world in decline, where the perfectly smooth and rounded orb of God's original creation was now defiled by mountains and other irregularities in the aftermath of the Great Flood, other theologians and philosophers offered a more positive, progressive view of the world, in which nature reflected the orderly design and benevolent purposes of its creator. At the same time, a growing awareness of the vastness of space and time contributed to an emerging aesthetics of the infinite.

Almost immediately, these ideas infused the poets' traditional mountain gloom with an element of ecstatic enthusiasm, typified by the "delightful Horrour and terrible Joy" that John Dennis experienced while traveling through the Alps in 1688. This conflicted emotional response provided the foundation for a new mountain aesthetic of the sublime, with English poets glorifying the awe-inspiring heights of mountains and extolling their irregularities and wildness as glorious expressions of God's plenitude. This new attitude toward mountains reached its highest expression in the works of great Romantic poets such as William Wordsworth, Lord George Gordon Byron, and Percy Bysshe Shelley, all of whom sought out mountains as sources of inspiration and sung praises to their sublime beauty, glory, and divinity.

Nineteenth-century Romanticism exerted a tremendous influence on American transcendentalists such as Ralph Waldo Emerson and Henry David Thoreau, as well as John Muir and other pioneering figures in the American environmental movement. Understood as sources of inspiration, objects of veneration, and places of spiritual renewal, mountains have been a major focus of conservation efforts in the United States. Muir, for example, founded the Sierra Club primarily to protect his beloved Sierra Nevada in California. National parks such as Yosemite, Yellowstone, Grand Teton, Glacier, Denali, and Great Smoky Mountains were established to protect the country's most treasured mountain environments, and the preponderance of mountain regions included in the country's national parks system and wilderness preservation system testifies to the great cultural value Americans attribute to mountains.

Changing attitudes toward mountains among Europeans of the late eighteenth and early nineteenth centuries also are reflected in the rise of mountaineering. No longer forbidding, repulsive, or hostile, the Alps quickly became a tourist destination as Europeans began climbing mountains for sport and adventure. Beginning with Mont Blanc in 1786, climbers reached the summits of all major Alpine peaks in the next hundred years. In 1857 the Alpine Club, the first of many alpine organizations, was established in London, with mountaineering journals and guidebooks appearing shortly thereafter. By the end of the nineteenth century, European mountaineers were looking for new challenges beyond the Alps and exploring the distant peaks of the Caucasus, Karakoram, and Himalayas.

As Europeans came to regard mountains and mountain regions in an increasingly positive light, these changing perceptions found expression in the literature and art of the nineteenth and twentieth centuries. In many cases these new mountain meanings were blended with traditional religious imagery. In Friedrich Nietzsche's *Thus Spoke Zarathustra* (1969 [1883–1885]), for example, mountains retain their traditional role as sites of purification, training, and revelation. The book's prologue begins with Zarathustra, upon attaining wisdom, descending the mountain, like Moses from Sinai, to proclaim his message to humankind below. Hans Castorp, the protagonist of Thomas Mann's novel *The Magic Mountain* (1924), undergoes an extended period of spiritual gestation in a mountain sanatorium that culminates in a revelatory vision of spiritual awakening and rebirth.

In the paintings of the Renaissance, baroque, and neoclassical periods, if mountains appeared at all, they usually provided a highly stylized backdrop for human action. By the nineteenth century, however, mountains began to take center stage in the works of Romantic landscape painters like Albert Bierstadt (1830–1902) and fellow members of the Hudson River School. Bierstadt's mountain scenes are filled with jagged and precipitous peaks, often surrounded with ethereal clouds and illuminated by rays of heavenly light. In paintings such as *Among the Sierra Nevada Mountains*, Bierstadt presents mountains as places of divine splendor and sublime beauty, drawing upon traditional religious imagery and Romantic sensibilities.

Albert Bierstadt,* Among the Sierra Nevada Mountains, California, *1868. *Bierstadt's oil on canvas painting is an example of the numerous depictions of mountains throughout the centuries in the arts. The representation of mountains has assumed various meanings throughout the centuries. They may connote stability and permanence, beauty and transcendence, or even the struggles and trials of contemporary life.* SMITHSONIAN AMERICAN ART MUSEUM, WASHINGTON DC, ART RESOURCE, NY.

Mountains and Conflicts of Meaning Many environmental conflicts of the twentieth and twenty-first centuries have involved mountains and their sometimes conflicting cultural meanings. The heated public debate over the damming of the Hetch Hetchy Valley in Yosemite National Park that occurred from 1900 to 1913 offers a prime example. Opponents of dam construction, led by John Muir, compared the flooding of the mountain valley to the destruction of a sacred temple. Using arguments loaded with religious and Romantic imagery, Muir celebrated the sublime beauty of the mountain landscape. Dam proponents like Gifford Pinchot, meanwhile, saw the Hetch Hetchy Valley and Tuolumne River as a valuable source of freshwater for lowland residents of San Francisco and surrounding communities. Arguing from utilitarian and democratic principles, Pinchot believed the "greatest good of the greatest number" could best be served by flooding the mountain valley to create a reservoir that would provide a reliable supply of freshwater for the growing metropolitan area.

In the 1970s the Hopi Indians of the southwestern United States argued, unsuccessfully, that the expansion of a ski area in the San Francisco Peaks would desecrate their holy mountains and interfere with their religious practices. In this case traditional religious meanings of mountains conflicted with European-American interests in mountain recreation. Similar arguments have been put forward by Native Hawaiians seeking to block geothermal development on the slopes of Kilauea and by Blackfeet Indians opposed to oil and gas drilling in the Badger-Two Medicine area of Montana's Rocky Mountains. Across the globe, such intercultural conflicts are likely to increase as mountain regions become more accessible and the global demand for, and consumption of, mountain goods and services increases. In Nepal and other Himalayan countries the relative ease with which international tourists can now access this once-remote area has resulted in the explosion of a mountain-tourism industry that is rapidly transforming the region's natural and cultural landscape (see sidebar on mountain tourism in Nepal).

MOUNTAIN CONSERVATION AND SUSTAINABLE DEVELOPMENT

In many parts of the world, rapid and unsustainable development is threatening the rich biological and cultural diversity of fragile mountain environments and diminishing the quality and value of the important ecosystem goods and services they provide. In response to

these threats, members of the global environmental community have recognized the need to develop policies and practices that promote conservation and sustainable, equitable development in mountain regions. At the Rio Earth Summit in 1992, delegates adopted a global action plan for sustainable development (*Agenda 21*) that includes an entire chapter devoted exclusively to mountains, titled "Managing Fragile Ecosystems: Sustainable Mountain Development."

Since 1992 mountain advocates have been working to implement the strategies outlined in *Agenda 21* (United Nations). The United Nations highlighted the importance of mountain issues by declaring 2002 the International Year of the Mountains, an event that culminated at the Bishkek Global Mountain Summit held in Kyrgyzstan. Recognizing the tremendous diversity of mountain regions and mountain communities throughout the world, the Bishkek Mountain Platform advocates regionally specific conservation and development processes that address the concerns of mountain regions and the lowland communities that depend on them. Through such efforts, mountain advocates are working to protect fragile mountain ecosystems and ensure that the world's mountains will continue to provide for the sustenance—and inspiration—of human communities far into the future.

MUIR, JOHN
1838–1914

John Muir was born in Dunbar, Scotland, on April 21, 1838. At age eleven he moved with his family to Wisconsin. Muir is best known for helping shape the modern notion of national parks and helping found the American conservation movement. He was the first to attribute rights to all creatures from snakes to microbes, and his concept of balance and harmony in nature, together with a sense of interdependence among all aspects of the environment, gave his earliest writings an underlying notion of ecology before the term, which was coined in 1866 by Ernst Haeckel, came to America. Muir died in Los Angeles, California, on December 24, 1914.

Muir developed these notions by using a metaphorical and impassioned style of writing rather than making explicit philosophical statements. A strong sense of the human capacity for hubris led him from a position of religious awe to that of a canny conservationist. His democratic belief in the influence of the voting public in recognizing the intrinsic value of the exploited forests and mineral-bearing American landscapes led to his

John Muir, circa 1902. *Muir was a writer and conservationist best known for establishing the modern notion of national parks and as the founder of the Sierra Club. In his writings, Muir espoused a truly nonanthropocentric appreciation of nature in all its forms.* **THE LIBRARY OF CONGRESS.**

campaign for the establishment of forest reserves and national parks and the formation of the Sierra Club.

In the journal (1867–1869) later published as *A Thousand-Mile Walk to the Gulf* (1992a [1916]) Muir developed a style that not only challenged common assumptions about notions of good and evil in nature but adopted a holistic mode of understanding natural processes. Reacting against the narrow and oppressive Calvinism of his upbringing, Muir took Emersonian transcendentalism into new realms of ecological inclusiveness. For example, the snakes and alligators in the swamps of Florida not only were "unfallen" in religious terms but were "cared for [by God] with the same species of tenderness and love as is bestowed on angels in heaven or saints on earth" (1992 [1916], p. 148).

Combining a holistic sense of the divine with ecological insight, he articulated a nonanthropocentric environmental ethic: "The antipathies existing in the Lord's great animal family must be wisely planned, like balanced repulsion and attraction in the mineral kingdom. How narrow we selfish, conceited creatures are in our sympathies! How blind to the rights of the rest of all creation!" (1992b, p. 148). The fundamental balance in predator-prey dynamics has to be observed as dispassionately as are the analogous dynamics in minerals if the community of animals, plants, minerals, landscapes, and weather is to be appreciated in all its interrelationships: "When we try to pick out anything by itself, we find it hitched to everything else in the universe" (1992b, p. 248). The natural processes by which things are hitched to one another must be viewed dispassionately, including destructive processes.

For Muir, the traditional judgments of culture that separated death and destruction from creation and growth had prevented ecological insights into the processes of nature. For example, when people can see that "everything is flowing—going somewhere, animals and so-called lifeless rocks as well as water," they may see that in Alaska "out of all the cold darkness and glacial crushing and grinding comes this warm abounding beauty and life to teach us that what we in our faithless ignorance and fear call destruction is creation finer and finer" (1992b, p. 841).

Muir deployed different modes of writing for different purposes and different audiences. He was an empirical scientist, celebratory nature writer, campaigning conservationist, authoritative naturalist, and wilderness polemicist. The keys to his concept of a series of "nation's parks" were long-term protection for future generations and short-term renewal through direct contact with nature by urban populations that then would vote for the protection of those iconic landscapes and their ecologies. Muir thus embraced tourism as an inspirational and educational conservation strategy.

Early in his writing life he came to see that the urban and Eastern audiences for his writing could become a constituency for the preservation of forests, wilderness, and iconic landscapes. On successive trips to Alaska he developed a growing respect for indigenous lifestyles and skills, together with concern about the future of those communities. For Muir culture, in the form of his writings, was a mode of communication with nature that could be used to mediate a sustainable relationship with it. If this required a preaching tone in his writing, he could rise to the challenge: "The outcries we hear against forest reservations come mostly from thieves who are wealthy and steal timber by wholesale. . . . Any fool can destroy trees. . . . But [God] cannot save them from fools—only Uncle Sam can do that" (1992b, pp. 604–605).

Muir had the ability to conduct an environmental campaign and employ the power of pressure-group environmental politics. He worked for a bill to preserve Yosemite National Park, teaming with Robert Underwood Johnson: Johnson lobbied in Washington, and Muir wrote up the evidence and arguments in a series of articles for Johnson's *Century Magazine*. Muir also worked with Charles Sargent's Forestry Commission on a tour of American forests to establish thirteen forest reserves in the face of opposition from lumber and mineral interests. As the founding president of the Sierra Club, Muir set up a pressure group of influential Bay Area businesspersons to defend the new Yosemite National Park and, through outings and meetings, expand the club's sphere of influence. The strain of the club's campaign against the building of Hetch Hetchy Dam, and the campaign's eventual failure, hastened the end of Muir's life but became a crucial lesson in his legacy.

N

NAESS, ARNE
1912–

The philosopher Arne Naess was born in Oslo, Norway, on January 27, 1912, and received a doctorate in philosophy from the University of Oslo in 1938. He is best known for his invention of the term *deep ecology* to indicate that environmental issues are questions of ethics and philosophy rather than science and politics. Through a combination of his ideas and his persona, Naess was probably the most influential living environmental philosopher in the first decade of the twenty-first century.

EDUCATION AND EARLY WORKS

In the 1930s Naess traveled to Vienna as a young student to join the Vienna Circle, working closely with Moritz Schlick and Rudolf Carnap in the field of analytic philosophy. In 1937 Naess became the youngest full professor in Norwegian history, and over subsequent decades he wrote a series of textbooks on introductory logic and the history of philosophy that became the foundation for reform of his nation's university system, which required for many years that all students take a semester of philosophy before working in their chosen disciplines. His first book, *Truth as Conceived by Those Who Are Not Themselves Professional Philosophers* (1938), used a survey approach to demonstrate that ordinary people hold a range of views on truth similar to those voiced by philosophers.

During World War II Naess was active in the clandestine resistance against the Nazi occupiers, and after the war he led a reconciliation project to bring war criminals together with the parents of the Norwegian soldiers they tortured and killed. In the Cold War period, Naess was asked by the United Nations to lead a philosophical effort to study the worldwide uses of the term *democracy*. The resulting book, *Democracy in a World of Tensions* (1951), revealed that the word could mean almost anything; because of that disturbing conclusion, the book never was reprinted.

LATER WORKS AND INFLUENCE ON ENVIRONMENTAL ETHICS

In mainstream philosophy Naess is best known for his work in the philosophy of language in *Interpretation and Preciseness* (1953) and *Communication and Argument* (1966). Other major theoretical works in English include *Scepticism* (1968), *Gandhi and Group Conflict* (1974), and *The Pluralist and Possibilist Aspect of the Scientific Enterprise* (1969).

Naess is a mountaineer and for a few years in the early 1950s, with his ascent of Tirich Mir, held the record for the highest mountain ever climbed. A decade later, inspired by Rachel Carson, he resigned from his professorship to devote himself to environmental issues. *Ecology, Community, and Lifestyle* (1989 [in Norwegian 1976]) is his main theoretical work in environmental philosophy and the work in which the theory of Deep Ecology is articulated in depth. It is an environmental philosophy, not an ethic, that encourages each individual to think of nature as the ground of his or her own interest so that the greatest sense of self-realization will encompass a "Self" of the environment and become "Self-realization." People should situate their identities and interests in nature uniquely, developing their own "ecosophies" that build on a personal sense of place and a duty of care for the earth and fit into their immediate surroundings with greater attention and dignity.

Together with George Sessions, Naess politicized Deep Ecology by putting forth a platform of eight points that turned his concept into an ethical manifesto:

1. The flourishing of human and nonhuman life on the earth has intrinsic value. The value of nonhuman life-forms is independent of the usefulness they have for narrow human purposes.
2. The richness and diversity of life-forms are values in themselves.
3. Humans have no right to reduce that richness and diversity except to satisfy vital needs.
4. Present human interference with the nonhuman world is excessive, and the situation is worsening rapidly.
5. The flourishing of human life and cultures is compatible with a substantial decrease in the human population.
6. Significant change of life conditions for the better requires change in economic and technological policies.
7. Quality of life should be given more primacy than a high standard of living.
8. Those who subscribe to these points have an obligation to implement the necessary changes.

This platform was adopted by radical environmental groups such as Earth First! as their guiding philosophy, but Deep Ecology might have reached its greatest popular prominence when Senator Al Gore wrote in his 1992 book *Earth in the Balance* that "we must change the fundamental values at the heart of our civilization" to solve global environmental problems (p. 144). By the dawn of the twenty-first century many people embraced this view even if they did not realize where the idea came from.

In 2002, at age eighty-eight, Naess published *Life's Philosophy*, a personal account of his history through ideas. It became the number one best-seller in Norway and catapulted its author to a new level of fame. In 2005 the *Selected Works of Arne Naess* was published in ten volumes. It is perhaps the most comprehensive publication of the works of any living philosopher.

At age ninety-five Naess continued to speak out in the name of nature and conservation and remained optimistic that humanity will be able to improve its relationship to the world around it "by the twenty-second century" (Sessions 1995, p. 501).

NANOTECHNOLOGY

Nanotechnology is defined by the U.S. National Nanotechnology Initiative as the "understanding and control of matter at dimensions of roughly 1 to 100 nanometers, where unique phenomena enable novel applications." At this small scale (1 billionth of a meter), matter takes on novel properties, such as greater reactivity, electrical conductivity, and penetrability. Nanotechnology was used as long ago as 10 C.E. in the first century to develop paints of different colors that varied only by the size of the particles. Yet it was not until 1959 that the idea of nanotechnology was introduced by Richard Feynman, a physicist at the California Institute of Technology, in a talk titled "There's Plenty of Room at the Bottom." Although Feynman did not use the word *nanotechnology*, he suggested the possibility of precisely manipulating atoms and molecules. In size, nanoparticles range from the size of several atoms to the size of biological molecules, such as proteins. Although nanoparticles exist in nature, only recently developed tools such as atomic-force microscopy and better scientific understanding of materials have allowed humans to manipulate matter at the nanoscale to achieve certain goals. As an example, in 1989 IBM performed a famous experiment using atomic-force microscopy to move individual xenon atoms to form the letters "IBM."

Nanotechnology is a broad term that encompasses a diverse set of applications, tools, and methods linked together primarily by scale. The technology can be applied to medicine, food, agriculture, manufacturing, health, consumer products, and environmental science and remediation. In medicine, gold and dendrimers (complex organic molecules) are used to specifically target and destroy cancer cells without the horrible side effects of chemotherapy. In renewable energy, barriers to greater use of solar energy include the high cost of materials for the panels. Some nanoparticles convert light to energy with greater efficiency,

and so less material is needed. Hence, nanomaterials can be used in solar panels to lower their cost. In the environment, iron oxide nanoparticles are used to remove arsenic, a potent toxin, from drinking water, and DNA-based nanoparticles are being developed for tracking pollution in natural environments. Finally, in agriculture, nanosensors are being considered for detecting agricultural growing conditions and responding only when needed for the timed release of fertilizer, water, or pesticides.

Environmental issues and ethics intersect with nanotechnology in several ways. Ensuring the environmental safety of nanomaterials, making decisions about funding priorities or their environmental release, and developing systems for broader oversight all involve value judgments. Ethical issues associated with nanotechnology generally fall into categories that also apply to other technologies, such as utilitarian accounting of risks, costs, and benefits and the examination of fundamental moral principles such as autonomy, justice, nonmalfeasance, or beneficence (Beauchamp and Walters 1999). Environmental ethics includes questions related to how nanotechnology affects the preservation of natural, nonhuman living systems; what obligation nanomaterial producers have to protect the environment; and how much certainty about environmental safety is needed prior to environmental release.

FUNDING

Several nations have significant research programs in nanotechnology, including Japan, the United States, and nations of the European Union. The United States was one of the first nations to fund nanotechnology research and development in a coordinated fashion at the federal level. The U.S. National Nanotechnology Initiative (NNI) formally began in 2000 with a research program funded at $400 billion. Key figures in the formation of the initiative were Mihail Roco of the National Science Foundation (NSF) and Neal Lane, President Bill Clinton's science adviser. The budget for the initiative grew to $1.4 billion in 2008. Over half of this funding goes to the U.S. Department of Defense, and a significant proportion goes to the NSF, the Department of Energy, and the National Institutes of Health. Smaller amounts are allocated to the Department of Commerce, Department of Agriculture, U.S. Environmental Protection Agency (EPA), Department of Transportation, and other agencies. Nearly every public agency has some responsibility for nanotechnology on account of the diverse methods, products, and applications of the technology.

In 2006, the NNI channeled about 8 percent of its funds into the societal dimensions of nanotechnology, which includes educational programs, research, and programs focused on ethical, legal, and social implications (ELSI); and environmental health and safety (EHS) research (National Research Council 2006). This designation of funding is an important statement on the part of the U.S. government: an acknowledgment that emerging technologies are embedded within social and cultural systems and that it is important to study societal dimensions alongside technological development. Yet some scholars argue that ELSI programs and research have not received as much support as they should. In the first four years of the NNI, Ira Bennet and Daniel Sarewitz (2006) estimate that less than 0.5 percent has specifically gone to ELSI work. Regardless, several interdisciplinary research teams across the United States are studying a range of ELSI issues from proper oversight of nanomaterials to public attitudes about nanotechnology and ethical issues arising from future nanotechnology applications. In 2005, the NSF funded the Center for Nanotechnology and Society at Arizona State University and the University of California, Santa Barbara.

Arguably, there has also been little funding for the study of environmental health and safety issues associated with nanotechnology. Funding for risk-related research is about 1 percent of total funding for the NI (Maynard 2006), and only a portion of this goes specifically to studies of environmental risk. In 2008 legislative hearings in the United States focused on the need to increase that percentage. The lack of significant levels of funding for EHS issues has created a situation in which over five hundred nanotechnology products are on the market while little is known about their environmental transport, fate, and toxicity. Applications are growing and will continue to progress from chemical nanomaterials in consumer products (passive nanostructures) to active biologically based nanostructures and nanosystems that can respond, change, and move through human and natural systems (Roco and Bainbridge 2005).

Toxicology studies suggest that nanoparticles are more toxic at lower concentrations than their larger counterparts, owing to their higher surface-area-to-mass ratio and greater reactivity. Little is known, however, on the amounts and nature of nanomaterials released into the environment (e.g., from manufacturing plants), and there are few comprehensive, field-based studies on nanoparticles and their risks to the environment, although frameworks for risk analysis have been developed (Morgan 2005). Buckyballs (made out of 60 carbon atoms and shaped like a soccer ball) and carbon nanotubes (thin-walled tubes made of carbon atoms) are two types of nanoparticles that have been shown to be harmful to fish and microorganisms. In 2008 government organizations in Japan, the European Union, and the United States proposed increasing resources for environmental health and safety studies of nanotechnology applications.

OVERSIGHT

A subset of ethical questions focuses on oversight of nanotechnology products. Typically, formal government regulation is limited to utilitarian considerations such as the risks, costs, and benefits of commercial approval. Yet oversight also encompasses ethical principles of fairness and justice, for example, through the distribution of risks and benefits among human communities and ecosystems. Another oversight question involves who or what entities should bear primary responsibility for overseeing nanotechnology products. Still another oversight issue is whether consumers and patients should have rights to know and choose products generated from nanotechnology (the ethical principle of autonomy). Finally, should oversight consider harm to natural systems and human responsibilities to protect the environment for its intrinsic value or for its use by future generations?

U.S. oversight of nanotechnology currently relies on agencies and regulations that have provided oversight for related technologies or products. There is no specific statute or mechanism for oversight of nanotechnology products. Yet existing laws and systems may not adequately address the novel properties and unique challenges of nanoproducts (Kuzma 2006; Davies 2007). National and international stakeholders and government organizations are currently considering how best to oversee the applications and products of nanotechnology.

Most chemical and consumer nanotechnology products do not require premarket testing and safety data. The EPA (2007) administers a voluntary stewardship program in which data generated by industry are collected by the agency, but there are no formal requirements for regulatory approval. The stated policy of the U.S. Food and Drug Administration (FDA; 2007) is to treat nanoscale drugs, devices, food products, and biologics as substantially equivalent to their larger counterparts. The nonprofit group Environmental Defense Fund partnered with DuPont to develop a risk-analysis framework for nanomaterials, and they are encouraging companies to use it. On the international level, the Organization for Economic Cooperation and Development is helping to form partnerships among nations to generate and share data about the safety of nanomaterials. The International Standards Organization and other standard-setting bodies are designing safety standards for nanotechnology products.

CONTROVERSY

Some stakeholders, citizen groups, and organizations, citing negative past experiences with other emerging technologies, such as biotechnology, are skeptical of the promise of nanotechnology. Although there has not been massive public outrage about nanotechnology, several interest groups have objected to the voluntary approaches to overseeing nanotechnology in place in 2008. The Erosion, Technology, and Concentration Group called for a moratorium on nanotechnology products in the marketplace until more information is obtained. The British Royal Society recommended a precautionary approach to the environmental release of freestanding nanoparticles until more is known about their transport and effects. The International Center for Technology Assessment (2007), in partnership with several other nonprofit organizations, has developed principles for regulation that include public transparency and mandatory premarket testing by independent experts. The center has also filed a legal petition against the FDA for its lack of premarket safety testing of cosmetics and sunscreens with nanoparticles.

One prominent example of debate about nanotechnology in the environment involves silver-coated nanomaterials. There are on the market in nanosilver washing machines, refrigerators, socks, and food-packaging materials. Silver ions kill microorganisms, and products coated with nanosilver stay fresh longer. Initially, these products were entering the marketplace with no premarket testing. However, several environmental and other interest groups brought attention to the potential release of silver ions into the environment (e.g., from the wash cycle of nanosilver-coated washing machines) and petitioned the EPA to regulate them. After about a year of consideration, the EPA decided in 2007 to regulate nanosilver under the U.S. pesticide law, the Federal Insecticide, Rodenticide, and Fungicide Act. This relatively strong statute requires premarket tests to be submitted to the EPA and products to be registered. However, the manufacturer must claim that its product is designed to kill pests or germs. As a result, some companies that produce nanosilver materials are removing this pest-killing claim from their products to avoid regulation.

As of 2008, producers of most nanomaterials are primarily responsible for ensuring the safety of their products through voluntary programs. This approach seems fair in that the financial burden of safety testing is placed on the entity that stands to profit. However, a body of literature suggests that citizens are less confident when oversight is placed in the hands of those who have vested interests. Public confidence is greater when independent bodies are responsible for oversight and regulation is mandated by government (Macoubrie 2006).

People also prefer that information about nanotechnology products be made available to them (Macoubrie 2006). As of 2008, there is a lack of transparency associated with what nanoproducts are in the marketplace and what environmental health and safety studies have been done on them. Manufacturers hold the information, since protecting their confidential business information and intellectual property is important for their survival.

The dilemma is that this lack of transparency, which seems necessary for business, may violate consumer rights to know and choose nanoproducts (autonomy).

To explore and increase dialogue about these and other policy issues, scholars have called for "upstream public engagement" as a mechanism for integrating the public's views about nanotechnology into decision making early in the process (Wilsdon and Willis 2004). Some upstream-public-engagement exercises have been conducted for nanotechnology (Toumey 2006), although there is not yet a formal and systematic way to get the public's input on nanotechnology oversight.

Ethical arguments about nanotechnology and the natural environment include viewpoints about the sanctity of nature. Nanotechnology involves the control and manipulation of matter at the atomic scale, and some people believe that humans do not have the right to tamper with nature at this fundamental level. Similar debates occurred in the context of genetically engineered organisms. Several groups are considering appropriate oversight for nanotechnology and the best way to learn from past technologies (David and Thompson 2008; Paradise et al. 2008).

In the context of nanotechnology, broad questions about the role of humans in the environment, human obligations to protect ecosystems at all or some costs, and the intrinsic value of nonhuman entities and Earth need more consideration. Because there are only a handful of environmental applications of nanotechnology on the market, there is an opportunity to study the ethical and societal implications of nanotechnology, create upstream-public-engagement activities, and proactively develop oversight-assessment strategies prior to full-scale development, use, and release. Also calling for quick yet careful consideration are the environmental impacts of nanomaterials released into the environment as by-products or waste from manufacturing, since there are hundreds of consumer products with nanomaterials already on the market.

NATIONAL SCIENCE FOUNDATION

The statute creating the U.S. National Science Foundation (NSF), which President Harry Truman signed in 1950, specified that the agency support the mathematical, physical, biological, and engineering sciences. The

emphasis on hard science, on big science, and on training engineers, meant to counter scientific advances in the Soviet Union, became entrenched with the 1957 launch of the Soviet satellite *Sputnik*. The governing National Science Board, raising concerns about "objectivity, verifiability, and generality," opposed the use of funds to support the social sciences. One member likened the social sciences to Pandora's box, except in limited areas, such as demography, where the science could be closely tied to empirical, mathematical, and experimental methods. When President John F. Kennedy sought to move the NSF toward applied and socially relevant research, the NSF began to support some projects in the social sciences. Pressure from Congress, culminating in 1968 with a radical amendment to its underlying statute, compelled the NSF to apply research to national needs, and as the agency funded projects dealing with politically salient and controversial issues, such as the environment, it created programs for the social sciences, such as economics. The requirement to fund applied, rather than just basic, research not only brought more support to the social sciences but also opened what had been a closed question: whether the NSF could support projects examining the social, legal, and ethical implications of science and technology. This entry describes how the NSF has responded to that question.

By the early 1970s, many NSF officials, especially those in the biological sciences, had become aware of public controversies over new technologies and recognized the need to investigate the normative conditions and consequences of the increasing power, and hence responsibility, that science gave society. Skeptics questioned whether research into values was suitably scientific, how it would be organized, and whether it would unduly emphasize risks over benefits. In 1976, following the recommendation of the Ethical and Human Values in Science and Technology program, an advisory committee established with the National Endowment for the Humanities, the NSF made its first grants in this area, some cofunded by the National Endowment for the Humanities until the latter withdrew in 1980.

The budget cuts of the Ronald Reagan administration in the early 1980s, which were aimed especially at the social sciences and at science education under the NSF, would have eliminated the Ethical and Human Values in Science and Technology program had not it moved to the Directorate for Scientific, Technological, and International Affairs. Although the program suffered substantial budget cuts, support from the scientific community and from NSF Director John Slaughter helped preserve the program. In 1986 a new NSF director posed an even greater threat by proposing to zero-out the roughly $1 million budget of the Ethics and Values in Science and Technology program in favor of funding large-scale engineering research centers. Dr. Rachelle Hollander, who had become the director of the program in 1980, helped bring the scientific community, including such groups the American Association for the Advancement of Science, into a lobbying effort that persuaded the Congressional oversight committees to restore program funding. Ethics and Values in Science and Technology, now housed in the Directorate for Biological, Behavioral, and Social Sciences, saw its funds distributed through an "ethics across the foundation" approach, which required a proposal-by-proposal management and negotiation effort. In this effort Hollander, by persuasion and collaboration, worked with a growing number of NSF programs, obtaining from them contributions that in effect increased by one-third the overall budget of the Ethics and Values in Science and Technology program.

Between 1977 and 1985 the Ethics and Values in Science and Technology program made more than 150 awards, many in the areas of the environment, hazards, and agriculture, including animal welfare. The timing of this support (along with the intellectual oversight of managers of the Ethics and Values in Science and Technology program) accounts in large part for the successful development of the field of environmental ethics, which drew little enthusiasm from mainstream departments of philosophy. Between 1986 and 1994, a period of bureaucratic turmoil and reorganization at the NSF, the Ethics and Values in Science and Technology program (renamed the Ethics and Values Studies program), together with the Science and Technology Studies program, moved into the new Directorate for Biological, Behavioral, and Social Sciences, under the general rubric of the Societal Dimensions of Engineering, Science, and Technology.

As public concern over the social, ethical, and cultural implications of emerging technologies grew—one need only think of nuclear power, recombinant DNA technology, pesticides, and the assessment of environmental risk—the NSF, from 1994, included in its budget specific funding for research in ethics and values studies and in science and technology studies. The Ethics and Values Studies program also continued to collaborate with, and thus garner additional support from, larger NSF projects. An ethics component is included in several big-ticket NSF initiatives, for example, the foundation-wide Integrative Graduate Education and Research Training program, which makes individual grants in excess of $2.5 million.

Congressional and public concern continued to direct the NSF toward applied research that would lead to measurable results in solving national problems. In 1996 a task force recommended that the competitive review of proposals center on two questions: "(1) What is the intellectual

merit of the proposed activity? (2) What are the broader impacts of the proposed activity?'' These criteria, which were implemented in 1997, required applicants to integrate the intellectual merits of their proposed research with its broader impacts (the social merits). The consideration of the impacts and thus the social value of proposed research brought a normative dimension to every project. At the same time, the NSF gave greater weight to the relation of science and society and to research, including normative and conceptual analysis, concerning the formation of science policy.

In 1976 only two major academic centers for ethics and public policy existed: the Hastings Center in New York, which specializes in medical ethics, and the Center (now Institute) for Philosophy and Public Policy at the University of Maryland. With NSF support—and later funding from the program on the Ethical, Legal, and Social Implications of the Human Genome Project at the National Institutes of Health—ethics and policy programs and centers have now become established in universities across the country. Professional organizations, for example, the Association for Practical and Professional Ethics (1991), formed for philosophers, social scientists, and scientists who see the study of the normative dimensions of science and technology as a legitimate field of scholarship. Several journals, such as *Science, Technology, and Human Values* and *Science and Engineering Ethics*, were founded to publish papers exploring the ''value,'' or social and cultural, dimensions of engineering, information technology, the environmental and social sciences, and technology.

Grants made under the Societal Dimensions of Engineering, Science, and Technology rubric have included normative and conceptual analyses of issues in the social sciences, but far more often address the social implications of environmental, engineering, and biological sciences and technology. Thus principal investigators in Ethics and Values Studies projects are as likely to be humanists (for example, philosophers) and natural scientists as social scientists. By ensuring that the projects it funded directly related to the social consequences and ethical implications of science and technology, the Ethics and Values Studies program to some extent avoided the skepticism often directed toward the social sciences within the NSF and by oversight committees. The Ethics and Values Studies program now appears integral to the attempt to understand and evaluate the broader impacts of scientific research.

As of 2007 scholars seeking support for research on the normative dimensions and social implications of science and technology may apply not only to the now integrated Science and Society Program, which includes the Societal Dimensions of Engineering, Science, and Technology program and awards grants from an annual budget of approximately $3 million, but also to other NSF programs, such as those involving science policy, ethics in engineering, and nanotechnology, all of which have been sensitized to the need for normative analysis. Much of this progress can be attributed to Hollander's nearly thirty years of leadership at the Ethics and Values Studies program. She retired in 2006.

NATIVE AMERICANS

The cosmologies, ways of knowing, and value systems of North American indigenous peoples (NAIPs) have attracted the attention of environmental philosophers and ethicists worldwide. A central reason for this attraction is the inspiration NAIP worldviews have provided for critics of the dominant Western European worldview and practices. NAIP worldviews articulate alternatives to the exploitative and ecologically destructive attitudes of the dominant society by directing thought, perception, and action in ways that promote a more harmonious, sustainable, and respectful human-environment relationship.

NAIP AND WESTERN WORLDVIEWS

In its *Agenda 21* of 1992 the United Nations has drawn attention to the environmental practices of indigenous people around the world as models of holistic thinking, ecological sustainability, and environmental protection. Although it is difficult to characterize this relationship precisely, the ideas of being connected to the earth, coming from or being intimately connected to the land, belonging to the land, and being keepers of the land express how most NAIP worldviews frame the relationship between people and the land.

These ideas are indicative of a holistic way of understanding and engaging the world. Accordingly, they are used to criticize the fragmenting tendencies of Western

thought, such as the idea of a radical separation between rational human beings and the land, which has characterized Western thought from Plato through Thomas Aquinas, René Descartes, and Immanuel Kant. The attraction to the worldviews of indigenous peoples has resulted from what critics view as fundamental failures and inadequacies of Western European metaphysical, epistemological, and normative systems. Metaphysical systems are ultimate explanations of the fundamental properties of nature and why things happen. Epistemological systems articulate ways of knowing or principles of knowledge acquisition. Normative systems tell people what is of value and what people ought to value.

DEFINITIONS AND NOMENCLATURE

The use of the term *North American indigenous peoples* in this entry represents an attempt to avoid some of the problems that labels create. The term *Indian* is acceptable to some people even though it is not based in NAIP languages. Others find it unacceptable because it helps propagate colonial attitudes. Some accept *Indigenous* (or *indigenous*) *peoples*, but this term generally is used to refer to the wider global community of what have been called native peoples. Some people insist on being called by their national names (e.g., Haudenosaunee, Anishnaabek). For this entry the more neutral term has been chosen

NAIP worldviews typically do not assume a radical detachment of body from mind, nature from culture, and rational beings from nonrational beings. They emphasize the importance of acting in accordance with Earth and its balances and respect for a creator or a greater power. The lowercase term *creator* is used in this entry to refer to both concepts. Many NAIP cultures today use expressions such as *all my relations* to indicate how they view their connection to the earth. People are fully relational beings; they are what they are by virtue of their relations to all others, including trees and rocks. People are first members of a community of beings and second distinct and private individuals. Origin stories describe how humans emerged from the land, not from an intellectual, noncorporeal realm.

The NAIPs who have been at the center of this attention belong to two linguistic groups: the Algonquian and Iroquoian. The reason for this focus is partly historical. British tradition has dominated the writing of North American history in regard to NAIP worldviews, and the British were engaged primarily with Algonquian and Iroquoian peoples; therefore, these three traditions have come to dominate the way in which NAIP worldviews have been conceived in the environmental arena. Other nations and cultures have become foci of study, partly because more NAIPs are participating in the dominant scholarly and publishing systems. The appeal of the environmental movement to Plains (especially Sioux) and West Coast NAIPs also has received more attention. Only a few of the roughly five hundred nations and two hundred linguistic communities that lived in the Americas before contact with Europeans, not to mention other continents, are mentioned in this entry. This is unfortunate, because the NAIP presence was far from insignificant. William Denevan (2007) figures the total NAIP population at contact was 40 million to 100 million (the U.S. census of 2000 puts that number between 2,475,956 and 2,663,818, or fewer than 1 percent of the U.S. total population).

The environmental practices and principles of NAIPs, such as taking only what is needed, avoiding the burning of woodlands and prairies, and using everything one takes, have been cited in an attempt to change the behavior of the so-called developed world and its conception of its relationship to ecosystems. Because NAIP worldviews would have people perceive the world as alive and occupied by other persons (nonhuman animals, trees, and rocks) who are conceived as relatives, they encourage Westerners to come into more intimate contact with and develop an awareness of the world as a community and in so doing become more respectful of Earth.

Many of the Algonquian and Iroquoian people have articulated this view in the concept of Mother Earth, the living giver and sustainer of life, who is owed the deepest respect. Accordingly, the practice of thanksgiving for members of the Earth community who give themselves so that others can live is guided by the principle of reciprocity (e.g., giving tobacco in exchange for the life they take to sustain themselves). This conception of Earth grounds what has come to be known as traditional ecological/environmental knowledge (TEK). Such knowledge involves different modes of becoming aware of the life force that is Earth. The drumming circle, for instance, produces the sound that represents the heartbeat of Mother Earth to which drummers, singers, and dancers connect.

CARICATURES OF NAIP WORLDVIEWS

NAIP cultures often have been romanticized, and the concept of the NAIP personality has been constructed as the noble savage (or ignoble savage). These caricatures have deep roots in North American and European history. From the seventeenth century through the eighteenth misrepresentations by, among others, Thomas Hobbes, John Locke, and Jean-Jacques Rousseau have cast NAIPs as politically and legally naive and/or innocent. Archie Belaney (Grey Owl) and Thomas Seton (the Boy Scout movement), with a different intent, viewed

Makah Indians at a Whaling, 1999. *The environmental practices of Native American indigenous peoples (NAIPs) are often seen as more ecologically friendly than Western practices. Certain principles, such as taking only what is needed and using everything one takes, are often cited as criticism of the "developed" world. However, this comparison does not always hold, as many environmentalists disapprove of other NAIP practices, such as the Makah whale hunt in Washington State.* **AP IMAGES.**

NAIPs as incapable of harming the land because they live in an honorable and constant harmony with it.

This caricature implies that NAIPs lack the capacity for reasoning and decision making and thus operate at the level of animal intuition. Where Rousseau saw this state as a golden age of humanity, Locke saw it as a ground for justifying the appropriation of NAIP land. A number of influential colonists used this conception to declare the lands of North America *vacuum domicilium* ("empty place"; in Australia the term *terra nullius* was used) because, as nonrational people, NAIPs did not understand what it meant to own the land and thus could not lay proper claim to it. The term *noble savage* was used by Rousseau and others to criticize what they saw as the degeneration of their own societies. Baron Lahontan, for example, recalled or perhaps fabricated accounts of his discussions with Adario (the Huron sachem [leader] Kondarionk) as a series of syllogistic arguments. He constructed those accounts to contrast the uncorrupted Indian mind with the degenerate European mind. To some extent later writers (e.g., Henry David Thoreau, J. Fenimore Cooper) and more contemporary proponents of wilderness awareness (e.g., Tom Brown Jr.) continue to propagate such ideas. Tom Brown was educated in the art of tracking by Stalking Wolf, one of the last Apaches to be trained in the old ways. He, along with others, continues the commentary on the degeneration of Western civilization.

REFUTATIONS OF THE CARICATURES

These one-sided and often distorted descriptions are challenged not only by NAIP teachers and scholars but by non-NAIP scholars as well. Careful perusal of early colonial records such as the Records of Indian Affairs of the 1600 and 1700s supports stories of shrewd Indian businessmen trading at Albany and Montreal and with

the Hudson Bay Company. They describe treaty-making processes that involved articles of agreement and arguments over the foundations of an intercultural law. Oral tradition, as John Borrows (2002) (Anishnaabe) and J. Baird Callicott (1989) show, corroborates the view that the NAIP relationship to the land was law-governed or normative. Many stories in these traditions are not about naive, innocent Indians living in perfect harmony with Mother Earth but about a people who could violate the creator's law and face consequences for doing so (e.g., stories involving Nanabush). Engagement with the land is a struggle to find balances between good and evil, individuality and community, peace and war. Humans must establish a balance of opposites, to use a phrase borrowed from the 1999 work of Taiaiake (Gerald) Alfred (Kanien'kehaka, Mohawk).

Stories of failing to achieve balance are corroborated by archival and archaeological records. The Haudenosaunee, aided by guns supplied by the Dutch, for example, used those weapons in what were known as the Beaver Wars to conquer Huronia (southern Ontario) and control the beaver trade. Long before those wars the origin story of the Iroquois Confederacy told of the creator's displeasure with the warring ways of the Haudenosaunee. Deganawidah, the peacemaker, was sent to bring the Great Law of Peace to the Haudenosaunee precisely because they were not living in peace and harmony even before contact. Poor irrigation methods resulted in salinization of soil, forcing communities such as the Hohokam to move. After contact, overtrapping in colonized areas resulted in a shift of the fur trade toward the west. Mistakes were made by NAIPs because of wrong intent (e.g., greed), inadequate planning (poor engineering), and bad judgment about the limits of what could be taken from Earth; hence, there was a need for normative direction.

It is wrong to suggest that seeking harmony implies an absence of human intervention and alteration of the land from a NAIP point of view. From the Aztecs, Incas, and Maya to the Anasazi and Cahokia, Native Americans were builders of towns and cities, devisers of political institutions, and planters of vast fields of crops long before contact. William Cronon (1983) describes how controlled burns were used to engineer environments. According to many practitioners of TEK, that practice extended all the way to the West Coast. Controlled burns fostered the maintenance of grazing lands for ungulates that the people would hunt. Increasing work in ethnobotany in collaboration with NAIPs is beginning to show how NAIPs used various techniques to shape the landscape for the production of edible plants, particularly berry-producing plants. Others used systems of weirs to trap fish. Still others developed manufacturing facilities for the production of trade goods such as wampum beads, turquoise, and copper.

With the historical understanding of NAIPs becoming more complex, conceptions of their worldviews have become more nuanced. As increasing numbers of NAIP writers, such as Vine Deloria Jr., Paula Gunn Allen, and N. Scott Momaday, have found it necessary to enter the dominant scholarly fray to correct and better represent NAIP perspectives and cultures, this complexity has become more evident. Until approximately the 1970s almost all that was written about NAIP environmental thought was by non-NAIP writers. However, since that time a growing number of NAIPs have helped enable the philosophical complexities of NAIP environmental thought to be brought to the attention of scholars, artists, and those in the general social/political arena. Others, such as Thurman Lee Hester, Sandy Grande, Viola Cordova, Jace Weaver, and Dennis McPherson, have brought those complexities more specifically into the environmental thought/ethics arena. Publications by NAIPs in the journal of environmental philosophy *Environmental Ethics* are also on the rise.

NAIP ENVIRONMENTAL PHILOSOPHY

As interpretive horizons have opened, awareness of NAIP environmental philosophy has deepened. The more people understand about dodemic (totemic) identification, for instance, the more they understand how complex the connection to the land is. Iroquoian and Algonquian peoples were and still are organized into clans according to their dodemic identity (e.g., wolf, turtle, bear). In various ways, dodems differentiate people's and clans' roles and responsibilities. Dodemic identity is connected to normative function. If one considers other cultural practices, such as the pipe ceremony and wampum belts and strings, and the way they were used in condolence ceremonies, acts of reciprocity, and the giving of thanks—all of which prepared minds and hearts to face the creator—it becomes clear that the connection to Earth was and still is not only of a normative but of a spiritual order. Prayers of thanksgiving for the waters, the plants, the creatures of Earth and air, and the wind are constant reminders of what it takes to have a good mind and lead a good life. This kind of awareness engages a sense of the sacred in the world, because the creator is in some way immanent, infused in all creation. This idea sometimes is captured in the idea of a sacred circle of life, a living mystery. Giving thanks, then, is more than an obligation or expression of gratitude for what is provided; it represents a recognition of the responsibility to maintain clarity and sincerity.

The connection to Earth also involves evil. Haudenosaunee at-the-woods-edge ceremonies took place when

travelers arrived at a community. They would be greeted just outside the community where they would be fed and allowed to rest. Wampum belts and strings would be used to "wipe away" the sweat from their bodies and the blood that the thorns and briars of the forest had inflicted on them. The forest was not just a kind benefactor of humanity but also a place where evil lurked. Moreover, in Algonquian traditions, manitous (some of whom are evil) sought to deceive and kill humans. To be connected to the land, therefore, was also to be attuned to its destructive forces.

To further complicate matters, the role of the trickster brings ambiguity to NAIP epistemologies. The trickster (e.g., Coyote, Raven) can take many human and nonhuman shapes. What appears to be a human being can in fact be a coyote and vice versa. It is not clear, therefore, what could verify a perception. Epistemic sensibilities thus must become attuned to a range of possibilities that go beyond what people might perceive to be the truth. Knowledge acquisition is not a straightforward task but involves reflection at various levels. It is not difficult to understand, then, why NAIPs avoid making confident assumptions about, for instance, rights to exploit and own the land.

THE NAIP CONCEPT OF LAND AND TERRITORY

North American history is replete with instances of colonials systematically employing misrepresentations of NAIP thought in order to exploit the NAIPs and their lands. Governor John Winthrop (known for his appeal to *vacuum domicilium*), for example, argued that because Indians had taken payment for a piece of land, that land belonged to the English. Roger Williams, who better understood his NAIP neighbors, countered Winthrop's claim by arguing that when sachems such as Miantonomo agreed to allow colonists onto their land, they were not transferring ownership but were giving rights to use the land.

Thus, the concept of territory is much more appropriate than that of property. Although others might have had a right to use a territory, they first had to establish an agreement with its occupiers. If they wanted to hunt in or travel through a territory, emissaries carrying wampum belts or strings would be sent to the villages of that territory to request permission. Failure to follow this protocol or an equivalent (e.g., carrying a calumet or peace pipe) while traveling or hunting on another group's land could be construed as an act of aggression and justification for war.

Part of the reason land ownership could not be transferred as it could be in European practices was the fact that territory was a communal responsibility. Communities, not individuals, laid claim to territory. They were keepers of the land. Thus, to impose the concept of property in the sense of having the right to alienate or exploit what is owned was a means for undermining NAIP systems of territorial governance and the underlying conceptual framework of those systems.

NAIPS AND THE ENVIRONMENTAL MOVEMENT

Similarly, NAIP environmental thought has been misrepresented and manipulated in service of the environmental movement. Despite good intentions, that movement has exploited certain caricatures, such as the image of the ecologically sensitive "Crying Indian" (Iron Eyes Cody, who was not a NAIP) in the "Keep America Beautiful" campaign of 1971. Some environmental historians trace the use of the idea of the ecological Indian to an 1810 meeting between the Shawnee war chief Tecumseh (Tekamthi), who led the western nations against the United States in the War of 1812, and General William Henry Harrison, who led the U.S. Army. Tecumseh is alleged to have said to Harrison after being invited to sit on a chair, "The sun is my father and the earth is my mother; she gives me nourishment and I repose upon her bosom."

By 1877, the connection had become popularized and the idea of Mother Earth began to be used by NAIPs (e.g., the Wanapum chief Smoholla) to gain popular support in their fight to retain traditional territories and resist colonial expansion. Sam Gill (1987) suggests that the emergence of the concept of Mother Earth in NAIP cultures is a political fiction based on Western ideas and images; it serves as a critique of U.S. expansionism by establishing an unassailable moral authority for the NAIP position. However, there are periodic references to an earth mother in earlier records, and previous descriptions of NAIP cosmologies suggest that Mother Earth is not incompatible with NAIP traditions. Origin stories, including those recorded by the Jesuits in the seventeenth and eighteenth centuries, form a pattern that implies an emergence of humanity from the earth. It is possible, then, that the popularization of the concept in the 1800s was part of a cultural and political evolution in which the Mother Earth cosmology was given more explicit expression after having been precipitated by the NAIP struggle for political recognition.

Since the 1800s various forms of activism and resistance have been employed by NAIPs in their struggle to establish land management practices (fairer resource allocations), protect sacred sites, and safeguard health. The ongoing Yucca Mountain case in Nevada, involving the storing of nuclear energy wastes, has been resisted by Shoshone and Paiute people partly to protect Mother Earth and partly to assert treaty rights. Tulalip efforts to gain resource management rights in Washington (a struggle related to the 1974 Bolt decision recognizing comanagement rights for the Tulalip) are similarly motivated. In other areas, NAIPs have used road

blockades and armed resistance (as in the Oka crisis in Canada) to reclaim land, protect sacred sites against development, and assert their treaty and aboriginal rights. The Oka crisis in Canada in 1990 began with Kahnasatake Mohawk efforts to reclaim a sacred site that was being developed for a golf course, and terminated in an armed standoff against Quebec police and the Canadian military. The Grassy Narrows Ojibway have been victims of mercury poisoning from pulp plants on the English River in northern Ontario, and the James Bay Cree have resisted initiatives to remove them from their land so that hydroelectric developments could proceed. The long list of environmental and legal disputes over disproportionate distribution of harms and benefits from waste management and resource extraction continues to grow as NAIPs struggle for a voice in the areas of policy making and decision making. Justice issues that concern the land can be divided roughly into two categories: (1) giving voice to NAIPs and recognizing treaty and aboriginal rights; and (2) balancing the harms and benefits (Vecsey and Venables 1980; Weaver 1996).

Conflicts between environmentalists and NAIPs over various environmental practices such as hunting suggest that the attempted marriage between environmental and NAIP philosophy and ethics may not be an entirely happy one. The Makah whale hunt (Washington State), hunting in national parks, and the harvesting of whales for ceremonial muktuk in the north are examples of conflict between conservationists and NAIP principles. These conflicts warn against making simplistic connections between NAIP philosophy and the aims of environmental protection.

NATURAL LAW THEORY

Natural law theory—the theory that the laws of human morality can be derived from an ordered, rational, and purposive universe—has existed in various forms since ancient Greek times. Central to natural law theory is the idea that the laws guiding human conduct are greater than or predate personal self-interest, the needs of the community, and the good of the state. Those laws are

natural in that they are the same as the laws that govern the natural world. They can be identified through the use of rational thinking combined with right-minded observation of the physical universe. Many advocates of natural law theory are theists and subscribe to the notion of a rational divine will as the supreme ordering force, but the concept does not depend on the existence of a divinity.

In general, natural law theories of morality assert three things:

1. The principles for human conduct exist in a universe governed by rational laws.
2. Those laws can be discerned by human reason to determine the moral good.
3. Moral principles are universal and unchanging.

HISTORICAL BACKGROUND

Ancient Greek philosophy emphasizes the concept of virtue (*arête* in Greek), which requires a constant striving toward perfection in accordance with one's true nature. Inherent in this principle is one of the kernels of natural law theory: Nature has provided fundamental principles that guide the development of all living things. Aristotle (384–322 B.C.E.) often is recognized as the father of natural law. In the *Rhetoric* he noted that, aside from the "particular" laws that each people has set up for itself, there is a "common" law that is in accordance with nature.

Natural law theory was developed further in Hellenistic and Roman stoicism. The stoics believed that there are empirical standards of truth and justice that are revealed to people by right reason according to nature. Theirs was a philosophy of cosmic determinism, or a world governed by inviolable natural laws. Stoicism includes an account of human freedom that holds that human reason is free to choose either to follow or to turn away from the laws of nature. Virtue consists of a will that is in accordance with nature. The most influential natural law stoics were Cicero (106–43 B.C.E.), Seneca (4 B.C.E.–65 C.E.), Epictetus (55–135 C.E.), and Marcus Aurelius (121–180).

Thomas Aquinas (1225–1274), especially in the *Summa Theologica,* established the concepts of natural law morality still used by the Catholic Church. The fundamental principle of Catholic natural law is that good is to be done and evil is to be avoided. The source of good is God, who is perfect actuality: "The only perfectly good thing in existence is God, who is pure actuality. But anything else is good to the extent that its potentialities are brought to actuality. A fully developed oak tree is better than a warped or stunted one" (Aquinas quoted in O'Conner 1968, p. 19).

The modern period in natural law theory began with Hugo Grotius (1583–1645), who argued that natural law does not depend on the existence of God. That argument went directly against Aquinas's doctrine of natural law.

Natural law is associated with, though not identical to, the concept of natural rights. In the seventeenth century natural law was linked to a liberal political theory. On the eve of the French Revolution, John Locke (1632–1704) envisioned humans as being born into a state of nature in which they are rational, tolerant, and happy. In that state humans enjoy the natural rights of life, liberty, and property. Society, according to his theory, exists to protect those individual natural rights.

CONTEMPORARY USE

Natural law in the ancient and theistic sense requires belief in a teleological universe, one that is purposive and in accordance with some higher principle, a concept that is challenged by a contemporary post-Darwinian view of the universe as a cosmic accident and/or belief in personal divinity. Recently, though, there has been a resurgence of natural law theorists. This movement sometimes is called the new natural law, or neo-natural law. The most prominent contemporary natural law theorists are the Australian John Finnis (1979), the Americans Germain Grisez and Robert P. George, and the Canadian Joseph Boyle. New natural law is usually nontheistic and focuses on "basic human goods," such as human life, knowledge, and aesthetic experience, which are self-evidently and intrinsically worthwhile.

Natural law is invoked in current public policy debates about biotechnology. Theorists affirm the need for biotechnological research to promote the vital natural goods of human health and human knowledge but emphasize the need to focus on technologies that produce those goods in nondefective ways, or ways that respect the integrity of the human person. For this reason they condemn the use of human embryos for research or new technologies. They also condemn assisted suicide, human cloning, and genetic selection of offspring.

APPLICATION TO ENVIRONMENTAL ETHICS

At its most basic, natural law requires that everything in the universe act in accordance with its nature. This principle applies not only to humans but also to nonrational natural beings. Because of its appeal to nature to guide human action, natural law theory is compelling to some in the field of environmental ethics. It is seen as restoring the proper relationship of humankind to the natural world. Traditionally, however, natural law theory is applicable only to humans. As rational beings, humans are the only entities who can participate in the rational laws of the universe. Also, it was used most often by those who related the concept of an ordered universe to the

idea that there is a state of equilibrium in nature. As that idea has fallen out of favor in ecology, so have appeals to natural law in environmental ethics.

There has been a connection between Catholic natural law and environmental ethics. Pope Benedict XVI saw in the environmental movement a promising route for the recovery of the natural law tradition and an antidote to the cultural situation in the West, in which notions of spirituality and morality have been excluded from the idea of rationality. For Benedict moral norms are a priori and absolute, not matters of individual taste and subjectivity, as they commonly are thought to be in contemporary Western culture. Benedict argued that contemporary ecological knowledge supports the idea of limits in nature that humans disregard at their own peril.

NATURE CONSERVANCY

The Nature Conservancy (TNC) is the world's largest environmental organization by amount of revenue. Created in 1950 and incorporated in Washington, D.C., in 1951, it attempted initially to protect land valued by its founders, largely university ecologists who wanted to save properties useful for studying unique biological features undisturbed by humans. Those scientists were pioneers in establishing the preservation of natural conditions as a primary environmental issue.

EARLY MISSION

In its first twenty years TNC succeeded in the narrow mission of buying properties in their natural state to stop development. It earned a reputation as the real estate arm of the conservation movement. Whereas other groups lobbied politicians and regulators or educated the public, TNC simply bought property. Most of its early efforts were confined to the eastern United States.

In the early years its scientific goals became blurred by opportunism. In a rush to amass acreage, it bought not just undisturbed ecological treasures but purchased green space of all kinds, including woodlots and part of a golf course. In 1971 alarmed ecologists on the board of governors hired a science director, Robert Jenkins, who had earned a doctorate at Harvard, to restore a science-based land-acquisition process.

Jenkins refocused the mission on protecting natural diversity, as biodiversity was called at that time. He launched TNC's most enduring legacy in 1974: the Natural Heritage Program. By 1989 he had opened offices for the program in every state. The state offices, staffed by scientists, assembled a computerized catalog of unique species and ecosystems. Those data enabled TNC to identify sites with true diversity, enabling the group to fulfill its mission: "to preserve plants, animals and natural communities that represent the diversity of life on Earth by protecting the lands and waters they need to survive."

BIODIVERSITY AND LAND PRESERVATION

In 2000 TNC spun off the Natural Heritage Program into a separate organization: NatureServe. That move accompanied a marked shift in the way the organization identified lands for protection. TNC began to move away from its single-minded focus of a quarter century of saving lands and waters rich in biodiversity. It moved toward saving lands and waters of every kind, no matter how rich. In that effort it began working with the World Wildlife Fund, Conservation International, and other groups.

Although not abandoning the Natural Heritage data, TNC divided the planet into thirteen "habitat types," such as boreal forests, savannas, and tropical grasslands. It then set a target, in concert with other conservation groups, to save 10 percent of all those habitat types globally by 2015. Using that new perspective, TNC research showed that many habitats that had been taken for granted had lost far more acreage than had "treasures" such as tropical rain forests. A far greater percentage of temperate grasslands had been lost, for example, than tropical rain forests. Biodiversity associated with less-vaunted habitat types thus was at equal risk.

As TNC's methods to identify lands evolved, so did its methods for protecting them. TNC protected land in its early years mainly through the use of fee-simple purchase, but it soon embraced conservation easements. In an easement TNC would buy development rights, leaving other rights with the landowner. The use of easements exploded

late in the twentieth century, and many groups began to use them to conserve land nationwide.

In the 1990s TNC staff in far-flung field offices adopted a flurry of other tools to save land. They engaged in community activism, regulatory influence, public land management, lobbying, and even for-profit enterprise to foster business development compatible with conservation. Throughout that period TNC continuously expanded its reach overseas, with operations in Canada, Latin America, the Pacific Islands, and Asia.

Overseas, TNC's flexible approach to saving land became especially prominent. In South America, for example, it partnered with a U.S. corporation, American Electric Power (AEP), to save a vast undeveloped forest in Bolivia. AEP, a Columbus, Ohio–based coal-burning utility, sought land for carbon credits to manage global climate change. In China it signed a deal to develop a conservation plan for 67,000 square kilometers in Yunnan. It negotiated in 2008 to manage floodplain risks downstream from the Three Gorges Dam.

As TNC began to protect biodiversity by all means possible, it promoted new thinking about the value of nature. Like no other organization, it put boots on the ground to back the conviction of a small band of scientists in the wake of World War II who believed that ecological preservation matters to everyone. TNC's entrepreneurial conservationists continued to press their efforts to stop irreversible loss of biodiversity as renowned ecologists such as E. O. Wilson, one of Jenkins's professors at Harvard, continued to trumpet the cause later in the century. TNC thus helped make a concern that had been the concern only of scientists a worry of the public at large.

At the same time TNC promoted the use of the capitalist system to protect natural resources. The leaders of the organization did not let the philosophical debate between environmental idealism and capitalism hinder their actions. Decades before other conservation groups they engaged business professionals in finance, real estate, law, and marketing to work with leaders from the nonprofit and for-profit sectors to advance conservation.

MEANS VERSUS ENDS

TNC insiders periodically wrestled with the obvious contradictions in their work between means and ends. However, pragmatism—"following the money" and a willingness to work with anyone—remained the guiding force. In the 1970s the president, Patrick Noonan, a champion of that notion, was accused of taking tainted money to fund conservation. His trademark response typifies the approach taken by TNC and, increasingly, other groups: "The problem with tainted money is there taint enough."

NEW ENVIRONMENTAL PARADIGM

In the 1970s the rapid growth of environmental awareness in the United States stimulated the development of ecological perspectives across a range of academic disciplines in addition to those which already existed in ecology and were developing in environmental science, earth science, and other natural sciences. As philosophers were elaborating versions of an environmental ethic, particularly those acknowledging the intrinsic value of the natural world, social scientists began to flesh out an environmental paradigm. Whereas philosophical efforts to develop an environmental ethic had a strong normative element, social scientists tended to adopt a Kuhnian perspective (see Kuhn 1996) by positing the need for an environmental paradigm to account for the anomalies of ecological problems and limits. The efforts of the social scientists tended to be less normative but shared with the philosophical work a desire to break with the strong anthropocentrism that had dominated Western thinking among scholars and laypersons.

DISCIPLINARY PARADIGMS AND SOCIETAL WORLDVIEWS

The concept of a new environmental paradigm (NEP), which was stimulated by the work of natural scientists such as Rachel Carson, Paul Ehrlich, Barry Commoner, and Garrett Hardin, had two general thrusts: At the disciplinary level social scientists critiqued the dominant anthropocentric assumptions (paradigms) of their disciplines and urged the adoption of a new environmental paradigm (later termed an ecological paradigm) to enable social scientists to appreciate the significance of ecological problems and their implications for modern industrial societies (Dunlap 1980).

At the societal level social scientists attempted to clarify the dominant social paradigm (DSP) through which Western societies viewed the world and demonstrate how its anthropocentrism contributed to environmentally destructive practices. They also explicated an alternative social paradigm or worldview that could help foster a more ecologically sustainable society and began to assess empirically the degree to which one was emerging. Efforts at the disciplinary and societal levels had the shared goal of overcoming an anthropocentric outlook and were designed to encourage both scholars and laypeople to "view the world ecologically" (Olsen et al. 1992).

Within academia efforts to establish an environmental/ecological paradigm have met with considerable success not only in the natural sciences, where fields such as ecology and environmental science are firmly grounded in such a paradigm, but also in the social sciences. Until the 1970s mainstream social science operated from a strongly anthropocentric human exemptionalism paradigm built on the largely implicit assumption that the exceptional characteristics of modern societies—heavy reliance on science, technology, and sophisticated social organization—exempted humans from the ecological constraints faced by other species and primitive societies. The prominence of global problems such as ozone depletion, loss of biodiversity, and climate change has made an exemptionalist stance increasingly difficult to defend, and the emergence of fields such as ecological economics, conservation psychology, and environmental sociology represents the institutionalization of a new environmental/ecological paradigm in the social sciences.

A Kuhnian paradigm shift has occurred or is in progress across numerous academic disciplines. An environmental/ecological perspective acknowledging that modern industrial societies remain ecosystem-dependent despite their technological sophistication and may be undermining their ecological viability because of unbridled technological development has taken root in many natural and social science disciplines. Unlike the Copernican, Darwinian, and Freudian paradigmatic revolutions that preceded it, the shift from human exemptionalism to an environmental/ecological paradigm does not have a singular instigator, although figures as far back as George Perkins Marsh helped lay the groundwork for Carson, Commoner, Ehrlich, Hardin, and the many other popularizers of the new paradigm.

EMPIRICAL RESEARCH

As scientific evidence supporting an environmental/ecological paradigm emerged in the 1970s, environmentalists used it to claim that contemporary societies are ecologically destructive and need to shift toward more sustainable practices. In the process many environmental activists and environmentally concerned citizens saw the necessity of replacing the current DSP—based on the assumption that limitless resources, promethean science and technology, and the ingenuity of humans ensure inevitable progress and a future of abundance—with a more ecologically realistic worldview. This potential shift in societal worldviews, which is analogous to the shift in disciplinary paradigms, attracted the attention of social scientists.

An early effort to measure public acceptance of a new environmental paradigm through the use of an NEP scale consisting of items that tap beliefs about the balance of nature, limits to growth, and human domination of nature soon was supplemented by more methodologically complex approaches. Stephen Cotgrove (1982); Lester Milbrath (1984); and Marvin Olsen, Dora Lodwick, and Riley Dunlap (1992) developed sets of bipolar items posing NEP and DSP choices as opposite ends of a continuum and asked survey respondents to choose between them. Their studies also drew on increasingly elaborated depictions of the two contrasting paradigms offered by numerous social analysts that included a wider range of components such as centralization versus decentralization and participatory democracy versus top-down decision making.

Those studies provided insights into the competing perspectives of groups such as environmental activists and industrialists, finding that environmentalists strongly endorsed the NEP and industrialists endorsed the DSP. However, what first appeared to be a rapid growth in acceptance of the NEP began to ebb with the sociopolitical shifts in the 1980s exemplified by the election of Ronald Reagan in the United States and Margaret Thatcher in the United Kingdom. Both personified the DSP, and the conservative trend they led slowed the growth of the NEP even though the discovery of new ecological problems continued to pose anomalies for the DSP. Societal worldviews are less affected by disconfirming evidence than are scientific paradigms, and particularly in the United States the growing power of the conservative movement and its success in demonizing "environmental extremism" hindered growth of the NEP.

Also, the emergence of sustainable development as a compromise between the traditional growth-is-good perspective and the 1970s limits-to-growth perspective created a more complicated situation. The endorsement of sustainable development (and implicit acknowledgment that past growth generated negative ecological impacts) by progressive industrialists, government officials, and laypersons as well as by most of the environmental community has made it more difficult to capture alternative worldviews by using a simple DSP/NEP dichotomy.

MENTAL MODELS AND THE NEP SCALE

As a result, efforts to measure the DSP and the NEP as polar opposites have faded, and a revision of the original NEP Scale has become the preferred measure of ecological worldviews (Dunlap, Van Liere, Mertig, and Jones 2000). Its validity was strengthened when anthropologists found that the mental models laypersons employ to understand ecological problems consist of beliefs akin to those tapped by the NEP Scale (Kempton, Boster, and Hartley 1995). The NEP Scale continues to be used in a growing number of nations to assess the degree to which various publics and more specific groups endorse key components of an environmental/ecological paradigm or worldview. It should be helpful in tracking the evolution of the new environmental paradigm throughout societies worldwide.

NONGOVERNMENTAL ORGANIZATIONS

By virtue of their numbers alone, which approached forty thousand worldwide in 2008 according to the Union of International Organizations, nongovernmental organizations (NGOs) have become significant players on the international stage. Much of their growth has been a product of heightened globalization spurred by the emergence of the Internet in the 1990s as NGO numbers increased from six thousand to twenty-six thousand (Nye 2004). That dramatic expansion tells only part of the story, however, for it is in their qualitative contributions that the role and growing importance of NGOs in the twenty-first century are best seen.

STRUCTURE

NGOs pluralize world politics by offering multiple channels of access across traditional nation-state borders. They act as both allies and adversaries to states, forming networks that advocate policy changes and define ethical standards.

Their activities affect almost every economic, political, or social facet, from health care to history, language to law, theology to ethics, and culture to security and defense. However, it is in the environmental arena where NGOs have had the greatest impact, from the climate change initiatives of the Sierra Club to the tropical forest protection programs of Rainforest Action Network to the campaign to protect the ozone layer by Environmental Defense Fund.

The environmental NGO community is not homogeneous, ranging from NGOs that work directly within the system and hire platoons of attorneys and MBAs to those which espouse monkeywrenching and embrace the label *ecoterrorists.* Just as there are many shades of green in the environmental NGO community, there is an array of advocacy methods among NGOs. Some groups focus on lobbying or litigation, others emphasize scientific research or property acquisition, and still others concentrate on monitoring international law. Beyond these mainstream approaches, participatory strategies such as grassroots networking and community education have gained more emphasis.

DEFINITION

However, despite agreement on their growing importance, there is no generally accepted definition of NGOs; the term has different connotations for different people. In one fundamental sense NGOs can be defined by what they are not: They are not governmental but nongovernmental. This is perhaps their greatest strength and greatest weakness. NGOs are nonparochial and much more flexible than states. They often are touted as the ideal antidote to traditional governmental bureaucracy, but this lack of statehood can be a handicap. NGOs are not subjects of international law and remain second-class citizens in international organization settings. Despite their frequent contributions to global governance, their only rights are those of observers, not voting entities.

The World Bank defines NGOs as "private organizations that pursue activities to relieve suffering, promote the interests of the poor, protect the environment, provide basic social services, or undertake community

development." The United Nations conceptualization offers a few more particulars, identifying four generally accepted characteristics. The United Nations, in fact, is largely responsible for the popular use of the term *NGO* as a result of its categorization in 1945 in Article 71 of Chapter X of the UN Charter granting consultative status through the Economic and Social Council (ECOSOC). The four UN characteristics start with the fact that an NGO is a nonprofit organization. Second, it operates independently of government; this is a complicated stipulation in that some NGOs receive governmental funding. Third, these groups must be noncriminal in nature. Fourth, NGOs are not constituted as political parties. Although they may be active in an election process, they do not run for office or serve.

Over the years, in this context, the socially constructed image of NGOs has come to be highly positive. Scholars such as Joseph Nye (2004) point out that NGOs utilize a vast reservoir of soft power to shape policy through attraction rather than compulsion of economic and military might. Others, such as Margaret Keck and Kathryn Sikkink (1998), point out that NGOs are a considerable democratic force, empowering disenfranchised areas of the world by giving voice to those who had none before. However, it is important to offer a few qualifiers. NGOs often have a narrow membership, and at times they exhibit little democratic accountability. Like their domestic counterparts, interest groups, NGOs have been accused of being elitist and operating on behalf of special interests. A key difference is that the interests NGOs pursue, unlike those of most interest groups, are not exclusionary benefits; people benefit from clean air or clean drinking water whether or not they support the Natural Resources Defense Council.

Because NGOs are not homogeneous, they are difficult to classify. To complicate matters, NGOs are constantly changing. Some smaller NGOs serve a specific purpose and die out. Others, such as Conservation International, are born out of political differences within a parent NGO, in this case The Nature Conservancy. More typically, the larger, richer NGOs of the global North actively foster the birth of smaller grassroots NGOs, hoping to continue a beneficial relationship for both parties in the future. Others, such as Birdlife International, offer an umbrella structure to link up with domestic-based organization such as the National Audubon Society in the United States.

ACTIVITIES

One way to categorize NGOs is by thematic scope. That is, what do NGOs seek to do? How is their mission oriented? Are they single-issue or multi-issue organizations? Do they target the protection of a particular set of species as in the case of the Royal Society for the Protection of Birds, or are they interested in broad biodiversity protection as in the case of the World Conservation Society?

Another approach is to categorize them by geographic scope. Where does the NGO operate? Is it a grassroots organization targeting specific local initiatives, such as the Friends of the Wekiva in central Florida or the Nobel Prize–winning Wangari Maathai's Greenbelt Movement in rural Kenya? Is it a nationally based group such as the Wilderness Society in the United States or perhaps more broadly but still regionally focused such as the Defenders of Wildlife in North America? Or is the NGO a truly global organization with both a global agenda and a global impact, such as the World Wildlife Fund and the World Wide Fund for Nature?

NGOs also vary widely in size, hierarchical structure, and financial budgets. The Sierra Club has over 1.3 million members in the United States alone, whereas Earthwatch has 20,000 globally. Some are highly centralized, such as Earthjustice Legal Defense Fund, whereas others have a loose federal structure, such as Greenpeace International. By and large, the wealthy environmental NGOs are found in the northern hemisphere, and the poorer groups in the southern hemisphere.

Environmental NGOs are an alternative power source to nation-states that enhance environmental justice around the world by creating new transnational political coalitions through the creation and maintenance of civil society. At times NGO activity targets business interests, particularly with "name and shame" tactics that hurt corporations such as Home Depot and Royal Dutch Shell in the pocketbook with the threat of consumer boycotts of their products: timber and petroleum, respectively. At other times this may entail direct clashes with states, as occurred when Greenpeace's *Rainbow Warrior* chased the French throughout the South Pacific to bear witness to that country's nuclear testing. Another example is Earth Island Institute filing a suit against the U.S. government for failing to enforce the Marine Mammal Protection Act and calling attention to Mexico's incidental takings of dolphin in fishing for tuna in the eastern tropical Pacific.

Sometimes the impact is much more conciliatory, such as Conservation International enhancing capacity building in Ghana with a shade coffee growing cooperative. Sometimes the activity of an NGO takes the form of participation in global dialogue, such as the 1992 United Nations Conference on Environment and Development (UNCED), popularly known as the Earth Summit, in Rio de Janeiro, Brazil, and the World Summit on Sustainable Development in Johannesburg, South Africa, in 2002. NGOs clearly are a set of actors with increasing influence in global politics, from the establishment of fundamental environmental ethical standards to specific policy formation.

NORTH AMERICA

Distinct, influential, and sometimes conflicting philosophical images and values about what humans are, what nature is, and what the relationship between humans and nature is and should be have been at the root of environmental controversies in North America over the last 500 years. Before European contact and the subsequent settlement of North America very different philosophical images and values reigned; those perspectives persisted, along with modifications of them. The confluence of those distinct philosophical ideas shaped both the

George Catlin,* Buffalo Chase Over Prairie Bluffs, *1844. *Scholars are undecided as to the environmental impact of the first populants of Native America (beginning roughly 14,000 years ago). Although it is commonly assumed that North American Indians had an environmental ethic similar to that of contemporary philosophers, others claim that their population of the continent caused mass destruction of native flora and fauna.* **THE ART ARCHIVE.**

environmental attitudes of North Americans and the landscape of the continent.

NORTH AMERICA BEFORE 1492

Both the practices and the environmental ethics of pre-Columbian North Americans are contested. Roughly 14,000 years ago Asian big game hunters crossed the exposed land bridge between what is now Russia and Alaska and also sailed along the western coast of North America to populate or greatly increase the population of North America. According to one theory (Martin 1967), those skilled hunters quickly swept across North America, Central America, and part of South America, slaughtering the unfamiliar megafauna; indigenous populations were drawn by the easy pickings of unwary animals, leaving extinguished species in their wake. Other scholars (Krech 1999) have suggested that although the arrival of big game hunters and the disappearance of many North American species corresponded, the demise of those species was attributable as much to changes in climate and perhaps other factors as it was to the newly arrived human hunters.

In environmental circles it commonly is assumed that before contact North American Indians (First Nations in Canadian parlance) had an inclusive environmental ethic on a par with the most inclusive contemporary environmental ethics, such as Deep Ecology and Aldo Leopold's land ethic. Although details varied from tribe to tribe, North American Indians considered nonhuman animals, rocks, rivers, mountains, and traditional myths and stories to have direct moral standing (Callicott and Nelson 2004). Contemporary ideas about the behavior of native North American Indians range from the assumption that they were skilled and intensive managers of the land to the belief that they were passive denizens of North America, a perspective that seems inconsistent with prevailing ethnographic and archaeological evidence. How is it possible to reconcile an inclusive ethic with the Pleistocene

extinction hypothesis or the overshoot of ecological carrying capacity, such as overuse of water resources in the Southwest six to eight centuries ago? N. Scott Momaday (1976) suggested that a profound ethical change occurred when the big game hunters gradually came to see the land of North America as home, then as beautiful, and then as intrinsically valuable.

Although the argument about an indigenous North American land ethic is an ongoing debate, knowledge about the extent of Indian impact is becoming more extensive. Many assumptions about Indian environmental ethics are premised on what is known about what pre-Columbian Indians did. In the last two decades of the twentieth century and the first decade of the twenty-first, however, much of the dogma surrounding those practices was challenged. For example, until recently the dominant figure for the North American human population was approximately 1 million. Currently, it is known that there were at least 4 million and up to 16 million inhabitants in 1491. Researchers also have come to appreciate that those humans affected the North American continent for over 14,000 years, sometimes in a very intensive fashion. For example, in the midwestern United States it is known that there were large agricultural complexes, each of which covered up to 200 to 300 acres, that supported thousands of people. It also is known that humans, through the intensive use of fire, actively and continually maintained much of what is considered the original prairie of North America and determined the composition and shape of forest ecosystems throughout the continent. Additionally, vast complexes of ceremonial and burial mounds, complex systems of trading, and cities housing tens of thousands of people (e.g., Cahokia in Illinois, which eventually overshot its carrying capacity and scattered its residents) existed in North America.

However, the myths, stories, and legends of precontact Indians seem to indicate very inclusive systems of ethics that guided and continue to govern subsistence practices of hunting, fishing, and gathering; those practices cumulatively shaped species distribution, diversity, and productivity (Blackburn and Anderson 1993, Frey 2001). Arguably, it was the animism—the belief that nature and/or natural entities are imbued with an indwelling spirit (Nelson 2004) and therefore possess what might be considered a kind of intrinsic value—of native North Americans that undergirded that inclusive ethic.

1492 TO 1776

Although Europeans had made forays into North America for perhaps 500 years, European settlement (or invasion) began to affect North American inhabitants and landscapes more seriously in the early part of the sixteenth century. Most immediately, waves of European-introduced diseases, generally introduced accidentally, began to decimate the populations of native North Americans. Because that anthropogenic disease regime effectively reduced the native population by as much as 90 percent and because the disease spread ahead of the settlers, Europeans felt justified in concluding that North America was a wilderness of continental proportions that was theirs for the taking. That assumption was affirmed by a tendency to perceive native peoples as having more the status of nonhuman wildlife than that of full-fledged humans worthy of moral consideration and respect. In light of the Puritan religious background of the early New England colonists, it may be safe to say that the conquest of the North American inhabitants and landscape was more than a consistent proposition; it was an expected and highly moral vocation. The Puritan leader and witch hunter Cotton Mather summarized this mentality when he asserted that "what is not useful is vicious."

At the same time that that internal pressure created a willingness to affect the North American landscape with little regard for the land or its native inhabitants, a more global market created a lucrative outlet for the products of the relatively unexploited North American continent, and that confluence had a major impact on the fish and wildlife populations. North Atlantic cod, which when dried provided a rich and easily transportable source of protein, and beaver pelts from English and French colonies, which when felted provided sought-after hats, are two notable examples. Exploitation also occurred in Spanish colonies, but it existed alongside traditions of caring for the common good; for example, water resources were shared as a community responsibility in places such as California and New Mexico. Although all Europeans participated in global market arrangements, the British did so with the greatest enthusiasm and the steepest ecological costs.

The meeting between native North Americans and the newly arrived Europeans was as much a clash of ideologies and ethics as it was a clash of technologies. Europeans brought with them not only the ability to alter the landscape but also the willingness to do that. Native North Americans, in contrast, had the ability to alter their landscape more seriously than they did but lacked the willingness and need to do so. Inclusive native ethics were inconsistent with the narrowly anthropocentric ethic of the European settlers. Although tempered, that Euro-American ideology is still in operation.

1777 TO 1899

In 1893 the historian Frederick Jackson Turner pronounced that the American frontier had closed three years earlier. Although historians have challenged that interpretation, the idea of a closed frontier resonated with Americans who saw the transition from the completion of Manifest Destiny (the belief that westward expansion

and territorial acquisition all the way to the western coast of the United States was inevitable) to the beginnings of a new and gentler ethic of relationship with nature. Analogously, Canadians linked the development of their nation to the exploitation of raw natural resources—staples such as furs and wheat—but did not develop a strong conservation ethic from that economic precariousness. Temporally and effectively corresponding to the beginning and the height of the Industrial Revolution, the late eighteenth and early nineteenth centuries saw the most brazen exploitive environmental practices that the technology of the time would allow. In the early part of that period North Americans of all types seemed limited only by their technical ability to affect nature and not at all by their willingness to do so. However, arising with these exploitive customs were challenges to that prevailing environmental ethic.

After the American Revolution the United States began purchasing and conquering what is now the Lower 48, a process that was complete by 1853 and that established the geography needed for accelerated economic exploitation. Canada, remaining until the present under the sovereignty of the British Crown, effectively emerged from British colonialism by 1873. Farmers moved quickly to fill the temperate North American continent and displaced native peoples and their environmental practices, except in the subarctic and arctic northern territories of Canada and Russian-owned Alaska. Laws such as the U.S. Homestead Act of 1862 and the Canadian Dominion Lands Act of 1872 served as powerful examples of a philosophical and ethical predisposition that manifested itself first legally and then on the land. These and similar laws privatized the public domain with an emphasis on small farmers, but often corporations such as railroads and mining companies fraudulently took advantage of the laws and wreaked ecological havoc for short-term economic gain.

This era also saw the boom and eventually the bust of many of the extreme extractive practices in North America. For example, the end of Great North Woods lumbering and massive commercial hunting occurred during that period. That era also witnessed the removal of American Indians from some would-be park areas and the relegation of most American Indians in the United States to reservations. The abuse of the environment in the form of the intentional slaughter of the herds of buffalo that fed certain Indian tribes (arguably a kind of biological warfare) is an example of the indifference and even contempt that the inhabitants of European descent in North America had for both the rights of nature and the rights of the native peoples. Similarly, mining rushes in the West extracted immense mineral wealth from the earth without considering the attendant environmental damage, such as deforestation, erosion, pollution, and habitat destruction (Isenberg 2005). The end of those practices, however, was due primarily to the end of the readily accessible resources that were the focus of the cut-and-run practices of the extractive industries. However, two separate and at times competing natural resource philosophies—resourcism and preservationism—were emerging at that time, neither of which allowed for the types of abuses seen in the past. The era of unthoughtful and uncontested resource exploitation in North America came to an end at about the turn of the twentieth century.

Largely in response to the profligacy of nineteenth-century capitalist development, many Americans began to question practices and reform policies, especially those concerning public lands. Figures such as George Perkins Marsh and John Wesley Powell warned of the social and economic harm that was likely to result from continued environmental degradation. Fearing that privatizing public lands was proceeding without a plan and in wasteful ways, reformers moved the federal government toward protecting land in addition to selling or giving it away. In 1872 the U.S. Congress reserved the first national park at Yellowstone; Canada followed in 1887 by reserving Rocky Mountain Park, later renamed Banff National Park. By 1891 the U.S. president had the power to reserve lands from settlement in what were known as forest reserves and now are called national forests. By the early twentieth century the Canadian Forest Service began recognizing problems with traditional harvest practices, but its regulatory presence remained weak for decades. Still, government-protected areas such as the national parks and forests were limited in terms of the types of economic activities that could be pursued there. Thus, the reforms initiated government involvement in checking economic exploitation and effectively announced that some environments were better left alone or managed with a longer-term perspective.

Besides government reform, private individuals and organizations instituted change in environmental practices. Early in the nineteenth century a few reform-minded farmers recognized the problem of soil erosion and attempted to initiate new practices on their farms that would yield long-term economic benefits without the ecological costs associated with most farming techniques (Stoll 2002). Organizations were even more active. In 1887 the Boone and Crockett Club was established by Theodore Roosevelt, a complex environmental figure known as much for setting aside vast tracks of land for national forests as he was for slaughtering vast numbers of African wildlife for American museums. Equally complex was the mission of the Boone and Crockett Club. Although its focus was the conservation of dwindling game populations and the habitats in which they lived, the foundational value of the club seems anthropocentric. That changed, however, in 1892 when John Muir founded the Sierra Club. Although Muir's Sierra Club

did not shun activities that humans enjoyed, it had an ultimate goal of preserving wild nature. The Sierra Club operated under the philosophy that exposure to wild nature would increase people's knowledge of a place and thus prompt in them a love for wild areas and a willingness to act on their behalf.

In an important early paper in environmental ethics the historian Lynn White, Jr. (1969), argued that the environmental abuses visited upon the North American continent by its denizens of European descent were simply the manifestation of a certain interpretation of their imported religious tradition, Christianity. Although White blamed the despotic interpretation of the human-nature relationship in the Christian tradition (the interpretation that informs humans that the earth is there for their use and abuse, that it is God's desire that people "dominate and subdue" His creation), he did not blame Christianity itself, a point that often is missed in reactions to his argument. Hence, for White and for environmental philosophers after him it was the philosophical and ethical predisposition, coupled with the emerging technological power, of the Old World arrivals that facilitated the radical alteration of the North American landscape in that period. By the end of the nineteenth century North America thus had experienced both massive ecological devastation and the roots of philosophical shifts that would thwart or at least complicate continued the pursuit of profit at the expense of nature.

1900 TO 1955

The early part of the twentieth century was marked by perhaps the most dramatic environmental battle in North American history and certainly the most continuously recognized one. The battle over the Hetch Hetchy Valley in Yosemite National Park pitted two contrasting environmental philosophies against each other. As early as 1864 George Perkins Marsh, the U.S. ambassador to both Turkey and Italy, had challenged the narrow and ultimately paradoxical anthropocentric justification of resource exploitation that had reigned on the North America continent. Employing the notion of the usufruct (use without destruction), Marsh suggested that it was inappropriate to believe and act as if the earth had been given to humans for "consumption" or "profligate waste" (Marsh 1864, p. 34). In 1905 the equally broad-minded and European-trained Gifford Pinchot was appointed the first chief of the U.S. Forest Service. Both Marsh and Pinchot developed their environmental philosophies in reaction to what they viewed as an overly exclusive and shortsighted human use of natural resources that they encountered in Europe. Although Pinchot argued for a more democratic and far-reaching form of conservation than the one he had encountered in Europe—he suggested that people should strive for "the greatest good of the greatest number for the longest time" and defined conservation as "the wise use of the earth and its resources for the lasting good of men" (Pinchot 1998, pp. 326–327)—he remained an anthropocentrist, stating that "there are just two things on this material earth—people and natural resources" (Pinchot 1998, p. 326).

In the Hetch Hetchy battle Pinchot argued from the point of view that the valley should be dammed to provide publicly owned water and electricity for San Francisco because those were the higher human benefits of resource use (Righter 2005). That stance pitted Pinchot against his old friend John Muir, who argued that the valley should be left as it was, a position that came to be known as preservation. Muir's position was a manifestation of the nineteenth-century transcendental philosophy of Ralph Waldo Emerson and Henry David Thoreau, who believed that only in nature could one witness the handiwork of God and transcend ordinary existence to find higher truths. Hence, for Muir, to destroy Hetch Hetchy was to display "a perfect contempt for Nature" (Muir 1992, p. 716) akin to destroying temples and churches. Here, for the first time since the European conquest, one can see a North American environmental philosophy suggesting that nature has a kind of value that transcends instrumental and anthropocentric ends, although Muir and his allies believed that tourists should benefit from such preservation (Righter 2005).

In the mid-twentieth century Aldo Leopold attempted to meld those two environmental philosophies. Although he worked to improve farming techniques and secure other human ends, Leopold also argued that people should judge the morality of actions, policies, and laws by their tendency to "preserve the integrity, stability, and beauty of the biotic community" (Leopold 1949, pp. 224–225), a community inclusive of human beings. Perhaps most important, Leopold's environmental philosophy turned away from a Judeo-Christian worldview and toward an evolutionary-ecological one premised on an assumed continuity between humans and the nonhuman world. A good example of Leopold's melded philosophy can be found in his ideas about wilderness preservation. Leopold and other preeminent ecologists of that time suggested that certain places in the United States should be set aside as designated wilderness areas as early as the late 1910s. However, Leopold's early rationale for wilderness preservation was dominated by arguments for human recreation that were common among other early wilderness thinkers. Later in his thinking about wilderness Leopold began to supplement such arguments with nonanthropocentric viewpoints that suggested that wilderness should serve as a place to house otherwise unwelcome wildlife and ultimately as a base datum of healthy land.

Although the moral will to enact a more inclusive environmental ethic was present by the mid-twentieth century, certain distractions prevented its full blossoming. The financial and psychic cost of two world wars that came on either side of the Great Depression, the Dust Bowl, and the New Deal legacy of U.S. President Franklin Delano Roosevelt (employing economic stimulus practices such as the Civilian Conservation Corps that transformed nature in a dramatic and narrowly anthropocentric manner), in combination with the advent of urban sprawl and subsequent forms of pollution, had an impact on the land and served as distractions from the development of an environmental ethic distinct from anthropocentrism. Moreover, the institutionalization of conservation in bureaucracies such as the U.S. Forest Service/Canadian Forest Service, the U.S. National Park Service/Canadian Dominion Parks Branch, the U.S. Soil Conservation Service, and the U.S. Bureau of Reclamation all meant that the North American political economy proved most influential in shaping national environmental policies and practices in both the United States and Canada. The emphasis on resourcism in Canada tended to go unchallenged even longer than was the case in the United States. At the same time, however, the science of ecology was emerging and beginning to influence and alter environmental discourse. This fusion of science and ethics soon would manifest itself in powerful and far-reaching ways.

1955 TO 1970

In the early 1950s a near replica of the battle over Hetch Hetchy Valley occurred at Echo Park within Dinosaur National Monument in Colorado. This time, however, nature won and the dam was not built. The political compromise arising from the debate, though, allowed the construction of Glen Canyon Dam, effectively creating a conceptual cleavage between sacred lands (those within the national park system) and profane lands (those outside the system). This episode, which was fought in Congress and in the national media, marked a revival of wilderness activism and paved the way for an ascendant environmentalism with a focus on particular, local issues and problems.

Environmentalism was becoming a popular, as opposed to an exclusive, concern, at least among many middle-class white Americans. In fact, many people attribute the emergence of their personal environmental concern as well as the dawn of the environmental movement to Rachel Carson's *Silent Spring* (1962). Even though the DDT that the book warned of was not banned until 1972 in the United States and 1985 in Canada, Carson's warning about unrestrained alteration of and impact on the natural world triggered the popular perception that the environment was endangered and worth worrying about. Other debates, such as Paul Ehrlich and Barry Commoner's debate over whether human population or technological invention was the fundamental environmental issue, also helped popularize environmentalism. More than ever North Americans debated environmental questions publicly and began to challenge narrowly anthropocentric treatments of nature forcefully.

A number of legislative successes for environmental causes emerged from that popular concern. In 1963 (2006 in Canada) the United States passed the Clean Air Act. In 1964 the U.S. Wilderness Act was passed, which ultimately would preserve nearly 5 percent of the country (one-half of that in Alaska) as designated wilderness. The National Environmental Policy Act (NEPA) that was signed into law on January 1, 1970, required federal projects to prepare an environmental impact statement (EIS) cataloging expected effects along with various alternatives (the Canadian equivalent went into effect in 1995 and is known as the Canadian Environmental Assessment Act). NEPA also opened the EIS to a period of public comment, giving interested citizens an opportunity to voice their concerns and furnishing the opportunity for lawsuits to compel more environmentally ethical planning. In 1970 Senator Gaylord Nelson of Wisconsin formalized environmentalism as a popular and urgent matter by sponsoring legislation creating an annual Earth Day. Originally established as a day for "teach-ins" focused on environmental problems, it evolved into a celebration of ecological values.

Meanwhile, academia was witnessing a great change. Departments of ecology were springing up at universities all over the European and North American world, supporting research that could be and was being employed in defense of nature. With the dominance of the ecosystem concept, ecology also appeared to have arrived as a full-fledged and quantifiable science. After that period of explosive growth in North Americans' concern for and willingness to act on behalf of the environment, a variety of philosophically astute and environmentally conscientious philosophers and other academics began to get into the game.

1971 TO THE PRESENT

Environmental philosophy and ethics, along with a number of other environmental disciplines (from history to sociology, economics to literary criticism), emerged in the early 1970s. It can be said that North America, along with England, Australia, and Norway, has been a point of origin for the field of environmental philosophy and perhaps its epicenter. Impelled by the first Earth Day, J. Baird Callicott taught the first course in environmental ethics in the world in 1971 at the University of Wisconsin–Stevens Point. In 1979 Eugene Hargrove launched the discipline's first and still preeminent journal, *Environmental Ethics.* Although the University of Georgia took the early

Dinosaur National Monument, U.S. *Dinosaur National Monument is a part of the Uinta Mountains, sitting on the border between Colorado and Utah. In the 1950s, a plan was proposed to build a dam in Echo Park, in the middle of the monument. A nationwide campaign of protest prevented construction of the dam, and many consider this event as the start of a successful conservationist era.*

institutional lead as the seat of environmental philosophy, eventually the University of North Texas became the continent's and eventually the world's leading philosophy department focused on environmental philosophy. Pioneering Canadian environmental philosophers included Allen Carlson, Peter Miller, and Bob Jickling. Nearly every

North American university now teaches at least one course in environmental ethics (though not always in the department of philosophy), and many have at least one scholar who focuses on the field.

Between 1971 and 1979 philosophers interested in environmental ethics and philosophy worked in relative isolation from one another. By the time they began to discuss their work more publicly, various positions already had emerged. Those positions centered on the matter of who or what deserved direct moral standing and who or what merited only indirect moral standing. The seemingly dominant way to discuss this topic was in reference to who or what had intrinsic value and why. There are dozens of textbooks, five or six journals, thousands of articles, and hundreds of books in the field. Moreover, there are a few graduate degree programs in environmental philosophy, undergraduate majors, and related university programs and courses featuring the works of environmental philosophers. Environmental philosophers also have begun to infiltrate conservation science in various ways.

This period also marked the beginning of what might be called the second wave of the environmental movement, beginning in the mid-1980s. That wave had a much more global and systemic focus than its predecessor, concentrating, for example, on issues such as the precipitous loss of biodiversity and the impending sixth great extinction, stratospheric ozone depletion, acid rain, social justice and human rights, and rapid global climate change as much as it did on more local forms of environmental harms. Old distinctions such as that between conservation and preservation no longer seemed to fit or make sense, although some people still employed them.

At the same time, clearly prompted by environmental philosophies such as Deep Ecology, environmental activism became much more radicalized with activist groups such Earth First!, whose motto was "No compromise in defense of Mother Earth," and Greenpeace, a Vancouver-based organization that grew to have more than 2.5 million members. Environmental politics also became more polarized as the result of some profound shifts in values. The U.S. (1973) and Canadian (1996) endangered species acts, for example, represent a significant moral shift suggesting that species and other categories of animal populations merit direct moral standing and deserve to exist for their own sake, apart from the impact they may or may not have on more narrowly conceived human economic interests. Dramatic and ongoing battles over owls, wolves, grizzly bears, and salmon have been the direct result of, among other things, this philosophical and ethical change.

A number of current and near future topics promise to occupy North American environmental philosophy in the coming years. Although historically an exceptionally relevant and respected discipline, philosophy took a turn toward specialization in the twentieth century and, in the opinion of some people, lost some of its relevance and influence. Many environmental philosophers, however, seek to make their work relevant to science and policy. Although it holds great promise, this renewed commitment to relevance and interdisciplinarity will continue to present a challenge to environmental philosophy. Making a commitment to relevance and thinking of ways to account conceptually and ethically for the moral relevance of human and nonhuman individuals as well as the environmental collectives that serve as the focal point of much contemporary environmental concern and navigate between the good of each when they are in conflict are issues that present another challenge to environmental philosophers. Finally, working to craft philosophical and ethical systems that account for the dominant ecological paradigm focused on flux and change presents a particularly difficult problem for environmental philosophy and for much of environmental discourse.

NORTH AMERICAN FREE TRADE AGREEMENT

The North American Free Trade Agreement (NAFTA) between Canada, Mexico, and the United States entered into force in January 1994 after three years of negotiation and extensive public debate. Canada and the United States had established the Canada-U.S. Trade Agreement (CUSTA) in 1989, so the new arrangements involved the addition of bilateral agreements between Canada and Mexico and between the United States and Mexico. The primary purpose of any trade agreement is to reduce barriers to trade with the expectation that trade liberalization will contribute to greater economic growth and prosperity. Trade is one element of the general process of globalization along with capital flows (foreign investment), migration, cultural and religious exchanges, and others. Because trade and other forms of economic integration contribute to economic growth, they have an impact on human well-being and the use of natural and environmental resources. This impact in turn means that trade and globalization have ethical dimensions related to distributive justice, the rights of future generations, and the integrity of ecosystems. The implications of trade liberalization and globalization for the environment have been the subject of intense debate since the 1980s; the political controversy surrounding NAFTA has helped to crystallize various positions on these issues.

There are two general approaches to trade liberalization. Multilateral trade liberalization is carried out by the 152 countries that belong to the World Trade Organization (WTO) through negotiation and private judicial proceedings aimed at resolving trade disputes. Multilateral agreements in the context of the WTO are based on the requirement that member countries treat all other members in the same fashion. In contrast, regional and bilateral agreements, the other approach to trade liberalization, are discriminatory. NAFTA is a regional trade agreement in which lower trade barriers are extended by each member only to the other members, each of which is free to pursue whatever trade policies it wishes with nonmembers. More ambitious regional agreements such as the European Union (EU) require harmonization of trade policies by the members as well as other measures to free up the movement of capital and labor.

David Vogel (2000) suggests that increasing environmental regulation in the 1970s and 1980s, along with rapid growth in trade and a rising number of trade agreements, led to tensions between environmentalists and advocates of free trade. Those who favor trade liberalization worry that environmental regulations will become de facto trade barriers, whereas environmentalists fear that progress in protecting the environment will be undermined as firms either relocate to countries with lax environmental standards (sometimes referred to as "pollution havens") or use the threat of job losses to push the government to lower standards in the name of competitiveness. Environmentalists also note that trade itself is polluting as energy and other resources are used to carry out international shipping, which may also spread invasive species and other forms of pollution. Trade advocates point out that concern for the environment tends to increase as a country's standard of living rises; they further argue that, because trade contributes to rising living standards, trade agreements actually encourage the development of better environmental policies.

NAFTA went further than most free trade agreements in its inclusion of provisions on capital flows (investment) and the environment. Mary Tiemann (2000) notes that national technical standards related to the environment were expressly allowed by the agreement, which also subordinates its provisions on trade liberalization to international environmental agreements on the ozone layer, hazardous waste, and trade in endangered species. Despite

these provisions the debate leading up to the ratification vote in the United States was contentious, and President Bill Clinton elected to introduce side agreements on the environment and labor to increase the likelihood that Congress would approve the agreement. The North American Agreement on Environmental Cooperation (NAAEC) and the North American Agreement on Labor Cooperation (NAALC) were ratified along with NAFTA in late 1993.

The principal goal of the NAAEC is to ensure that the three governments actually enforce their environmental regulations. It also aims to promote cooperation on environmental issues and increased environmental safeguards. The organization created to oversee the agreement is the Commission for Environmental Cooperation (CEC), based in Montreal. The CEC is an international organization with several special features. First, in addition to a council made up of representatives from national governments, nongovernmental organizations (NGOs) can participate in its operations through membership in the joint public advisory committee. Further, individual citizens have the right to submit complaints to the CEC secretariat that a country's environmental laws are not being enforced, which reviews the complaint and provides technical information to the council, which adjudicates the case. The focus of the CEC is on air and atmosphere, biodoversity, pollutants, and water. The CEC has also been working on devising methods to measure the environmental impact of NAFTA in particular and, beginning in 2003, of trade in general.

Assessing the environmental impact of NAFTA is complicated because so many other events occurred as NAFTA was being implemented. Some observed changes that have taken place since NAFTA went into effect may have been caused or influenced by NAFTA, but many more would have happened even if NAFTA had not been approved. For example, based on data available from the Energy Information Administration (2008), North American greenhouse-gas emissions increased by more than 17 percent between 1993 and 2005. NAFTA probably played little if any role in this change, which was driven primarily by the energy and environmental policies of the United States, the producer of some 85 percent of North American greenhouse-gas emissions.

In addition to NAAEC, there are several agreements between the United States and Mexico directed at monitoring and controlling pollution along the border between the two countries. Chantal Carpentier (2004) and Vogel (2000) both conclude that cross-border trade under NAFTA has had a minor impact on the environment. Unfortunately, the various environmental agreements adopted in conjunction with NAFTA do not appear to have had positive impacts on the environments that were expected, perhaps because they have been underfunded by the three governments. But these arrangements do lay the groundwork for increased environmental cooperation in the future, and the innovative structure of the CEC holds out the possibility for extensive citizen participation in attaining important environmental goals.

NORTON, BRYAN

1944–

Bryan Norton was born on July 19, 1944, in Marshall, Michigan. He is best known in the field of environmental ethics for his rejection of nonanthropocentrism—a philosophical worldview in which nonhuman nature is treated as an object of independent moral concern—and challenging the view that an adequate environmental ethic must acknowledge intrinsic natural value and direct moral duties to nature. Norton has been the leading figure in the "pragmatist wave" that began in the mid-1990s, and his work is also significant for its practical, policy orientation and interdisciplinary character. He is among a handful of environmental philosophers who have expanded the intellectual universe of environmental ethics to incorporate disciplines in the natural and social sciences, including conservation biology, environmental economics, and environmental policy and management.

EARLY WORKS

As with most philosophers whose writing shaped the field during its first two decades, Norton's interest in environmental philosophy developed well after his graduate studies in the philosophy of language, science, and epistemology at

the University of Michigan, where he received a doctorate in 1970. At Ann Arbor he wrote a dissertation on the metaphilosophy of Vienna Circle philosopher Rudolf Carnap; that work later resulted in Norton's first book, *Linguistic Frameworks and Ontology* (1977).

Norton's career in environmental ethics and philosophy can be traced from its beginnings in environmental value theory in the 1980s, to a growing emphasis on epistemological issues (especially justification) in the late 1980s and early 1990s, to its later focus on language and the pragmatics of environmental communication. His first publications in the journal *Environmental Ethics* (Norton 1982, 1984) focused on the rights of nonhumans and future generations; the philosophical problems afflicting both positions led him to conclude that rights-based approaches in environmental ethics are not viable.

Norton was skeptical about environmental philosophers' emerging focus on the intrinsic value of nature, which he felt was both philosophically flawed and politically unnecessary. Accordingly, in the mid-1980s he developed "weak anthropocentrism," an approach that did not require the recognition of the intrinsic value of nature (Norton 1984). Norton described weak anthropocentrism as accommodating a broadly instrumentalist and pluralistic theory of environmental value within a humanistic worldview. His argument emphasized the role of nonhuman nature as a teacher of human ideals and a good shared between present and future generations. Weak anthropocentrism thus was positioned as a moderate alternative to both narrow forms of economic valuation ("strong anthropocentrism") and nonanthropocentric, intrinsic-value-of-nature arguments.

Norton continued to develop this line in his 1987 book *Why Preserve Natural Variety?*, which surveyed the range of economic and ethical options for valuing species and ecosystems (biodiversity). In that book Norton presented the concept of "transformative value" as the normative core of weak anthropocentrism. Contact with wild species and ecosystems could, he argued, prompt individuals to evaluate critically and transform their exploitative, consumer-centered preferences into more environmentally benign ideals compatible with an ecologically enlightened worldview (Norton 1987). The significance of his argument was that one could justify the protection of endangered species and ecosystems on anthropocentric grounds while steering clear of both economistic and nonanthropocentric arguments.

LATER WORKS

In the 1990s Norton's weak anthropocentric stance evolved into a more explicitly pragmatic approach to environmental philosophy. As early as 1988 he tapped into pragmatism in his 1988 contrarian reading of Aldo Leopold, author of *A Sand County Almanac*. Norton argued that Leopold subscribed to an informal pragmatist epistemology and theory of environmental value, an interpretation that went against the dominant reading of Leopold as perhaps the major nonanthropocentrist in the history of environmental ethics (Callicott 1989, 1999).

Norton's writing assumed an increasingly strong policy focus in the 1990s. Among other things, that orientation led him to reverse the traditional logic of applying philosophical principles to practical problems in favor of a greater emphasis on the problems themselves. That approach appeared in *Toward Unity among Environmentalists* (1991), in which he described an emerging policy consensus among environmental activists—in short, support for multivalue, sustainable ecosystem management—that existed despite disagreements over deeper environmental values and motives. In *Toward Unity,* Norton concluded that the anthropocentric-nonanthropocentric debate in environmental ethics was not as important as previously thought because it did not thwart political agreement on common policy goals. Termed the convergence hypothesis, Norton's argument proved controversial, attracting rebuttals from a number of nonanthropocentrists (Minteer 2009).

Later in the 1990s Norton's work continued to explore a range of philosophical and policy questions, including the relationship between economic and pragmatic approaches to environmental valuation, the role of ecological science in the policy process, and analyses of ecosystem health, biodiversity, and sustainability (Norton 2003). His 2005 book *Sustainability: A Philosophy of Adaptive Ecosystem Management* marked a return to the analytical pragmatism of Carnap that Norton had explored early in his career. In *Sustainability,* Norton proposed an integrated scientific and value discourse for discussions of sustainability across the environmental science, policy, and management domains. In doing so, he reframed environmental problems as linguistic failures rather than ethical ones, in the process setting a new agenda for environmental philosophy in the pragmatics of language and communication.

NUCLEAR POWER

When the nucleus of an atom is divided or joined to another nucleus, an enormous amount of energy is produced. When these processes of fission (division of the nucleus of an atom) or fusion (joining the nucleus of an atom with another) take place under controlled conditions, this energy can be used to drive turbines that can do work: for example, to propel a large vehicle such as a ship or to generate electricity. These same processes, however, can be adapted to produce weapons with massive destructive power. Nonmilitary uses of *nuclear power* refer to the generation of energy through a controlled process of fission in a nuclear reactor.

NUCLEAR POWER THROUGHOUT THE WORLD

According to figures of the Power Reactor Information System (PRIS) of the International Atomic Energy Agency (IAEA), an independent international organization that was established in 1957 to promote the safety and security of the peaceful use of nuclear science and technology, there were at the beginning of 2008 a total of 439 nuclear power plants in operation in the world in 30 countries, with a total net installed capacity of 372,202 Gigawatts. At this time, there were also five nuclear power plants in long term shutdown, whilst 34 nuclear power plants were under construction (IAEA 2008). At the end of 2006, there were 103 licensed nuclear power plants in the United States located at 65 sites, predominantly situated in the eastern half of the country. As of 2008, about 20 percent of the electricity used in the United States is generated by nuclear reactors, placing nuclear power second to electricity generated by coal (IAEA 2003a: 7-9; IAEA 2007a). In comparison, over 78 percent of the domestic energy production in France comes from its 59 nuclear reactors (IAEA 2007a). Other countries with relatively large numbers of nuclear reactors include Japan (with 55 operational nuclear reactors that generate 30 percent of its electricity), Russia (with 31 reactors that generate about 16 percent of its electricity), South Korea (with 20 reactors that generate about 39 percent of its electricity), the United Kingdom (with 19 reactors that generate just over 18 percent of its electricity), Canada (with 18 reactors that generate about 16 percent of its electricity), Germany (with 17 reactors that generate about 32 percent of its electricity), and Ukraine (with 15 reactors that generate 47.5 percent of its electricity) (IAEA 2007a).

In its *Annual Report 2006*, the IAEA (2007b: 3) points out that about three-quarters of the world's operating nuclear reactors are 20 or more years old. Since the life span of a nuclear reactor is between 20 and 40 years, depending on the type of technology and design used, it can be expected that decisions about decommissioning a large number of nuclear plants, as well as investing large sums of money to replace these reactors will have to be made over the next two decades. The British government already announced in January 2008 that up to 10 new nuclear reactors will have to be built in the United Kingdom by 2020 in order to replace those that need to be decommissioned. Similarly, Russia announced in March 2008 that it will put four new nuclear reactors into operation by 2020.

In the United States, no new nuclear power plants have been ordered since the late 1970s, since the anticipated growth in electricity demand slowed, and nuclear construction costs soared. The nuclear accident at Three Mile Island in 1979 strengthened the reluctance of utilities to further invest in nuclear reactors. Instead of ordering new reactors, the current trend in the U.S. is rather to increase the

Nuclear Plant near Berwick, Pennsylvania. *The use of nuclear power is becoming increasingly popular as a replacement for fossil fuels becomes more and more necessary. Proponents also cite the cheap cost of production and lack of carbon dioxide by-products as other reasons in support of nuclear power. However, the drawbacks of nuclear power in terms of safety and health can be seen in such instances as the Chernobyl disaster.* **AP IMAGES.**

efficiency of existing nuclear plants. The last new reactor (Watts Bar 1) was completed in 1996 (IAEA 2003a: 6-9). Most of the reactors that are currently under construction, or recently completed, are located in developing countries such as China, Russia, South Korea, and India.

THE BENEFITS AND DRAWBACKS OF NUCLEAR ENERGY

All commercial nuclear power plants generating electricity make use of fission technology, of which there are many varieties; the commercial use of fusion reactors is projected to become a reality only in forty to fifty years. Because nuclear fuel releases exponentially greater amounts of energy than that produced by chemical fuels, and because this fuel (usually uranium^{235}) is abundant and therefore relatively cheap, many policy makers view nuclear power as an attractive option for the provision of a steady supply of energy for the world's economy as the price of fossil fuels continues to rise. These proponents of nuclear power point to two other key advantages of nuclear power: It emits almost no carbon dioxide, one of the major greenhouse gases that have contributed so heavily to global climate change; and renewable energy sources like wind, the Sun, and waves are, in their present state of development, unable to replace fossil fuels.

The main concern of critics of nuclear power is that the by-products of fission are radioactive, and some of them remain so for hundreds of thousands of years. High doses of exposure to radioactive by-products can cause a variety of cancers and genetic deformities. Hence the generation of nuclear energy poses two major safety issues: the permanent disposal of nuclear waste and the operation and decommissioning of nuclear reactors. These concerns are not merely hypothetical: Widespread radioactive contamination resulted from the partial reactor meltdown in 1979 at Three Mile Island in Pennsylvania and from the 1986 disaster in Chernobyl, in Ukraine, which led to the evacuation and resettlement of more than 200,000 people. The risk of exposing present and future generations to unsafe levels of radioactivity is at the core of the political and ethical controversies that surround the use of nuclear energy.

THE MILITARY CONTEXT OF NUCLEAR ENERGY

The first fission nuclear reactors were built in the United States in the early 1940s. They were the product of research conducted by the Manhattan Project (1942–1946), a top-secret program (funded mainly by the United States with help from the United Kingdom) that met its goal of creating the world's first nuclear weapon in 1945. The military origins of nuclear energy are never far from the minds of its critics. Although touted by its champions as a purely peaceful, nonmilitary application of atomic energy, the use of nuclear power poses the risk that plutonium—one of the by-products of nuclear fission—can find its way back from civilian nuclear plants to military applications, thus contributing to the problem of the proliferation of nuclear weapons. With the emergence of so-called rogue states and increasing concerns about global terrorism since the attacks of September 11, 2001, the issue of nuclear proliferation has acquired renewed urgency, as reflected in the search for weapons of mass destruction in Iraq and the monitoring of nuclear programs in Iran and North Korea. Concerns have also arisen about the possibility that terrorist groups might acquire and use a dirty bomb, a "radiological dispersal device" (RDD) that spreads radioactive material with a conventional explosive, such as dynamite.

DEBATES OVER NUCLEAR ENERGY

Given the controversies that swirl around the use of nuclear energy, its future remains cloudy. Since the initial use of nuclear power for civilian purposes in the 1950s, a sociopolitical and ethical debate has raged, centering on the issues of operational safety, costs, permanent disposal of waste, and the risk of proliferation. These debates are dominated by two central questions: (1) Do the benefits of nuclear power outweigh its risks and costs? (2) What principles should guide decision making about nuclear power?

The first question usually elicits utilitarian answers on both sides: Proponents contend that even with all risks and costs considered, the widespread implementation of nuclear power would be a net gain for society; opponents argue that the long-term health and ecological risks are so dire that renewable energy sources are preferable. Both sides of this utilitarian cost-benefit analysis quote facts and figures, often citing sympathetic scientific authorities. Supporters of nuclear power such as the World Nuclear Association (WNA) typically claim that it will provide us with an endless supply of energy, that it is cheap, that it is safe if managed properly, that the problem of long-term storage of high-level nuclear waste will be solved in due course, that we do not have any viable alternatives to provide the energy needs of both industrialized (developed) and developing countries, and that it could help us to reduce emissions of greenhouse gases in the fight against global climate change (World Nuclear Association 2008). It is not just major lobbying groups such as the WNA who are pushing for this form of power—even some notable environmentalists, such as Greenpeace cofounder Patrick Moore, have done an about-face on the question of nuclear energy, viewing it as the only technologically feasible alternative to fossil fuels. He writes that "nuclear energy may just be the energy source that can save our planet from another possible disaster: catastrophic climate change" (Moore 2006).

Quoting different facts and figures, opponents of nuclear power (of which the various reports of Greenpeace [2008] or the Heinrich Böll Green Political Foundation [2008] are examples) typically claim that uranium mining is environmentally destructive and makes use of carbon-intensive technologies; that nuclear power is not safe; that it generates high-level waste that will need long-term management, even with underground burial facilities (geological disposal); that nuclear power is much more expensive than it is claimed to be if the costs of decommissioning of plants and the management of long-term waste storage are included; that nuclear power is economically viable only through direct or indirect state subsidies; that nuclear power exposes the world to the risks of radioactive materials and proliferation; and that nuclear power is not the solution to the challenge of climate change.

The irony is, however, that although this emphasis on quantifiable costs, risks, and benefits is highly important and revealing, the utilitarian debate about nuclear power has fallen into gridlock for a very long time now, with neither side able to convince the other of the merits of its arguments.

NUCLEAR ENERGY AND DECISION THEORY

A similar standoff has resulted from debates about what kind of principles should inform decision making about the development, use, maintenance, and management of nuclear power. Kristin Shrader-Frechette, in her critical analysis of the nuclear industry and its historical evolution (in which she has also contributed substantively to a critical analysis of quantitative risk assessment), argues that typical forms of governmental decision making about nuclear power run against the grain of the principle of prima facie political equality (1983a, 1983b, 1993, 2002). Instead of following the democratic principles of procedural justice and informed consent, nuclear power decisions usually exemplify a heavy-handed, top-down, authoritarian approach, dominated by secrecy and even deception. She seeks to demonstrate that such procedures engender environmental injustices that single out already

marginalized members of society, disproportionately exposing them to the risks of nuclear power while insulating those who benefit from it. A hypothetical example of such injustice would be to offer a very poor, drought-stricken country in sub-Saharan Africa the option of establishing several nuclear waste storage facilities within its borders with a view to stimulate the local economy.

Shrader-Frechette's approach clashes head-on with that of nuclear-power advocates who argue that the confidentiality of energy deliberations is a nonnegotiable principle because national security is at stake; strategic decisions about the provision of energy cannot, therefore, be exposed to public questioning and scrutiny. Such considerations, they believe, justify their rejection of appeals to incorporate measures of open discussion and deliberative democracy in decisions about nuclear energy.

This deadlock shows that further analyses are needed to gain an understanding of channels through which ethical issues related to nuclear power can be better understood and resolved. There have been promising contributions in these areas from the philosophy of science and sociology. Philosophers of science have focused on the relationship between science and technology, particularly on how conceptions about the nature of science can influence—indeed, have influenced—policy decisions about technology development, management, and use. Prominent examples of this approach are found in the work of Robert Frodeman, Carl Mitcham, Christine Turner, and Roger Pielke who show that a simplistic, positivist account has fostered the notion that science works with nothing but unequivocal empirical data and the logical conclusions that follow from them. From this view it follows that deliberations about the significance, use, and applications of science are left to politicians and managers, who eventually decide which technology-development paths should be followed or avoided.

Pielke (2003) points out the irony that, within this decisionistic model, so-called value free science is called upon by decision makers to provide objective facts on the basis of which policy choices can be made. Science is thus invoked to justify policy choices, but only by precluding public discussion of these choices on the grounds that the policies are portrayed as indubitable (scientific) truths. Within the nuclear debate this appeal to the inherent objectivity of science has been used in the past to settle policy issues (for instance, the very choice of adopting nuclear power as a source of energy) without a thorough discussion of the manner in which nuclear technology affects the values of society.

Some scholars propose a different conceptualization of science, one that views it as a social institution, not merely as an insular domain of objective truth. They argue that science affects society in ways that cannot be fully portrayed and assessed by science itself. Accordingly, they argue for a reconceptualization of the relationship between science and policy making, one that takes cognizance of the uses to which science can be put by various societal interest groups. Appeals to science itself often cannot settle disputes between these groups (Sarewitz 2000). Hence there is a need for a constant critical assessment of all claims about the significance and policy implications of science.

Pielke (2003) argues that scientists should actively participate in this process of assessment, whereas Frodeman and Mitcham (2007) introduce the notion of a broad, deep, and critical interdisciplinary approach that fosters collaboration among scholars from the sciences, social sciences, and humanities. They hope to encourage such cooperation not only by asking the "fundamentally humanistic question of what counts as *pertinent* knowledge: Knowledge for what?" but also by describing and assessing the values of society "as it struggles to address questions of social and environmental justice, human freedom and responsibility, and the proper roles of the public and private sectors." An example of such an interdisciplinary approach to nuclear power can be found in the work of Turner and Frodeman (1995), which combines the resources of philosophy and geology in asking how the proposed Yucca Mountain site for the permanent disposal of nuclear waste can be evaluated by the criteria of both science and social values (Frodeman 1995).

Frodeman and Mitcham (2000) have proposed the integration of science and the common good through a process of critical public conversation. Critics of their work have argued that it neglects the power dynamics at play in deep ethical differences about issues such as nuclear power or the permanent disposal of nuclear waste (Rouse 2000). Frodeman and Mitcham's later work on interdisciplinary approaches to these issues does critically address the power relations underlying such differences (2007).

Sociological perspectives on the "social, institutional and technical processes through which technologies become constructed, enacted and maintained" (Irwin et al. 2000, p. 81; Jasanoff et al. 1995) indicate a pathway that can be further explored to engage with some of the power relations that are implicit in any public conversation. Alan Irwin focuses on the discourse used by authoritative speakers to establish and maintain confidence in civilian nuclear power—even in the face of severe obstacles such as major nuclear accidents. He examines the justification of nuclear power (a) in a discourse of modernity in which nuclear power is portrayed as one of the first manifestations of Big Science and thus inevitably constitutes social progress; (b) in technical arguments based on the assumption that any technical problems will surely be ironed out by advancing scientific understanding (which means that nuclear "accidents can be dismissed as part of

the technological learning curve or else viewed as a consequence of non-scientific design choices''); (c) in a view of the environment ''as resilient and robust in the face of radioactive contaminants provided emissions are kept at a 'reasonable level'''; and (d) in the opinion that the acceptability of risks can be determined objectively and rationally on quantitative scales that function independently from institutional processes and particular contexts (Irwin et al. 2000, pp. 82–83).

Perhaps these critical perspectives from the philosophy of science and sociology will fail to find a receptive audience among real-world decision makers. But faced with the specters of global climate change and rising prices for ever scarcer fossil fuels, these officials will be searching for grounds on which to decide whether to replace aging nuclear plants with newer ones or to turn instead toward heavy investments in research into renewable energy technologies. The contributions of philosophers and sociologists can help to shift the debate about nuclear power from utilitarian arguments about its costs and benefits to dialogues about the form of rationality at work in science and policy making—perhaps even to public conversations between decision makers and the citizenry that can self-consciously and critically consider the impact of policy choices on the values, aspirations, and ideals of society.

O

OCEANS

The oceans, which cover about 71 percent of the surface of Earth, are composed of a great variety of life-filled habitats that range from the dark and cold of the deep ocean-floor trenches to the sunlight and warmth of tropical lagoons. The oceans support a tremendous degree of biological species diversity and account for just less than half of annual carbon fixation via photosynthesis. The great volume of ocean water absorbs carbon dioxide, oxygen, and other gases as well as heat from the Sun. Major currents such as the Gulf Stream and the Humboldt Current circulate both warm water and cold water across the face of the planet. Marine environments are thus critical to the composition of the atmosphere, the production of weather, and the long-term regulation of climate. Humans always have utilized marine resources ranging from edible algae, to cleansing sponges, to whale oil, to petroleum pumped from offshore platforms. Travel across the ocean surface is integral to the international shipping of goods. Coasts are prime locales for recreation, such as surfing and snorkeling. Humans have evolved unique maritime cultures, with art, myth, technology, and even religion focused on the sea.

RELIGIOUS AND MYTHIC TRADITIONS

In Middle Eastern and European myths the oceans are critical to primordial creation events. The opening chapter of Genesis gives aquatic and marine environments priority in the narrative of creation as God's spirit "moves over the face of the waters" (Genesis 1:2). God closes the separation of the land from the waters by declaring the physical structure of the emerging planet to be "good" and, by using the Hebrew word *tob* ("beautiful"), granting the oceans inherent worth. The ancient world associated the oceans with chaos, mystery, and uncontrolled physical force. The story of Noah's ark is one of many variants of the flood myth in cultures worldwide that describes the oceans exceeding their boundaries and serving as agents of divine displeasure or universal social reorganization.

In Greco-Roman cosmology water is one of the four basic elements, along with earth, air, and fire. The capricious and temperamental deity of the oceans, Poseidon or Neptune, although rewarding sailors who respect him with fair winds, often invokes his physical power, causing storms and other disasters. In ancient Roman art, sea monsters were associated with chaos, whereas dolphins symbolized rescue and therefore religious salvation or the afterlife. In the religions of eastern and southern Asia the oceans also convey universal values, such as the vastness and depth of the Buddha. Ancient Greco-Roman and biblical conceptualization of the oceans strongly influenced Western philosophical and literary perceptions until the modern era.

Regional religions, especially those of cultures dependent on oceanic resources, often personify sea creatures and emphasize their organic productivity. In the *Kumulipo,* a chant recounting the Hawaiian creation myth, the coral polyp, a keystone species of tropical reefs, is the first creature born of the divine pair of primary deities, Kumulipo and Po'ele. The *Kumulipo* describes the faunal diversity of the reef, including fishes, turtles, lobsters, and other invertebrates, such as starfish, sea cucumbers, limpets, and

mollusks. The impressive inventory classifies marine life by similarity of form and by habitat.

Tribes of the Pacific Northwest treated salmon as a separate animal society, with their villages situated beneath the waves. Regional religions often deify marine phenomena such as tidal waves and marine organisms such as sharks and whales, which also may serve as family or clan totems. Cultures dependent on oceanic resources utilize laws and rituals to guide the management of marine harvest. The cultures of the Pacific Northwest have a First Fish ceremony, which precludes the harvesting of salmon for several days at the beginning of an upstream run, ensuring the escape of an adequate number of spawning adults to replenish the stocks.

THE HISTORY OF MARITIME MANAGEMENT

The ancient Greeks were the first western philosophers to consider the oceans, and Aristotle (384–322 BCE) wrote treatises on the biology and diversity of marine organisms. Before the twentieth century, however, philosophical ethicists usually did not treat the oceans as a separate topic and thus wrote little that specifically concerns marine issues. Much of the intellectual tradition concerning the oceans is the product of legal thinkers such as Hugo Grotius, who in 1625 published *Mare Librum*, which argued for international freedom of the high seas for the shipping trade and other commercial uses. During the twentieth century the implementation of treaties and conventions concerning harvesting and environmental care of the oceans greatly expanded. Some early efforts in multinational cooperation include the North Pacific Fur Seal Treaty (1911), which restricted harvesting of both fur seals and sea otters; the Migratory Bird Treaty (1918), which regulated the capture, transport, and sale of migratory birds such as waterfowl; and the International Convention on the Regulation of Whaling (1946), which restricted the harvesting of whales and established the International Whaling Commission.

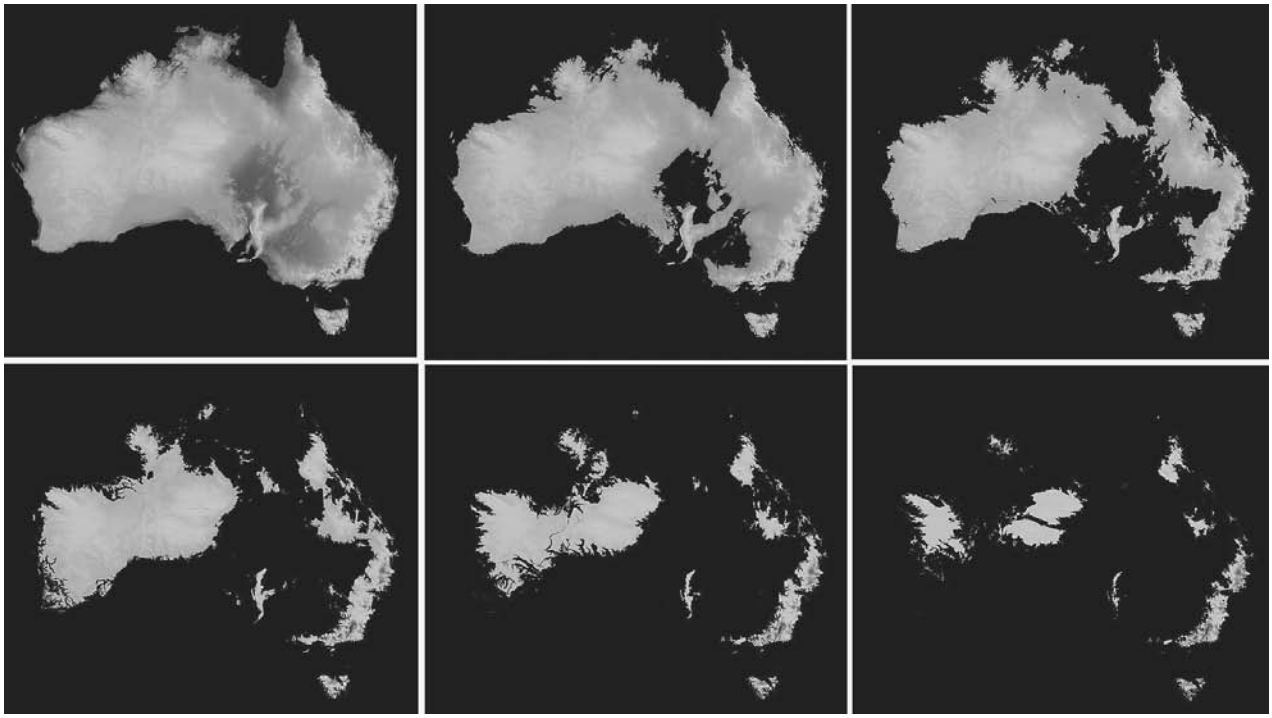
The regulatory trend since the 1970s has been toward negotiating conventions and agreements for managing specific regions such as the Mediterranean, protecting the high seas from destructive activities such as the dumping of radioactive waste, and expanding national jurisdictions farther offshore. A particularly influential instrument is the United Nations Convention on the Law of the Sea (UNCLOS III) of 1982, which has tied the right to manage the seas to responsibility to protect their biotic and environmental resources and encouraged individual countries to manage the adjoining continental shelves. Before World War II most nations claimed exclusive jurisdiction over three to six nautical miles of ocean contiguous to their shorelines. Since that time many nations, including the United States, have claimed Exclusive Economic Zones of two hundred nautical miles.

ENVIRONMENTAL ETHICS AND THE SEA

One of the first ethical models applied to fisheries in response to the environmental movement of the 1960s was Garrett Hardin's tragedy of the commons, which describes the human tendency to overutilize commonly held resources. Before the modern period the high seas were treated as common property, open to any nation able to send ships to harvest from them. That resulted in the depletion of a number of species of marine mammals, including the Atlantic gray whale and Steller's sea cow, both now extinct, and all three species of right whales, which are endangered. Hardin's model suggests not just regulating resource extraction but requiring those utilizing ocean resources to contribute to their care and management, a value reflected in UNCLOS III.

More recently the philosopher J. Baird Callicott (1992) proposed extending the principles of Aldo Leopold's land ethic to the oceans. This model encourages humans to view themselves as participants in the ocean community and recognize the inherent value of the living organisms that inhabit the seas. In 2004 Susan Bratton suggested using Rachel Carson's writings on the oceans to develop an ecotonal ethic of the oceans that compensates for human perceptual limitations in understanding ocean processes and ecosystems. The oceans present a suite of environmental issues that differ from those on land because of the prevalence of public domain, the limited exploration of the deep seas, and the international nature of ocean conservation. Recent volumes dedicated to ocean values include L. Anthea Brooks and Stacy VanDeveer's *Saving the Seas* (1997) and Dorinda Dallmeyer's *Values at Sea: Ethics for the Marine Environment* (2003). Since the 1970s academic dialogue and publication concerning ocean ethics have been oriented increasingly toward specific cases, four of which are discussed below.

Shoreline Development and Sea-Level Rise A major source of damage to inshore ecosystems such as those of barrier islands, tidal marshes, inlets, and coral reefs is the human attempt to stabilize the inherently dynamic boundary between the oceans and the land. Protection of docks and channels is of course necessary to shipping and international commerce. When they are not interfered with, natural processes such as major storms and long-term changes in climate restructure and relocate shorelines as sea levels rise and fall. Contemporary archaeologists find the remains of ancient cities and settlements below the current tide line.



Projection of Australia as Sea Levels Rise. *In this series of images, U.S. geographer Stephen Young has calculated how the Australian continent would appear if the seas were to rise by increments of 100 meters (a total of 500 meters in the final image). Such a rise in sea levels would transform Australia from a massive continent into an archipelago of smaller islands.* **STEPHEN YOUNG/SALEM STATE COLLEGE VIA GETTY IMAGES.**

At the height of the continental glaciations, ending about 18,000 years ago, shallow-water regions currently below the low tide line, such as part of the Irish Sea, were above sea level. This former terrestrial zone was flooded slowly as the glaciers melted. In the contemporary period accelerated changes in global climate and atmospheric change resulting from the use of fossil fuels and land clearing are speeding the recession of the ice caps; thus, sea levels are continuing to rise, threatening to flood many low-lying coastal regions, such as the coasts of Florida, the Polynesian islands, and much of Bangladesh. Aside from climate change, storms, tsunamis, and other disturbance events continually re-form coastlines through the processes of erosion and deposition. Hurricanes, typhoons, and other major weather events can move great volumes of material, overwashing barrier islands, cutting shorelines back many meters, and flattening entire dune systems. On Cape Hatteras, North Carolina, for example, one major storm can fill an inlet across the islands, leaving a bridge spanning sand flats while cutting through roads and forming new inlets completely across the islands at other locations.

Preindustrial cultures usually avoided permanent construction on unstable shorelines, elevated buildings above flood levels, or occupied beaches by using temporary camps and portable infrastructure. The demand for permanent facilities for industry served by paved roads and the development of recreational or seasonal residences within an easy walk of the ocean have made modern coastal communities vulnerable to severe damage and financial loss from both sea-level rise and storm-induced flooding. The sprawl and inflated land values of modern coastal cities also encourage construction on high-risk properties.

When Hurricane Katrina flooded New Orleans in 2005, the older portion of the city, established on higher ground, avoided complete inundation because of its elevation. Wards at lower elevations were under several meters of water, causing major loss of life and billions of dollars of property damage. New Orleans, with its hurricane-breached levees, is also a lesson in the difficulty of protecting coastal municipalities with artificial barriers. Immobile sea walls such as the one in Galveston, Texas, offer little protection from the most severe storm surge while disrupting the natural process of sand deposition, which provides the buffer zone between land and sea.

The current engineering solution to eroding shorelines is often to dredge millions of cubic meters of sand from the ocean bottom and ''nourish'' the beaches. The dredging damages ecosystems on the ocean bottom.

Many of the major sand deposits are of Pleistocene origin and are not being replenished, and so beach nourishment may not be a long-term solution, at least in terms of current geologic resources. Global climate change, especially if the primary trajectory is toward warmer temperatures and the melting of the glacial ice sheets, will increase the impacts of storm surge and coastal erosion caused by sea-level rise. Some scientific models also conclude that cyclonic storms of oceanic origin will have greater average intensity.

The issues presented by shoreline change include whether some natural environments should be exempt from human development, at-risk coastal environments should remain in the public domain, and governments should prevent development in coastal areas with a high risk of flooding. Ethicists have invoked the precautionary principle in the case of beaches known to be dynamic. Coastal regulations may require buffer zones or exclude highly unstable sites from construction. Barrier islands, for example, have high value for recreation and protect mainland shorelines from wave damage. The designation of Cape Hatteras and Cape Lookout as U.S. National Seashores has made those areas accessible to the public while reducing storm-inflicted property damage. The concept of sustainable energy production based on renewable energy is a concrete approach to the issue of accelerated sea-level rise because a reduction in emissions of greenhouse gases would slow global climate change.

Fisheries and Harvest of Marine Life Humans long ago discovered that inshore marine resources such as coral reefs are easily overexploited. Polynesian cultures have chiefs who regulate the taking of reef resources and enforce the seasons for the harvesting of different species as well as the numbers and sizes of the organisms removed. Tribes and nations have fought wars over access to lucrative fisheries, such as those for salmon and cod. Industrialization has increased the human capacity to deplete marine fisheries. When engine-powered craft and winches began to displace fishing with hand lines and nets hauled by muscle power in the nineteenth century, fishers who long had fished by hand protested the potential damage to spawning beds and to the invertebrates and bottom-dwelling creatures on which many fisheries depend. The tonnage harvested increased, as did the amount of by-catch, or marine creatures caught and killed by accident. Scientists of the nineteenth century, including Thomas Huxley, rejected the concerns of experienced commercial fishers, whom they considered uneducated. Huxley believed the oceans were so vast and productive that their fisheries could not decline significantly. The industrialized methods, however, damaged the fertile shallow banks off Britain, and fishers had to travel farther and farther out to sea to find fish.

Current ecological research indicates that many fisheries management programs that are based on obtaining maximum sustainable yield have resulted in declines not just in fish population numbers but also in the size and quality of the fish harvested. The mathematical formulas used to predict yield did not incorporate adequate information about fish demography, population geography, ocean food webs, or environmental variations in ocean conditions, such as fluctuations in ocean temperature caused by El Niño. Oceanographers using underwater cameras have surveyed ocean bottom sediments plowed by trawling and discovered that invertebrate populations critical to the food chains that support commercial fisheries have been disturbed. Another example is the Chesapeake Bay of the eastern United States, where the use of dredges has destroyed the oyster beds necessary for oyster larvae to establish and grow on the solid substrate of old shells.

The degradation of some ocean fisheries has been so great that many, such as the ground fisheries of Georges Bank off New England, have been closed temporarily by national governments or international agreements. The larger fishing vessels of heavily capitalized fleets and the wealthier countries often have driven less well financed or indigenous fisheries out of business. International fishing fleets are reducing fish availability for regional fisheries from the coasts of Africa to the shores of the Bering Sea. The human populations of forty countries worldwide are dependent on fish or marine food sources for a majority of their protein intake. All but one of those nations would be classified as less developed.

Ethical models applied to fisheries include the precautionary principle, sustainability, the inherent value of all species, and ecojustice or environmental justice. The precautionary principle holds that new capture and processing technologies should not be deployed to harvest an entire fishery or used under the supposition of extracting the maximum sustainable yield until the impacts of the technology have been studied fully and understood. Unfortunately, regulation of new fisheries often lags behind the development of the technology to exploit them, and so the international norm is still overharvesting of species such as orange roughy and Patagonian toothfish (Chilean sea bass).

The concept of sustainability requires leaving resources available for harvest in the immediate and distant future. This requires closing or limiting extraction from fisheries in decline and may mandate less destructive methods of capture, such as the use of hand lines. The concept of the inherent worth of all species requires reduction of incidental catch (by-catch) of nontarget organisms such as sea turtles and seabirds. This may be accomplished by banning technology prone to accumulating incidental harvest, such as drift nets; improving technology, for example, by installing turtle excluder devices on shrimp nets; or simply

closing offending fisheries by, for example, banning the use of trawl nets near seabird rookeries. Ecojustice calls for defense of the livelihood of indigenous and inshore fishing communities and fair access to ocean resources. These principles also encourage the preservation of cultural and linguistic diversity.

An additional issue for fisheries is the proliferation of fish and aquatic species culture. Salmon farming has displaced the harvesting of wild stocks through much of northern Europe. Salmon farms harbor diseases, produce waste, and disturb coastal ecosystems. Shrimp culture for export has spread ponds through coastal southeastern Asia, displacing mangrove forests and natural lagoons. Scientists are skeptical about the use of hatchery-reared salmon to replenish oceanic stocks. Interbreeding between hatchery fish and wild fish may decrease the genetic viability and ecological fitness of the salmon populations. Environmental ethical responses include ecosystemic rights in which there would be a requirement for the preservation of substantial and representative areas of natural ecosystems and the concept of maintaining wilderness areas or zones free of human interference, which may be applied to marine as well as terrestrial habitats. The global trend toward industrializing and privatizing fisheries is also an environmental justice issue in that it replaces family-owned fishing boats with large corporate fleets or fish farms.

Ocean Pollution Human pollution of ocean environments is of two geographic origins. The first is direct dumping or release of materials and toxins into the oceans either from ships or by discharge in ports or on the coast. Examples include ships spilling or leaking oil, sewage being pumped into estuaries by towns, oceanic dumping of sludge, freighters emptying bilges, and a ship's crew tossing garbage overboard. Lisa Newton, Catherine Dillingham, and Joanne Choly (2006) proposed three ethical imperatives that would prevent disasters such as the *Exxon Valdez* grounding in Prince William Sound, Alaska: holding those accountable legally responsible and enforcing the law, protecting the last remaining stretches of wild coast by restraining economic development, and pursuing sustainable energy polices that would reduce dependence on oil. Ocean drilling for oil and gas may also cause spills, and adds to greenhouse gas emissions. Offshore deposits of gas hydrates, such as methane hydrate, represent a major untapped energy source on the continental shelves, and may contain twice the carbon of all other fossil fuel reserves. Methane hydrate is trapped in ice crystals in relatively deep water; thus new technologies are necessary to exploit it. As methane is among the most powerful of greenhouse gases, the extraction of gas hydrates could add significantly to global climate change and sea-level rise.

The second source of ocean pollution is items and substances, often originating in the middle of continental landmasses, that are carried long distances by rivers or the atmosphere and eventually reach the ocean. Fertilizer spread in the midwestern United States reaches the Gulf of Mexico via the Mississippi River, and pesticides spread on marshes or farm fields make their way into aquatic food chains and eventually end up in coastal sediments. Atmospheric transport of nitrogen and sulfur compounds released by factories, electrical power generation, and automobiles produces acid rain over estuaries such as Chesapeake Bay. The additional nitrogen may act as a fertilizer, stimulating algal blooms. As the algae die and bacteria draw oxygen from the water during the process of decomposition, even marine environments can become anoxic (without oxygen) and thus fatal to fish and other animals.

Regulation of ocean pollution was slow to develop because much of the offending material was diluted or washed into international waters, where the impacts were not visible to the public. Although offshore disposal is regulated by the Convention on the Prevention of Marine Pollution by the Dumping of Wastes and Other Matter of 1972, also known as the London Dumping Convention, people still have difficulty comprehending the damage their activities do to the oceans. Among the environmental problems people have difficulty seeing—at least without the assistance of marine science—is the spread of dead or toxic zones where cities have deposited their sludge and other wastes or where major rivers have carried high loads of pollutants out to sea. A dead zone extending for many kilometers has appeared offshore from the Mississippi River Delta. Although the causes of this environmental disaster are not known completely, marine ecologists suspect pollutants such as fertilizers and industrial effluents. If this happened in a forested or agricultural region, the U.S. public would be outraged.

A potential environmental ethical response to both the damage caused by dead zones and the plowing of the ocean bottom with drag nets is to invoke ecosystemic equity and integrity: Humans should use the same standards for protecting ocean habitats that they use for managing habitats on land and should not protect some marine ecosystems while degrading others. Further, people should maintain the basic ecoystemic function and components of the ecosystems they purposefully harvest (bottom fisheries) or affect coincidentally (the dead zones). In the case of bottom disturbance, regulating more destructive fishing methods is appropriate and helps conserve the reproductive potential of the fish. In the case of dead zones, humans should reduce pollution inputs until the zones can recover their natural species diversity and food webs.

The public is more likely to observe trees dying from acid rain than to notice the impacts of additional

nitrogen on an estuary. Under the concept of ecosystemic equity, both a mountain spruce forest and submerged flats of eel or turtle grass merit human care and protection. Regulation of ocean pollution has made increasing use of the precautionary principle. The 1996 Protocol of the Convention on the Prevention of Marine Pollution by the Dumping of Wastes and Other Matter allows oceanic disposal only of listed materials; all other forms of waste are excluded until proved safe and officially added to the inventory of permitted wastes.

Marine Parks There has been a global expansion of networks of marine parks and reserves. The twentieth-century strategy was primarily to protect the aesthetic and the tourism-worthy. A majority of marine parks currently steward coral-studded lagoons, kelp forests, rocky reefs, and other ecosystems popular with swimmers, scuba divers, and recreational fishers. Application of the concept of ecosystem equity, however, implies that the representative areas of open continental shelves, deep trenches, and even shallow banks such as Georges Bank, which is critical to North Atlantic fisheries, should be protected from human disturbance. Recent scientific studies have found that setting aside protected areas in more ordinary habitats preserves fish spawning and feeding areas and maintains populations of a wide variety of marine organisms, including invertebrates taken as bycatch.

ODUM, EUGENE
1913–2002

Eugene Odum, born on September 17, 1913 in Newport, New Hampshire, was one of the most influential figures in twentieth-century ecology. Best known for his advocacy of the concept of ecosystems and holistic ecosystem-based perspectives in ecology and environmental problem solving, he has been called the father of modern ecology.

Gene Odum received his Ph.D. in zoology from the University of Illinois in 1939, writing a dissertation on environmental influences on bird physiology. While at the University of Illinois he came under the influence of the animal ecologist Victor Shelford. Odum's holistic conception of ecological systems was strongly influenced by Shelford's and Frederic E. Clements's conception of the plant-animal community as a complex superorganism. According to this conception, the plant-animal community responds as a dynamic unit to changes in abiotic conditions, progressing through a sequence of developmental stages until it reaches a self-perpetuating stable equilibrium. Odum defended a modified version of Clements's succession theory throughout his career, but instead of treating the plant-animal community as the fundamental unit of analysis, Odum adopted Arthur Tansley's concept of an ecosystem. Odum's mature theory of ecosystem growth and development draws on thermodynamic and cybernetic concepts found in the work of Alfred J. Lotka, Raymond Lindeman, G. Evelyn

Hutchinson, and his own younger brother Howard T. Odum.

In the 1940s at the University of Georgia, Gene Odum began writing *Fundamentals of Ecology*, which was to become the most successful textbook in the history of ecology. *Fundamentals of Ecology* was first published in 1953, a second edition (coauthored with his brother Howard) appearing in 1959, and a third edition in 1971. *Fundamentals of Ecology* is notable for its emphasis on the ecosystem as the fundamental unit of analysis for ecology and its systematic integration of general ecological principles, applied conservation science, and environmental advocacy. Odum believed that ecological science could and should function as a foundation for environmental problem solving and ecologically sustainable economic and social development. *Fundamentals of Ecology* is credited with attracting a generation of students that shared Odum's optimistic vision of ecology as an integrated-systems science with the potential to transform humanity's relationship with the natural environment in positive ways.

The popularity of Odum's style of ecosystem ecology reached its peak within academic ecology by the end of the 1960s. In plant-community ecology in the 1970s, Clements's succession theory was effectively replaced by more reductionistic models of plant communities that emphasized their lack of internal coherence and the radical contingency of successional trajectories. Evolutionary ecology also emerged as a powerful new integrative perspective that challenged the group-selectionist assumptions in Odum's model of ecosystem development. By the end of the 1980s, holistic, systems-oriented ecosystem ecology was effectively marginalized in academic ecology in the United States. Nevertheless, ecosystem ecology in the tradition of Gene and Howard Odum continues to be developed and practiced by ecologists around the world.

In the last two decades of his life, Gene Odum devoted more of his time to promoting and presenting his vision of ecology and sustainable living to a broader audience. In 1989 he published *Ecology and Our Endangered Life-Support Systems*, and in 1998, *Ecological Vignettes: Ecological Approaches to Dealing with Human Predicaments*. In these works Odum argued that principles of ecosystem growth and development apply equally to human socioeconomic systems, and he developed a prescriptive model of social organization based on these principles. For example, Odum believed that ecosystems with more extensive mutually beneficial interactions between system components are more stable than ecosystems with less such interactions, and that diversity of components promoted system stability by enabling redundancy in critical ecosystem functions. Consequently, he recommended modes of social organization that increased cooperative relationships and decreased competition, and argued for diversification of energy and food sources to ensure stable supplies of these resources.

Odum argued that this transformation of human social systems to ecological maturity requires a new set of ethical and political values. The values of free-market industrial capitalism may be adaptive in the early stages of economic and social growth, but become liabilities in later stages when limiting constraints on growth become evident. The transition to a more harmonious relationship between humanity and the natural environment requires a shift in values that promotes efficient use of resources, recycling and reduction of waste, higher degrees of cooperation and diversity among social groups, and greater appreciation of the dependence of human welfare on the quality of environmental resources. Such values promote the conditions for stability of mature social systems, just as they do the stability of mature ecosystems.

Odum's ethical writings have been compared to Aldo Leopold's land ethic, though Odum's rhetoric is more consistently anthropocentric than Leopold's. Nevertheless, Odum's style of ecosystem ecology has often been used to underwrite the views of nonanthropocentric environmental ethicists and deep ecologists.

ORGANIC FARMING

The term *organic farming* was first used in 1940 by Lord Walter Northbourne in *Look to the Land* (p. 81), to describe an alternative to *chemical farming*. Organic farming is a method of agricultural production that eschews chemical fertilizers and pesticides. But organic farming is not simply a way of growing food; it is also a social movement. From its inception, strong ideological

notions relating to soil, health, nature, politics, science, and spirituality have offered both a critique of and alternative to modern orthodox farming practices. At times the subject of passionate and polarizing debates, organic farming has often been considered marginal, antiquated, or even subversive. Around the turn of the twenty-first century, it became increasingly important economically and culturally, but new questions have begun to emerge regarding the effect of this success on its ideological and philosophical underpinnings.

ORIGINS

Organic farming is based on traditional agricultural practices, but its emergence as both a method and a movement was mainly a reaction to the increasing industrialization of agriculture in the early twentieth century. Philip Conford describes the history of the early movement, centered in England, in *The Origins of the Organic Movement* (2001). At this time, organic farming was mainly promoted by members of the social and intellectual elite. Their political motives ranged widely, but organic thought was consistent in a number of aspects. Belief in the importance of soil and the necessity of humus (organic matter) for sustainable production of healthy crops has always been central. More than merely a scientific argument, this idea is based on a holistic worldview that emphasizes interconnectedness and an agriculture that mimics natural systems. Early organic advocates believed that healthy soil was connected to healthy crops, healthy crops to healthy people, and healthy people to healthy societies. This holistic worldview is fundamentally at odds with the scientific reductionism of modern agriculture, and the organic movement has long been based on opposition to this emerging orthodoxy.

Other concerns of the early movement included preserving rural populations, culture, and livelihoods. Organic proponents opposed agricultural mechanization and argued that agriculture rather than industry should form the basis for a healthy nation. In this way, the early organic movement embodied philosophical and political beliefs similar to the agrarianism of Thomas Jefferson and others. Early organic thought also parallels agrarian philosophy in its promotion of small, independent, diversified farms, and its rejection of agriculture singularly focused on economic efficiency.

Perhaps the most prominent and influential of the early organic proponents was Sir Albert Howard. Howard developed and promoted a systemic vision of agricultural production and land stewardship based on returning composted organic waste to farm fields, and rejected the economic materialism of industrial agriculture. Howard emphasized the role of organic farming in promoting individual and social health, and maintaining soil fertility for future generations. A prolific lecturer, Howard also presented his ideas in a number of published works, including *An Agricultural Testament* (1940) and *The Soil and Health: A Study of Organic Agriculture* (1947).

Though a trained scientist himself, Howard states in *An Agricultural Testament* that "Instead of breaking up the subject into fragments and studying agriculture in piecemeal fashion by the analytical methods of science, appropriate only to the discovery of new facts, we must adopt a synthetic approach, and look at the wheel of life as one great subject and not as if it were a patchwork of unrelated things" (p. 22). Like many in the early movement, his holistic vision of farming was connected to a Christian spirituality that included a concept of nature as divine. Like many others, he was also highly influenced by Asian thought.

Another important figure in the development of organic farming was the Austrian philosopher Rudolph Steiner. Like Howard, he rejected the materialism and reductionism of modern agricultural practices and emphasized the living soil as the basis for health, vitality, and spiritual connection. Steiner's philosophy was influenced by Franz Brentano, Friedrich Nietzsche, Hinduism, and Theosophy, but was based most heavily on the works of Johann Wolfgang von Goethe and Christian spirituality. Steiner published several works on Goethe's epistemology, spirituality, and concepts of nature and science. Though his writings span a variety of subjects, among his most important and lasting influences was his development of *Biodynamic Agriculture*, an intensive, integrated production method that conceives of the farm as a self-contained system balanced by the interconnected life-forces of both the earth and cosmos.

Both Steiner and Howard were important influences for Jerome Irving Rodale, a magazine publisher and health crusader who would become the foremost advocate for organic farming in the United States. Unlike most of his European counterparts, Rodale promoted organic in a way that was primarily pragmatic, secular, and apolitical. Among his most important contributions were his promotion of organic gardening, which introduced its methods to non-farmers, and his establishment of long-term research trials comparing organic and conventional production methods.

Rodale's publications were highly influential for the American counterculture, which embraced organic farming and gardening passionately during the late 1960s and early 1970s. During this time, young people participated in a vast rural migration to conduct utopian experiments in homesteading and communal living. Warren Belasco details this phenomenon in *Appetite for Change: How the Counterculture Took on the Food Industry* (1989). This "back to the land" movement was based on a neo-agrarian

Examining Organic Produce, Springfield, Virginia. *Ogranic food—produced without chemical pesticides —has become more and more popular, and is found in grocery stores and markets throughout the world. Proponents of organic food cite that it is more environmentally friendly than chemical dependent and/or land-intensive agriculture.* **AP IMAGES.**

worldview that rejected consumerism in favor of self-sufficiency, simplicity, and a closer connection to the natural world. Like the early organic movement, it emphasized small farms, soil conservation, and crop diversity, as well as environmentalism and energy conservation. In contrast, its social goals were promoted more through lifestyle decisions than political advocacy.

This movement formed the basis for a community of like-minded individuals who worked to develop, define, and promote organic farming and production standards. By the late 1980s organic food had gained significant popular status, and was beginning to command premium prices. At the same time, production standards had become more complex, and certification schemes were increasingly sophisticated and numerous. Recognition of the emerging economic importance of organic products and a perception that their commercial development was limited by the lack of consistent standards led to the legislative institutionalization of organic farming through the development of national certification programs.

A MOVEMENT IN CRISIS

In the United States, a National Organic Program (NOP) administered through the Department of Agriculture was authorized through the 1990 farm bill to establish rules defining appropriate practices and a process for certifying organic farms and production facilities. Initially organic growers and advocates were encouraged by this legitimization, but the implementation and repercussions of the NOP have caused considerable frustration and disillusionment over time. Appropriate materials and practices have always been controversial, and remain contested.

Enacted in 2002, the NOP Final Rule describes organic farming as ''A production system that is managed in accordance with the [Organic Foods Production] Act and regulations in this part to respond to site-specific conditions by integrating cultural, biological, and mechanical practices that foster cycling of resources, promote ecological balance, and conserve biodiversity'' (Subpart A, Section 205.2). As such, the NOP ignores social movement issues related to health, labor standards, farm size, energy conservation, and rural development. Critics have claimed that the NOP has robbed organic farming of its philosophical basis, and facilitated its commercialization and industrialization. Since its implementation there have been substantial increases in the size of organic farms, the number of farms growing both organic and conventional produce, the prevalence of organic products originating outside of the United States, and the concentration of ownership in the organic food processing and retail sectors.

In response, many traditional organic producers have sought to differentiate themselves and their products based on their adherence to traditional elements of the organic philosophy. One result has been the emergence of the terms *beyond organic* and *moreganic*, the *local food* movement, and the reframing of organic principles using terms such as *civic agriculture*, coined by Thomas Lyson in his 2004 book *Civic Agriculture: Reconnecting Farm, Food, and Community*. The rapid development of civic agriculture and the local food movement are evident in the proliferation of farmers markets and *community supported agriculture,* which invites consumers to participate directly in the labors, risks, and rewards of food production. The growth of such direct marketing practices is consistent with organic movement support for small, diverse, independent farm enterprises, and is being led by farmers committed to traditional organic production methods.

For almost a century, organic farming has been an evolving, negotiated, values-based activity related to ideological notions regarding the relationship between nature, society, and food production. Small, diverse, ecologically conscious growers continue to maintain farm operations based on the kind of holistic, postmaterialist, agrarian values that have been the hallmark of organic philosophy. Organic farming practice is thriving today, but the organic farming movement is very much in crisis. Caught between two equally uncertain and divergent scenarios, its adherents are struggling simultaneously to maintain as many of its principles as possible within the current rules, and to redefine a movement that has lost its name, and is unable to divest itself from the system that has usurped it.

ORTEGA Y GASSET, JOSÉ
1883–1955

José Ortega y Gasset, the most important Spanish philosopher of the twentieth century, was born on May 9, 1883, in Madrid. He held the chair of metaphysics at the Central University of Madrid. He was elected to the constituent assembly during the Second Republic. After the outbreak of the Spanish Civil War, he lived in exile, first in Argentina and various parts of Europe, settling in Portugal 1945 and returning permanently to Spain in 1948.

THE FOUNDATIONS OF ORTEGA Y GASSET'S ENVIRONMENTAL PHILOSOPHY

Ortega y Gasset's philosophy, beginning with his programmatic statement (1914), "I am I and my circumstance" (Ortega y Gasset 1963, p. 45) has been called "the first expression of an ecological approach in philosophy" (Rogers 1994, p. 505), Ortega y Gasset's concept of "circumstance" having been influenced by Jakob von Uexküll's (1864–1944) concept of the *Umwelt* (surrounding world, environment) of the organism and by Edmund Husserl's (1859–1938) phenomenological concept of the *Umwelt* (Marías 1970). Uexküll's concept is biologically oriented, focusing on the structure of the organism. Husserl's concept is phenomenological, focusing on the practical world (later the "life-world") as it is given to consciousness. Rejecting Husserl's transcendental turn, Ortega y Gasset was able to draw on both Uexküll's naturalistic concept and Husserl's phenomenological concept.

Although Ortega y Gasset did not concentrate on environmental issues in the contemporary sense, he did emphasize the impact of the environment on culture and individuals. His theory of "vital reason" began to take shape in his account of a forest in El Escorial, the reality of which he views as a function of vital experiences (Ortega y Gasset 1963, pp. 59–69; Marías 1970). Noting the sad state of ethical theory, he wrote, "There are people who believe in good faith that we have no obligations toward the rocks and therefore have tolerated advertisers' smearing with pitch . . . the venerable rocks of the mountain ranges" (2007, p. 99). The rocks of the mountain can only be what they are, "venerable," as a function of individual perspectives (Marías 1970).

ORTEGA Y GASSET ON HUNTING

Ortega y Gasset's most important work on broadly environmental issues is his *Meditations on Hunting* (1942), originally written as a preface to a memoir on big game hunting by his friend Edward, Count Yebes. It has become one of the most influential philosophical works on this subject, especially among hunters. His approach is explicitly existential: "The life that we are given has its minutes numbered, and in addition it is given to us empty. . . . Thus, the essence of each life lies in its occupations" (2007, p. 35). Ortega y Gasset notes that most human work is unsatisfying, draining life rather than filling it up. Therefore, the human being "finds it essential to divert" himself or herself (2007, p. 29). Hunting—along with dancing, racing, and conversation—is one of the diversions traditionally practiced by human beings for their own sake. Hunting is an activity in which, rather than losing time, we are "gaining it, filling it satisfactorily and as it should be filled" (2007, p. 37).

Distinguishing hunting from fighting, Ortega y Gasset defines hunting as "what an animal does to take possession, dead or alive, of some other being that belongs to a species basically inferior to its own" (2007, p. 62). But Ortega y Gasset insists that it is essential to hunting that the hunted animal has its chance to avoid capture. "There is, then, in the hunt as a sport a

supremely free renunciation by man of the supremacy of his humanity. Instead of doing all that he could do as man, he restrains his excessive endowments and begins to imitate Nature—that is, for pleasure he returns to Nature and re-enters it" (2007, p. 63).

In addition to this hunter's ethos, Ortega y Gasset recognizes ethical issues pertaining to the activity of hunting itself. "Every good hunter is uneasy in the depths of his conscience when faced with the death he is about to inflict on the enchanting animal. He does not have the final and firm conviction that his conduct is correct. But neither, it should be understood, is he certain of the opposite" (2007, p. 98). But Ortega y Gasset insists that "the greatest and most moral homage we can pay to certain animals on certain occasions is to kill them with certain means and rituals" (2007, p. 101). He attacks "photographic hunting" as an ethical "mannerism" (2007, p. 103), because "In the preoccupation with doing things as they should be done—which is morality—there is a line past which we begin to think that what is purely our whim or mania is necessary. We fall . . . into a new immorality . . ., which is a matter of not knowing those very conditions without which things cannot be" (the goal of killing the animal is essential to hunting). "The hunter seeks this death because it is no less than the sign of reality for the whole hunting process. To sum up, one does not hunt in order to kill; on the contrary, one kills in order to have hunted" (2007, p. 105). Only in hunting is one truly an active participant in the countryside, intensely attuned to every aspect of it, perceiving it from both the hunter's and the prey's perspective. Hunting does not objectify the prey; it is the natural and appropriate response to the animal itself. "The only adequate response to a being that lives obsessed with avoiding capture is to try to catch it" (2007, p. 129).

Describing the hunter as "the alert man" (2007, p. 138), Ortega y Gasset views sport hunting as "a vacation from his human condition" (2007, p. 121), a reprieve from the draining tedium of everyday life. "Life is a terrible conflict. . . . Hunting submerges man deliberately in that formidable mystery and therefore contains something of religious rite and emotion in which homage is paid to what is divine, transcendent, in the laws of Nature" (2007, p. 106).

CRITICISMS OF ORTEGA Y GASSET'S VIEWS ON HUNTING

Questions about Ortega y Gasset's views on hunting can be raised from a number of perspectives. Ortega y Gasset's anthropocentric position is based in part on his hierarchical view of the natural world, but this view is itself difficult to sustain. There is no defensible sense in which the hunted animal is necessarily "inferior" to the hunter. The fact that Ortega y Gasset approaches sport hunting purely from the point of view of "diversion" limits the meaning that can be found in it. He makes it clear that eating the hunted animal is not part of hunting and has nothing to do with the meaning of the hunt. A truly ecological approach to hunting might replace Ortega y Gasset's hierarchy of superior hunter and inferior hunted with the notion of "webs" to which both hunter and hunted belong. One who hunts as an end in itself can do so as a member of an ecosystem, taking from it, by hunting, a portion of nourishment and giving back to it by participating in and protecting the very wildness that makes hunting possible in the first place. From this perspective hunting can be more than a mere diversion.

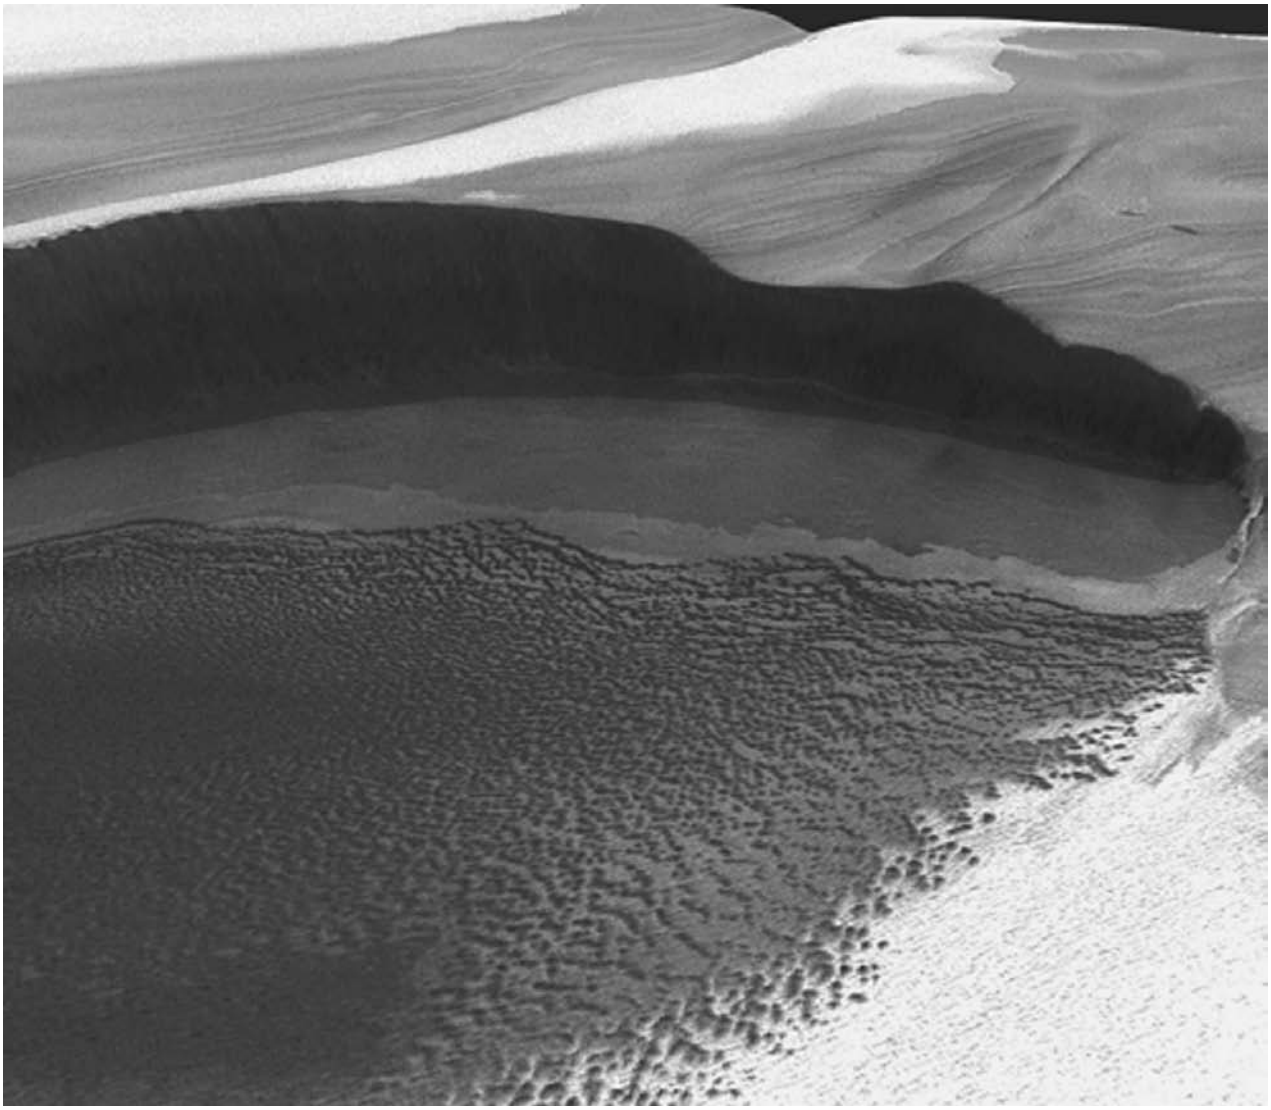
OUTER SPACE

Humankind lives in a gravity cocoon that contains all the ingredients—rocks, gases, water—that allow life and consciousness to flourish. This cocoon is probably one of many similar tiny dots floating in the vastness of space, but whether there is life elsewhere is unknown. What is remarkable about Earth is that it is a distillation of a tiny fraction of the elements of the universe: the ones that provide rocks, water, and atmosphere. The universe consists mostly of hydrogen gas, but a small number of heavy rock-forming elements condense at certain distances from nascent stars.

Many terrestrial, or Earthlike, planets will have abundant water as long as they reside in their stellar habitable zone (Kasting et al. 1993). Water is one of the most abundant molecules in the universe, and typically clouds of ice-rich comets form at the outer reaches of the domain of a new star. Scattering of comets and asteroids into the inner or habitable zone planets ensures that water and volatile gases collect on the newly formed extrasolar terrestrial planets (Morbidelli et al. 2000).



Martian North Polar Ice Cap. *This image of the north polar region of Mars, taken from a high resolution camera on the European* Mars Express *spacecraft, shows layers of water, dust and ice in perspective view. The cliffs are nearly 2 kilometers high, and the dark material could be volcanic ash. The possibility of life on other planets would likely dramatically alter our conceptions of society and the environment. It seems clear that the tourism industry will be focusing on outer space sometime in the near future.* **PHOTO COURTESY OF ESA/DLR/FU BERLIN (G. NEUKUM).**

EXTRATERRESTRIAL SOCIETY

Earth arguably is a closed system in that human society is bound to it and to the limits of its resources. There may be other closed systems: terrestrial planets around nearby stars that have sentience and society as well. The detection of life in any location other than Earth will change what people think of as society. The global society, with its quirks and conveniences and homogeneity, has emerged in recent years. How will human views of society and environment change when people learn that versions of them exist on other worlds?

It is somewhat likely though not probable that scientists will find microbes in the Mars polar ices or along the edges of the steam vents of Saturn's moon Enceladus (Spencer and Grinspoon 2007). It is more likely that in the middle of the twenty-first century it will be possible to detect the composition of Earthlike atmospheres and surfaces around other stars. These observations could be of high enough fidelity to indicate whether a global biosphere altered the nature of that atmosphere or surface.

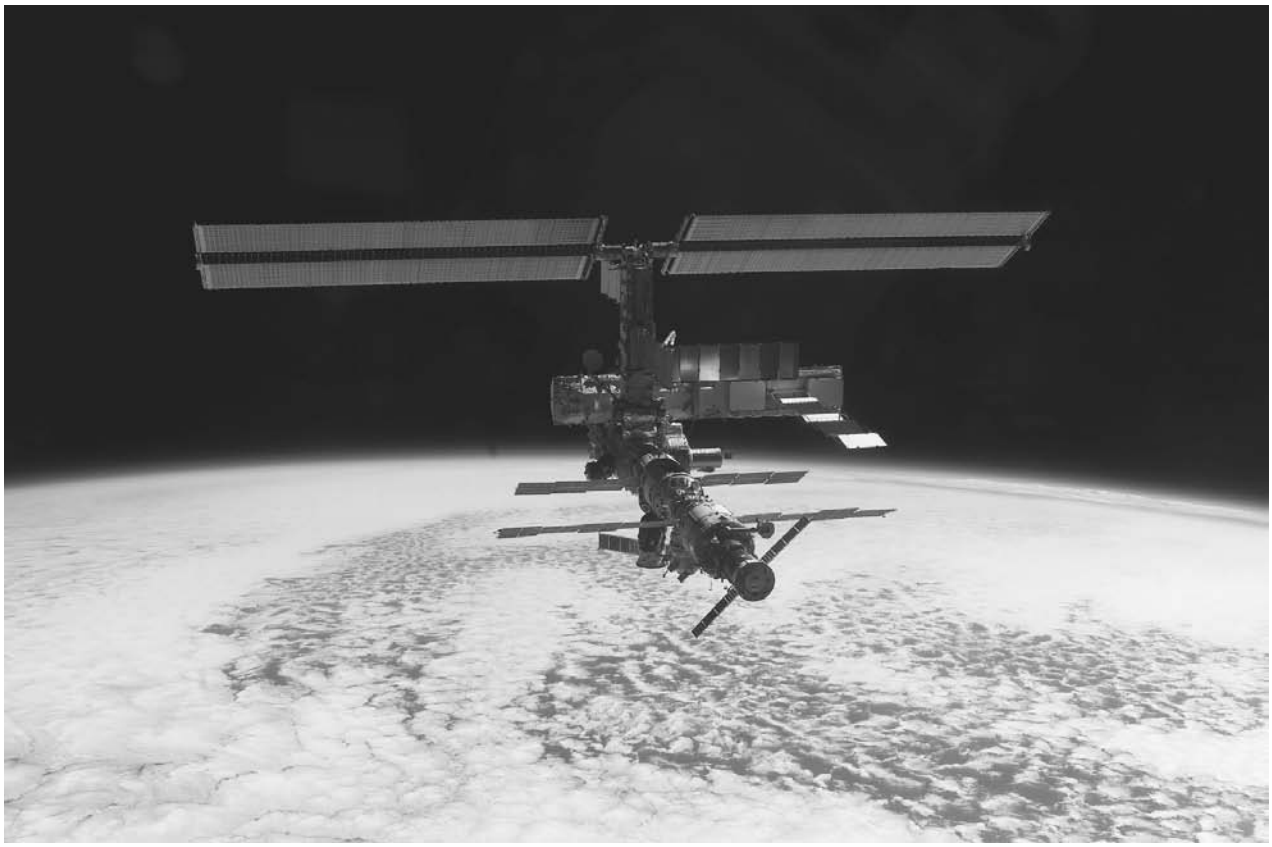
Humankind's view of life certainly will change if microbes are found on other bodies in the solar system.

Will they be related genetically to Earth organisms, or will they have worked out an evolutionary method all their own? During the first 600 million years after Earth formed, the inner planets still were being bombarded with leftover planetary building blocks. Calculations based on shock-wave physics from atomic explosions show that a certain percentage of the planetary surface, dislodged by those collisions and blasted into space, never experiences temperatures greater than 1,000 degrees Celsius. Rocky blocks would get transported throughout the solar system and fall on other planets as they do today (Gladman et al. 1996). During reentry into a new atmosphere, many of those blocks never experience temperatures greater than 1,000 degrees Celsius (Melosh 1988). Thus, from the perspective of life the early solar system is best viewed as a vast sea with constant transport of material across the voids and its delivery to other worlds. Life would have opportunities to take such rides. People would be forced to face the fact that the environment, if defined by life, would include fragile enclaves that might be found on Mars or the moons of Saturn. Some of the ancestors of human society may live elsewhere, but they will deserve respect if they are discovered.

Alternatively, the solutions that life worked out to use its environment to replicate and evolve may be entirely different on Mars or Enceladus. In this case people's sense of environment must be reexamined because this finding would show that life is able to evolve under conditions that people cannot now imagine.

THE NEW SPACE

The days of Earth as the cradle and unique home of human civilization are drawing to a close. In rapid succession there have been successful private trips to space, and a large number of investors and players in the new space business are preparing to take tourists, investigators, honeymooners, artists, poets, engineers, and doctors into space. Some go on suborbital flights with just minutes of microgravity. Others circle Earth and see their home planet for what it is: a globe



The Human Outpost in Space, 2002. *The International Space Station (ISS) is a massive scientific laboratory in low Earth orbit, allowing it to be seen with the naked eye. NASA's goal is to have a similar outpost on the Moon by 2026. One of the research areas aboard the ISS is biology; scientists hope to improve their understanding of the effects on the human body of long-term exposure in outer space. The results of this and similar research are expected to contribute to the possibility of human colonization in space.* **NASA.**

overflowing with life, floating in emptiness. In the early decades of the twenty-first century space hotels may accommodate visitors in an environment with relaxing zero gravity and spectacular vistas where sport, art, and culture may evolve in new ways. Eventually commercial trips may take passengers to the moon, and one day adventurers and tourists may explore lunar highlands and fissures never before seen by humans.

In civil space efforts the National Aeronautics and Space Administration (NASA) is spending billions of dollars to develop a new and safe transportation system that can shuttle astronauts to the International Space Station. That system also may be part of the means of transportation to the Moon and may play a prominent role in NASA's stated goal of building a human outpost on the nearest solar system by 2026. Investment in the future lunar infrastructure is strong, with NASA studies of habitats, vehicles, and in situ resource utilization ongoing. It is envisioned that some versions of these systems will be used to explore nearby asteroids, ancient rocks that can bring and have brought global disaster to Earth in an instant.

Perhaps most ominously or excitingly, it appears that another space race is shaping up. The United States will have to ground the space shuttles in 2010 and contract for rocket rides with Russia to visit the International Space Station (ISS). The new NASA manned space transportation architecture will not be ready until 2014, at which time it will be able to take over transport between Earth and the ISS. The Chinese have an aggressive program of lunar robotic and manned exploration of the moon. China has leveraged its soft power by partnering with countries that the United States does not want to deal with or regards as an investment risk. The influence of the Chinese space program has increased as it has helped develop space system capabilities for Third World countries that cannot afford them on their own.

A conservative 2006 estimate of the value of the potential market for space tourism by 2021 is $1 billion (Taylor 2006). Space tourists already have gone to the ISS despite objections from NASA. Economies of scale and rapidly developing technologies make it likely that space tourism will grow along with the international push to do more and invest more to put more humans into space.

ENVIRONMENTAL ETHICS IN SPACE

Society will be different in space. Some see a utopian or utopian-libertarian universe of infinite space and infinite possibilities. However, as far as can be foreseen, people will be transported in small, highly dependent groups. They will bring their sense of ethics and environment with them, but how will they adapt to the realities of living in space? Dropping a tool with a mass of a kilogram outside the space station during repairs is not a big deal because it can be tracked and the risks of collision with the ISS can be mitigated. However, those people will be living on palpably finite and severely limited resources for the first time, and colonies off Earth are likely to develop a set of environmental or conservation values and ethics very different from those of their forebears. Moreover, the distinctive experience of the minicultures that evolve when humans are isolated is well documented at scientific stations such as the one at the South Pole.

The Moon is vast: Is leaving a burned-out rocket engine behind on it a significant environmental concern? Can people explore the Moon scientifically without regard for what is happening to its environment now or, as a consequence of what they do now, in the future? There is already a lot of human-made debris on the Moon, including Apollo landers with their buggies and equipment for experiments and a dozen or so crashed probes that provided movies of approach and immolation. Are these relics garbage littering the otherwise pristine surface of the Moon, or are they proud monuments to the achievements of the human race? Would people be better off if their motto was "leave nothing but footprints"? The footprints left on the Moon during the Apollo visits will last many times longer than a plastic bag thrown on the ground in a park on Earth, yet it is difficult not to see the extraordinariness of this first lone human boot print on a world other than Earth.

The exploration of space already has led to the extraterrestrial exportation of a familiar environmental ethic: the unexamined, consumer-driven sense of infinite vastness to absorb humankind's effluent that people implicitly employ in their everyday lives on Earth. Leaks of atmospheric gases, chunks of metal, tools, gloves, waste, garbage, burned-out rocket stages, dead satellites, and abandoned landers on the Moon, Mars, and Venus are among the environmental legacies of humankind to space. The debate about space debris is in full swing, largely because low-Earth-orbit pollution, even in the vastness of space, is bad enough that it is likely to cause a catastrophe on the ISS, along with the threat that some of the larger objects pose to humans, other life-forms, and ecosystems on Earth when they fall back down through the atmosphere onto the surface of the planet.

A turning point in the issue of space debris occurred in October 2006, when the Chinese chose to test an antisatellite weapon on one of their dead communications satellites. The debris from the explosion instantly increased the total amount of space debris (10,000 tracked objects larger than 4 centimeters) by 10 percent. Worse, the orbit of the target was high enough that

debris scattered into orbits covering a wide range of altitudes, polluting some of the orbital ranges used most heavily by commercial satellites. Because of the high orbit of the target, much of the debris will take centuries to degrade into lower orbits as a result of friction with the upper reaches of the atmosphere. Most of the debris will burn up, but it will be raining pieces of Chinese space hardware for a century.

The United States performed a similar feat in the interest of keeping the world safe from hydrazine. A large military satellite had gone astray, and it was in a low enough orbit that blasting it to pieces would result in a debris cloud that would reenter the atmosphere in months. The U.S. test in February 2008 was equally successful, although because its stated goal was to destroy a hydrazine tank that if it survived reentry would be hazardous to people and the fact that it created a more responsible debris cloud constitute a weak argument that the United States holds the moral high ground on ground-based antisatellite tests.

Nevertheless, the fundamental ethical underpinnings of the lost gloves and wrenches floating in near-Earth space, the abandoned equipment on other planets, and the spraying of near-Earth space with debris from military exercises are the same. Space is an infinitely large sink; if one drops an empty bag of potato chips, nobody will ever see it and it will never be a part of the phenomenological landscape. It has been learned painfully on Earth that with increasing population density that type of thinking is flawed. If space, like land or ocean or sky, is to be exploited for human purposes, must it also become the ultimate wastebasket, as has been the history of the human use of all other media?

The expansion of people and then society into outer space inevitably will carry with it an environmental ethic. If the safety and survival of crews are at stake, it is certain that environmental protection or sustainability will be on the bottom of the list of priorities, and it can be assumed that space will be considered a convenient dumping ground. The occasional radioactive power source or debris cloud of heavy metals will be ejected randomly into space if it is expedient for the safety of the astronauts, whether they are governmental or private space voyagers.

Outer space is currently in the realm of science and engineering, yet when one considers that people soon may be exporting Earthly genes to other planets, one must conclude that they also will be exporting human culture. The conditions of a human mission to Mars are likely to be highly stressful; situations in which the moral and ethical fortitude of the astronauts will be tested are sure to arise. It is therefore important that a nascent colony or even an expedition be well informed about both ethics and environmental ethics. Stress reduction and time to adapt psychologically must have a high priority. Efficient and effective mechanisms for conflict resolution must be in place. Time and energy should be put into fostering a culture that places a premium on respect and boundaries, one in which each astronaut is motivated first and foremost by compassion for his or her colleagues. The possibility that romantic relationships may develop should be anticipated and analyzed, and a policy regarding such relationships must be formulated.

To some researchers the idea of living off new worlds and building colonies on other planets is absurd. The expense would be enormous, and the benefits and risks both to the colonists and to Earth-bound humanity are unknown. To others, however, it appears to be inevitable. It is human destiny to explore and then colonize. The frontier now is space, they think, and it has no limits.

Those who think that exploring space and colonizing other planets is absurd believe that the required spatial and temporal scaling of the concepts of exploration and colonization stretches those concepts to the breaking point. Christopher Columbus's voyage of discovery and colonization covered only 5,000 kilometers, and he made the pelagic crossing from the Canary Islands to Cuba in just over a month. Moreover, when he arrived, he could breathe the air and drink the water. He was back in Spain in less than a year. Mars, the nearest planet that can be explored by humans, is 23 million kilometers distant at its closest approach to Earth. By current means of propulsion it could be reached in at best 150 days. Once explorers arrive there, water must be mined from the ice, and the atmosphere is oxygenless. The nearest star, Alpha Centauri, is more than four light-years distant. Even if advanced propulsion could be developed for that journey, for the astronauts who attempt the trip it would mean forever leaving the society they know. If nearly unlimited energy could be harvested, it would be possible for humans to travel at speeds close to the speed of light. Albert Einstein's special relativity has been used to calculate both the energy necessary to get to Alpha Centauri and the effects of time dilation. For the astronauts on such a mission it might take ten years to get to the nearest star. During those years, moving at near-light speed relative to Earth, approximately ten thousand years would have gone by on Earth. Near-light speed is a time machine, and astronauts on a trip to Alpha Centauri would return twenty years older to an Earth that was twenty thousand years in the future. A nearly infinite supply of energy would be required to reach those velocities, although such a supply is not ruled out by the laws of physics.

Nevertheless, Carl Sagan (1994) and others have argued that there is a moral imperative to colonize other planets. By spreading its genes beyond one small world the human race would survive even in the case of a

Boot print of Buzz Aldrin. *This image commemorates one of the first steps ever taken on the Moon, by American astronaut Buzz Aldrin on the* Apollo 11 *mission in July 1969. In the pristine environment of the Moon, this boot print will last for millions of years, until it is slowly eroded away by atoms from the solar wind.* **NASA.**

planetary catastrophe. However, that thought may lead to the idea that there is little reason to try to avoid an anthropogenic planetary catastrophe. Having colonized other planets, the human race would survive even after a human-made catastrophe on Earth, so why should the prospect of such a catastrophe concern people from the point of view of environmental ethics? After humans use up Earth to the point where it is no longer habitable, they will emigrate to other planets; this is precisely the environmental ethic of the frontier.

THE OUTER SPACE WILDERNESS

For most of human civilization the world was infinite, with more land, trees, and resources than could be used. Now humankind lives on a small world where the fuels that have driven human technology are being depleted. Forests are disappearing. The limits of freshwater, ocean resources, and the atmosphere are being felt, but the ultimate consequences are unknown.

Habitat loss for wild species is one of the most profound changes that the planet has experienced as a result of human civilization. The interconnected nature of plants, animals, seasons, and water is disrupted over much of the planet, and as a result species extinction is occurring at a rate faster than it has after nonanthropogenic global catastrophes such as asteroid impacts.

National park and wilderness systems have been somewhat effective at preserving natural habitat in perpetuity. Wolves have returned to Yellowstone, and the entire ecosystem is adjusting. People treasure wild spaces not just for what Earth was before they arrived and flourished but also for their natural beauty and the diversity of animals and birds and insects, with which people have an evolutionary and genetic bond.

Space, the new frontier, is in most respects effectively infinite. The immediately accessible extraterrestrial surfaces, such as those of the Moon and Mars, are huge but not unlimited. However, beyond them are Ganymede and Titan and Pluto and eventually Earthlike worlds around other stars, most of them more light-years distant than the number of years in a human lifetime. Mars has about the same solid surface area as Earth because although it is smaller in circumference, it has no oceans.

Planetary park systems that would preserve unique and diverse elements of planetary environments have been proposed (Cockell and Horneck 2004, 2006). Through human exploration of Mars and other places with robotic spacecraft, it has been discovered that there is natural beauty on other worlds as well. A planetary park system would designate large swaths of planetary surfaces to be wilderness if that becomes necessary, although it would appear to be difficult to preserve a portion of the surface of any planet from the corrosive effects of oxygen if that planet is to have a breathable atmosphere. An anticolonial extraterrestrial environmental ethic, in contrast, might require that other planets not be touched by robotic or human spacecraft or be used as a dumping ground for hardware falling from orbit. Such an ethic carries with it more than the practical issues of preservation of the unique and beautiful; it extends the concept of wilderness and people's duty to consider their impacts on the environment into space.

On Mars there is the possibility that colonies of organisms live within the ice or in lava tubes. Current NASA planetary protection policies require primarily that a landed spacecraft on Mars not disrupt any life to the extent that it is not analyzable. Some consideration is given to avoiding contaminating a possible biosphere, and even greater consideration is given to avoiding contaminating Earth with alien microorganisms from returned samples.

THE CONDUCT OF HUMANS IN SPACE

These considerations suggest that the injection of environmental ethics into the use, exploration, and eventual colonization of space is necessary. Philosophical practices such as contemplation and meditation may play a vital role in establishing a self-sustaining and self-correcting astronaut minisociety on which future colonists can build to create an extraterrestrial society that is based on mutual respect and sustainability. Exploring methods of stress reduction and coping mechanisms to adapt psychologically to extended

periods away from Earth and its familiar environments must have a high priority. Efficient mechanisms for conflict resolution must be in place. Time and energy should be put into developing a culture that retains mutual respect and boundaries among the astronauts and the extraterrestrial environment, including space stations and spaceships and is motivated by compassion for colleagues. Whether this will result in a code of conduct that includes explicit respect for the space environment, a set of international laws, or both requires discussion. It is important to develop methods that introduce a conscious awareness of the values that spacefarers bring with them and to examine how they change with the realities of working and living in space.

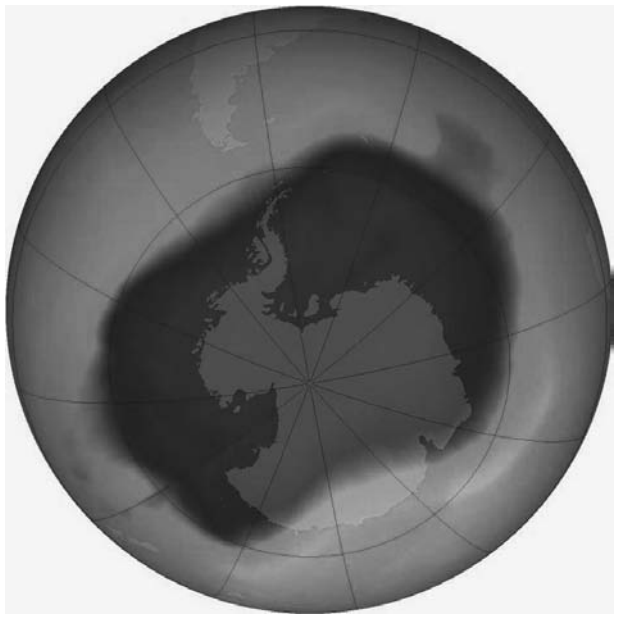
OZONE DEPLETION

Ozone depletion, the thinning of ozone in the upper atmosphere, has been observed since the late twentieth century and is due to anthropogenic emissions of ozone-depleting chemicals. Stratospheric ozone shields Earth's surface from damaging solar radiation, which can harm humans, other animals, plants, and ecosystems. Steps to control ozone-depleting chemicals began in the late 1970s in the United States and were followed by the institution of the international Montreal Protocol in 1987. Ozone depletion raises ethical issues associated with indirect and diffuse harm, collective action, and obligations under conditions of risk and uncertainty.

THE SCIENCE OF OZONE DEPLETION

Depletion of stratospheric ozone is caused primarily by anthropogenic emissions of halogen source gases—gases containing chlorine and bromine that break down in the upper atmosphere. Halogen source gases include chlorofluorocarbons, historically used in refrigeration, aerosol propellants, and air-conditioning systems; bromine-containing chemicals called halons, used as fire retardants; and methyl bromide, used as an agricultural fumigant. Although some halogen source gases arise from natural sources, these are not the primary cause of ozone depletion.

Ozone (O_3) is a molecule that occurs in the troposphere (lower atmosphere) and stratosphere (upper atmosphere). In the troposphere, excess ozone is considered a pollutant. It damages plant and animal tissues and is a major component of smog. Ozone in the upper atmosphere, however, has a protective effect. It shields Earth's surface from ultraviolet (UV) radiation—particularly UV-B radiation, with



Satellite Image of the Ozone Hole. *This image provided by NASA in 2006 shows the atmosphere's ozone "hole," a region where there is severe depletion in the layer of ozone (a form of oxygen) that protects Earth from the Sun's ultraviolet rays. At the time this image was recorded, on September 24, 2000, the Antarctic ozone hole was approximately 11.4 million square miles.* **AP IMAGES.**

wavelengths of 280 to 315 nanometers—which can cause health problems in humans and other animals as well as damage in wild plants and agricultural crops.

Stratospheric ozone breaks down through a set of chemical reactions involving reactive chlorine and bromine molecules. Although many ozone-depleting chemicals do not react directly with ozone, when these gases move from the troposphere to the stratosphere, they are converted into reactive halogen gases that catalyze the breakdown of ozone molecules.

The chemical breakdown of ozone by reactive halogen gases has had stronger effects on some parts of the globe than on others. Ozone depletion has been most significant at the poles, particularly over Antarctica, where seasonally severe ozone depletion, known as the ozone hole, has been observed since the 1980s. Winter weather conditions in the southern polar region favor rapid breakdown of ozone, and this leads to the formation of an ozone hole in austral late winter and early spring. Thus, although global ozone has been reduced on average by 4 percent, seasonal declines of up to 37 percent have been observed over Antarctica.

EFFECTS OF OZONE DEPLETION ON BIOLOGICAL SYSTEMS

Ozone depletion leads to increased ultraviolet radiation, and such radiation harms humans, other animals, crops, and ecosystems. Humans' increased exposure to ultraviolet radiation can cause skin cancer (both carcinoma and melanoma), cataracts, and suppression of the immune system. In addition, UV-B can damage the eggs of fish and amphibians; alter the DNA, lipids, and proteins of plants; modify plant-growth patterns; and reduce the yields of some crops. UV-B can also harm phytoplankton and has the potential to disrupt marine food webs. Though there are experimental studies showing effects of UV-B on plants and animals, the ecological consequences of increased ultraviolet radiation are not well understood, since they involve complex interactions.

POLICY RESPONSES TO OZONE DEPLETION

Scientific research linking anthropogenic chemicals to ozone depletion gained significant public attention in 1974 after the chemists Mario Molina and Sherwood Rowland published a paper in *Nature* outlining the mechanisms by which chlorofluorocarbons could destroy ozone. Later that year Molina and Rowland presented their work at a scientific meeting and publicized their findings to the press. Media coverage of their hypothesis led to significant debate and to reduced consumer use of chlorofluorocarbons. Then in 1978 the U.S. Environmental Protection Agency banned nonessential use of chlorofluorocarbons in aerosol sprays.

A comprehensive international response to ozone depletion came later. Shortly after a 1985 international meeting in Vienna to consider restrictions on ozone-depleting chemicals, new research revealed the Antarctic ozone hole, a severe thinning of stratospheric ozone over the South Pole. This renewed concern and led DuPont, a leading chlorofluorocarbon producer, to increase investment in the development of substitute chemicals. These events, in conjunction with pressure from U.S. environmental groups, laid the groundwork for the Montreal Protocol.

The Montreal Protocol on Substances that Deplete the Ozone Layer, an international treaty, was instituted in September 1987. The protocol, which went into effect in 1989, outlined a timeline for the reduction of certain chlorofluorocarbons and halons. The treaty required signatories from developed nations to cap chlorofluorocarbon emissions at 1986 levels by the middle of 1989, then to cut emissions to 50 percent of 1986 levels by 1998. Halons regulated under the treaty were to be reduced to 1986 levels by 1992. Less developed countries were allowed a ten-year grace period before restrictions went into force.

The initial cuts sought by the Montreal Protocol were modest and by themselves would not solve the problem of ozone depletion. However, the protocol included ongoing assessment provisions, which provided a process for collecting improved data on emissions of ozone-depleting chemicals, tracking ozone depletion, and synthesizing scientific research on its causes. These provisions allowed the protocol to be adapted as new data emerged showing ozone depletion to be worse than originally believed and identifying additional chemicals contributing to the problem.

In light of new data, the Montreal Protocol was strengthened at subsequent international meetings. A 1990 agreement entered into in London required complete phaseout of chlorofluorocarbons and halons by 2000; regulated two additional chemicals, carbon tetrachloride and methyl chloroform; and established a fund to assist developing nations in reducing ozone-depleting chemicals. Subsequent modifications to the treaty include the Copenhagen Amendment of 1992, which added controls on hydrochlorofluorocarbons and methyl bromide and accelerated timelines for reducing ozone-depleting chemicals; the Montreal Amendment of 1997, which sped reductions of methyl bromide; and the Beijing Amendment of 1999, which mandated earlier control of hydrochlorofluorocarbons.

The regulation of ozone-depleting chemicals kick-started industry investments in research on and development

of substitutes, including less-damaging chlorofluorocarbons, hydrochlorofluorocarbons, and hydrofluorocarbons. These alternative chemicals were much less potent than early chlorofluorocarbons. In addition, it was found that many aerosols could be produced without ozone-depleting chemicals at all. Mechanical pumps and chemical propellants such as carbon dioxide could be used instead. Effective substitutes for the strongest ozone-depleting chemicals also have been found for refrigerants, foams, solvents, and many fire retardants.

PROGNOSIS FOR OZONE RECOVERY

Although some ozone-depleting chemicals remain in use, overall production has declined substantially, and the total concentration of ozone-depleting chemicals has decreased since the 1990s. Because atmospheric lifetimes of some ozone-depleting chemicals are long (up to 100 years), a substantial lag time can occur between cuts in ozone-depleting chemicals and effects on ozone recovery. Nevertheless, according to the 2006 *Scientific Assessment on Ozone Depletion* (World Meteorological Organization 2007), stratospheric ozone levels outside the polar regions have stabilized. Severe ozone depletion continues to be observed at the poles, but variability in ozone levels in the polar regions is attributable to variable weather conditions rather than to increased concentrations of ozone-depleting chemicals. The 2006 assessment predicts a return to pre-1980 ozone levels by midcentury for most latitudes, with recovery over Antarctica occurring between 2060 and 2075.

ETHICS OF OZONE DEPLETION

Stratospheric ozone depletion raises a number of ethical issues. As mentioned above, ozone depletion can harm humans, nonhuman animals, plants, and ecosystems. Yet unlike paradigmatic cases of ethically significant harm, the harm caused by ozone-depleting chemicals was initially unknown, unintentional, indirect, and diffuse. Producers of ozone-depleting chemicals were at first unaware that their products could harm the environment and/or people, and they had no intention to cause harm. The harm was indirect because it was not the chemicals themselves, but rather the effects of the chemicals on stratospheric ozone, that caused damage. Lastly, the harm was diffuse in that it was not the action of a single individual, but rather the cumulative effects of many corporations and individuals producing and using ozone-depleting chemicals, that caused the problem.

The philosopher Dale Jamieson (2007) argues that nonparadigmatic ethical problems are more challenging than paradigmatic ones. Paradigmatic cases involve direct and immediate harm, with an obvious perpetrator and recipient, as when a single individual knowingly strikes another. In such cases, assignment of moral responsibility is straightforward. Nonparadigmatic cases are more complex. For example, should people be held responsible for harm that they did not know they were causing? Do corporations and nations have the same moral responsibilities as individuals? What obligations exist when the nature and magnitude of the harm are unknown? When harm is caused by the joint actions of many parties, how should responsibility be allocated?

Two types of issues are of central concern in the ozone case: issues of collective action, and issues of ignorance, risk, and precaution. Collective-action issues arise when the realization of a particular goal—in this case, prevention and mitigation of damage to stratospheric ozone—requires cooperation of multiple parties. Collective-action problems can be difficult to resolve when incentives for individual actors do not support collectively beneficial outcomes. In the ozone case, for example, in the absence of regulation, individual chemical companies had little incentive to invest in alternatives to ozone-depleting chemicals, because ozone-depleting chemicals were profitable and the costs of developing and producing alternatives were unknown. This collective-action problem was largely overcome by regulation. Once the Montreal Protocol went into effect, all companies were required to cut production of ozone-depleting chemicals and to seek alternatives.

It is controversial whether individual actors have moral obligations to refrain from contributing to collective-action problems in the absence of regulation or other forms of collective agreement. Some argue that unilateral restraint under such circumstances will accomplish little. In the ozone case, however, the unilateral move by the United States in the late 1970s to ban ozone-depleting chemicals in aerosol sprays may have induced later collective action to resolve the ozone problem.

A second issue of concern in the ozone case involves the appropriate ethical response to uncertainty and risk. Ozone depletion was suspected well before discovery of the Antarctic ozone hole. The initial science on ozone depletion was based on chemical theory and was borne out by empirical data only later. When the problem was first being discussed, the nature and extent of the problem and associated risks were unknown.

There is no philosophical consensus on the appropriate ethical response to risk, though it is widely agreed that the magnitude of the risks and the reversibility or irreversibility of potential harms are important factors to be considered. Some moral philosophers and environmental advocates favor a precautionary approach, where action is taken to avert harm associated with an activity even when the nature and magnitude of the potential harm are not fully known. Others hold that risks should be considered in the context of cost-benefit analyses, in which potential risks are weighed against potential benefits. In the ozone case, this would involve asking whether

the benefits of continuing to use ozone-depleting chemicals outweigh the risks of predicted ozone depletion. The cost-benefit approach is intuitively appealing and widely employed, but can be difficult to operationalize. Cost-benefit analysis requires quantification of risks and benefits to enable their comparison on a single scale (often monetary). Some object to cost-benefit analysis on the basis that not all goods are commensurable and that some goods should not be given a price. On the opposite side of the ledger, those who support cost-benefit analysis and oppose the precautionary principle emphasize that it is sometimes worth taking risks when significant benefits can be gleaned by doing so. In the ozone case, the debate over precaution was not fully resolved, yet by incorporating provisions for ongoing assessment, the Montreal Protocol stimulated research and innovation that clarified both the importance of restricting ozone-depleting chemicals and the feasibility of doing so.

The regulation of ozone-depleting chemicals through the Montreal Protocol and its successor agreements is often highlighted as an environmental success story from which we can learn. Indeed, international cooperation to address the ozone problem has been impressive, with each successive agreement accelerating reductions in ozone-depleting chemicals. Technological innovation has produced viable substitutes in almost all economic sectors, emissions of ozone-depleting chemicals have declined substantially, and full recovery to pre-1980 levels of stratospheric ozone is expected during this century.

Global climate change shares a number of features with ozone depletion: Effective control of greenhouse-gas emissions requires collective action, and while the scientific understanding has improved substantially, the precise magnitude and effects of climate change remain uncertain. Whether lessons from the ozone case can be applied to help address climate change will depend on similarities and differences in the structure of each problem from scientific, economic, political, and social perspectives. Despite parallels, there are important differences. While it may have been relatively easy for individual consumers to stop using aerosol sprays, for example, it may be more difficult for individuals significantly to reduce their use of fossil fuels. In addition, the kinds and sources of greenhouse gases are more diverse and diffuse than was the case with ozone-depleting chemicals, and this makes coordination to solve the problem more complex. Nevertheless, development of alternative technologies was much more successful than anticipated in the ozone case; perhaps the same will hold true for greenhouse gases and climate change.

P

PAGANISM

Phenomena labeled *Pagan* vary considerably but have, or allegedly have, in common a stress on physical being and belonging. In the mid-twentieth century, *Paganism* was chosen as the name of a religious movement that claimed to be reviving ancient nature veneration and polytheism. In North America, it is common to call this religion *Neo-Paganism* to distinguish it from pre-Christian religions (such as those of classical Rome). *Pagan* is also used in a derogatory sense to allege that some people, religions, activities, attachments, and passions are worldly, bodily, and materialistic, and fail to value the transcendence privileged by Christianity and some other monotheistic religions.

ORIGINS AND APPLICATIONS

Pagan derives from a Latin term for an administrative district. A Roman *pagus* was something like a parish, a township, or a neighborhood perhaps. In the early twentieth century, however, it was thought that *pagus* originally referred to rural rather than urban places. The notion that people in the countryside live in close harmony with the seasons, and with their environment more generally, was linked to the theory that Christianity was initially more successful in the cities than in the conservative backwaters of rural agricultural communities. This understanding had obvious appeal to people who claimed to be reviving pre-Christian religions (initially drawing on classical Egyptian, Greek, and Roman sources), contested the denigration of nature, and were dissatisfied with the alienation from nature that they experienced in urban and suburban modernity. The designation of Paganism as a "nature religion," in contrast with religions that have either transcendent deities or self-realization as their primary focus, shows recognition of the central place that nature has in Paganism.

Paganism has also been used to label adherents of nonmonotheistic religions and cultures. In particular, indigenous people have been called *Pagan* when they continue to practice ancestral, local religions. Some indigenous people, rhetorically admitting to being *Pagan*, challenge others' rights to define them negatively and contest their denigration of place, land, and belonging. All uses of the term *Pagan*, whether as a chosen self-appellation or as a derogatory epithet, carry associations with physicality, materiality, belonging, and also require careful consideration of the categories "nature" and "natural."

SELF-IDENTIFIED PAGANS

As documented by Ronald Hutton in *Triumph of the Moon* (1999), Paganism was created as a new religion in the early to middle twentieth century by people who blended a number of elements together. In addition to stressing the positive value of natural (nonurban) places, Pagans popularized forms of European esotericism, such as the practice of magic, claimed to be reviving various forms of pre-Christian (Egyptian, Greek, Roman, Celtic, and Germanic) polytheism, and integrated these with folklore. Pagans developed attractive rituals and new calendar customs for natural living and earth-based spirituality. The continuing international spread and diversification of Paganism, discussed in Graham Harvey's *Listening People, Speaking Earth: Contemporary Paganism* (2006), is evidence of the popularity of this effort and its evolution.

Paganism has no single central authority or hierarchy, and no sacred scriptures. Pagans are inspired in their quest to understand and celebrate the natural world by a wide range of literature, including botanical treatises, ancient epics, archaeological reports, and fantasy fiction (see Clifton and Harvey 2004). Some Pagans belong to subdivisions or denominations, which they prefer to call "traditions" or "paths," such as Druidry, Heathenry, Witchcraft (or "the Craft"), and Goddess Spirituality. There are also many ethnic Paganisms (e.g., Hellenic, Lithuanian, Norse), drawing on regional and ancestral traditions, archaeology, history, and folklore. In some respects these efforts parallel indigenous revitalization movements that emphasize locally meaningful knowledge and lifestyles. The many variations in ways of being Pagan are usually celebrated by Pagans, some insisting that "diversity is natural, many different types of trees make up a forest."

Common ground among Pagan movements is found in seasonal and calendar festivals. Most Pagans mark the solstices and equinoxes with rituals, and many add other festivals to their annual cycles. These can be honored as key points in the changing seasons (the beginning of summer or the end of winter) or as significant moments in the relationship between Earth and Sun (the longest day or the longest night). Communal events can draw humans into seasonal relations and encourage them to see their personal life cycles as paralleled by changes in larger, cosmic events. Human birth, growth, aging, death, and possibly rebirth can be celebrated as matching the growing and diminishing strength of the Sun in the annual cycle of the seasons. Creativity, intentionality, and productivity are not only human attributes but are also recognizable in the natural world. Springtime festivals may celebrate the growth of plants, the birth of young animals, the increase of light and warmth, and an intention to live creatively in the following seasons.

POLYTHEISM AND MAGIC

In addition to the relationship between the Sun and Earth, full and new moons are of considerable importance to many Pagans. They are valued as particularly good times to venerate divine beings and perform magic. The moon is important to Pagan polytheism and magic because Pagans inherited the idea that the Moon is a favored manifestation of a divine being, a goddess, willing and eager to help people perform magic for the benefit of life.

Paganism is generally polytheistic. While this last term draws attention to a contrast with the monotheistic assertion that there is only one deity, the important issue for polytheists is not how many deities exist, but what results from engaging with a particular *kind* of deity. Polytheism generally encourages a celebration of the material, physical world and embodied life. Rather than an interest in a possible afterlife, it promotes locally meaningful attempts to live as good members of communities conceived of as including not only humans but all other living beings, including deities. Common elements in many Pagan rituals are songs and speeches addressed to the Goddess, where "the Goddess" can be an individual divine being or an entire community of deities. The "Goddess" can also serve as an all-embracing category equivalent to *life* or *nature*; and in some cases it refers to the powerful sense of unity experienced in ritual gatherings. Lack of dogma allows Pagans to celebrate together without requiring conformity to particular beliefs or manifestos. The essence of Paganism is the celebration and enhancement of life for oneself and others.

Pagans explain magic as the art of causing change according to will or the art of changing consciousness according to will. In these formulations, *will* refers to the best sense one has of oneself. Thus, magic requires effort to live up to one's highest standards and to seek to improve oneself. Practitioners are encouraged to think that in rituals they are empowered to change their consciousness about the way things are, improving their understanding and appreciation of the world (realizing that what is bad for an individual may be good for a community, or vice versa). Practitioners are also encouraged to seek to cause change to improve life. The precise means by which magic works, the natural or metaphysical energies that might be drawn on, and the tools for manipulating either consciousness or the world vary according to particular traditions and teachers. In all cases, magic promotes a participative and positive engagement with the world, rooted in the notion that all acts (however small they may seem) have effects that may be of considerable scope.

ANIMISM AND SHAMANISM

If polytheism has been labeled *Pagan* (whether in the positive or negative sense), so too have animism and shamanism. *Animism* has borne two meanings. Initially, it summarized a theory that religion is, by definition, founded in a "belief in spirits." Here, *spirits* meant "nonempirical entities" and the theory asserted the falsity of religions. However, when Pagans and indigenous people talk about spirits, they rarely focus on questions of belief or matters of definition. They might talk about spirits of ancestors, the elements (earth, air, fire, and water), or place, adding the term *spirits* to indicate that these are somehow living, communicative beings who participate in ceremonies. In a second, more useful use, *animism* refers to the view that the world is a community of persons, most of whom are not human, but all of whom deserve respect. *Persons* here points to the importance of

Pagan Celebration in Rakov, Belarus. *Neo-Pagans dance around a fire to celebrate Ivan Kupala, with festivities similar to those of Mardi Gras. Paganism is actually a newer religion, blending different forms of pre-Christian polytheism. Although Paganism is strongly associated with nature, it does not necessarily follow that all pagans are environmental activists.* **AP IMAGES.**

personal relationships with other beings. Like polytheistic Paganism, this variety of animism roots people in the everyday, physical world and even more radically rejects the transcendentalizing project of monotheism.

Along with the understanding of animism, the understanding of shamanism has also changed. *Shamanism* was initially attractive as a label for ecstatic techniques that seemed to result in powerful visions of alternative realities. But shamanism is beginning to be seen as the element of animism in which experts mediate between human and other-than-human communities. The individual experience of transcendence has been replaced by a desire to learn skills for communicating with neighboring beings. Animism and shamanism have become increasingly important as Paganism has moved from its Romantic roots and negated the dualism that separates culture from nature. Pagans may insist either that humans are part of nature, or that the whole world is cultural, in both cases pointing to the inadequacy of language influenced by dualism. Pagans have also insisted that a dualism of good and evil cannot be mapped onto the more messy relationships that make shamanism (as mediation) necessary. All of this may be seen as part of the process of indigenizing Paganism.

INDIGENIZING NATURE

Pagan understandings of nature have evolved quickly since the mid-twentieth century. The Romantic notion that authenticity and meaning are best found in wild places has been replaced by a more indigenous stress on the importance of belonging and participation. Wilderness may remain important, but now as a domain of richer diversity and communicative possibility, rather than in opposition to domains of human culture. Celebration of biodiversity may even lead to *more* (sub-)urban ritual as gardens are recognized as richer habitats than most agricultural land. Along with the shift in academic understandings of the origins of the term *Pagan* (from country dweller to local citizen), Pagans have increasingly insisted that all places are sacred, or at least part of

nature. Just as Roman shrines at key natural places enshrined or animated the concept of a limit to human utilization and commodification of the world, at least nodding toward the rights of other-than-human life, as Ken Dowden (2000) suggests, so contemporary Pagans have contested globalization on the grounds of a more participatory cosmology. In opposing anthropocentricism, Pagans seek to realign human culture away from consumerism toward respectful, local engagement. Experience of belonging in place and of valuing the rumors of ancient practices aid in this indigenizing process.

PAGAN ECOLOGY AND ENVIRONMENTALISM

Paganism is an umbrella term for a religion focused on nature following a variety of practices. Pagan festivals celebrate natural seasons and alignments between Earth, Sun, and Moon. They express the positive value of human participation in natural cycles, but may equally seek to inculcate the notion that plants, animals, and planets act intentionally and relationally, that is, culturally. Leitmotifs of Pagan discourse point to the centrality of materiality, physicality, performance, of secular belonging, of place and emplacement. This is not to assert, however, that as celebrants of a religion of nature, Pagans must be or inevitably are environmental activists. Nature is certainly central to Paganism, but Pagans may prefer to work out their Earth ethic in the quietist domains of their homes (eating organically and recycling) rather than to engage in confrontational activism. They may also insist that Paganism consists more in being at home in the world (one sense of *ecology*), as achieved during seasonal festivals that reconnect people to abiding patterns of cosmic life, than in engaging in environmental activism focused on human activities.

PANTHEISM

Western religious and philosophical traditions do not obviously ground an ecological and environmental ethic. Even those who favor such a program for grounding an environmental ethic might agree that any attempt to ground an environmental ethic in such traditions requires interpretive dexterity and a good deal of charity. Those who think that the route from such traditions to sound environmental ethics and attitudes is too tortuous, if it exists at all, may well look to other traditions for a philosophical or spiritual basis.

Pantheism, with roots in both Eastern and Western traditions, is an obvious source for grounding environmental ethics, because, from a pantheistic point of view, nature itself is divine, and what is in any sense divine is not something to be trifled with or exploited. As John Toland, author of the *Pantheisticon*, wrote, "In a Word, every Thing in the Earth is organic. . . . This justifies my Answer to a German Inn-Keeper, who impertinently importuned me to tell him, what Countryman I was? The Sun is my Father, the Earth my Mother, the World's my country, and all Men are my relations" (1976 [1751], pp. 32–33). Similarly, Bertrand Bronson sees the pantheistic ethos of John "Walking" Stewart as grounding not just an environmental ethic but all morality—or perhaps an environmental ethic is an ontological grounding of all other morality. "The universe is altogether composed of eternal and indestructible matter. All matter is one infinite whole . . . , Nature. . . . It follows from this community of matter that the interests of the whole material universe are intimately the interests of every individual man. This is the basic truth of morality" (1943, pp. 146–147).

WHAT IS PANTHEISM?

Pantheism is a metaphysical and religious position. It is broadly defined as the view that "God is everything and everything is God. . . . The world is either identical with God or in some way a self-expression of his nature" (Owen 1971, p. 74). Similarly, it is the view that everything that exists constitutes a unity, and that this all-inclusive unity is in some sense divine (MacIntyre 1967, p. 34). Baruch Spinoza's *Ethics* (1675) is regarded as the most thoroughgoing account of a pantheistic position. Aside from Spinoza, other possible philosopher pantheists include some of the pre-Socratics, Plato, Laozi, Plotinus, Friedrich Schelling, Georg Wilhelm Friedrich Hegel, Giordano Bruno, John Scotus Erigena, and Paul Tillich. Possible pantheists among literary figures include Ralph Waldo Emerson, Walt Whitman, D. H. Lawrence, and Robinson Jeffers. For a notion of just what pantheism is, the Force in *Star Wars*, while very different from Spinoza's "singular substance," is a good

popularization. Pantheism is the traditional religious alternative to theism, and many profess pantheistic beliefs, though obscurely. The central claims of pantheism are prima facie no more fantastic than those of theism, and possibly less so.

UNITY AND DIVINITY

Different versions of pantheism offer different accounts of unity and divinity. The central problem of pantheism is to determine how to understand these central terms. For example, philosophical Daoism is one of the best articulated and thoroughly pantheistic positions there is. The Way (*dao*) is the central unifying feature, but understanding just what is meant by the Way and how it operates and what its implications are is a hermeneutic and philosophical task in its own right. What kind of unity is, or should be, claimed by pantheists, and which, if any, is plausible? There may be acceptable alternative criteria, and each will have implications for a pantheistic understanding of ethics, including environmental ethics. Like theism, pantheism is by no means a univocal view.

Attributing unity to the world simply on the basis of all-inclusiveness is irrelevant to pantheism. To understand the world as everything is to attribute a sense of unity to the world, but there is no reason to suppose that this sense of all-inclusiveness is the pantheistically relevant unity. Similarly, mere numerical, class, or categorical unity is irrelevant, since just about anything (and everything) can be one or a unity in these senses. Unity may also be explained in terms of divinity. The all-inclusive whole may be a unity because it is divine, either in itself (Spinoza's substance) or because of a divine power informing it. The latter is the case in the thought of some pre-Socratics, for whom the unifying principle is divine because it is immortal and indestructible. Neither of these positions satisfactorily explains the relation between unity and divinity, or why divinity might be seen as a basis of unity. Less naturally, the question arises as to whether the all-inclusive whole is divine because it is a unity.

PANTHEISM, THEISM, ATHEISM

When pantheism is considered as an alternative to theism, it involves a denial of at least one, and usually both, central theistic claims. Theism is the belief in a personal God, who in some sense transcends the world. Pantheists usually deny the existence of a personal God—a minded being having the properties of a person, such as having intentional states. As an alternative to, and denial of, theism and atheism, pantheism denies that God is a completely transcendent being distinct from the natural world. The dichotomy between immanence and transcendence (that is, between a god that is part of this world and a god that is outside of it) has been a principal source of philosophical and religious concern in Western and non-Western traditions, and all major traditions have at times turned to pantheism as a way of resolving difficulties with the theistic notion of a transcendent deity.

A. H. Armstrong says that the term *pantheistic* is a "large, vague term of theological abuse" (1976, p. 187), primarily, it seems, because it is deemed as an expression of atheism. With some exceptions, pantheism is nontheistic, but it is not atheistic. It is a form of nontheistic monotheism, or even nonpersonal theism. The primary reason for equating pantheism with atheism is the assumption that belief in God must be belief in a personal God. In his nonpantheistic phase, Samuel Taylor Coleridge claimed, "Every thing God, and no God, are identical positions" (McFarland 1969, p. 228). H. P. Owen wrote, "If God (theos) is identical with the Universe (to pan) it is merely another name for the Universe. It is therefore bereft of any distinctive meaning; so that pantheism is equivalent to atheism" (1971, pp. 69–70). Similarly, Arthur Schopenhauer (1951, p. 40) said that "to call the world God is not to explain it; it is only to enrich our language with a superfluous synonym for the word 'world.'" If what Schopenhauer, Coleridge, and Owen want to show is that believing in a pantheistic God is a confused way of believing in something that can adequately be described apart from any notion of deity, they are mistaken.

PANTHEISM, ETHICS, ECOLOGY

Pantheists, like theists, tend to be moral realists. They believe that some kinds of actions are objectively right and others wrong, and that what is right or wrong is independent of what any person thinks is right or wrong. With the exception of religious ethics, moral realism has not been a widely accepted philosophical position since about the 1970s.

Not accidentally, pantheism is often taken to be a view inherently sympathetic to ecological concerns. There is a tendency to picture pantheists outdoors and in pastoral settings. This tendency has roots in the Stoics' veneration of nature, and in the much later nature mysticism and perhaps the pantheism of some nineteenth-century poets, such as William Wordsworth and Whitman. This notion was fostered in the twentieth century by possible pantheists such as John Muir, Jeffers, Lawrence, and Gary Snyder, who explicitly identify with and extol nature, and claim that people's close association and identification with nature and the natural is necessary to well-being. Belief in a divine unity and some kind of identification with that unity are seen as the basis for an ethical framework and way of life that extends beyond the human to nonhuman and nonliving things. The divine unity is, after all, all-inclusive.

Consider some examples of alleged connections between pantheism, ethics, and ecology. Armstrong wrote,

> Plotinus may give us a lead to a better understanding of the world and may help us to adjust our attitudes and evaluations in a way which may help us to deal with some of the most pressing problems of our time, and especially to do something towards closing the gap between man and non-human nature which has been widening through the Christian and rationalist centuries with, as we are now beginning to see, disastrous results. (1976, p. 188)

Armstrong denies that Plotinus was a pantheist. But he does claim that there is in Plotinus a metaphysical basis for an environmental ethic in which there are significant pantheistic elements. He suggests how aspects of Plotinus's thought can change our attitudes and evaluations concerning nonhuman nature. Grace Jantzen (1984, pp. 156–157) makes a claim similar to that of Armstrong's in her proposal of a model of the world as God's body. Armstrong's view concerning Plotinus and Jantzen's view concerning the implications of her model for ethics and ecology are often taken to be true of pantheism in general. For religiously inclined nontheists, pantheism is supposed to have the resources capable of (in Armstrong's words about Plotinus) "closing the gap between man and nonhuman nature which has been widening."

Whatever critics allege the shortfalls of pantheism to be, there is a prominent, if not prevalent, view that its implications would be a good thing for ecology and for aspects of ethics dealing with the nonhuman, as well as the human. The work of Spinoza is most prominently cited in this context (Naess 1980; Mathews 1990). Genevieve Lloyd (1980), for example, attempts to extract from Spinoza a ground for environmental ethics, arguing that this can be done without assigning rights to nonhuman natural entities and nature as a whole on the basis of his system.

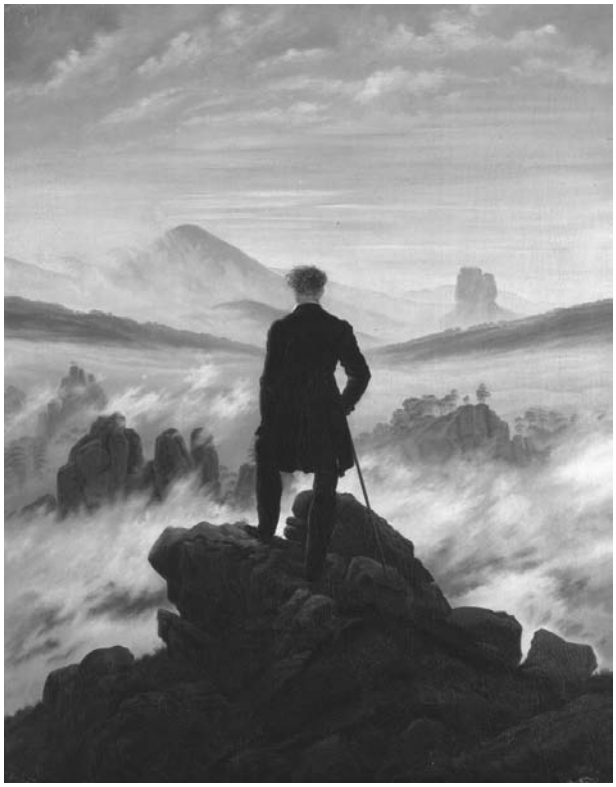
Although Spinoza is the best-known pantheist, looking in his metaphysics for a foundation for environmental ethics is, as Lloyd points out, not without its difficulties. After all, Spinoza rejected animal rights, and despite his view that man is part of nature, environmental ethics is in "apparent tension" with "his treatment of morality as circumscribed by what is good for human beings . . . [and his view] that other species can be ruthlessly exploited for human ends" (Lloyd 1980, p. 294).

Whether or not Spinoza provides a suitable metaphysical basis for an environmental ethic depends, in part, on whether his metaphysics and ethics are plausible. For that reason alone, one might be suspicious of grounding an environmental ethic on Spinoza's philosophy. But Spinoza's particular system aside, it is often supposed that pantheism can offer a more suitable basis for an environmental ethic, and perhaps for ethics generally, than the Judeo-Christian tradition and some nonreligious alternatives, such as utilitarianism, contractarianism, and Kantian views. It is unlikely, however, that the committed theist or utilitarian would, or can, agree that pantheism, if true, offers a better basis for an environmental ethic than their own ethical theories—for metaethical reasons. The meaning of key ethical terms and the conditions governing their use in normative ethical theories are described in terms of normative principles characteristic of a particular system. Utilitarians, for example, would not allow that a pantheist's ethical reasoning provides a sound basis for moral deliberation unless utility, defined in terms of happiness or some other greatest good, were the pantheist's supreme normative principle, which it is not.

Harold W. Wood Jr., a founder of the Universal Pantheist Society, claims that pantheism provides the foundation for an environmental ethic not offered by the Judeo-Christian tradition. He wrote, "Instead of a 'conquer the Earth' mentality, pantheism teaches that respect and reverence for the Earth demands continuing attempts to understand ecosystems. Therefore, among religious viewpoints, pantheism is uniquely qualified to support a foundation for environmental ethics" (1985, p. 157). He talks about interacting with "God-as-nature." With the important exception of Spinoza, pantheists generally do not equate God with nature, but rather believe that nature is a divine unity.

The idea of unifying principles is also present in nature mysticism, as manifest in the work of Wordsworth and some other Romantics. Nature mysticism (as found in the poetry of Wordsworth, Jeffers, and Snyder) has in common with more philosophically robust versions of pantheism the idea that unity is rooted in nature, and this common feature explains why nature mysticism and philosophical pantheism are often conflated with one another. They are distinguishable, however, for nature mysticism need not attribute divinity to nature.

As noted, a pantheistic environmental ethic cannot self-consistently be anthropocentric. Arne Naess (1980) pointed out that Spinoza's anthropocentrism was inconsistent with his pantheism. The pantheist's ethics—environmental ethic and ethics more generally—is metaphysically grounded in the divine unity, the unifying principle that accounts for our commonality with other living and nonliving things and the grounds for extending our notion of moral community to those other living and nonliving things. Everything that is part of the divine unity (as everything is) can be thought of as also part of



Caspar David Friedrich,* Wanderer above a Sea of Fog, *Ca. 1817. *The pantheistic tradition views nature as divine, and asserts that anything divine should not be trifled with or exploited. Moreover, pantheists believe in an all-inclusive God who is "everything and everywhere;" this allows the religion to be an obvious source of environmental ethic. Friedrich's painting of the Wanderer depicts the artist's interest in nature, and alludes to the idea that morality involves oneness with nature.* **BILDARCHIV PREUSSISCHER KULTURBESITZ / ART RESOURCE, NY.**

the moral community. Aldo Leopold wrote, "The land ethic simply enlarges the boundaries of the community to include soils, waters, plants, and animals, or collectively, the land. . . . A thing is right when it tends to preserve the integrity, stability, and beauty of the biotic community. It is wrong when it tends otherwise" (1949, pp. 219, 240). Looking to pantheism as a metaphysical justification of, for example, Leopold's "land ethic" is not unreasonable—or at least no more unreasonable than pantheism itself is.

Philosophically minded ecologists and others who argue, on the basis of pantheistic metaphysics, that our notion of moral community must be enlarged to include nonhuman and even nonliving entities, also claim that practical consequences are involved. The issue is not merely one of providing a rational basis for an environmental ethic. The metaphysically minded ecologist or pantheist claims that the desired results can be obtained only by changing our concept of what constitutes the moral community.

The pantheist, like the theist or atheist, takes reality as determining ethical requirements. Since unity is predicated for some evaluative consideration, value is a focal point and principal concern for pantheism. The pantheist's ethical discourse is related in complex ways to the nature of the divine unity. The pantheist tries to discern and live in accordance with the unity and the kind of values intrinsically associated with it. This is clearly seen in Daoism. To act correctly, one acts in accordance with the Way (*dao*), which is the unifying principle. The *Daodejing*, like most other primary scriptural sources, is at one and the same time an ethical treatise on how to live and a metaphysical treatise about the nature of reality. The Indian doctrine of karma can also be interpreted pantheistically: Action that accords or defies the all-pervasive principle of retribution is by its very nature associated with value and promotes the good.

ETHICS, THE ENVIRONMENT, AND IMMORTALITY

Living an ethical life for the pantheist means, in part, living a life in accordance with ultimate reality. In attempting to conform to ultimate reality, the pantheist is no different from the theist, Daoist, Confucian, Buddhist, or atheistic existentialist. Pantheists strive to live in accord with reality as the divine unity of which they are a part. The nature of the unity is the metaphysical basis for a regulative ideal of how one should live. One achieves well-being and happiness only to the extent that one pursues and achieves the ideal. Living in accordance with the unity is to live in accord with one's nature, with the nature of other things, and with conditions in the world generally.

The notion of an ethical and valuable life, of pursuing an ideal and realizing the good life, is linked to the idea that living involves a *telos* or goal. Thus, pantheistic ethics can be seen as partly teleological, even Aristotelian. Pantheistic ethics may also be related to the theistic notion of salvation. Jeffers, for example, writes,

> I believe that the universe is one being, all its parts are different expressions of the same energy, and they are all in communication with each other, influencing each other, therefore parts of one organic whole. . . . The parts change and pass, or die, people and races and rocks and stars; none of them seems to me important in itself, but only the whole. This whole is in all its parts so beautiful, and is felt by me to be so intensely in earnest, that I am compelled to love it, and to think of it as divine. . . . This whole alone is worthy of the deeper sort of love; and . . . there is peace, freedom, I might say a kind of salvation, in turning one's affections outward toward this

> one God, rather than inwards on one's self, or on humanity. (Quoted in Sessions 1977, p. 512)

Consider further this celebrated passage from Emerson's *Nature*:

> In the woods is perpetual youth. Within these plantations a decorum and sanctity reign, a perennial festival is dressed, and the guest sees not how he should tire of them in a thousand years. In the woods we return to reason and faith. There I feel that nothing can befall me in life—no disgrace, no calamity (leaving me my eyes) which Nature cannot repair. Standing on the bare ground—my head bathed by the blithe air, and uplifted into infinite space—all mean egoism vanishes. I become a transparent eye-ball; I am nothing. I see all. The currents of the Universal Being circulate through me; I am part or particle of God. (1971 [1836], p. 10)

Pantheism, like Aristotelianism and theism, has its own notion of the *telos* of life and its own concepts of the good life.

PASSMORE, JOHN ARTHUR
1914–2000

John Passmore, an Australian philosopher, was the author of the first philosophical monograph on environmental ethics, *Man's Responsibility for Nature* (1980; first edition, 1974). Although Passmore's anthropocentric approach was widely rejected in favor of nonanthropocentric alternatives in the decades immediately following the appearance of his book, Passmore was enormously influential in persuading philosophers that environmental issues merited serious attention.

Unlike his professional colleagues in the 1960s and 1970s, who ignored environmentalists' charges that the anthropocentrism of Western traditions of metaphysics, morality, and science made these traditions incapable of criticizing or condemning large-scale environmental destruction, Passmore took these charges seriously. In *Man's Responsibility for Nature*, he evaluates arguments for these charges and for the solutions critics were

proposing: a radical revision of Western metaphysical, moral, and scientific theories. Passmore argued that while the dominant metaphysical traditions of Western thought are guilty as charged, Western moral and scientific traditions are not. Divested of the metaphysical baggage that has distorted them, these latter two branches of the Western tradition, despite their anthropocentrism, provide sufficient resources to condemn our environmentally destructive practices. He presented his argument in three parts.

In part 1 of *Man's Responsibility for Nature* Passmore considered and largely endorsed the charge that the Christianizing of Western metaphysics encouraged Westerners to see human beings as possessing a value and destiny fundamentally divorced from that of the natural world and to view the latter's value and purpose as limited to its utility in helping us to fulfill divine injunctions to multiply on and subdue Earth. This conception of our status in relation to nature, Passmore agreed, licenses our adoption of environmentally destructive practices. But although this view of our relation to nature has long been dominant, he argued, it has always had rivals. Even within Christianity, we find minority traditions holding that our role is to act as nature's steward, preserving its fruitfulness for the future, and/or to cooperate with nature in the ongoing creation of the world.

In part 2 he considered and rejected the charges that Western moral and scientific traditions lack the means to condemn environmentally destructive practices and thus should be replaced by nonanthropocentric alternatives. Passmore's strategy was to adopt the anthropocentric outlook typical of Western moral and liberal political theories and then apply it to current controversies about human exploitation of nature to show that it neither blinds us to the problematic character of human exploitation of nature nor denies us grounds for criticizing destructive exploitation as harmful, unjust, selfish, and/or wrong. From an anthropocentric perspective, he argued, any environmental practice is problematic whose consequences are undesirable in themselves without also being unavoidable byproducts of those human practices genuinely essential to desirable social life. Using this anthropocentric definition, Passmore argued that he is no less able than nonanthropocentrists to recognize that industrial pollution, depletion of nonrenewable resources, extermination of wild species and wilderness areas, and unrestricted human reproduction are all problematic. In each case, Passmore argued, the responsible practices have consequences that are undesirable while being largely nonessential for desirable social life. Hence, our standing moral and social traditions can and rationally must condemn the greed, insensitivity, and shortsightedness that motivates these practices, as well as the callousness and injustice inherent in imposing their avoidable consequences upon their unwilling victims, present and future.

Unless the dominant metaphysical conception of humanity's relation to nature can be displaced by conceptions more in keeping with the minority traditions of stewardship and/or cooperative partnership with nature, the forces of greed, shortsightedness, and insensitivity cannot readily be overcome by appeals to morality and justice alone, Passmore felt. He argued that Western scientific reasoning is playing an important role in helping to bring about this change in perspective. Science has challenged the old belief that Earth's resources exceed our ability to consume them, forcing upon us the realization that they may not sustain future generations if loving stewardship is not practiced. Furthermore, as scientific understanding of ecological complexity increases, it becomes increasingly evident that bending nature to our will is an impossibility. Ongoing creativity in art, science, morality, and culture will become impossible unless we learn to partner with nature to develop more sustainable practices. Passmore concluded that enlightened anthropocentrism, coupled with conceptions of humanity as stewards of nature and cooperative partners with nature, possesses the necessary resources to condemn our current destructive practices and demand their reform—if only we can find the will to act accordingly.

PATENTING LIFE

The extension of patents to living matter has raised a host of political, economic, ethical, and practical concerns. New science and new institutions offer expanded

opportunities for individuals and organizations to claim ownership and control of components of life or entire living organisms. This entry examines the historical context for ownership of living matter, the modern structure of ownership, the current status of ownership and control, and an array of issues triggered by expanded private ownership of life.

THE HISTORICAL CONTEXT FOR OWNERSHIP OF LIFE

The modern debate about ownership of life is embedded in the history of the science and the institutions designed to advance and use that science. Before recorded time, most people lived as hunters and gatherers, gathering plants and hunting animals for their immediate use but not really controlling or nurturing those organisms. As peoples settled down and began to identify and improve, adopt and adapt, a range of plants and animals as foods, they exerted ownership by asserting individual or communal possession of breeding stock or by controlling knowledge about its characteristics (Diamond 1997).

The concept of intellectual property rights—the right to exclusive ownership and exploitation of useful inventions—originally came in the form of trade secrets. In some cases these secrets involved know-how that could be passed along to others and repeatedly used to make or improve goods or services (e.g., bread making or brewing). In other cases, innovations were embedded in a living reproducible organism, but only the products of those organisms (e.g., grafted fruit trees) were widely exploited. This de facto form of intellectual-property protection was relatively inefficient, however, because the owner had to make often expensive and wasteful efforts to keep the intellectual property secret.

MODERN PROPERTY-PROTECTION MECHANISMS

Explicit, legally sanctioned property rights for technologies, products, processes, or business practices are relatively new. Our modern patent system is firmly rooted in Enlightenment England. The evolving common-law system in England first accepted and confirmed that individuals have the right to the "fruits of their labor" (Locke 1950 [1689]) and then developed a patent system that ultimately protected "inventions" of new and useful products, processes, and technologies.

Patents are essentially a bargain between society and inventors. Inventors get an exclusive period of twenty years to exploit their inventions in exchange for full disclosure of their methods. To patent an invention, the technology, process, product, or business practice must be "novel, useful and non-obvious." This precludes patents on mere discoveries (e.g., an unimproved plant from nature), concepts not reduced to practice, and previously known ideas and products. Patent rights are granted only in the country of application, and rights must be enforced by the inventor. There are no automatic exemptions for others to use patented material for further advances, so researchers and those seeking to commercialize follow-on inventions need to negotiate with related patent holders. Once the patent has expired, the protected knowledge enters the public domain.

Living matter was excluded from early patent systems because the state of science and technology was at a level where new plant varieties or animal breeds could not meet the tests of being novel, useful, and nonobvious. Modern science began to break down the divide between living and nonliving inventions. While modern biology is usually dated from the 1860s, with the emergence of Charles Darwin's theory of evolution (1859) and Gregor Mendel's laws of inherence (1866), it took another generation before these concepts were reduced to practice and systematically applied to breeding plants and animals.

The legal system began to adapt in 1930, when the United States allowed patents on asexually propagated plants, such as fruit trees produced by grafting. Then in the 1940s a number of European countries created property protection, called plant breeders' rights, for sexually reproducing plant varieties. Plant breeders' rights provide developers of new, stable, and uniform plant varieties an eighteen-year right to control the sale of propagating material and to levy royalties for use by others. As with patents, these rules are nationally based; there are no automatic international rights. Plant breeders' rights are cost-effective but offer less protection than patents, as farmers may save seed for replanting and researchers are allowed to use existing varieties to develop new varieties.

The biotechnology era may be dated from 1953, with the discovery by James Watson and Francis Crick of the double-helix structure of deoxyribonucleic acid (DNA), but it practically began in 1973 when Herbert Boyer and Stanley Cohen invented a method of cloning genetically engineered molecules in foreign cells—what has become known as the "cut and paste" method.

The legal system converged with the new science in 1980, when the U.S. Supreme Court granted a utility patent for claims related to a human-engineered microorganism, on the basis of a definition of the organism as a new composition of matter (*Diamond v. Chakrabarty*, 447 U.S. 303, 206 *USPQ* 193). This decision was followed in 1985 by a utility patent for a genetically modified plant, and in 1988 for a genetically modified animal (*Ex parte Hibberd*, 227 *USPQ* 443 [Bd. Pat. App. & Inter.]).

Since the 1980s these developments in the United States have been replicated around the world. In some

cases governments legislated or courts ruled in ways that adjusted national rules to conform to the U.S. system. Meanwhile, international negotiations knit together groups of national systems through treaties. Finally, in 1995 the World Trade Organization Agreement and its associated Trade Related to Intellectual Property (TRIPs) Agreement extended intellectual-property rights internationally, requiring all 150 member countries to provide inventors the option of either patent protection or, in the case of living organisms, some form of protection, such as plant breeders' rights. As of 2006, all member states of the World Trade Organization, including developing countries, are required to provide protection.

CONTEMPORARY OWNERSHIP OF LIFE

As a result of the evolution of science and the complementary development of property-rights systems, there are now thousands of ownership claims to living matter and the tools and structures needed to make use of that living matter. One way to examine the scope of ownership is to take a slice through the information, knowledge, tools, and processes used to manipulate living matter.

In 2008 more than 1,500 organisms, ranging from unicellular yeast to the human genome, are being or have been sequenced. While there was a great flurry of patenting activity of some gene sequences in the 1990s, as of 2008 most genomic information is freely and publicly available in databases. About the only people with effective property protection in this domain are the owners of the machines and inputs used in the sequencing process.

There are also a variety of public and private gene banks, where living plants (mostly seeds), microbes, and animal and human tissues (e.g., blood and cell lines) are preserved. While much of this genetic material is in the public domain (e.g., the more than 600,000 seed accessions of the eleven gene banks of the Consultative Group on International Agricultural Research), there is increasing private interest in genetic material, especially human tissues (e.g., in Iceland and Estonia, where a mix of public and private interests have been developing population gene banks) (Sheremeta and Knoppers 2007).

While the conventional tools of plant and animal breeding have now all entered the public domain, the tools of biotechnology are so recently patented that most remain closely held by firms, universities, hospitals, or public research labs. Some large multinational companies have a bundle of complementary technologies that enable them to operate freely, but most firms and public research programs need to negotiate licenses from other patent holders to assemble the rights to undertake research or to commercialize the resulting products of that research.

Downstream in the products of biotechnology, two somewhat different systems have emerged. Plants and animals can be protected by plant breeders' rights or animal-pedigree rules. While there are no conclusive data, one can probably safely say that virtually all commercially developed plant varieties and animal pedigrees are protected by one or more property mechanisms. Meanwhile, patents have been used in a variety of ways to protect the products of biotechnology. In the plant and animal world, most countries of the Organization for Economic Cooperation and Development offer protection to inventors who insert proprietary genes in plants, and in the United States and the European Union, inventors can claim patents on an entire multicellular organism that is genetically modified. Although Canada, among others, has declined to extend patents to multicellular organisms, the Supreme Court of Canada, in its 2004 review of *Monsanto v. Schmeiser*, ruled that while patents are not permitted on whole plants, the presence of the Roundup Ready gene in every cell of the plant provides the right to exert control over an entire plant (Phillips 2007a). So the rule of thumb for farmers wanting to use commercially developed genetically modified plants and animals is that they should conclude licenses with the owners.

Patenting human genetics is different. Although most countries allow patents on genes and in some cases organs, no country will allow patents on entire humans. Such an extension of rights is deemed by all to offend the *ordre public*. Nevertheless, patenting has proceeded apace. A recent study by Kyle Jensen and Fiona Murray (2005) concluded that 4,270 human genes (in 4,382 claims), nearly 20 percent of all known human genes, have been claimed in U.S. patents. Nearly two-thirds (63%) of these patents are assigned to private firms, with the rest assigned to individual researchers, hospitals, research labs, and universities.

CONTROVERSIES

There has been vociferous debate about the most appropriate systems to deal with intellectual advances—those ideas, recipes, formulas, and processes that generate increases in economic productivity and social well-being. Some controversies involve the ethics of what we are doing, while others relate to the ethics of the outcomes we are generating (for a survey of the economic issues, see Phillips and Stovin 2000).

The Morality of Ownership of Life Many are unhappy with the scope of what is patentable. There is virtually unanimous agreement that it is immoral to patent whole humans, and no systems allow such patents, but there is a wide range of views about what other potential living matter should be excluded or have restricted protection.

Many of the cases related to living matter (e.g., *Moore v. Regents of the University of California* 793 P.2d 479, Cal. 1990) have touched on this issue, but frequently the issue has been related more to who should own the invention rather than whether a patent should be issued.

Nevertheless, many environmental groups, developmental nongovernmental organizations, church groups, and farmer advocates have called for patents to be removed from all higher life forms, including animals and plants, arguing that patenting living organisms is either immoral, inequitable, or inefficient. Also, developmental nongovernmental organizations and indigenous communities have called for much tighter control on patenting of indigenous knowledge and genetic resources and seek broad exemptions from patent enforcement for indigenous farmers and for humanitarian purposes.

Because moral issues are hard to legislate, governments have generally set up systems to allow individuals or groups to raise specific concerns. The TRIPS Agreement permits an *ordre public* provision to address noneconomic values in the patent system. On a case-by-case basis, patents can be refused should the commercial exploitation of the invention violate public order. European Directive 98/44 on the Legal Protection of Biotechnological Inventions (European Commission 1998), for example, states that processes that use human embryos for commercial purposes and processes that clone human beings violate the *ordre public*. In practice, this provision is usually invoked by a third party in an opposition procedure after the patent has been granted. Some systems provide an opportunity to challenge patents while they are being evaluated. Australia, the European Patent Office, France, Germany, India, and Japan currently have opposition processes, and a recent U.S. report has recommended establishing an opposition procedure in the U.S. patent system.

Intellectual-Property Rights and the Freedom to Operate The creation of private intellectual-property rights for biotechnological innovations in the past thirty years has opened the system to substantial private involvement, and this has raised the concern that intellectual property rights make research and commercialization more complex, costly, and inequitable.

One of the most pressing issues for many scientists and companies is the freedom to operate in a world of overlapping and interwoven claims to intellectual property. One often cited example is golden rice, which was developed by public-sector scientists in Switzerland for public-good purposes. When they realized that seventy patented technologies owned by thirty-two different entities had been used, they decided that they did not have the capacity to acquire freedom to operate without assistance, and ultimately decided to assign the product to a large multinational company to commercialize it (Kryder et al. 2000). A big part of the problem is that markets for intellectual property are just beginning to emerge. It is still expensive and time-consuming to search for patent owners or their agents; negotiations for licensing are often protracted; and enforcing rights through contracts or the courts can be prohibitively expensive.

There is rising concern that patents constrain research activity. There is clear evidence in the plant biotechnology industry that since the extension of property rights, many multinational firms have entered and as of 2008 a few dominate some crops. Even though smaller ventures may be able to do research, no start-up firms have successfully commercialized any new genetically modified crops. Meanwhile, in the field of human health, Mildred K. Cho et al. (2003) surveyed clinical laboratory directors in the United States and found that 53 percent had decided not to develop some new clinical genetic tests because of patent concerns.

Patents are also having an effect in product markets. Percy Schmeiser's unsuccessful challenge of Monsanto's patent on Roundup Ready canola was at one level a question of freedom to operate—in this case Schmeiser attempted to assert a farmer's privilege to seed. The Canadian courts ruled that Monsanto has both the right to patent their invention and the authority to commercialize it under their own rules (a contemporary case in the United States, *Monsanto v. McFarling*, delivered similar results). A slightly different argument was made by a group of organic farmers in Saskatchewan, Canada, in an unsuccessful class-action suit (*Hoffman and Beaudoin v. Monsanto and Bayer*). The organic producers argued that the presence of openly pollinated genetically modified canola released by the defendants made it impossible for organic-canola producers to assure foreign buyers of their organic status, and this led to losses in the European Union. The trial courts, upheld at the appellate level, ruled that there was no basis for a class-action suit because there was too much diversity in the farming population. Any claims would have to proceed through other means. This case left unclear whether firms commercializing genetically modified crops are liable for any economic damage they cause other producers (e.g., by commingling in fields or the supply chain).

There is no doubt, however, that firms producing genetically modified crops are liable for health and safety risks. In 2000 Aventis CropScience ended up recalling StarLink hybrid feed corn, with the insecticidal Bt gene, which was not approved by the U.S. Food and Drug Administration for human consumption. In 2000 the feed corn, after two years of use as a commercial feed, was found

Altered Tomatoes. *A German biologist examines a genetically transformed tomato plant. The transgenic plant has a safety lock, which means that the release of its altered genes, for example, through pollen, is not possible.* **AP IMAGES.**

commingled with food corn in the U.S. and other food systems. The company spent an estimated $100 million to remove the variety from the market, paid penalties to the regulators, and settled a class-action suit on behalf of farmers with a $110 million settlement (Phillips 2007b).

Patents and Traditional Knowledge Although only a small part of the agricultural revolution in Europe in eighteenth and nineteenth centuries can be traced to species and varieties of plants from other ecosystems, the major advances in the twentieth century are directly attributable to the collections of landraces and germplasm assembled from around the world. With the availability of the modern tools of biotechnology, there has been a renewed interest in examining genetic resources—regardless of whether they are located in situ in traditional settings or ex situ in modern seed banks—to identify and adapt any useful genes.

The debate about the source and use of traditional varieties of crops (and even human genetic traits) has shown up in two venues. First, a number of groups have disputed and formally challenged patents issued in the United States and the European Union for purportedly new varieties that are actually traditional cultivars from developing countries. High-profile cases include the Mexican yellow bean (a U.S. patent by Pod-Ners for Enola was challenged in U.S. courts by the International Centre for Tropical Agriculture), Indian turmeric (a patent for its wound-healing properties issued in the United States was challenged and subsequently canceled), the Indian neem tree (a series of patents for industrial and pharmacological properties assigned to W. R. Grace and Company issued in the United States and the European Union were challenged and struck down in Europe), and basmati rice (a patent in 1997 by RiceTec Inc. was challenged in the United States and subsequently amended). These and other proven or alleged acts of biopiracy have increased debate about the concept of invention, the definition of prior art, and the ethics of using traditional knowledge and genetic resources in patents.

Second, there is extensive international debate about, and effort directed toward, protecting traditional knowledge and indigenous genetic resources through legal agreements. Efforts are underway at the International Labor Organization, the United Nations (via various declarations on rights of indigenous peoples), the development banks, and the Convention on Biological Diversity. The International Undertaking on Plant Genetic Resources for Food and Agriculture (1983) and the International Treaty on Plant Genetic Resources (2001), which establish genetic materials as the common heritage of humankind, have led to further negotiations under the aegis of the TRIPS Agreement (article 27.3b), the Doha Declaration (article 17), the Convention on Biological Diversity (article 8j), and the World Intellectual Property Organization. Nevertheless, the issue remains unresolved and a point of contention among indigenous communities and governments around the world (Phillips and Onwuekwe 2007).

CONCLUSION

At one level, the debate about ownership of living matter is not new. A variety of strategies for protecting inventions related to living organisms—including trade secrets, private contracts, and commercial strategies—predate patents. What is new is that patents have created a new mind-set about the opportunities and threats of global development using living matter.

Some believe that patents on living matter are absolutely essential for scientific and commercial development. Without patents, they argue, development would slow or cease on many projects related to food, health, and the environment. They argue that patents offer an open, transparent, and relatively economically efficient means of encouraging investment and commercialization. Moreover, patents facilitate our broader governing system by creating clearly defined assets and sets of owners, which provide the basis for financing, marketing, regulatory assessment, safety monitoring, and enforcement. All key regulatory processes formally or informally rely on the ownership assigned through patents. Without any owner, there might not be any concerted effort at development.

Others see patents on life as a dangerous development. They see patents as contributing to winner-take-all races among large multinational corporations and developed countries that seek to dominate nature. The fear is that by and by patents on living matter will distort our

economic system, deliver inequitable economic effects, generate undesirable social outcomes, and ultimately exacerbate many of the problems we wish to resolve.

At root, the issue of ownership and control is a long-standing and fundamental division in cultures and societies. The debate over their role in biotechnology and nature is just one in a long line of ownership controversies.

PESTICIDES

Although it has no biological validity, the term *pest* is assigned to any organism that is doing something that someone finds unpleasant. The word *pesticide* comes from the Latin *pest*, "a plague," and *caedere,* "to kill." Pesticides are chemicals, cultured organisms, or their products that are used to disrupt an organism's physiology long enough to kill it or severely reduce its growth. There are at least twenty-one groups of pesticides, each defined by the organism or organisms they control. The most familiar are insecticides (insects), herbicides (plants), fungicides (diseases), and rodenticides (rodents). Other groups include algicides (algae), avicides (birds) nematicides (nematodes), piscicides (fish), and silvicides (trees and woody plants).

Agricultural applications account for 83 percent of all the pesticides used in the United States. Industry, commerce, and government use 13 percent, and home and garden users are responsible for only 3 percent. Herbicides account for 58 percent of all the pesticides used, insecticides 28 percent, fungicides 8 percent, and all others 7 percent (U.S. Environmental Protection Agency 2001). Agricultural uses generally are regarded as essential to continued production of abundant food. Many believe that improved pesticide technology will eliminate the problems pesticides cause and enhance the sustainability of agriculture, but that claim is debatable. Pests and pesticides have been scientific issues for many years. Only recently have they become subjects of philosophical inquiry.

PESTICIDE REGISTRATION

Most nation-states have some sort of pesticide registration. In some developing countries procedural and data requirements are few to nonexistent, primarily because of fiscal constraints but also because of lack of awareness of the importance of registration. The laws are not well implemented in some countries. Pesticide regulators have the goals of providing protection from adverse effects and gaining the benefits of pesticides. Those objectives are achieved through registration and control of the pesticide label, which allows control over use, performance claims, use directions and precautions, packaging, and advertising. Registration protects the interest of the public and the rights of the manufacturer by ensuring proper use and environmental and human protection.

In many developed countries pesticides have been subject to some kind of governmental regulation for decades. The public is aware of potential problems with pesticides and fearful because of the mistakes that have occurred. Nearly everyone knows something negative about DDT (banned in 1971 in the United States; all use ended in 1973), and many are aware of problems caused by the use of Agent Orange during the Vietnam

Crop Duster, Hebron, Maryland. *A farmer sprays chemicals on a field of snap beans. The beans had been showing signs of white mold due to heavy rainfall. The use of pesticides in agriculture has been heavily debated, with the main issue being production (of crops and goods) versus protection (of humans and the environment).* **AP IMAGES.**

War. The public does not know about the complex and continually reviewed procedures necessary for the registration of a pesticide before it is used. Registration is not a matter simply of recording ownership and paying a nominal fee. It mandates compliance thorough a regulatory process that demands proof of safety but usually not proof of efficacy.

The U.S. system is among the most complex and successful; however, it is not perfect, and there are many complaints from persons who argue that protection is not sufficient and also from manufacturers who find the process slow, expensive, and unnecessarily cautious. The United Kingdom (UK) used to have a voluntary approval process in which a consensus was reached among the manufacturer, the government, and users about appropriate regulation. It was abandoned in the mid-1980s, and the UK and the European Union now regulate advertising, storage, application, and crop use. Many nations follow the standards put forth by the United Nations Food and Agriculture Organization Codex Committee on Pesticide Residues, which establishes maximum residue limits for pesticides in food and guides countries on safety regulations for the use, storage, and analysis of pesticides. Egypt reduced pesticide use 90 percent from 1971 to 2002. No herbicides are permitted on crops grown for export.

FEDERAL INSECTICIDE, FUNGICIDE, AND RODENTICIDE ACT

Pesticide development after World War II created the need for stronger laws. The U.S. Department of Agriculture (USDA), supported by the pesticide industry, developed the 1947 Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA). No other federal law controls pesticides and their labeling. The FIFRA added two new ideas to pesticide regulation. The first was that all pesticides intended for shipment in interstate commerce must be registered with the secretary of agriculture before shipment. The second was that the USDA had control over all precautionary statements on a pesticide label and was empowered to review the public presentation of safety procedures. Manufacturers have the burden of proof.

These provisions stopped the shipment of untested or improperly labeled products in interstate commerce. Withholding registration effectively stopped unapproved

uses. The USDA could withhold registration until data were provided to prove that a pesticide could achieve the degree of pest control claimed and did not cause human harm. The act protected users from physical injury and economic loss and protected the public from injury (previously only purchasers were protected). Manufacturers had to prove effectiveness, and pesticides were defined and limited to economic poisons, which the act defines as "any substance or mixture of substances intended for preventing, destroying, repelling, or mitigating any insects, rodents, fungi, weeds, and other forms of plant or animal life or viruses except viruses on or in living man or animals."

THE PESTICIDE USE DEBATE

Public debate about pesticide use began with publication of Rachel Carson's *Silent Spring* (1962), which was followed by *The Pesticide Conspiracy* (Van den Bosch 1978), which was less widely read but had notable effects. There have been many books and papers published since that time, but none has had Carson's influence.

The debate about pesticides is similar to other debates about agricultural technologies (e.g., biotechnology). Thomas DeGregori expresses the enduring scientific perception of the problem when he states that "public discourse is being driven by emotional language" (DeGregori 2002, p. 125). Norman Borlaug argues that scientific progress "must not be hobbled by excessively restrictive regulations" (Borlaug 2001, p. 28). If the needs of the 8.3 billion people who are likely to be alive in 2025 are to be met, Borlaug claims, conventional technology and biotechnology will be essential. He also claims that "extremists in the environmental movement, largely from the rich nations or the privileged strata of society in poor nations, seem to be doing everything they can to stop scientific progress in its tracks" (p. 29). Borlaug acknowledges the debt of agriculture to the environmental movement, whose efforts have led to "legislation to improve air and water quality, protect wildlife, control the disposal of toxic wastes, protect soil, and reduce loss of biodiversity" (p. 29). However, antitechnology extremists have gone too far and their policies will have "grievous consequences for the environment and humanity." Borlaug's claim is ironic in that those in the environmental movement continue to pursue improvement of the things for which he thanks them.

The 1947 FIFRA was a truth-in-packaging law that emphasized the value of production over protection. The ensuing DDT debate and other pesticide problems (e.g., the dependence of production on pesticides, pesticide resistance, the lack of sustainability of the agricultural production system) have shifted regulation and public discussion away from the initial emphasis on production toward the protection concerns of the environmental movement.

According to the scientistic view of science, "science can determine a fact, that these facts represent objective reality, and that values or beliefs play no role in determination of facts" (Barker and Peters 1993, p. 5). Scientism sees science as objective and value-free and states that it is not the scientist's task to create or change social, economic, or political policy. Scientism is a caricature of the actual nature of science, which is socially embedded, value-driven, theory-laden, and dynamic, so that today's scientific "truth" is tomorrow's falsehood. Scientists attempt to understand and explain the natural world, and technology applies scientific findings to the world. In general, science has been regarded by the public as good and technology has been judged to be good or bad depending on how it is used (Boulter 1997). However, science and its underlying values have moved from being viewed as an unalloyed public benefit to being regarded with suspicion, if not distrust. Scientists used to be seen as being guided by wholesome curiosity and a search for the elusive truth. Now the public is wary. Science, like all human activities, is influenced by social, economic, and political pressures. It is equally well known that some bad consequences that scientists said were unlikely actually have occurred. For example, there are pesticides in some drinking water supplies and food, and nitrates pollute water. Yet there is little debate in the agricultural community about how such things come to be. Within the agricultural community these situations are regarded as unfortunate technological accidents, not moral failures.

Public and scientific debates about pesticides frequently are based on scientific facts—often selected facts—but the disputants nearly always disagree about the story (Charles 2001). All stories are in some sense true, especially when one knows the preconceptions of the storyteller. The dispute is over the goodness of the characters (their virtue or lack of virtue), the plot (why is this happening?), the editing (what facts count?), and how it all will end (Charles 2001). What one hears or reads in these conflicting stories is often not a reasoned debate of the issues. It is a presentation and defense of one of the polar views: Pesticides are good and are required to feed the expanding human population versus pesticides are bad (for a variety of reasons, especially the unpredictability of future effects) and will not help feed people. Pesticides, many argue, are unpredictable, threatening, and a product of the type of human folly that leads people to believe that they can and should control the environment.

PERCEPTION OF RISK

Science can measure risk and determine the probability of the occurrence of a defined risk. Safety, in contrast, is a normative personal or political judgment. Judgment of

safety is not and should not become a scientific decision. Science creates the data on which many judgments and decisions are based, but scientists, through the scientific process, cannot determine individual actions or public policy on the basis of their data. Something may be described as unsafe because it is found through observation to increase the risk of undesirable consequences. For example, a pesticide can have high human toxicity or be an environmental hazard. Scientists can measure the risk (the likelihood) of human or environmental effects. Farmers may decide not to use a pesticide, insurance companies may charge high premiums if it is used, and legislative bodies may pass laws requiring special use precautions. Scientists may agree with those actions, but science does not create them.

People perceive risk in different ways depending on where they live, how rich or poor they are, their level of education, their friends, the scientific evidence they are aware of, what they read, and so on. Perception of risk may differ from the facts as determined by scientific study. But what degree of risk is acceptable and to whom? The answer may be determined legislatively, or it may be determined by one's perception of the risk. Many people are much more likely to accept a very risky activity (e.g., mountain climbing, hang gliding) if they assume the risk voluntarily, the likely effects are perceived to be delayed, the risk is a known common hazard, there are no alternatives available, and the consequences are thought to be reversible. When the opposite situation prevails, risks are accepted less readily. There are 2,000 to 3,000 cases of pesticide poisoning in the United States each year but only about 30 deaths. There are several thousand cases of pesticide poisoning and many more deaths in developing countries each year. In the United States pesticides are regarded as more risky and dangerous than the data show they really are. This is the case because they are seen as uncontrolled, involuntary risks with irreversible, severe, rapid consequences. There is uncertainty about long-term negative effects on human health or the environment. Pesticides are perceived as things that are likely to be misused and are regarded as dreaded, uncommon hazards.

There should be debate about whether pesticides can be hazardous to humans or the environment. They are toxic to people and will poison and may kill if they are not used properly. Many prescription pharmaceuticals, household cleaning agents, aspirin, automotive fuel, and other common products also are dangerous if they are not used properly. Their inherent toxicity does not change with use, but the possibility of danger increases with improper use. Neither stupidity nor ignorance increases the inherent toxicity of anything, but both increase risk.

PHENOMENOLOGY

Feelings have a central place in ethics. Although their importance or centrality varies across major schools of thoughts, how we feel about various kinds of activities and behaviors forms at least part of what an ethical theory will seek to explain. Environmental ethics focuses special attention on the activities and behaviors that affect the natural environment. And so it focuses attention as well on the feelings we have regarding these behaviors, and on the constituent parts of that environment, including, among other things, plants, animals, species, ecosystems, and human beings. Phenomenology studies the nature of our first person experiences, which include our moral feelings toward the environment and our behaviors with respect to it. And so a discussion of phenomenology is appropriate in any comprehensive examination of environmental ethics.

THE PHENOMENOLOGICAL METHOD

Phenomenology is the study of conscious experience, *as* experienced. As such, it is intrinsically a first-person endeavor, an examination of the nature of conscious experience, rather than a third person characterization of the objective features of experience.

Etymologically, *phenomenology* is the study of phenomena, or of how things appear. Implicit in this is the distinction between how things appear and how they are. Consequently, phenomenology is concerned with how things appear to subjects of experience rather than with how they are independently of such experiences. This focus upon our experiences of objects in abstraction from questions concerning their existence apart from experience is what is sometimes referred to as phenomenological reduction.

From the standpoint of the natural sciences, we can, for example, study the neurobiology of the perceptual states of organisms, and the causal interactions between such organisms and their environments. We can study the behavior, linguistic and otherwise, of sentient animals, or examine the influence of social and cultural practices on human beliefs and desires. In each case, we are examining experience from a third person point of view: We are concerned with the objective properties necessary and/or sufficient for something to be a conscious experience, or for some entity to undergo a conscious experience. Phenomenology, on the other hand, studies what it is like to have a conscious experience. Its concern is the nature of experience as it is lived, that is, as it is experienced by a subject of experience, described from the first-person point of view.

It might seem that phenomenology is an entirely personal, indeed, individualistic undertaking. As I write this sentence, I can feel the firmness of the chair beneath my body, I have a visual sensation of the computer screen in front of me, I feel a throbbing pain in one of my toes, and I am fighting the urge to get up and smoke a cigarette. No doubt, the current experiences of the reader are considerably different. If phenomenology were nothing but the cataloging of such individual experiences, it would amount to little more than what Immanuel Kant (1925 [1781], p. 21) called a ''random groping,'' that is, a mere sampling of empirical descriptions without attention to any underlying theoretical framework.

However, phenomenology seeks more than such a cataloging of individual experiences. It is an attempt to describe and explain immanent structures within all conscious experiences as such. This is at once it most controversial feature, and, if successful, its greatest theoretical strength. It is controversial in that it apparently involves an inductive generalization from one case to all (typical) cases. That is, the phenomenologist looks at his or her own individual conscious experiences and proceeds, on this basis, to make general statements about the nature of all experiences as such.

The phenomenologist thinks that if others engage in serious and unprejudiced reflection, they will discover their own experience to be similar.This is essential to phenomenological method: Claims to have uncovered or described some universal aspect of or immanent structure within experience are always subject to empirical disconfirmation by any other conscious subject of experience. It is as though the claims of the phenomenologist are always followed by an implicit ''Right?'' or ''Don't you agree?'' Their purported universality presupposes the tacit agreement of the reader or listener. Conversely, as purportedly universal claims, they are open to disconfirmation by the existence of even a single individual who, ''upon serious and unprejudiced reflection,'' observes his or her own experience to be otherwise. (Although Martin Heidegger, a leading phenomenologist, prefaced his own claims by the caveat ''approximately and for the most part.'')

THE PHENOMENOLOGICAL TRADITION

The phenomenological movement in philosophy has its most explicit roots in the early twentieth century works of Edmund Husserl. This tradition continues through the works of Martin Heidegger (1962 [1926]), Maurice Merleau-Ponty (1962 [1945]), Jean-Paul Sartre (1956 [1943]) and others, and remains prevalent today in the work of contemporary Continental philosophers. It is typical for those working within this tradition to view phenomenology as a foundational discipline within philosophy. Phenomenology, that is, is understood as the proper starting point for dealing with fundamental philosophical problems, rather than beginning from within epistemological, metaphysical, or ethical frameworks.

Husserl's first major work dealing with phenomenological themes, *Logical Investigations* (1970 [1900–1901]) shows the influence of both Franz Brentano (1995 [1874]) and Bernard Bolzano (1973 [1837]), among others. From Brentano, Husserl inherited an interest in descriptive psychology. Rather than focusing on the causal relations of mental states, descriptive psychology seeks to describe and classify them. Bolzano's work on logic emphasized the distinction between subjective and objective ideas or mental representations. While subjective ideas are, in Kantian terms, ''mere modifications'' of the subject (Kant 1925 [1781], p. 182), objective representations point to something that has an existence apart from individual subjects of experience. The combination of these two influences can be seen in Husserl's interest in the structural or immanent features found in all

conscious states (or, more narrowly, within certain kinds of conscious experiences) as such.

Following Brentano, Husserl believed that the most fundamental structural feature of conscious states was their intentionality, that is, the fact that they are of or about something, that they are directed toward an object (or state of affairs). That is, if I am seeing, there is something that I see. If I remember, there is something I remember. If I hope, there is something for which I hope. For Brentano (1995 [1874], p. 88), intentionality is in fact the mark of the mental, involving an "intentionally in-existing" object. For Husserl, the ontological status of this intended object apparently varies between his earlier and later works. In *Logical Investigations*, it seems that the intentionality of experience is best viewed as a structural feature of consciousness, and that the intended object, if there is one, is typically an existent object in the natural world. In his later works, beginning with *Ideas* (1969 [1913]), intentionality consists in a relation to a kind of mental object, leading to the charge that Husserl moved from a realist position in his earlier works to an idealist one later on. The ontological status of such phenomena or objects *as* intended remains a controversial one both within and apart from the phenomenological tradition.

THE ROLE OF PHENOMENOLOGY IN ENVIRONMENTAL ETHICS

Phenomenology is concerned with the universal or immanent structural features of our consciousness of objects, while environmental ethics is concerned, among other things, with the moral status of (human and) nonhuman aspects of the natural world. A typical claim of environmental ethicists is that at least some nonhuman parts of the environment have intrinsic or inherent value, that is, that they have a kind of value that is in some important way independent of their relations to human beings and their various desires and needs. But this claim appears to run counter to the prevalent view that all values are relative to valuers, and that the only valuers are conscious beings, typically human beings or other sentient animals. And so the claim that natural entities have intrinsic or inherent value apparently runs afoul of the belief that values, of necessity, can be values only for human (or other sentient) beings. While environmental ethicists such as Holmes Rolston (*Philosophy Gone Wild*, 1986) seek to deny that the value of natural entities need be dependent upon human valuers, philosophers such as J. Baird Callicott (*In Defense of the Land Ethic*, 1989), while stressing that values need not be human-centered, concede that the source of all value must lie "in the breasts" of human or other valuing subjects.

This constitutes a core issue for environmental ethics, as it probes to the very foundations of such an ethics. But it is here that phenomenological methodology may have something to contribute. Phenomenology looks at the nature of conscious experience of objects, including, of course, our experiences of objects in the natural environment. The claim that such objects have some kind of value (whether intrinsic or otherwise) often stems from our experiences of those objects. For many it seems clear that we experience natural objects as having value, and so the role of phenomenology is in examining those experiences.

A key question is whether we experience the values of natural entities as residing in them, independently of our individual wants and needs, or whether we experience those values as in some way projected by us upon those objects. Does the value of these entities "lie in the eye of the beholder" as does (it is often said) the beauty of works of art, or does it lie in the objects themselves, as an objective or natural property, such as its size, shape, and weight?

A phenomenological approach to this question requires investigating the nature of our subjective conscious awareness of such objects. Is the value that we associate with such objects a contingent, idiosyncratic, feature of our individual experiences, or is it a necessary and universal feature of conscious experiences as such? Answering such a question goes beyond the scope of this discussion, but the role of phenomenology in such an inquiry is evident. We must look to our first-person experiences of such entities. Do we experience natural value as something we contribute to natural objects, or as something we discover in them? And if the latter, what is the necessary structure of consciousness in virtue of which such attributions of value can be understood as objectively valid and not merely as subjective fancies? These are phenomenological questions regarding the very nature of our first person subjective awareness of natural objects, and our answers to them have profound and pervasive implications for environmental ethics.

Debates in ethics, environmental and otherwise, are often settled by an appeal to our moral intuitions, that is, to our shared individual feelings about certain kinds of entities and behaviors. As the study of the immanent structure of such subjective experiences, phenomenological method has a critical role to play in our understanding of any ethics of the environment.

PINCHOT, GIFFORD
1865–1946

Gifford Pinchot was born in Simsbury, Connecticut, on August 11, 1865. A major figure in the history of conservation in the United States, Pinchot played a key role in shaping environmental consciousness during the late nineteenth and early twentieth centuries. As the first chief of the U.S. Forest Service (1905–1910) he helped define the mission and policies as well as the organizational structure and institutional culture of that agency. He was the driving force behind the Progressive conservation agenda of President Theodore Roosevelt and the leading spokesperson for the Progressives' utilitarian philosophy of conservation. Pinchot died on October 4, 1946, in New York City.

The oldest son in a wealthy and influential family, Pinchot decided at an early age to become a professional forester. After his graduation from Yale University in 1889, he studied forestry with the leading foresters of France, Germany, and Switzerland. In Europe he learned forest management methods that emphasized long-term planning, efficiency, and profitability; those principles later would be the hallmarks of his conservation philosophy.

Upon returning home, Pinchot proclaimed himself the first scientifically trained American forester and embarked on a long public career that blended passion for forestry with political ambitions and ideals. As a member of the National Forest Commission (1896) and a special forest agent with the Department of Interior (1897), Pinchot played an important role in the expansion of the federal forest reserve system under President Grover Cleveland. In 1898 he became chief of the U.S. Division of Forestry. Seven years later, when the Division of Forestry became the U.S. Forest Service, he was named its first chief. Between 1901 and 1908 Pinchot was a key member of Roosevelt's "Tennis Cabinet" and helped launch many of the president's conservation initiatives.

Gifford Pinchot. *Pinchot is often referred to as the "father of the Forest Service," being named chief of the U.S. Forest Service and contributing to the development of the agency's mission, policies, and structure.* **NPS PHOTO.**

Throughout his career Pinchot was at the center of political controversies. The most famous was his long battle with his former friend and hiking companion John Muir over the flooding of the Hetch Hetchy Valley in Yosemite National Park. In 1909 Pinchot and Secretary of Interior Richard Ballinger engaged in a highly publicized battle over allegedly fraudulent Alaskan land claims. That controversy led to Pinchot's dismissal as chief of the Forest Service in 1910 and ultimately contributed to the splintering of the Republican Party in 1912.

Among his many accomplishments Pinchot helped establish the Society of American Foresters and, with the financial support of his father, played an instrumental role in founding the Yale Forest School. He was a leading figure in the rise of the Progressive Party in the 1910s and eventually served two terms as the Republican governor of Pennsylvania (1922–1926 and 1930–1934).

Throughout his career Pinchot advocated conservation policies that promoted "the use of natural resources for the greatest good of the greatest number for the longest time." Although Pinchot credited his fellow Progressive W. J. McGee with formulating that phrase, Pinchot was its most visible and zealous proponent. Echoing Jeremy Bentham's (1748–1832) utilitarian maxim ("greatest happiness of the greatest number"), Pinchot and his

Progressive colleagues added a temporal element ("for the longest time") to emphasize the role of conservation in ensuring the continued availability of natural resources for the benefit and use of future generations.

In addition to its debt to utilitarianism, Pinchot's conservation philosophy was influenced by George Perkins Marsh's 1864 book *Man and Nature; or Physical Geography as Modified by Human Action*. For Pinchot, Marsh's account of past civilizations whose declines could be linked directly to the destruction of their forests and watersheds served as a warning to a rapidly growing nation bent on the unrestrained exploitation of its rich but limited supply of natural resources. Of equal concern to Pinchot was the inequitable distribution of the social and economic benefits derived from that unregulated assault on the public domain.

Pinchot summarized his philosophy of conservation in terms of three guiding principles: (1) the wise use of natural resources for the benefit of people currently alive; (2) the prevention of waste and the preservation of resources for the benefit of future generations; and (3) the development and preservation of natural resources for the benefit of the many, not the profit of the few. For Pinchot, conservation was an all-encompassing idea that could address national environmental and social ills while delivering equality, freedom, and lasting peace. To be effective, however, he believed that conservation policies needed to be based on sound science and required strong regulatory efforts by the federal government and in particular a powerful executive branch.

Occasionally Pinchot's ideas about conservation put him at odds with preservationists such as John Muir, who called for the protection of certain areas from all forms of development. More often, however, Pinchot's conservation ethic found its strongest opposition among those who demanded unregulated access to natural resources for private gain, often at the expense of land health and public welfare.

PLUMWOOD, VAL
1939–2008

Val Plumwood created and articulated a critical ecofeminist version of ethics and political philosophy and importantly lived as a philosopher sage with and within the natural world about which she wrote. She was born Val Morrell on August 11, 1939, into a poor family that ran a poultry farm near Sydney, Australia. She studied philosophy at the University of Sydney in the 1960s. In the 1970s she was a prominent member of a group of philosophers at the Australian National University that set in motion the first wave of Australian environmental philosophy. This group argued that environmental problems stemmed not merely from faulty policies, practices, and technologies but also from underlying human attitudes toward the natural world that were built into European and North American thought. These thinkers were especially critical of the anthropocentric idea that only humans matter morally and that people have no obligation to protect nonhuman nature for its own sake.

With her second husband, the philosopher Richard Routley, Plumwood coauthored a number of important early treatises, including several articles arguing that human chauvinism (exceptionalism) was detrimental to environmental ethics (Routley and Routley 1979). The Routleys divorced in 1981, and Val became the sole inhabitant of a stone house she had built with Richard in a temperate rain forest in southern Australia. Through her experiences in living in this rural environment she acquired a deep knowledge of nature that became legendary. She changed her name to Val Plumwood, after Plumwood Mountain—the location of her home—which in turn was named after the plumwood tree.

Plumwood was an independent scholar and took irregular teaching positions at a number of places, including Macquarie University, the University of Sydney, Murdoch University, the University of Tasmania, North Carolina State University, the University of California at Berkeley, and the University of Montana. The Australian National University awarded Plumwood a Ph.D. in 1991. She was also an important environmental activist and in the 1970s and 1980s played a key role in an environmental campaign to save rain forests in eastern Australia. She was attacked by a crocodile while she was canoeing alone through Kakuda National Park (Australia) in 1985. After three "death rolls" in the water, she escaped the crocodile's jaws with horrific injuries and

crawled for hours through tropical swamps before she was rescued. She wrote about the experience of being prey, which ironically reaffirmed her vegetarianism (Plumwood 1999).

Much of Plumwood's environmental philosophy focused on analyzing, critiquing, and providing alternatives to the dualisms that she believed lie at the heart of the domination of women, nature, and others. In her view the division between mind and matter that supposedly sets humans apart from nature became codified into an opposition between reason and nature in the European and North American tradition. This polarity, in turn, informed many categories of thought and created an ideology of dualisms that deemed "nature" to be inferior to "reason." Plumwood contended that this dualistic ideology was used to legitimize the subjugation of many social groups, including women, people of color, the working class, the poor, colonized peoples, indigenous peoples, and nonhuman nature. This led to the central ecofeminist insight that struggles for social justice and environmentalism are inseparable.

In 1990 Janna Thompson ventured a critique of Plumwood's outlook in her article "A Refutation of Environmental Ethics." She argued that that there were no foundations beyond sentience for environmental ethics; in response Plumwood (1991) argued that many entities beyond sentient animals—such as rocks, mountains, and ecosystems—possess teleological properties that are worthy of respect and that any adequate environmental philosophy must incorporate an ethic that challenges the purely instrumental human treatment of nature.

In her first book, *Feminism and the Mastery of Nature* (1993), Plumwood develops a feminist critique of dualisms and instrumentalism to argue that the master form of European culture's rationality has been unable to acknowledge its dependence on nature, women, and other dominated groups of people that it constructed as inferior. This "rational" distortion, she argues, has shaped the basic categories of European and North American thought and has threatened the survival of people and nonhuman nature. In "Wilderness Skepticism and Wilderness Dualism" Plumwood (1998) teases out the androcentrism, anthropocentrism, and Eurocentism that she believed to be embedded in the idea of wilderness; she further analyzes the roles dualisms have played in constructing the traditional concept of wilderness as a nonhuman nature that is opposed to human culture.

Plumwood steered her ecofeminism through both environmental ethics and political philosophy, developing what she called a critical-feminist-socialist ecology. At the time of her death, her work was directed toward death as a philosophical theme, especially in her unpublished article "Tasteless: Towards a Food-Based Approach to Death" (2007).

POLLEN FLOW

The possibility of the movement of genes from engineered crops to wild relatives has been one of the primary concerns associated with the release of genetically modified crops. Such gene flow could result in the evolution of increased competitive ability in wild relatives, making them more noxious weeds (Ellstrand 2003a, Hancock 2003, Snow et al. 2003).

FREQUENCY OF CROP/WILD HYBRIDIZATIONS

Although the early consensus was that hybridization between crops and their wild relatives occurred infrequently, later research showed that crop/wild hybridizations are relatively common. The reproductive barriers between wild and domesticated taxa are so minimal that they are often considered subspecies, and breeders can

readily transfer genes between them. A number of parameters, such as breeding system, flowering time, hybrid viability, and isolation distance can affect the rate of gene transfer, but if compatible relatives are within the area where pollen is dispersed, genes will eventually escape. Evidence for crop introgressions into wild populations of native relatives has been provided for many crops (Ellstrand et al. 1999).

Concerns about the deployment of genetically engineered crops have now shifted to the issue of whether transgenes will persist in native environments and have negative consequences. It has been generally assumed that crop/weed hybrids would be poorly adapted in nature and that transgenes would not, therefore, spread and persist; a few experiments have now shown, however, that the initial hybrids between crops and their native relatives do occasionally have fitness equal or superior to the wild antecedents and that genes from crops often persist for long periods in natural populations (Ellstrand 2001).

THE EFFECT OF TRANSGENES ON NATIVE POPULATIONS

The impact of transgene escape into wild populations will be strongly associated with the plant characteristic that the gene affects and the invasiveness of its wild progenitors (Hancock 2003). Transgenes that have a neutral effect on fitness, such as the marker genes used to recognize transgenic plants during experimental development, might spread randomly in natural populations but would have no subsequent impact on native fitness. Genes with detrimental effects on growth and development, such as male sterility or reduced woodiness in trees, would most likely be selected against in the natural environment and would not spread beyond a narrow area adjacent to commercial plantings. The transgenes associated with pest resistance would have variable effects, depending on the invasiveness of the recipient species and the level of natural control. If a wild species is an agronomic weed, the escape of a herbicide-resistance gene could make it a more noxious pest. Virus- fungal- and pest-resistant genes could increase the fitness of wild populations and make them better competitors if damage from the pest is controlling the size of natural populations. Those transgenes with direct positive effects on fitness, such as those broadening environmental tolerances, could result in dramatic adaptive shifts and have a major impact on the fitness of native populations, depending on the invasiveness of the species.

It has been suggested that the escape of transgenes into native populations could have a negative impact on levels of genetic diversity (Rissler and Mellon 1996). The addition of the transgene itself would, however, actually increase genetic diversity slightly, and any subsequent loss in genetic diversity would occur only at those loci tightly linked to a selectively beneficial transgene. The genes that are adjacent to such a transgene would be ''dragged'' along, possibly replacing any native diversity at these loci. The relative impact on native diversity would still be small, because the loci tightly linked to the transgene would make up only a small fraction of the species genome.

Another concern that has been expressed is that transgenes will have unexpected secondary genetic effects in natural populations. There could be ''epistatic effects,'' where the transgenes interact uniquely with those of the native species, or ''pleiotropic effects,'' where the transgenes influence more than the target trait. Although these possibilities can never be completely excluded, it is unlikely that the transgenes that have been selected for deployment will have dramatically different effects in the wild than they would in a cultivated background. The crops were originally derived from the wild species, and the transgenes have faced numerous evaluations, from the initial transformations to the final field screens, before release. Genes have been moved from native species to crop species by conventional breeders without any unexpected ramifications.

ENVIRONMENTAL IMPACT OF TRANSGENIC CROPS

Concerns have been raised about the environmental impact of crops engineered to produce pharmaceutical compounds, the so-called ''pharma'' or ''industrial'' crops (Ellstrand 2003b). The transgenes producing these products might escape into native populations via pollen flow and present a risk to humans and other animals that might consume them if the compounds are toxic. They also could reduce the fitness of native populations if they had a significant negative effect of competitive ability. It would seem prudent to regulate the release of these engineered industrial crops, as with other transgenic crops, taking into account the likelihood that someone or something could be harmed by them. If they do produce compounds that are potentially toxic or have a significant effect on reproductive fitness, their ability to reproduce needs to be severely restricted through mechanical means, or they need to be engineered into a crop that does not have any proximal native relatives. Although several methods of engineering sterility have been proposed or developed, none is ready for deployment (Chapman and Burke 2006).

One additional concern that is commonly expressed is that the introduction of transgenic crops could contaminate organically grown crops, in which purity from transgenes is a requirement. Relatively short isolation

A Bumble Bee Foraging for Pollen. *One of the major concerns with using genetically modified crops is the possible effects on native plants through hybridization. Some believe that transgenes could have a negative effect on genetic diversity. Other concerns include the contamination of native populations from "pharma crops," via pollen flow.* **ELIZABETH SELLERS/NBII.GOV.**

distances can be used to prevent all but a small percentage of transgene contamination into nontransgenic crops, but at present there are no restrictions on where genetically engineered (GE) crops are grown in relation to non-GE ones.

CONCLUSION

In summary, transgenes will escape into natural populations through pollen flow if compatible relatives are in proximity. Decisions on the risk of transgenic crops to native relatives should be based on three questions about risks: (1) Is a compatible relative present in the areas of deployment? (2) Is the native relative highly invasive? (3) Will the engineered trait significantly affect the invasiveness of the native relative? The degree of risk associated with the unrestricted release of potential GE crops depends on the answers to these three questions.

POLLUTION

Pollution refers to energy or substances that contaminate the environment, causing harm to humans or other living organisms. It can also refer to the act or process of releasing these pollutants. Major examples include air pollution, water pollution, and soil contamination caused by the release of toxic chemicals, particulates, or radioactive substances. Less well-known examples include noise pollution (noise that is loud enough to be physically harmful or annoying), thermal pollution (changes in water temperature that affect aquatic life), and light pollution (light from cities that interferes with animal life or astronomical observations). These examples illustrate that a substance can be harmless or even beneficial when present in small quantities while becoming harmful at higher concentrations. Because the status of these substances as pollutants depends on their quantity, there is room for debate about whether to label them as pollutants whenever they rise above "natural" levels or only if they cause harm to particular organisms or biological systems. Efforts to alleviate pollution played a major role in the growth of the environmental movement during the middle of the twentieth century, and the contribution of pollution to global climate change is one of the most important contemporary environmental concerns.

HISTORY

Humans have released pollution since prehistoric times. For example, early efforts at metal grinding and mining resulted in a variety of harmful emissions, culminating in widespread lead pollution during the Roman Empire. Nevertheless, the Industrial Revolution of the 1700s and 1800s produced air and water contamination on an unprecedented scale. These concerns became especially prominent within the environmental movement during the mid-twentieth century. London, which had suffered from smog for centuries, experienced a severe episode of air pollution in 1952 that killed thousands of people in a few days. Rachel Carson's classic book *Silent Spring*, published in 1962, questioned the wisdom of releasing large quantities of pesticides into the environment and

especially challenged the widespread spraying of DDT. A famous 1969 fire on the Cuyahoga River in northeastern Ohio stimulated concerns about water pollution. Public outcry regarding these environmental problems led to the creation of the U.S. Environmental Protection Agency (EPA) in 1970 and the passage of several important laws, including clean air acts in a number of countries, the U.S. Clean Water Act of 1972, and the U.S. Toxic Substances Control Act of 1976.

A number of the most famous environmental and public-health disasters of recent years were connected to pollution. In Japan the discovery of Minamata disease in the 1950s (a severe human neurological syndrome caused by mercury contamination in seafood) highlighted the hazards of heavy metal pollution in wastewater. One of the most catastrophic industrial accidents of modern times occurred in Bhopal, India, in 1984. Toxic methyl isocyanate (MIC) gas was accidentally released from a Union Carbide pesticide plant, killing up to 5,000 people within days and causing serious health problems in some 100,000 people in the ensuing decades. During the 1970s the Love Canal chemical waste landfill (near Niagara Falls, New York) became a symbol of the dangers of old toxic-disposal sites. The many serious illnesses suffered by residents of a neighborhood built over the site prompted the EPA to remove the citizens from their homes and reimburse them. The case galvanized support for the U.S. Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) of 1980, often called Superfund. It established fees, paid by the petroleum and chemical industries, to help pay for the cleanup of heavily contaminated waste sites for which responsible parties could not easily be identified.

EXXON VALDEZ

The oil tanker *Exxon Valdez* ran aground on March 24, 1989, in Prince William Sound, Alaska. This incident illustrates the wide range of impacts on humans and the environment from pollution-related environmental disasters. The tanker spilled more than 10 million gallons of crude oil, damaging 1,000 miles of Alaskan coastline and killing thousands of seabirds, sea otters, fish eggs, and other organisms. Millions of dollars were lost because of decreased fishing and tourism, contributing to the bankruptcy of the Chugach Native American group. The spill spurred economists to improve their techniques of contingent-valuation analysis, a set of approaches used to measure how much the public values particular environmental areas and how much of that value is lost by contamination. In the case of Prince William Sound, the public assessed the lost environmental value at several billion dollars.

ETHICAL AND PHILOSOPHICAL SIGNIFICANCE

Pollution raises a number of important ethical and philosophical questions. Although it was central to the environmental movements of the mid-twentieth century, many philosophers have questioned whether it provides the most appropriate motivation for environmental concerns. For example, Deep Ecologists such as Arne Naess have criticized those who focus solely on pollution and resource degradation as "shallow" environmentalists, concerned primarily about the needs of wealthy humans in the developed world. Nevertheless, a strong case can be made that those concerned about nonhuman organisms, developing countries, and underprivileged groups should also be worried about pollution. In the 1996 book *Our Stolen Future*, which Vice President Al Gore likened to *Silent Spring*, Theo Colborn and her coauthors argued that low-dose exposure to a variety of industrial chemicals was much more harmful to wildlife and humans than previously thought. They claimed that many of these toxins are endocrine disruptors, interfering with the delicate hormonal system of animals and causing species losses, damaged eggs, skewed sex ratios, disturbed mating practices, and abnormal development.

Kristin Shrader-Frechette argued in her book *Environmental Justice* (2002) that pollution is also taking a disproportionate toll on vulnerable groups: children, minorities, and poor citizens of developing countries. Many particularly hazardous pesticides that have been banned in wealthy countries are still produced there and then exported abroad, where they are often used improperly. Another concern is that, as environmental regulations have increased in Europe and North America, polluting industries (along with old, high-emission factory equipment) are moving to developing countries such as China, where they are producing serious threats to human health. Harmful electronic wastes (from computers, cell phones, and other electronic equipment) have also been exported to developing countries, where they are often recycled by poor workers under extremely toxic conditions. The Basel Convention, which entered into force in 1992, is an international treaty designed to reduce and regulate the flow of hazardous waste between countries. In response to critics who argued that the original treaty was inadequate, a Basel Ban Amendment (which prohibits the transfer of hazardous waste from a number of developed countries to developing countries)

Water Pollution in China, 2005. *A woman collects plastic bottles near a river in China's Jiangxi Province. The riverwater is polluted with a reddish dye discharged from a small paper factory nearby.* **AP IMAGES.**

was proposed in 1995 and has been ratified by a number of countries, as well as the European Union.

An important ethical question is how to determine acceptable levels of pollution. Many analysts argue that market forces should play an important role in these decisions. In a particularly striking example, Lawrence Summers, the former chief economist of the World Bank (and former president of Harvard University) signed an internal World Bank memo in 1991 that was later leaked to the *Economist* magazine ("Let Them Eat Pollution" 1992). The memo argued that developed countries ought to export more pollution to developing countries. The rationale was that the economic costs of pollution-related deaths or injuries are lower in developing countries because wages are so much lower. A more moderate and perhaps more justifiable appeal to market forces for regulating pollution involves setting a "cap" on the allowable emission levels of a particular pollutant and then allowing a group of industries to "trade" rights to emit the substance under the cap.

A common objection to many of these economic approaches is that they focus primarily on overall efficiency and not on maintaining a fair distribution of health risks among members of the population. Numerous ethicists argue that people have rights not to suffer significant risks of harm or death from pollution, no matter what the economic benefits to others might be. This position raises difficult problems of its own, however, because of the need to decide what level of risk is acceptable; critics frequently argue that it is impossible to eliminate all pollution-related risks. One solution is to claim that there is some threshold of risk that is so small (sometimes called *de minimis*) that it can be ethically ignored. Others worry that the aggregation of many *de minimis* risks could still pose significant ethical concerns.

Another important philosophical issue is how to balance the perspectives of experts and citizens when making societal decisions about pollution. The psychologist Paul Slovic has found, for example, that ordinary citizens appear to incorporate a wide variety of considerations (e.g., voluntariness, dread, and fairness) into their risk assessments, whereas experts focus more narrowly on the probability of a particular harm. Some

ACID RAIN

Sulfur and nitrogen compounds released from power plants, factories, and motor vehicles can react in the atmosphere to form acidic precipitation. This acid rain harms insects, aquatic organisms, forests, soils, and possibly human health. Acid rain has the potential to produce adverse effects that are very distant from the source of the pollution, much like the effects of chlorofluorocarbons on the ozone layer, the damage caused by fertilizer and pesticide runoff into waterways, and the global warming caused by greenhouse gases. These long-distance forms of pollution raise a number of difficult ethical and social issues:

- They frequently require regulatory cooperation across state and national boundaries.
- They create significant challenges for scientists who seek to identify precise cause-effect relationships between pollutants and harms.
- They make it more difficult to assign ethical responsibility to polluters, because small releases by many individuals can aggregate into large-scale effects.
- The agents who gain economic benefits by causing the pollution are frequently not the same individuals who suffer ill effects from it.

commentators argue that these differences justify respect for the risk perception of nonexperts, but critics such as Cass Sunstein argue that citizens' perceptions usually involve poor assessments of risk probabilities. Another concern about deferring to experts is that, in situations of scientific uncertainty, ordinary citizens sometimes have local expertise that rivals the understanding of scientists. The sociologist Brian Wynne argues, for example, that analysts made serious mistakes when evaluating risks from radioactive contamination of British sheep following the Chernobyl nuclear accident of 1986. Notably, they failed to account for details of sheep behavior and soil type that were well known to farmers. In her book *Taking Action, Saving Lives* (2008), Shrader-Frechette emphasizes another reason to doubt many expert analyses: Polluting industries fund questionable studies designed to obtain results that further their interests. In order to mitigate the effects of financial conflicts of interest on scientific research, she calls for independent sources to fund more studies on the environmental and public health effects of pollution.

PERSISTING ISSUES

The contribution of pollution to climate change is perhaps the most profound environmental issue of the twenty-first century. Emissions of greenhouse gases such as carbon dioxide are warming Earth's atmosphere, producing a wide range of deleterious effects that could include increased flooding in some areas, drought in other places, increased spread of some diseases, and major species extinctions. Some less certain but particularly serious potential consequences include a massive rise in sea levels (especially if ice sheets on Greenland or West Antarctica melt) and alteration of the Gulf Stream that warms Europe. Developing international cooperation on policies to mitigate climate change is one of the major challenges facing world leaders.

As nations attempt to lower their emissions of carbon dioxide in response to climate change, they are debating another crucial issue: pollution risks from nuclear power plants. Although these plants do not directly emit greenhouse gases, they have the potential to release large amounts of radioactive material, either through reactor accidents or through improper waste disposal. The possibility of accidents has become more worrisome as countries with poor industrial safety records begin to pursue nuclear power. In the United States, the plan to locate a repository for high-level radioactive waste at Yucca Mountain, Nevada, has become a focal point for nuclear concerns. Experts from the U.S. Department of Energy and the EPA have claimed that the site would be safe for thousands of years, but critics have questioned the validity of these estimates. The case has stirred renewed citizen and activist scrutiny of "official," "expert" analysis: Critics again are questioning claims to objectivity and seeking to uncover any hidden conflicts of interests. Such issues illustrate the importance of an informed and vigilant citizenry that can deliberate intelligently about the difficult ethical issues raised by pollution.

POLYNESIA

The Polynesian islands form a triangle in the Pacific Ocean from Aotearoa (New Zealand) at the southwestern corner, to Rapa Nui (Easter Island) at the southeastern corner, to the Hawai'ian archipelago at the northern apex. Lying within the triangle are Samoa, Tonga, the Cook Islands, the Society Islands (including Tahiti), the Marquesas, and many more islands. Genetic analysis indicates that the Polynesians are descended from both the indigenous Taiwanese and the peoples of Melanesia, north and east of Australia. Those peoples began expanding farther eastward into the pelagic Pacific around 3,000 years ago. By the fourth century CE, the Polynesians had reached Rapa Nui, and by the fifth, Hawai'i.

HUMAN SETTLEMENT IN POLYNESIA

Aotearoa was peopled by the Polynesians last, only about 1,000 years before the present time. Genetic analysis and radiocarbon dating of chicken bones found in Chile indicate that they reached South America (3,600 miles from Rapa Nui) a century before the Spanish arrived. Sweet potatoes, native to South America, appeared on mid–South Pacific islands as early as the eleventh century. These facts suggest that the Polynesians were trading with South American Indians for half a millennium before Europeans crossed the Atlantic. The navigational skills required for locating, settling, and traveling between tiny bits of land in the largest ocean indicate great sensitivity to the environmental interface of land, sea, air, sky, and the behavior of other animals—in regard to winds, currents, stars, and birds—by means of all five senses.

COSMOLOGY AND CULTURE

Polynesia is united by dialects of a common language and variations of a common material, social, and cognitive culture. Its cosmology is among the most distinctive features of Polynesian cognitive culture and is especially germane to environmental ethics. Although there are many popular and local Polynesian origin myths, a more abstract and esoteric evolutionary epic is extant in both Hawai'i and Aotearoa—the northernmost and southernmost enclaves of Polynesia, respectively—suggesting a common ancestor in the Society Islands, which can be thought of as the cultural motherlands of eastern Polynesia.

An especially detailed expression of that epic is given in the *Kumulipo*, a Hawai'ian genealogical chant composed for Kalani-nui-ia-mamao, a Big Island chief, in the seventeenth century (Johnson 1981). This chief's genealogy is traced all the way back to the coral polyp, and the progression forward from there is quite similar to that of modern biology, moving from coelenterates (corals), to annelids and nematodes (segmented and unsegmented worms), to echinoderms (starfishes and sea urchins), to mollusks (shellfish), and on to marine and terrestrial vertebrates. The biological knowledge recorded in the *Kumulipo* was greater than that which existed in Europe when James Cook made contact with the Polynesians in the eighteenth century.

Of course, missing from the *Kumulipo* is Charles Darwin's major nineteenth-century scientific achievement: the concept of natural selection. From a scientific point of view, the explanation of the proliferation and increased complexity of species by natural selection is the crux of the modern theory of evolution. However, from an environmental-ethical point of view, whether evolution is blindly driven by natural selection or bootstrapped by reproductive *mana* (spirit power) is irrelevant. What is ethically important is the sense of relationship, of kinship, between human and nonhuman life implied in an evolutionary understanding of origins.

SOCIETIES AND SOCIAL ORDER

In most of Polynesia—Aotearoa being the exception—the islands are relatively small and the resource base is limited. Except for birds, some of them flightless and very vulnerable, there were virtually no native wild animals to hunt, although the Polynesians did introduce pigs. In addition to pork, they subsisted mainly by fishing the surrounding waters and cultivating enclosed fishponds and growing taro, the staple of their diet, and a few other domesticated food plants that they imported.

As island populations grew, highly organized and stratified societies developed to maximize the yield of the limited resource base. The volcanic island homes of the Polynesians were divided into wedge-shaped watersheds—bounded on two sides by lava ridges and on the third by the sea—steeply descending from the mountainous interior to the coastal lowlands. Commoners worked the land and sea. Their activities were overseen by stewards (*konohiki*) coordinated by aristocratic administrators (*ali'i*) who were governed by high chiefs (*ali'i nui*), all ruled by a paramount chief (*moi*) who might reign over a whole island. War between neighboring paramount chiefs was common as they struggled to expand their territories to aggrandize themselves but also to relieve population pressure and perhaps keep growing populations in check.

Polynesian social order was maintained by an elaborate system of taboos (the word is of Polynesian origin) or *kapus,* especially the *'aikapu,* or sacred eating, according to which men and women eat apart from one another and certain foods are forbidden to women. Food flowed up that social food chain from the bottom to the top. Polynesian social organization thus mirrored the natural ecological organization of Polynesian lands, for in ecology, energy flows through ecosystems from the bottom of the trophic pyramid to the top, from autotrophic plants, to herbivores, to omnivores, to carnivores. The analogue in Polynesian thought to energy in ecological thought is *mana*, of which the paramount chief, at the apex of the social food chain, has the most. In their conception of their social order, as in the scientific conception of the ecological order, Polynesians included the land as the base of their society. In the Hawai'ian dialect they call themselves *kama-aina*, "children of the land." Love of the land, *aloha aina*, is a pervasive sentiment, and *malama aina*, serving or caring for the land, is a cardinal duty. When the social order and the ecological order are in perfect harmony, everything is *pono* in paradise.

Aotearoa is different from the rest of Polynesia, consisting of two relatively large islands and lying in temperate, not tropical, latitudes, with richer and more diverse terrestrial and marine natural resources. The Maori social order is less vertically organized into gentry and common people and more laterally organized into tribes and clans, with each of the *hapu* established by its own voyaging canoe that came to Aotearoa from a legendary Polynesian motherland. Thus, there was less pressure on the Maori to cultivate the land intensively and efficiently or to develop a highly organized and stratified society. Hence, individuals experienced a greater sense of identity with their tribe, clan, and extended family.

LAND OWNERSHIP

In the modern West, land usually is owned by individuals. This concept of individual ownership is based on a theory crafted and defended by the English philosopher John Locke (1632–1704), who argued that when an individual "mixes" labor with an uncultivated piece of land—clearing it of rank vegetation and planting it with crops—its natural productivity greatly increases. Thus, the industrious individual has a right to "enclose" it and exclude others, to make private property of it. When land becomes private property, it may be "alienated": transferred, bequeathed, divested, bought, and sold. One may husband the land—manage it sustainably—and pass it on to one's offspring in its full productive capacity. Alternatively, one may overwork, mine, or strip the land, thus drawing from it not a living but a windfall profit to invest in another enterprise: One may sell or abandon it, move away, and leave the land in a ruined condition.

In the Maori concept of land ownership, by contrast, the tribe, not the individual, owns the land. Unlike an individual, whose lifetime is finite, a tribal community endures if not forever, at least indefinitely. Moreover, Maori tribal identity is merged with a particular landscape, and an individual's identity is merged with that of the tribe. Thus, for the Maori dislocation from ancestral lands constitutes a loss of tribal and therefore personal identity. Correlatively, from a traditional Maori point of view, sustainable development is the only kind of development that makes sense. The Treaty of Waitangi, signed by a number of Maori tribal chiefs in 1840, effectively established New Zealand as a British colony and guaranteed the Maori certain rights in perpetuity, including land rights. It was largely ignored until 1975, when the Waitangi Tribunal was established to adjudicate Maori claims under the treaty, including those regarding Maori cultural associations with various sites.

ENVIRONMENTAL ETHICS

Ethics often is rendered paradoxical by disparities between attitudes, values, and beliefs, on the one hand, and actions, practices, and behavior, on the other hand. For example, how is it conceivable that militant crusades, brutal inquisitions, and genocidal pogroms went on in the name of Christianity, which professes ethical precepts such as turning the other cheek, walking the extra mile,

and loving one's enemy? Environmental ethics is no exception. For all the environmental sensitivity of the Polynesians evident in their navigational skills and for all their evolutionary kinship with and knowledge of the local biota, and despite the fact that many of their social organizations mirrored the ecological organizations of their island habitats and the fact that in some Polynesian societies personal and tribal identity were melded and vested in their homelands, Polynesian environmental behavior has not been beyond reproach.

The Hawaiian royalty wore robes made from the red and yellow feathers of two species of honeycreeper; it took thousands of those small birds to make one cloak. The flightless birds that had enjoyed freedom from mammalian predators were devastated by Polynesian hunters, their dogs and pigs, and the rats that had stowed away on their voyaging canoes. The moa of Aotearoa is only the most infamous example. Hundreds of species of birds went extinct during the interval between the arrival of the Polynesians and the arrival of Europeans from Aotearoa to Hawai'i to Rapa Nui. Lowland forests were cleared for the cultivation of crops, and the composition of upland forests changed radically as a result of anthropogenic causes that are still under investigation.

If the extinction of the Moa and the other flightless birds on Aotearoa is the most notorious instance of the hundreds of avifauna extinctions wrought by the Polynesians, the deforestation of Rapa Nui is the most notorious instance of the ecological devastation they perpetrated. The major reason its Polynesian inhabitants cut down the trees of Rapa Nui was to move their distinctive giant stone busts from the place where they were quarried and carved to the places where they were erected. Ironically, although these were the images of the beings that the islanders propitiated to sustain them, they turned out to be the instruments of their destruction. Without forests to hold the soil, it rapidly eroded. Birds had no place to roost and nest. The people had no wood to make boats, and so they could not go to sea to fish. They literally destroyed the Rapa Nui ecosystem and thus destroyed themselves.

Global climate change will continue to pose a particular challenge to Pacific island peoples, including the Polynesians, during the remainder of the twenty-first century and beyond. The predicted rise in sea level will swamp some low-lying atolls. On all the islands, even those with high mountains, coastal areas will be affected. Island peoples are more vulnerable to the increased frequency and intensity of cyclones, fueled by higher ocean temperatures, than are those who live on large land masses where they can seek refuge in the interior. Rising ocean temperatures may have significant impacts on the marine biota and thus on marine resources. Thus, a discussion of Polynesia and environmental ethics would be incomplete without mention of the concept of environmental justice and the duties owed by those most responsible for global climate change to those affected most adversely by it.

POPULATION

In the year 1 C.E. there were approximately 200 million people on Earth—less than the population of the contemporary United States alone. It took nearly two thousand years for the global population to increase sixfold: In 1850 the world population was an estimated 1.26 billion. The next increase of nearly sixfold has taken only 150 years, less than one-tenth the time of the previous sixfold jump: As of 2008 the world human population was 6.5 billion. This rapidly increasing growth rate of population, with attendant steep increases in consumption of natural resources, threatens the well-being of Earth's current and future inhabitants.

Environmental philosophers hold differing views on how humans affect the environment. Many questions and controversies have arisen in relation to the issue of population: Are resources disappearing? How do consumption patterns of a rising population change the human impact on the planet? Is there an optimal size of the human population? To what extent do humans have duties to other humans, other species, and future generations? Do ever-increasing rates of population growth augur more hunger, environmental degradation, and poverty? How do cultural and religious attitudes about gender, birth control, reproduction, and the institution of motherhood affect the size of families? How do gender, race, and class affect reproductive choices? How can population growth be restrained?

MALTHUS'S GLOOMY ARITHMETIC

Until the early nineteenth century little thought was given to human population growth except as evidence of the success of the human enterprise on Earth. That view changed with the initial publication, in 1796, of *An Essay on the Principle of Population* by the English political economist Thomas Malthus (1766–1834). Malthus argued that population increases geometrically or exponentially (1, 2, 4, 8, 16, 32, and so on), whereas agricultural productivity can increase only arithmetically (1, 2, 3, 4, 5, 6, and so on), leading to an inevitable strain on resources. For example, a farm couple might own and cultivate a hectare of land and from its yield feed themselves and four children; if those four children each had four children of their own, then in the next generation the same hectare of land must feed sixteen people; then, at the same rate of fertility, there would be sixty-four mouths to feed in the following generation and then 256 in the one following that.

On Malthus's calculation the ingenuity of the farm family might allow it to double the productivity of its hectare of land during the lifetime of the first generation, but any further doubling in productivity would be difficult. For example, suppose that the first-generation farm family produces 100 bushels of corn on its hectare of land, which would be adequate for six people. The next generation manages to produce 200 bushels on the same hectare, which must be divided not among twelve but among sixteen people. With great effort the subsequent generation might eke out an additional 100 bushels of corn from the same hectare for a total of 300, but that would have to be divided among sixty-four people. The share per person of food resources would therefore have gone, in the course of only three generations, from 6:100 to 16:200 to 64:300. At the same rate of fertility, in yet the next generation 256 people must share 400 bushels of corn if, by the most ingenious means, the original hectare can be made to produce as much—in which case the person to food ratio will be 256:400. At this point the hectare of land has reached its maximum possible productivity; hence the person-to-food ratio will shrink in the following generation to 1,024:400.

At this point several scenarios are imaginable: (1) starvation reduces family numbers to the "carrying capacity" of its hectare of land; (2) uncultivated wild land is appropriated and made to produce corn; (3) cultivated land belonging to another family is taken by force. Of course, an enlightened farm family might have foreseen the consequences of its own fertility and consciously limited its fertility rate to two—the replacement rate—by one means or another. But there are only two means of achieving a steady-state population: reduced fertility or increased mortality.

The "population problem," first articulated by Malthus, is captured only iconographically in the parable of the farm family and their single hectare of land. In the real world the human population consumes and depends on resources other than corn—indeed, on resources other than food. The fertility rate of the actual global human population varies from decade to decade, having peaked in the 1980s; as of 2008 it was running only a few tenths of 1 percent above the replacement rate of approximately 2.1. As the fertility rate exceeds the replacement rate, the population grows by an annual percentage. Even a seemingly small rate of increase of only 1.3 percent would result in a doubling of the population in just fifty-three years. The fertility rate and the rate of population increase is not

uniform throughout the world. In some regions fertility rates and rates of population increase are negative and in others positive; a region's population growth or decline is also affected by emigration and immigration.

JULIAN SIMON VS. THE EHRLICHS ON POPULATION GROWTH

Malthus's concerns echo loudly in the debate between the late Julian Simon and Paul and Anne Ehrlich on natural resources and the size of the human population. According to Julian Simon (1981), natural resources are not limited; he argues that when one resource—such as petroleum—is depleted, its price rises, stimulating research and the development of substitutes such as biofuels. Simon thus encourages unbridled consumption of current natural resources, which generates wealth, which in turn may be invested in the development of new technologies to meet the increasing demands of a growing human population. He rejects research calling into question the patterns of consumption and trading practices of the wealthy nations of the global north. He thus contends that economic incentives working in free markets will result in less pollution and a better environment. In sum Simon believes resources will expand as a result of human ingenuity, and the environment will be shaped to fit human needs. He encourages the creation of artificial substitutes for things in nature and argues that our survival capacities will increase from generation to generation, despite (or because of) changes such as reduction in the number of species in the world.

Simon questions the reasoning behind negative views about population growth. For Simon human intelligence is the ultimate resource. He rejects policies that pressure people to have fewer children and instead argues that population growth offers positive benefits, despite short-term costs. According to Simon human talents and capabilities offer endless possibilities that can translate into innovative solutions to challenges such as pollution abatement and resources availability.

In Simon's view population growth will not lead to more famine and desertification. The world eats better now than it ever has before, even in poor countries, according to Simon. He argues that when more food is needed, as both more land is brought under cultivation and advancing agricultural technology increases production per hectare, more food will be available. In addition, even as population increases, the number of farmers decreases while the amount of land per farmer is rising, and he views this as economically more efficient. In Simon's view environmental degradation, habitat loss, and species loss are problems only if economic losses also occur.

In contrast to Simon's view, the Ehrlichs (1998) contend that humans pose a dangerous threat to the environment. According to the Ehrlichs the growth of human population and consumption is responsible for the earth's increasingly degraded environment and global insecurity. They believe that effective remediation is possible, but only if there is a halt and then a reversal of human population growth. They question the optimistic representations of the future of economic growth because such projections, in their view, do not include the significant environmental costs of pollution, environmental health risks, and faltering ecosystems. They question the ability of current market mechanisms to allocate resources properly and doubt that technological advances will be able to address the problems of depleted natural resources and environmental degradation. They do not believe that curbing the use of natural resources should be left to the market. Although some economic studies have focused almost exclusively on the negative economic effects of reducing the use of fossil fuels such as oil, the Ehrlichs argue that there are many possible benefits to reducing per capita energy consumption—especially improving the health of both human and nonhuman beings.

The Ehrlichs also distinguish between biological wealth, or natural capital, and economic wealth and capital. They argue that human consumption and pollution deplete biological wealth and threaten entire ecosystems; they note that there are no artificial substitutes for some natural resources such as air, land, and water, which are subject to unprecedented deterioration. Acid rain, water pollution, toxic waste, climate change, deforestation, and loss of biodiversity are a few of the many environmental problems that the Ehrlichs attribute to the unsustainable scale of human population and patterns of consumption. They point to anthropogenic climate change as a potential cause of biodiversity loss and argue that extinctions of species will in turn cause more serious disruptions of ecosystems such as forest destruction in Eastern Europe by acidic air pollution, the desiccation of the Aral Sea in the former Soviet Union, and desertification in the Sahel region of Africa.

The Ehrlichs believe that limiting the human population size and reducing consumption are preconditions of a sustainable future. In their view eating is one of humanity's most ecologically destructive activities. They call attention to the problems associated with increasing the production of food, including use of synthetic agricultural fertilizers, irrigation, and chemical pesticides in green-revolution technology, which has been touted as the key to boosting food production to keep pace with population growth. They cite substitutions of synthetic pesticides for natural pest control, inorganic fertilizers for natural ones, and chlorination for natural water purification as examples of unsatisfactory attempts to create artificial alternatives to ecosystem services. They argue

that humanity's struggle both to feed the poor and to overfeed the rich is one of the principal causes of environmental degradation. They also note that human population growth and proportionately increasing pressures on food production result in the urban sprawl that devours agricultural land, which in turn spurs the conversion of forests and other natural plant communities into cropland for food production. Thus the task of saving the remaining forests is made harder because of the demands of a growing human population and its need for more food and wood products.

"TRAGEDY OF THE COMMONS," FAMINE, AND FUTURE GENERATIONS

Garrett Hardin (1974) critically examines the once-popular metaphor of the earth as a spaceship that we all live on and must share equally. Hardin prefers the metaphor of a lifeboat. Each wealthy nation can be conceived of as a lifeboat, full of rich people with low fertility rates, whereas the rapidly reproducing people of poor countries are swimming in water, begging for admission to a lifeboat. He argues that we need to recognize the limited carrying capacity of any lifeboat. Sharing in accordance with the spaceship ethic will soon swamp lifeboats and everyone will drown.

According to Hardin spaceship ethics is problematic because it leads to the "tragedy of the commons." Using the example of pastureland, Hardin argues that an owner adequately cares for his privately owned pasture because overshooting its carrying capacity will lead to a deterioration of the health of his herd and, therefore, economic losses. A farmer would recognize and restrain himself within the carrying capacity of his privately owned pasture. If, however, a pasture becomes a commons open to all, it is less likely, Hardin argues, that each individual will refrain from overshooting the carrying capacity. If one person increases his herd by one, the health of all the animals grazing on the commons will suffer, including his own; the value of adding an additional animal will benefit him alone, whereas the cost of doing so will be shared by all.

In Hardin's view common ruin is inevitable if there is no "mutual coercion mutually agreed upon"—regulations, in a word—and he points to air and water as examples of resources that are polluted because they are treated as an unregulated commons. The economic benefits of a polluting industry flow to its owners, whereas the costs of pollution are borne by all. Hardin argues that a free good is likely to become an overused or wrongly used good. He calls into question relief for nations in need by a world food bank, which he regards as a commons in disguise that will eventually bring ruin upon all who share in the commons, according to Hardin. Despite its good intentions, he believes such a system of sharing would encourage the population-growth differential between rich and poor countries. Because poor countries have faster rates of population growth than wealthy countries, this trend, he argues, would only increase with a global system of sharing. He contends that with increasing population growth some nations threaten to exceed—or have already exceeded—their carrying capacity. Hardin argues that when assistance is offered from abroad in order to save poor people plagued by famine, this well-intentioned humanitarianism backfires by diminishing the quality of life for those who remain and for future generations. He calls for those in the lifeboat to consider their commitment to future generations as well as to themselves.

William Aiken (1980) calls into question Hardin's judgment that it is a nation that has a carrying capacity. Aiken argues that the biological notion of carrying capacity is not applicable to the concept of a nation. Nor, in his view, is the natural environment, artificially carved up into nations, a boat that will necessarily "sink" when extra people are added. Aiken suggests that the concept of carrying capacity is ambiguous. Because technology leads to continual increases in the human carrying capacity of the environment, there is no way to determine that capacity precisely. Surely, he argues, there is an absolute limit to the number of people Earth can accommodate, but what that limit is or whether we are beyond it, closely approaching it, or still far from it is not known. Aiken also notes that Hardin focuses on mortality and ignores alternative fertility-focused methods of reducing population such as birth control.

CONSUMPTION PATTERNS AND POPULATION

Humans do not all consume the same amount of resources and generate the same amount of waste. Resource consumption and waste generation vary significantly between developed and developing nations. Only one-fifth of the planet's population lives in industrialized north, but it consumes more than two-thirds of the world's resources. The rest of the world shares what remains. The United States has less than 5 percent of the world's population and uses approximately 25 percent of the world's resources. In *Women and the Environment* (1993) Annabel Rodda notes, for example, that in the industrialized nations the average person is likely to consume more than 200 pounds of paper and 900 pounds of steel per year, compared to approximately 17 and 94 pounds, respectively, consumed by the average Third World resident. The industrialized nations use significantly more energy than the rest of the world; Julie Sze (1997) notes that the average citizen in the United

Table 1. CENGAGE LEARNING, GALE.

States uses energy at the rate of 3 Japanese, 6 Mexicans, 12 Chinese, 33 Indians, 147 Bangladeshis, or 422 Ethiopians. The environmental footprint of First World residents is much deeper than that of the typical citizen of the Third World.

WASTE

Residents of the industrialized nations generate more waste than people living in the rest of the world. For example, the average person in the United States produces almost 2,000 pounds of solid waste per year. Americans and Europeans are consumers of high-tech consumer electronics such as computers, cell phones, and televisions, which now constitutes the fastest-growing part of municipal waste in the United States and Europe. According to a 2001 Environmental Protection Agency report, this discarded electronics waste generated approximately 70 percent of the heavy metals and 40 percent of the lead now found in landfills in the United States.

Citizens of wealthy nations are largely responsible for toxic dumping, the destruction of biodiversity, and soil and water depletion. Often race is the main factor in the location of hazardous-waste disposal sites in the United States. This inequitable burden also occurs on a global scale. Developed countries produce large amounts of waste that are often transported to poor nations and can cause environmental degradation. Despite international regulations, approximately 80 percent of the electronic waste generated in a year in the United States is being exported to poorer countries such as China, Pakistan, and India, and to countries in West Africa. Large

containers of computer parts are shipped to less-wealthy nations and workers in these countries crack open and melt computer parts over open flames to retrieve metals. The toxic chemicals, vapors, and particles released in this process include lead, polyvinyl chloride (PVC), and polycyclic aromatic hydrocarbons (PAHs), all of which are persistent toxics. According to Elizabeth Grossman (2006), samples taken in Guiyu, China, in 2005 found levels of copper, lead, tin, and cadmium 400 to 600 times higher than what would be considered normal and safe. These samples also found polychlorinated biphenils (PCBs), PAHs, brominated flame retardants, nonphenols, phthalates, and triphenyl phosphates. As a result of this exported e-waste, the air and water in this region have been severely polluted.

POVERTY ECONOMICS AND POPULATION

Affluent, developed countries have lower fertility rates and thus lower rates of population growth than poor, developing counties. Jack Hollander (2003) believes that poverty is the root of population growth—indeed, of all environmental problems; he asserts that only a free and affluent society can achieve zero population growth and environmental protection. Hollander therefore argues, in contrast to the Ehrlichs, that population growth is not a serious long-term global problem. He points out that the Ehrlichs' predictions of massive famines have not been borne out. Instead of focusing directly on limiting population growth—by, for example, withholding food aid or promoting contraception—he recommends economic development, technological progress, and unregulated capitalism to eliminate poverty and thus to slow and ultimately halt population growth.

Hollander also believes that eliminating poverty will improve environmental quality. He thinks that for the 80 percent of the world's people who are not affluent, life's basic necessities take on a higher priority than environmental quality. He maintains that when people have economic and educational opportunities, the human population will stabilize and efficient agriculture will reduce or eliminate hunger and the demand for more land for food production. He contends that economically secure people demand environmental protection.

The Ehrlichs insist, in opposition to Hollander, that a rich person contributes much more to the damaging of Earth's life-support systems than does one living in poverty. Restricting the size of human population, not increasing affluence, should be the first priority for healing the planet, in their view. The Ehrlichs call attention to the energy trap. More energy is required to give all human beings an affluent lifestyle; although developing and deploying these energy sources would be very difficult and costly; using that much energy would create an even larger threat to ecosystems. The Ehrlichs therefore emphasize two key imperatives: reducing consumption and waste generation by the rich and limiting the population growth of all humans, rich or poor.

GENDER, RACE, CLASS, AND POPULATION

Gender, race, and class have been prominent issues in debates about human population. Some argue that gender, race, and class are often not adequately addressed in Ehrlich-style population-restraint perspectives. Recommendations of a reduction of population growth can be seen as racist and classist in condemning the rapid growth that occurs mostly in areas outside of the ambit of the developed countries. Such critics argue that the Ehrlichs' arguments fail to address the reasons for rapid growth in the third world.

Vandana Shiva (1989) argues that there is a link between the destruction of nature and the oppression of women. She argues that agriculture has shifted into two sectors: the cash-mediated masculine sector and the subsistence-oriented feminine sector. As a result the cash economy draws men away from the land, increases women's workload in producing subsistence, and disrupts ecosystems because of the green revolution's focus on growing irrigation-dependent cash crops through the use of synthetic chemicals. Shiva asserts that, as more land is diverted to cash crops and degraded by green-revolution technologies, women have less access to land and other resources but increased burdens in food production for family subsistence. As a result of the environmental degradation caused by industrial agriculture, Shiva notes that women must walk longer distances for water, fodder, and fuel.

Val Plumwood (1991) argues that numerous studies have shown that, in the Third World, ecologically insensitive, high-technology agriculture and forestry strengthen the control of the elites over natural resources and aggravate social inequalities, including men's control over women. Ecofeminists such as Shiva and Plumwood argue that the key to stanching population growth in developing countries is not withholding food aid and promoting contraception or increasing affluence and consumption: They believe that the solution lies in ensuring women's economic and reproductive autonomy. When women are empowered with education, economic means, and reproductive choices, they are more likely to be able to choose to have fewer children because their status may not be as dependent on bearing many children. In addition, they may not feel the need to increase the economic workforce of children as a means of making ends meet. Fewer births may benefit these women in several ways including their health and their efficiency in managing natural resources.

The ecological feminist Chris Cuomo stresses the importance of considering categories such as gender, race, class, and sexuality in an analysis of the complex issues involved in population growth (1994). She points out that some approaches to population control lack a critical analysis of the many social factors underlying gender oppression. She notes that these social factors—including the institution of motherhood and attitudes about sexuality and women's bodies—which contribute to the growth of human population, are ignored in many biology-based theories about "carrying capacity" and "standard of living." She calls attention to the inadequacy of viewing humans as a homogenous species and thus failing to recognize the impact of gender, race, and class on population growth. Cuomo asks, "Why do women bear many children, even in areas or communities where high population density impacts on individual lives very directly, through overcrowding, shortages of food and other necessities, poor health and hygiene, and the obvious destruction of local land and species?" (1994, p. 95).

Cuomo argues that sexism, the institution of motherhood, racism, classism, cultural factors, sexuality, and health issues fuel population growth. The ecofeminist approach acknowledges and examines in detail the need for the disempowerment of women in various ways: in terms of control over their own bodies, their roles in culture, and their sexuality, and their identities as they relate to the environment in which they live. According to this view, women's systematic oppression in patriarchal societies directly relates to the degradation of the natural environment.

Ecofeminist writers have linked women's oppression and the feminization of poverty to human population growth. Ronnie Zoe Hawkins (1992) notes that, although women often seek to limit family sizes, they are sometimes denied access to the means for doing so. Cultural beliefs and values in a patriarchal society often pressure women into bearing many children, even at the expense of their own health. Forms of birth control and abortion may be prohibited by religious or cultural views or both. In addition, women may be alienated from their own bodily functions and processes.

The roots of population growth are thus seen to lie in the poverty and patriarchy that form institutionalized barriers to women's freedom of reproductive choice. For example, many Third World cultures discourage the open discussion of birth control, and contraceptive devices are not readily accessible. In many cultures male babies are seen as more valuable than females; the overwhelming majority of abortions in countries such as China and India are performed to prevent the birth of females, resulting in de facto gendercide. Although this practice may limit population growth because there will be fewer mothers to bear children, feminist critics have pointed with alarm to its grave ethical implications.

Of all the roles traditionally assigned to women, motherhood is the one that is most common across cultures. The ideal of a good mother as a woman constantly bound to her children, physically and emotionally, willing to sacrifice herself and put the children's welfare before anyone else's, including her own, is a demanding ideal, but its perceived nobility offers insight into the reasons that some women continue to reproduce in circumstances where high population lowers their standard of living. Another explanation turns on the economic value of children as part of a family workforce in poor agrarian communities. Third World women often participate more than men in the food system. Women in Africa produce more than 70 percent of Africa's food. Andy Smith (1997) argues that it is often in the economic interest of Third World women to have more children in order to raise more export crops and earn more money.

Smith argues that population-control measures are needed most urgently among the prosperous citizens of the United States because of their rapid rate of consumption of resources. Sze (1997) notes that Third World immigrants and refugees of color with high fertility rates threaten to outbreed the low-fertility white populations of industrialized countries. Sze argues that white fears of "Third World-ification" by Latinos and Asians assume that the world's people of color are to blame for environmental degradation caused by overpopulation.

Some further argue that methods of population control have been threats to the reproductive health among women of color. For example, Smith and Lori Gruen call attention to the history of forced sterilization of women of color and the history of U.S. contraceptive companies marketing dangerous drugs such as Depo-Provera to other countries.

CONCLUSION

While gender, race, and class issues are crucial for consideration in analyses of human population size and growth, it is important that such studies do not use women, particularly women of color, as scapegoats. Reproductive choice is a human rights issue as well as an environmental issue. Policies geared toward the empowerment of all women in their reproductive choices are necessary in order to move toward a more sustainable human population and a healthy planet for all.

POSTCOLONIAL ENVIRONMENTAL ETHICS

The term *postcolonial environmental ethics* refers to the view that any globally relevant environmental ethic must recognize the legacy of Euro-American resource extraction from subordinate states over the last five centuries. The term *postcolonial* draws attention to the fact that the contemporary period has followed the demise of Euro-American colonial empires that lasted from the late 1400s through the 1960s and that people in the West still are affected by neocolonial attitudes toward nature and the human categories (indigenous/women) that are conceptually connected with nature. At the core of these attitudes is Eurocentric diffusionism (Blaut 1993), the idea that Euro-American cultures have dominated world resources over the last five centuries because of their innate cultural economic superiority over dominated cultures in Africa, Asia, and the Americas; that is, colonial resource extraction is ethically justified. The utilitarian philosopher John Stuart Mill embodied this attitude when he described British colonies as "hardly to be looked upon as countries, . . . but more properly as outlying agricultural or manufacturing establishments belonging to a larger community. . . . The West Indies . . .are the place where England finds it convenient to carry on the production of sugar, coffee, and a few other tropical commodities" (Mill 1965 [1848], p. 693).

Postcolonial environmental philosophers typically critique contemporary economic and cultural globalization for its neocolonial policies. Postcolonial environmental ethics today works constructively toward an environmental ethic that will replace the Euro-American hierarchy with a more diverse, horizontal, historically infused view of environmental problems that integrates environmental and social justice. It therefore brings forward sources of understanding that often are marginalized, such as understanding based on gender, race, caste, and class. Instead of separating people from nature—imagining nature as a pristine sanctuary separate from human beings—it works to undercut conceptual and practical dualisms such as nature versus culture, feminine

versus masculine, emotion versus reason, and the Orient versus the West.

HISTORICAL BACKGROUND

In the wake of Christopher Columbus's claim to have discovered the Western Hemisphere, Pope Alexander VI issued the papal bull *Inter Caeteras,* granting the world east of the Canary Islands to Portugal. Ferdinand and Isabella of Spain were granted the lands to the west so "that in our times especially the Catholic faith and the Christian religion be exalted and be everywhere increased and spread, that the health of souls be cared for and that barbarous nations be overthrown and brought to the faith itself" (Alexander VI 1917 [1493]). In 1498 the Portuguese sailor Vasco da Gama established the eastern water route to the same territory that Columbus coveted by rounding the Cape of Good Hope and landing at Calicut in southwestern India. Thus, Europe, whether looking east or west, had staked its claim to the non-European world as its colony. The reason was primarily environmental, for as Madhav Gadgil and Ramachandra Guha wrote, "Colonialism's most tangible outcome (one whose effects persist to this day) related to its global control of resources" (1992, p. 116). The 24 acres of land available to support each European in 1491 increased to 120 "ghost acres" per European inhabitant with the advent of colonialism (Gadgil and Guha 1992).

As the historian J. M. Blaut has recounted, in the years from 1561 to 1580, 85 percent of the silver in the world came from the Americas. Potosí, a silver-mining city in the Andes, had a population in the 1570s of 120,000 people, more than Paris, Rome, or Madrid. Sugar exports from Brazil in 1600 were double the value of all English exports to the entire world in that period. Blaut estimated that more than a million people were working for the European economy in the Western Hemisphere at the close of the sixteenth century (Blaut 1993).

European economic, cultural, and military dominance over the last five centuries has been due largely to smallpox, not innate European superiority. Although the numbers are disputed, most historians believe that the Western Hemisphere was more populous than Europe in 1491, with perhaps 112 million people, roughly 95 percent of whom died within 130 years of European contact (Mann 2006). The American wilderness that explorers such as René-Robert de La Salle encountered in his voyage up the Mississippi in 1681, "a solitude unrelieved by the faintest trace of man" (Mann 2006, p. 360), was in fact an artificial wilderness created by genocide and disease. John Winthrop, the first governor of the Massachusetts Bay Colony, observed in 1634, "For the natives, they are neere all dead of small Poxe, so as the Lord hathe cleared our title to what we possess" (quoted in Crosby 1986, p. 208).

POSTCOLONIAL ENVIRONMENTAL THEORY

Postcolonialism has influenced many disciplines in the humanities, but it often has remained human-centered. Postcolonial environmental ethics therefore issues a challenge to understand colonialism and its contemporary legacy in terms of the ways in which colonial exploitation of resources is intertwined with the exploitation of people who are understood as being connected to nature. Thus, women, indigenous peoples, and people of color occupy ambiguous spaces when they are constructed in colonial narratives as intermediaries between nature and culture.

Postcolonial environmental ethics is pluralist because its proponents recognize that resistance and solutions grow out of local conditions. A model is the Self Employed Women's Association (SEWA), a trade union founded in 1972 by Elaben Bhatt because in India most women (94 percent) work outside the wage labor economy, finding employment in the informal sector. Their contributions to the economy and to environmental stewardship usually go unrecognized. SEWA embraces Gandhian principles of *satya* (truth), *ahimsā* (nonviolence), *sarvadharma* (integrating all faiths, all people), and *khadi* (propagation of local employment and self-reliance). The association includes a Forest Worker's Campaign because many poor women sustain themselves and their families through the collection of forest produce. The workers raise and sell saplings as well as produce from their nurseries. SEWA contends that the government forest department undercuts women's activities and has launched a campaign to "Feminise Our Forests."

Informed by SEWA's emphasis on local self-reliance (*khadi*), postcolonial environmental ethics often opposes attempts by the so-called First World to develop the Third World as another chapter in what historian Ranajit Guha (1989) termed the "idiom of improvement." The economist William Easterly (2006) compared the West's post–World War II attempt at Third World development with Rudyard Kipling's urgent plea to the United States to colonize the Philippines:

> Take up the White Man's burden—
> Send forth the best ye breed—
> Go bind your sons to exile
> To serve your captives' need

Authors such as Vandana Shiva (2001) and Deane Curtin (1999, 2005) have questioned the attempts of U.S. Agency for International Development (USAID), the World Bank, the International Monetary Fund, and the World Trade Organization to extend the ownership society to the genetics of seeds, medicines, and the human genome. These efforts threaten the security of dispossessed peoples, who need dependable access to nature

for health, safe food and water, and fundamental human dignity.

POWELL, JOHN WESLEY
1834–1902

John Wesley Powell is best known as the one-armed explorer of the Colorado River, but his later work as an advocate of land reform earned him consideration as North America's first great bioregional thinker. As a leading intellectual of his time, he also made lasting contributions to geology, linguistics, and anthropology. Born on March 24, 1834, in Mount Morris, New York, Powell grew up on a succession of family farms in Ohio, Illinois, and Wisconsin.

An ardent abolitionist, he enlisted in the U.S. Army at the outbreak of the Civil War, ultimately attaining the rank of major. Wounded at the Battle of Shiloh in 1862, he suffered amputation of his right arm but eventually returned to active duty and served in the Vicksburg and Nashville campaigns.

Soon after the war he conceived the idea of exploring the largest remaining blank spot on the map of the United States south of Alaska: the canyons of the legendary Colorado River and its tributaries. Powell aimed to map the region, ascertain its character, and assess its usefulness.

On May 24, 1869, at Green River Station, Wyoming Territory, Powell and nine others shoved four wooden dories into fast water and floated out of sight, bound either for history or oblivion. The loss of a boat and its provisions to an early rapid strained group cohesion. Later, in the Grand Canyon, weeks of scant food, brutal heat, arduous labor, and terrifying rapids prompted three men to leave the expedition and attempt to walk to civilization. They died in the attempt. Powell and the remaining five (one other had departed in June) safely reached the Virgin River in Nevada Territory on August 30, after a wilderness journey of some 900 miles.

The success of the expedition led Congress to create the Geographical and Geological Survey of the Rocky Mountain Region, with Powell in charge. In that capacity, through the 1870s, Powell explored and mapped the Colorado Plateau. He also pursued his long-standing interest in Native American ethnography, producing *Introduction to the Study of Indian Language* in 1877. Two years later he became head of the newly created Bureau of Ethnology in the Smithsonian Institution.

Powell produced an even more groundbreaking work in 1878. His *Report on the Lands of the Arid Region of the United States* proposed a thorough overhaul of laws and policies governing settlement of western lands. He based his argument on two ideas, which, he said, the government and its people would ignore at their peril.

The first was that the land had limits. Most of the United States west of the hundredth meridian received fewer than twenty inches of precipitation annually, which

John Wesley Powell, 1873. *Best known for his explorations of the Colorado River, Powell is also remembered for his contributions to geology, linguistics, and anthropology. He is seen here talking to a Paiute Indian during a survey of northern Arizona.* **U.S. GEOLOGICAL SURVEY.**

was inadequate to sustain unirrigated agriculture. The nation's homestead and preemption laws, which were predicated on development of 160-acre farms, were therefore a prescription for failure. Powell's second idea was that the character of institutions governing settlement—systems for water rights and land tenure, for instance—would directly shape society's prospects for wealth, justice, and democracy.

Powell offered an alternative system, which he continued to revise for another dozen years, culminating in three articles published in *Century Magazine* in 1890. The cornerstone of Powell's plan was to redraw the political landscape of the West as a system of what he called "watershed commonwealths," achieving "local self-government by hydrographic basins" (Powell 2001, pp. 306, 308). Citizens in each watershed would use the land as they collectively wished, while the interlocking interests of irrigators, stock raisers, loggers, and others kept abuses to a minimum.

Powell published the articles because he was under attack. Since 1881 he had directed the U.S. Geological Survey, which Congress formed by combining Powell's survey with two others. In 1888, at Powell's urging, Congress authorized the Irrigation Survey within the Geological Survey to identify reservoir sites and other lands necessary for development of irrigation agriculture throughout the West. As a result of events that Powell neither controlled nor advocated, the work of the Irrigation Survey led to a temporary ban on settlement within the public domain in 1889. The resulting furor destroyed much of Powell's public influence, and he resigned from the Geological Survey in 1894.

He continued as director of the now-renamed Bureau of American Ethnology until his death in 1902; among his important contributions to anthropology is *Indian Linguistic Families of North America*. Nevertheless, Powell's legacy is richest as a philosopher of land use. He held a largely utilitarian view of nature and was no environmental saint, but like few others in his time or since, he fathomed the interrelation of society, land, and water and spoke its truth relentlessly.

PRAGMATISM

Pragmatism as a school of philosophy is concerned with practical consequences of ideas. Because environmental issues are practical by their very nature, the central doctrines of pragmatism have been of interest to philosophers and others concerned with environmental ethics.

ORIGINS AND BASIC PRECEPTS OF PRAGMATISM

The formalization of pragmatism began in the United States during the 1870s as a reaction to the epistemological foundationalism and mind-body dualism of René Descartes, the doctrine of the transcendental ego and the "thing in itself" advanced by Immanuel Kant, and the sensory atomism of British empiricists such as John Locke. Although the movement had many contributors, including Jane Addams, George Herbert Mead, and F. C. S. Schiller, the most influential among the founding pragmatists were Charles S. Peirce (1839–1914), William James (1842–1910), and John Dewey (1859–1952).

Reduced to its most basic form, pragmatism is a family of theories of meaning, truth, and inquiry. Pragmatists hold that the meaning of a concept lies in its conceivable practical consequences. Peirce treated truth as a limit toward which disciplined scientific inquiry would eventually converge. For James true ideas are those that we can assimilate, validate, corroborate, and verify. Dewey identified truth with warranted assertibility.

What these treatments of truth have in common is a rejection of key elements of traditional correspondence and coherence theories of truth, as well as an emphasis on the active, selective, reconstructive activity of human inquiry. Peirce, James, and Dewey agreed that inquiry begins with a state of doubt or disequilibrium that is genuinely felt (and not just theoretical or feigned); that it proceeds by way of problem formation, hypotheses, and tests; and that, when successful, it results in a new state of belief or equilibrium in which the subjective and objective conditions that occasioned the original doubtful state have both been satisfied. Dewey characterized this as a process of accommodation of an organism to relevant external conditions and alteration by the organism of relevant external conditions. These two processes together he termed "adjustment" (Dewey 1934, p. 12).

PRAGMATISM AND NATURE

In addition to these basic tenets, there are pragmatism's commitment to the continuity between human life and the rest of nature; its rejection of control or mastery over nature in favor of management of undesirable conditions; its doctrine of fallibilism (or the view that absolute certainty regarding existential affairs is unattainable); and its treatment of ethics as contextual and constructive. Although the roots of pragmatism are in the sciences, it is not scientistic: It rejects the idea that the methods and the conclusions of the natural sciences are applicable to all areas of experience, as well as the notion of the natural sciences as value-free. Each of the founding pragmatists accepted some variety of evolution, and each held some variety of naturalism (as opposed to supernaturalism).

Although Peirce, James, and Dewey shared these and other basic ideas, they differed regarding other matters, including issues that are now debated by environmental philosophers. Peirce and James, for example, accepted various forms of panpsychism, or the view that preference or feeling at the very least (Peirce), or perhaps even consciousness (James), pervades the universe. It was Dewey, however, whose published work most directly interfaces with contemporary debates among environmental philosophers.

Dewey, for example, responded to Thomas Huxley's argument that the world comprises two orders: a "cosmic" order of struggle and strife and an "ethical" order of sympathy and cooperation. He rejected the underlying dualism of Huxley's argument, suggesting instead that there is only one nature, that human beings are a part of nature, and that the relation of human beings to the rest of nature is like that of a gardener who artfully utilizes one part of nature in order to manage another part (Dewey 1898). Dewey's concept of the relation of human beings to their environment thus anticipates the work of the pioneering environmentalist Aldo Leopold, for whom management was a key concept.

PRAGMATISM AND THE ENVIRONMENT

Early in the twentieth century, Dewey's critique of idealist and mystic approaches to environmental issues anticipated some issues currently under debate. He understood idealism, for example, to posit ultimate, inherent environmental value or values that transcend mere human valuation. Contemporary versions of this view have been advanced by those such as Holmes Rolston III, who has held that there are inherent values in nature that transcend human experience and that should be the basis of human values.

Dewey understood the mystic position to hold that rational debates about the environment are pointless—that environmental value is romantically or aesthetically felt and thus requires an attitude of direct vision. A contemporary version of this view has been held by those such as Michael Zimmerman, who has argued for a spiritual appreciation of nature that can only be precipitated by a new type of nondualistic awareness.

Dewey criticized both of these positions. Against the idealist he argued that it is not some ultimate or transcendent value beyond our experience that properly informs our decisions, but instead careful deliberation about real alternative courses of action that is based on the best available evidence. Against the mystic he argued that a romantic or aesthetic appreciation of nature might be a good place to begin deliberation, and that aesthetic qualities pervade inquiry about alternative courses of actions, but that inquiry into wider environmental concerns would be blocked if human relations to the rest of nature were to remain purely romantic or aesthetic.

ENVIRONMENTAL PRAGMATISM

The term *pragmatism* as used in the phrase *environmental pragmatism* has been used by Andrew Light and others to denote an approach to environmental philosophy that incorporates some of the central insights of the founding pragmatists in a general sense but that is at the same time broader and more open-ended. In 1996 Light and Eric Katz published a watershed collection of essays titled *Environmental Pragmatism*. Their aim was to vitalize what they regarded as a sluggish and deadlocked discipline by transcending received methodological dogmas. They argued that environmental ethics up to that point had been too dependent on theoretical considerations and that in order to establish its relevance as a discipline it must begin to address areas of practical decision making in which experimental results trump what Dewey termed the vice of "intellectualism"—that is, neglect of

concrete experiences. They issued a call for metatheoretical pluralism that would be open to the "plausibility of divergent ethical theories working together in a single moral enterprise" (Light and Katz 1996, p. 4). Since the publication of that volume, Light has been actively engaged with issues such as environmental justice and ecological restoration.

The work of Bryan G. Norton provides an excellent example of how this new, broader pragmatism can be married to the insights of the classical pragmatists. Norton's distinction between felt and considered preferences, for example, recalls Dewey's distinction between what is merely valued and what has proved to be valuable. Both Norton and Dewey reject what Norton has termed *strong anthropocentrism*, or the view that felt preferences are sufficient guides for action with respect to the environment. Both prefer versions of "weak anthropocentrism," a view that rejects the underlying subject-object dualism of strong anthropocentrism, with its tendency toward the domination of nature. Weak anthropocentrism advances a transactional view of nature according to which the source of environmental value lies within considered preferences that are the result of experimental inquiry, although the locus of such value may be in nonhuman nature.

Although Norton's work is built on strong theoretical foundations, it is also manifestly practical. His experience at the Environmental Protection Agency led him to conclude that the agency suffers from a structural defect that he terms *towering*: He argues that the two towers of scientific analysis and policy decisions fail to connect (Norton 2005, p. 27). His alternative, a pragmatic model that he terms "adaptive management," attempts to build bridges between the two towers by emphasizing the experimental nature of successful inquiry of all types. He argues for a methodological naturalism that "advocates developing self-corrective processes in public discourse, whether scientific or evaluative" (p. 203). Norton's work is thus grounded in experimentalism.

Norton attempts to supplant metaphysical and ideological debates about environmental issues with deliberation based on the development of sets of "indicators." Indicators express but do not represent values. They are "certain processes and changes in the system [that are] important enough to monitor. Once these processes are chosen for monitoring, it will be possible to identify goals that can be stated as desired levels to be achieved and maintained with respect to the chosen indicators" (Norton, p. 453). Norton describes his method as a kind of "disciplinary stew" in which ordinary language and commonsense policy discourse make up the broth, whereas the meat and potatoes is the work of the empirical sciences (p. 461).

Paul B. Thompson's work stands out as an excellent example of the ways in which environmental pragmatism can be applied to the ethics of food biotechnology. Like Norton, Thompson has been strongly influenced by the work of the founding pragmatists; like Dewey, for example, he just brackets traditional metaphysical debates such as those that concern the existence of inherent or intrinsic values in nature. A key feature of his work is his rejection of "rational-choice" decision models in favor of more pragmatic "context" models that take into account both the social institutions that inform and condition decisions about values, and the needs and interests of specific communities at specific times and places. In his view, "people do not frame their lives as a series of objectives for which they are seeking the most effective means," (Thompson 2007, p. 286) but rather, "people apply their own values in selectively adopting or rejecting scientific knowledge claims" (p. 287). For Thompson the task of the environmental philosopher is to function as a kind of liaison between scientific communities and the individuals and communities that are attempting to find ways of applying their values amid changing circumstances.

Rejection of rational-choice models is also a key element in the work of the pragmatist economist Daniel W. Bromley. Bromley rejects the positivist dogma that "correct decisions necessarily follow from the correct methods of discovering the 'truth' about monetary values of nature and nature's many services" (Bromley 2004, p. 85). Applying his alternative pragmatist model, he treats preferences as constructed rather than fixed, stable, and known. He follows Dewey in arguing that warranted assertions about environmental issues are not the result of the identification of "causes" that are external to deliberation. They are, instead, the result of "the incessant working out of . . . what seems the better thing to do in the current setting and circumstances" (p. 86).

Environmental pragmatism in the Netherlands exhibits a rich blend of classical pragmatism at the same time it builds on the type of discourse ethics developed by Jürgen Habermas. In their 2002 proposal for a pragmatic environmental ethics, Jozef Keulartz, Michiel Korthals, Maartje Schermer, and Tsjalling Swierstra embraced the founding pragmatists' antifoundationalism, antidualism, and antiskepticism. They argued that work toward Dewey's goal of a creative democracy will be more oriented to process than to product and that it must develop procedures to ensure that all involved parties have their say in ethical debates. But they also recognized that procedures can become deadlocked and that substantive interventions are sometimes necessary. They therefore embraced activities such as "studying problem translations, sketching possible future scenarios, and developing new moral vocabularies" in order to facilitate participation across

communities of interest (Keulartz et al., 2002 p. 16). They are concerned to demonstrate methods by which environmental ethics can begin to cope with the dynamic character of our technological culture.

PRECAUTIONARY PRINCIPLE

The basic message of the precautionary principle (PP) is that on some occasions, measures against a possible hazard should be taken even if the available evidence is not sufficient to consider the existence of that hazard as a scientifically established fact. Thus, PP is about acting to prevent harm in situations in which it is uncertain whether there is a threat or, if there is a threat, how serious it is.

PP has been used primarily in environmental contexts but also in regard to risks to human health. The areas in which it has been thought applicable are highly diverse and range from the regulation of chemicals and genetically modified organisms to research into life-extending medical therapies. It generally has been discussed in the context of threats of serious or irreversible harm, that is, threats that cannot be compensated for easily, such as species extinction.

PP refers both to principles that can be applied by decision makers and policy makers in general (PP in the broad sense) and to principles of national or international law (PP in the legal sense). In the broad sense, some commentators have interpreted it as one or another familiar principle from decision theory, such as maximin, a decision rule that states that an agent should choose the action for which the worst possible outcome is the least bad. They typically take the assumedly risk-neutral strategy of maximizing expected utility (MEU) to be the default rule in risk management and regard PP as more risk averse than MEU.

PP in the broad sense is regarded sometimes as a moral principle and sometimes as a principle for decision making that can be justified on moral or prudential grounds. Those who attempt to make a moral argument for PP have, among other things, appealed to some principle of responsibility emanating from the huge scope of human action, as Hans Jonas did in *The Imperative of Responsibility* (1984) before the term *precautionary principle* was coined. Another suggestion refers to a Rawlsian thought experiment, in which agents behind a veil of ignorance choose a PP. John Rawls (1921–2002) was a philosopher who argued for the maximin principle by using a thought experiment in the form of a hypothetical bargaining situation in which agents agree on the basic principles for a just society. To ensure fair bargaining in the thought experiment, the participants are supposed to be behind a "veil of ignorance." This means that each person is ignorant about what his or her own chances in society will be. He or she does not know anything about his or her sex, ethnic origin, skills, personal characteristics, intelligence, and so on. Rawls argued that these bargainers would choose a maximin principle that maximizes the position of the least well-off in society.

Several commentators also treat PP as a principle of common sense, citing proverbs such as "better safe than sorry" and "an ounce of prevention is worth a pound of cure."

It is fruitful to distinguish between precaution and precautionary principles. Someone might take precautions in a particular case without subscribing to any principle of precaution. For a principle to be present, it may be necessary to demand that the agent at a minimum subscribe to a claim such as "precaution should be taken in situations of type T." The fact that the agent believes that precaution should be taken in the particular situation S is not sufficient. In addition, there must at least be a claim such as "precaution should be taken in situation S and in relevantly similar situations," with the meaning of "relevantly similar" somehow specified.

Various versions of PP have been included in several international legal and policy documents. PP has had proponents primarily among environmentalists, and it has been subject to a heated debate, in particular since the mid-1990s.

HISTORY OF THE PRECAUTIONARY PRINCIPLE

The origin of the term *precautionary principle* is not clear. Obviously, examples of precautionary regulatory and policy measures in regard to health and environmental issues appeared long before the term was coined. One example is the British Alkali Act of 1874. A more recent example is the so-called Delaney Clause, a 1958 amendment to the U.S. Federal Food, Drug, and Cosmetic Act, which banned the use of potentially carcinogenic food additives. A common claim in the literature is that PP first emerged in West German environmental law in the 1970s under the name of *Vorsorgeprinzip*. The United Nations *World Charter for Nature* (1982) contained PP-like wording without using the phrase *precautionary principle*. The term was used explicitly in the Ministerial Declaration of the Second International Conference on the Protection of the North Sea (1987).

IMPORTANT USES OF THE PRECAUTIONARY PRINCIPLE

The most prominent and frequently cited version of PP is probably the one found in Principle 15 of the 1992 Rio Declaration (United Nations Conference on Environment and Development 1993):

> In order to protect the environment, the precautionary approach shall be widely applied by States according to their capabilities. Where there are threats of serious or irreversible damage, lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation.

This version of PP has been included nearly verbatim in many other documents, although the English text of the declaration does not use the term *principle*. However, translations into several other languages use an expression that corresponds to it directly, and the passage cited here commonly is referred to as expressing PP.

PP has had a prominent place in the European Union (EU), at least since its inclusion (without a definition) in the Maastricht Treaty (1992). An important document is the *Communication from the Commission on the Precautionary Principle* of the Commission of the European Communities issued in 2000 and endorsed at the European Council's meeting in Nice in December 2000. The text and reasoning in these documents are reflected in several other EU documents, such as the so-called General Food Law.

Though not in any way binding, the Wingspread Statement on the Precautionary Principle that was adopted by a conference of environmentalists in 1998 has had considerable influence in the PP debate:

> When an activity raises threats of harm to human health or the environment, precautionary measures should be taken even if some cause-and-effect relationships are not fully established scientifically (cited in Raffensperger and Tickner 1999, pp. 354f).

The Wingspread version has been cited by both advocates and critics of PP. Its advocates regard it as an example of a powerful version of PP that would have the ability to change policy in a more precautionary direction, and its critics see it as an example of an extreme, rigid, and stifling principle.

VERSIONS OF THE PRECAUTIONARY PRINCIPLE

Whether one regards PP in the broad sense or the legal sense, there are numerous versions of it. They can be classified in at least three perhaps overlapping groups that regard PPs as (1) rules of choice; (2) epistemic rules or principles; or (3) procedural requirements.

When interpreted as rules of choice, many existing versions of PP have four common elements and a common structure: (1) the threat dimension; (2) the uncertainty dimension; (3) the action dimension; and (4) the prescription dimension. The common structure can be expressed in the following "if" clause containing the four dimensions:

> *If* there is (1) a threat, which is (2) uncertain, *then* (3) some kind of action (4) is mandatory.

The actual phrasing varies among different versions of PP, and the action can refer to abstaining from action as well. Some versions of PP are very strict, whereas others are significantly more permissive. The Wingspread Statement is an example of PP as a rule of choice.

Epistemic versions of PP are rules not for choosing courses of action but for determining what to believe. One example would be to demand that evidence suggesting a causal link between an activity and possible harm should be given greater weight than it would in other circumstances. In this way, some commentators have wanted to apply PP in the appraisal or assessment of risks rather than in the management of risks. One possible version of PP along these lines is the use of precautionary defaults, that is, a cautious or pessimistic assumption that is used in the absence of adequate information in the assessment of risks; that assumption can be replaced when such information is

obtained. Epistemic versions of PP have been discussed primarily in academic contexts.

Procedural versions of PP are not algorithms for choosing particular courses of action but requirements for how such decisions are to be made. For instance, what arguments are to be considered legitimate? On whom does the burden of proof fall? The version of PP from the Rio Declaration belongs to this broad group of PPs. In this category, burden-of-proof requirements have been discussed extensively. Commentators who propose burden-of-proof versions of PP claim that those who wish to carry out a potentially harmful activity should be required to demonstrate that that activity will be safe before it is allowed to proceed rather than demanding that regulatory authorities provide evidence of harm before banning the activity. Thus, for example, genetically modified (GM) foods and the use of hormones as growth promoters in meat production should be presumed to be harmful until the producers can provide evidence that the products are safe. Another procedural version of PP concerns the level of scientific evidence required to trigger precautionary action. Some PP proponents have suggested that comparatively scant scientific evidence should suffice to warrant treatment of something as harmful (pending further information), whereas a lot more evidence should be required for it to be accepted as safe.

THE PRECAUTIONARY PRINCIPLE AND ENVIRONMENTAL RISK MANAGEMENT

There are two primary ways in which PP has been thought to be able to contribute to improved management of environmental risks. The first is the possibility of increased safety. Proponents of PP often contrast their approach with that of traditional cost-benefit analysis. Citing historical examples, they argue that cost-benefit analysis has led to overly large risks being taken. They also have been critical of the idea of safe levels, as expressed in concepts such as assimilative capacity and threshold doses for toxic substances and radiation. (A threshold dose is a level of exposure to, for instance, a toxic substance below which no harmful effects occur.) Researchers may be mistaken about the threshold or about which level is safe or whether there is a safe level at all, and it is better to err on the side of caution. In radiation protection, this is expressed in the acronym ALARA, which recommends that exposure be kept *a*s *l*ow *a*s *r*easonably *a*chievable.

The second application concerns the role of science in policy. Proponents of PP argue that too much faith in scientific evidence has led to the neglect of some risks. Science has limitations, and sometimes policy makers have failed to consider those limitations. For example, in pure science, type I errors (false positives: concluding that there is a phenomenon or an effect when there is none) generally have been regarded as much more problematic than type II errors (false negatives: missing an existing phenomenon or effect). However, from a policy point of view, type II errors such as believing that a highly toxic substance is harmless may be more serious. Burden-of-proof and other procedural versions of PP have been seen as offering possibilities for balancing this situation. In addition, it is hoped that PP, in particular its procedural versions, will offer a way of ensuring public influence and legitimacy. This view has been put forward by those who see risk management as an activity run by experts with too little regard for public concern about environmental matters.

OBJECTIONS TO THE PRECAUTIONARY PRINCIPLE

Obviously, not everyone shares these views, and PP has been subject to criticism. There are at least five main types of objections to it. First, it has been criticized for being ill defined and too vague to be useful in regulation. It is true that there are definitional problems with PP and that there are many different versions of it. However, this criticism is not necessarily devastating because vague principles and concepts abound in regulation; they can be made more precise through explication and practice. Furthermore, some argue that to be operational, political principles such as PP need a certain vagueness or flexibility that allows for different interpretations.

Second, PP has been criticized for forcing decision makers to pay unreasonable attention to extremely unlikely scenarios. In the extreme, it thus may be self-refuting. If PP is understood as prohibiting courses of action that may lead to harm, PP will prohibit every action, including the action of taking precautionary measures, because any action may have unforeseen harmful consequences, and it never can be proved that there are no such consequences. A principle prohibiting every course of action, then, is self-refuting. Some decision theorists have produced a version of this argument in which a formalized version of PP is shown to be incoherent or incompatible with reasonable desiderata.

The third objection is a related but weaker claim. According to this objection, PP is not incoherent but counterproductive. That is, the precautionary measures prescribed by PP would lead to more risk taking, not less. For instance, precautionary measures against pesticides or potentially unsafe GM crops might lead to famine. This is known as risk trade-off. Increased costs induced by regulation might lead to greater risks than the ones against which the regulatory measures were supposed to

safeguard. This argument has been proposed by a number of U.S. commentators who see PP as a disguised form of trade protectionism.

The fourth objection is that PP is a value judgment, not a scientific judgment. This objection is dismissed by proponents of PP because it is a principle for decision making, and such principles are necessarily normative.

The fifth objection is that PP does not take science seriously and marginalizes the role of science in policy making. This objection is relevant, but it may have more to do with differing views on how to treat scientific uncertainty. Several PP proponents emphasize that decisions should be based on science but that more attention should be paid to the handling of scientific uncertainty.

Proponents of PP have responded to these and similar objections by amending or revising their versions of PP. For instance, to meet the charges of incoherence and counterproductivity, it has been suggested that PP should be supplemented with some sort of de minimis principle, which requires that extremely improbable scenarios be disregarded. An example of an attempt at amending PP can be found in the 2000 communication from the Commission of the European Communities, which states that precautionary measures should, among other things, be proportional to the chosen level of protection, nondiscriminatory, consistent with other similar measures, based on an examination of potential costs and benefits of action (and lack of action), subject to review in the light of new scientific evidence, and capable of assigning responsibility for who should produce the scientific evidence needed for a more thorough risk-benefit assessment.

Such proposals aim at making PP more operative. However, their implementation might mean that in the end very little is left of PP.

PRESERVATION

By the late nineteenth century Americans began to think seriously about setting aside areas of land to protect them from commercial development. Proponents of preservation believed that certain places should be shielded from human exploitation and devoted to less intrusive human ends—recreational, aesthetic, and spiritual—or protected simply as a gesture of respect for the landscape itself. Preservation became an early focal point of a set of concerns that later fell under the rubric of environmentalism. Preservation later came to overlap and compete with related philosophies such as conservationism (sometimes called resourcism) and restorationism.

The idea of preservation gives rise to two philosophical questions: First, what does it actually mean to preserve something? Second, what should be preserved? The historical and contemporary debates over preservation center on these questions.

EARLY PRESERVATION: 1800s TO 1960s

Early gestures at environmental preservation focused as much on the preservation of heritage (or the preservation of origins)—whether of the nation or the human species—as they did on preserving particular physical places. The American transcendentalist Henry David Thoreau (1817–1862) worried that the preservation of wildness

Avalanche Peak, at Yellowstone. *Avalanche Peak is a part of the Absaroka Mountain Range, on the eastern border of Yellowstone National Park. The peak is one of the most popular sites for hiking in the park. Although popular for recreational activities, national parks are concerned first and foremost with preservation and conservation. Yellowstone was established in 1872, when the main focus of preservation in the United States was on wilderness areas.* **NPS. PHOTO BY BOB GREENBURG.**

(often misquoted as "wilderness") was necessary to offset the looming development of America; he wrote, "in Wildness is the preservation of the world" (Callicott and Nelson 1998, p. 37). Concerned mainly with protecting the remaining wild places or wilderness areas in the United States, John Muir (1838–1914) was also a leading nineteenth-century preservationist. Muir grounded his preservation efforts in a variety of arguments: heritage ("going to the mountains is going home"), a wide-range of instrumental values (from watershed protection to mental therapy for "tired, nerve-shaken, over-civilized" urbanites), and even deeper intrinsic value ("This Sierra Reserve . . . is worth the most thoughtful care . . . for its own sake") (Callicott and Nelson 1998, pp. 48–62).

Muir's commitment to a specific place—Yosemite's Hetch Hetchy Valley—pitted him against the utilitarian-motivated U.S. Forest Service chief, Gifford Pinchot (1865–1946). Pinchot proposed damming the Tuolumne River to provide cheap water and electricity to the burgeoning human population of San Francisco (a proposal that was considered conservationist at the time), whereas Muir proposed preserving the valley from this human encroachment. This famous philosophical and political battle sharply and dramatically delineated the distinction between conservation and preservation. This distinction still divides the American environmental movement as well as environmental philosophy and serves as the touchstone of American natural resource education today.

From 1919 until his death, the American ecologist, forester and environmentalist Aldo Leopold (1887–1948) wrote extensively on the importance of wilderness preservation. His early writings focused almost exclusively on the recreational value of such areas, whereas his later writings reflected on the value of preservation to science as a criterion of ecological normality and a measure of "land health."

From the late 1800s to the 1960s, preservation efforts focused largely on setting aside large landscapes and ecosystems such as national parks and wilderness areas in the national forests. The desire for preservation appears to be correlated with our success at fulfilling our

Manifest Destiny (the belief that the United States was destined to expand from the Atlantic to the Pacific seaboards) and a growing sense that we had conquered enough, that it was time to set some areas aside for the preservation of our human and national heritage. The preservation of specific places was codified in the U.S. Wilderness Act of 1964, which sought to establish "a National Wilderness Preservation System" (Callicott and Nelson 1998, pp. 120–130). This characterization is echoed in contemporary discussions of preservation. The philosopher G. Stanley Kane, for example, defines *preservation* as "setting aside areas that still remain undisturbed and protecting them against human encroachment," and he defines *restoration* as "bringing degraded areas back to something resembling an unspoiled condition" (Kane 2000, p. 221). Early preservationist philosophy was manifested in the creation of environmental groups such as the Sierra Club in 1892, the Wilderness Society in 1935, and the Nature Conservancy in 1950.

PRESERVATION SINCE THE 1960S

Although philosopher-scientists such as Leopold and Victor Shelford (1877–1968) had urged the preservation of representative ecosystems, their concerns were not translated into public preservation policy, which was motivated by the aesthetic appreciation of monumental scenery (as served by the national park system) and the desire to provide outdoor recreation (as served by the national wilderness preservation system). Beginning in the late 1960s, however, preservationist concern shifted from scenic landscapes suitable for recreation to the preservation of species of plants and animals. As early as 1920, scientists began noticing with alarm the loss of species—what later became known as the loss of biological diversity or biodiversity. The biologist Francis Sumner, for example, wrote in 1920 of the "importance of saving from destruction the greatest possible number of living species of animals and plants, and saving them, so far as possible, in their natural habitats and in their natural relations to one another" (Nelson and Callicott 2008, p. 32). In the 1970s and 1980s, the biologist Edward O. Wilson became the most prominent proponent of the preservation of biodiversity. In 1985 biologists such as Michael Soulé, Reed Noss, and David Ehrenfeld founded the Society for Conservation Biology as a "mission-driven" effort to preserve Earth's biological diversity.

Environmentalists began to see that biodiversity preservation was a more urgent concern than was the preservation of heritage landscapes. The concern for the preservation of biodiversity was codified in 1973 in the U.S. Endangered Species Act (ESA), which implicitly attributes intrinsic value to, and confers legal rights on, species, subspecies, and distinct population segments, protecting them from the "consequence of economic growth and development untempered by adequate concern and conservation" (Endangered Species Act of 1973, Sec. 2(a)(1), p. 3). The ESA is one of the most powerful conservation laws in the world, shaping much of contemporary discourse about preservation; it has, therefore, become the focus of much antienvironmental critique. In fact, environmentalists themselves sometimes criticize the ESA for its overemphasis on various species and its implicit indifference to the fate of entire ecosystems.

Since the 1960s preservationists have come to focus on four main areas of concern:

- species;
- ecosystems, which include biota and abiota (the nonliving parts of an ecoystem) with an emphasis on the preservation of the functions or processes performed or the services provided by the ecosystem (e.g., nitrogen cycle, carbon budget, water filtration);
- community, which emphasizes the preservation of certain end states of biota (e.g., wilderness, grassland, wetland);
- genetic diversity.

Contemporary preservation efforts have been buoyed by scientific advances such as the ability to readily quantify and understand DNA and the realization that in the face of environmental change, it is genetic diversity (i.e., heterozygosity, allelic diversity, inbreeding coefficient, and population subdivision and structure) that promotes a species' or population's chances for survival. For example, in addition to the preservation of species, the ESA, in later amendments, allows for the preservation of distinct population segments (DPS). Although the ESA does not precisely define a DPS, most scientists use the term to refer to a population representing an important component in the evolutionary legacy of the species (U.S. Fish and Wildlife Service 1996). Conservation geneticists, however, have suggested that DPSs become more definite when defined in terms of genetic diversity and future evolutionary potential, or what are sometimes called evolutionarily significant units. There are, however, limits to scientists' understanding of the relationship between population viability and genetic diversity. Moreover, efforts to champion the preservation of species in more precisely quantifiable terms still entail normative decisions—such as what constitutes "significant" in the evolutionarily significant unit.

CRITIQUE OF PRESERVATION

There are significant disagreements among philosophers about the meaning and goals of preservation. What does

it mean to preserve something? Why would you want to preserve something? It might be tempting to think that all these various foci of preservation all really converge on the same thing, that a focus on preserving scenic landscapes would result in preserving biodiversity, and further that the end result of restoration would be the same as that of preservation. There is reason to think, however, that this is simply not true, that different foci would lead to different actions on the ground with different end states. For example, the philosopher Sahotra Sarkar has pointed out that

> biodiversity conservation . . . cannot be identical with wilderness preservation. . . . [They] differ not only with respect to their explicit and implicit long-term objectives, but also with respect to their justifications, their immediate targets and obstacles, and the strategies that are likely to achieve these targets. . . . [Sometimes] the tasks of biodiversity conservation and wilderness preservation converge, but at least as often they do not. (Nelson and Callicott 2008, p. 231)

There is also a growing scientific literature indicating that actions that maximize the conservation of a species are not necessarily those that maximize the preservation of overall biodiversity, much less scenic or recreationally suitable landscapes. For example, scientists have growing doubts about the value of umbrella species—large "charismatic" species with large home ranges, the preservation of which was once assumed to preserve many other smaller, less "popular" species that might also exist in the critical habitat of the umbrella species.

One standard criticism suggests that preservation upholds interests of nature over the interests of humans. This criticism has been pressed most sharply by scholars and activists from the developing world. In 1989 the Indian scholar Ramachandra Guha (Callicott and Nelson 1998) pointed out that certain preservation tendencies (most notably wilderness preservation) have been ethnocentric and therefore not easily transferable to other contexts around the world without grave human consequences. Similarly, the protected-areas scholar David Harmon, echoing the views of the environmentalist Norman Meyers, suggests "that the whole notion of 'setting aside' has in fact done great damage to the conservation movement around the world" given the lack of attention that has been paid to varying ecologies in various parts of the world and the "top-down" fashion in which such environmentalism is perceived (Callicott and Nelson 1998, p. 228).

Defenders of preservation sometimes concede that they are choosing nature over humans. Philip Cafaro and Monish Verma, for example, argue that when human needs "conflict with measures that are necessary to preserve species, we believe they should be met in ways that preserve wild nature" (Rothenberg and Ulvaeus 2001, p. 60). Other preservationists deny the conflict between nature and humans. The wilderness advocate Dave Foreman, for example, suggests that these criticisms of preservation emanate from "Third World jingoism" and "chronic anti-Americanism" and that preservation "need not conflict with the needs and rights of the downtrodden" (Nelson and Callicott 2008, pp. 399–400).

Another more conceptual criticism suggests that preservation either creates or perpetuates a mentality that alienates humans from nature, whereby humans are despoilers of nature, chronic ecological malefactors. In this view the measure of successful preservation, then, is the degree to which human intervention is absent. This conceptual alienation opens up the door for the misanthropy and elitism that we have sometimes seen in the environmental movement The book *Defending the Earth: A Dialogue between Murray Bookchin and Dave Foreman* (Bookchin and Foreman 2001) nicely captures the tension between advocates and opponents of this viewpoint.

Others have taken exception to preservation strategies that attempt to reconcile the dualism between humans and nature; these critics view such strategies as preventing preservation efforts in areas that are moderately or heavily affected by humans. Referring to a concern about the ways in which preservation (in this case, of the Arctic National Wildlife Refuge in Alaska) can divert attention from other, equally important environmental issues (such as the agrarian landscape), the writer Wendell Berry confesses that he "made a sort of vow . . . [to not] support any more efforts of wilderness preservation that were unrelated to efforts to preserve economic landscapes and their human economies. . . . We can[not] preserve either wilderness or wilderness areas if we can't preserve the economic landscapes and the people who use them" (Berry 2008, p. 601). William Cronon likewise laments the need to ignore and even erase the rich legacy of erstwhile human settlement in the Apostle Islands of Wisconsin in order to create a "proper" Apostle Islands wilderness area (Nelson and Callicott 2008).

BEYOND PRESERVATION

Instead of a focus on the preservation of either processes (e.g., evolutionary) or end states (e.g., wilderness areas or biodiversity reserves), some have suggested that the goal should be preservation (or conservation or restoration) of an appropriate human relationship with nature. In this approach preservation implies the implementation of virtues such as humility, respect, attentiveness, and care. On this view the problem of preservation is the problem of figuring out how humans ought to relate to nature. Some have suggested that preservation is much more a

gesture of respect than it is a desire to preserve a state or process. For example, the philosopher Andrew Light writes that the value of restoration lies "in the revitalization of the human relationship with nature" (Kane 2000, p. 95).

PRIVATE PROPERTY

The term *property* is used to refer to entities for which an individual or group has certain rights. Important types of property include real property (land), personal property (other physical possessions), and intellectual property (inventions and intellectual and artistic creations). Private property is defined in contrast to public property: The possessor of private property customarily has exclusive rights to dispense with the property as he or she sees fit, including its use, transfer, and ownership.

NATURAL RIGHTS

To talk about property is to talk about property rights. Theorizing about property rights in the Anglo-American philosophical tradition has its roots in theorizing about natural rights and natural law. To claim a natural right is to assert that some rights are grounded in human nature rather than in legislation or other acts of government. Claims about natural rights and natural law purport to say something about what legal rights should be rather than what they are. Human rights and property rights often are represented as natural rights.

The Dutch thinker Hugo Grotius (2005 [1625]) secularized the idea of natural law. In his treatment natural law theory became a naturalistic inquiry into the question of which social arrangements were most conducive to the betterment of humankind. Grotius argued that there would be laws of nature, as dictated by the requirements of human nature, even if there were no deity. According to the Grotius scholar Stephen Buckle (1993), property rights are a social creation generated and defined by agreement but still are natural rights in a crucial way insofar as they are inevitable in human social life.

John Locke followed in the footsteps of Grotius. That made his work enormously influential among secular philosophers even though Locke was a theist. Locke (1960 [1690]) argued that God gave the world to humankind in common for the betterment of humankind and therefore intended that people should have the right to do what they need to do to put the earth to work. Individual persons own their own selves. Persons are God's property, but in relation to other humans, the individual alone holds the right to decide how his or her body is to be put to work.

This right to choose how to put people's bodies to work would be useless in that original state and God would be leaving humankind to starve unless people also were at liberty to make a living by laboring on otherwise unowned objects in the world. People normally are not at liberty to seize what already belongs to someone else, but when a resource is not owned, a person can come to own it by mixing his or her labor with it in a way that makes it more useful. Thus, people acquire a crop by virtue of being the ones who planted and harvested it and acquire the land underneath the crop by virtue of being the ones who made that land more productive than it had been in its unappropriated wild condition.

Working within the Lockean tradition, William Blackstone characterized property as the "sole and

despotic dominion which one man claims and exercises over the external things of the world, in total exclusion of the right of any other individual in the universe'' (1765–1769). In practice, though, property rights in the Anglo-American tradition are and always have been hedged with restrictions. The dominion to which Blackstone referred is limited by easements, covenants, nuisance laws, zoning laws, regulatory statutes, and, more generally, the public interest.

THREE KINDS OF RULES

In normal cases property is protected by a property rule that states that no one may use it without the owner's permission. In other circumstances one might say property is protected by a liability rule that states that no one may use it without compensating the owner. In a third kind of case one might say property is protected by an inalienability rule that states that no one may use it even with the owner's permission (Calabresi and Melamed 1972).

The fundamental rationale for liability rules is that sometimes it costs too much or is impossible to get consent to use someone's property and sometimes the contemplated use is compellingly important. For example, people have no right to use their cars to run over a neighbor's fence. Yet every time one pulls out of a driveway, there is some risk that that person's plans will go awry and he or she will accidentally damage someone's property. Whereas a property rule would require people to get advance permission from every property owner against whom they run the risk of committing accidental trespass, a liability rule requires instead that they compensate the owner of a fence after the fact if they accidentally damage it. The analogous rationale for an inalienability rule is that there are forms of property so fundamental that people would cease to be persons in the fullest sense if they were to, for example, sell them. A person may, for example, regard his or her kidney or vote as his or her property yet deny that this confers right to sell such things. In this respect the person would be treating his or her right as inalienable.

Spur Industries, Inc. v. Del E. Webb Development Co. 494 P.2d 701 (Ariz. 1972) is a case that was settled almost simultaneously with the publication of Guido Calabresi and A. Douglas Melamed's article. In this case the judge, who had not read the article, ruled in favor of the housing developer Del Webb, granting an injunction against the feedlot operator Spur Industries while holding that Del Webb had to compensate Spur. The judge reasoned that Spur's property claim was valid but that because the feedlot was a public nuisance, Spur could be forced to move, with compensation paid by Del Webb because Del Webb's housing development brought the public to the nuisance. Thus, Spur's property right in effect was protected by a liability rule rather than a property rule. The takings clause of the Fifth Amendment to the U.S. Constitution can be interpreted as specifying that in cases of compelling public interest property titles are protected by a liability rule rather than a property rule.

PROPERTY RIGHTS AS RIGHTS TO EXCLUDE

In 1913 Wesley Hohfeld distinguished between rights and liberties. One is at liberty to use something just in case one's using that thing is not prohibited. One has a right to a thing just in case one's using it is not prohibited, plus one has the additional liberty of being able to prohibit others from using that thing. That is, the difference between a mere liberty and a full-blooded property right is that with a property right there is an owner who holds a right to exclude other would-be users.

In the contemporary era, though, the term *property rights* generally is understood to refer to a bundle of rights that could include the rights to sell, lend, bequeath, use as collateral, or even destroy. (John Lewis [1888] generally is regarded as the first person to use the ''bundle of sticks'' metaphor.) The fact remains, though, that at the heart of any property right is a right to say no: a right to exclude nonowners. In other words, a more or less Blackstonian right to exclude is not just one among many sticks in a property bundle. Rather, property is a tree, and whereas other sticks are branches, the right to exclude is the trunk. One conceptual reason for saying this is that without the right to say no, the other rights are reduced to mere liberties rather than genuine rights. For example, one can be the owner of a bicycle in a meaningful sense even if for some reason one has no right to lend it to anyone else. By contrast, if one has no right to deny another permission to lend it to anyone else, one is not the owner of the bicycle in any normal sense. Thus, there is a conceptual reason why, among the various sticks that make up the bundle of rights people call property, the right to exclude is the most essential.

In addition to this conceptual reason, there is a practical reason why the right to exclude is the core of a property right. The evolution of property law is driven by an ongoing search for ways to enable people to avoid commons tragedies. Commonly held resources are subject to indiscriminate overuse. If a productive asset is held in common, there is an additional risk that no one will be willing to bear the cost of investing in making the resource more productive. In practice, communal regimes also lead to indiscriminate dumping of wastes that range from piles of unwashed dishes to substances that lead to ecological disasters that threaten whole

Private Beach in Malibu, California. *Many theorists believe that the right to exclude nonowners is at the core of any property right. While this American homeowner boasts such rights to private property, other nations have an eminent domain clause that stipulates that coastlines are the property of the state, and therefore no property owner can prohibit access to the sea. Private property as it is commonly understood is defined in contrast to public property, and grants its possessor exclusive rights to dispense with the property as he or she sees fit.* **AP IMAGES.**

continents. When people's activities impose a cost on innocent bystanders, economists describe those costs as external costs or externalities. There also can be external benefits, or positive externalities, as in a case where one person notices that a second person has developed an innovative new technique for plowing land and copies that technique. The first person is reaping some of the benefit of the second person's research without having paid for it. Property in patents is one tool for "internalizing" the benefits of research and development.

Centuries before the analytical tools of game theory, ecology, and contemporary economics were available, Locke noted that the option of fencing the commons and creating private property enables people to make land more productive than land is when left in the wild. The reason for this is that the right to exclude empowers owners to capture the positive benefits of productivity and at the same time internalize the negative impact of overuse. The right to exclude is for practical purposes the essence of property in general, not only private property. A national park service must be able to exercise a right to exclude cattle ranchers to do its job of protecting national parks. An Israeli kibbutz must be able to exercise a right to exclude nonmembers to be able to feed its members.

FORMS OF PROPERTY

Commonly held property is not necessarily an ecological disaster. For example, the open-field agricultural practices of medieval times gave peasants exclusive cropping rights to scattered thin strips of arable land in each of the village fields (Ostrom 1990). The strips were private only during the growing season, after which the land reverted to the commons for the grazing season. The custom of "stinting" allowed the villagers to own livestock only in proportion to the relative size of their land holdings in the growing season. Governance by custom enabled communal owners to avoid commons tragedies. David Schmidtz and Elizabeth Willott (2003) described a modern case of successful communal management.

Private property is not necessarily an ecological success. Privately managed parcels also are subject to indiscriminate dumping of wastes and various other uses that ignore spillover effects on neighbors. One advantage of private property is that owners can buy out one another and reshuffle their holdings in a way that minimizes the extent to which their activities bother one another. However, this does not always work out well, and the reshuffling itself can be wasteful because there are transaction costs. Such costs include all the expenses incurred in concluding a transaction: commissions, time and money spent on transportation to and from the market, equipment and space rentals, time waiting in line, and so on.

A plausible social goal would be to have a system of property that minimizes the sum of transaction costs and the cost of externalities. For example, a public freeway may minimize transaction cost if the alternative is a private toll road, but the toll road may invest revenues in road repairs, minimizing the external cost of damage to the road caused by thousands of other drivers. There often is a trade-off. Harold Demsetz (1967), Robert Ellickson (1993), and Carol Rose (1986) considered which mix of private and public property best meets this goal. Especially when there are far-flung externalities among people who do not know one another, there is no easy way to determine which mix of private and public property is best. The difficulties in detecting such externalities, tracing them to their source, and holding people accountable for them are difficulties in any kind of property regime.

Privatization exists in different degrees and can take different forms. Simply parceling out land or sea is not always sufficient to stabilize possession of resources that make land or sea valuable in the first place. Suppose, for example, that fish are a fugitive resource, that is, a resource known to migrate from one parcel to another. In that case owners have an incentive to grab as many fish as they can whenever a school passes through their territory. Thus, simply dividing fishing grounds into parcels may not help fishers avoid collectively exceeding sustainable yields. It depends on the extent to which the sought-after fish migrate from one parcel to another and on conventions that are evolving continuously to help neighbors deal with the inadequacy of their fences or other

ways of marking off territory. Thus, not all forms of privatization are equally good at internalizing externalities. Communal management generally does not work, but privatization per se is not a panacea.

PROCESS PHILOSOPHY

Process philosophy names a range of philosophical theories. The term *process* implies rejection of substances as inherently or ontologically primary. It normally identifies philosophies that assert the independent existence of nature and the location of human beings within it. These philosophies encourage people to take seriously the course of natural events, and, indeed, the rise of evolutionary thinking was one key source of process philosophies. However, in the twentieth century, developments in physics took on primary importance, and evolutionary thought fell into the background.

ALFRED NORTH WHITEHEAD

In the twenty-first century, process philosophy refers chiefly to that of Alfred North Whitehead (1861–1947) and those influenced by him, and it is on this broadly Whiteheadian tradition that this entry will focus. Whitehead was a mathematician, logician, and theoretical physicist who devoted extensive attention to relativity theory. He arrived at his philosophical views partly through reflection about physical fields and partly by the analysis of his own experience. He thought that all the indivisible entities that constitute the world are something for themselves as well as for others. They are all momentary experiences consisting largely of unconscious feeling and emotion. This view can be called *panexperientialism*. This term is better than the more common *panpsychism* because the latter suggests consciousness and even high-grade experience, whereas in panexperientialism consciousness is limited to fairly complex animals. Whitehead's point is that to be at all is to be something in and of itself and not simply an object in the experience of others.

Humans as subjects are aware that some feeling states are preferable to others. They can thus form some judgments from their own experience that are applicable to what occurs elsewhere. In Whitehead's magnum opus, *Process and Reality* (1929), intensity serves as the measure of the value of an experience. In *Adventures of Ideas* (1933) he developed a much more complex theory of value in which "strength of beauty" plays the central role.

Whitehead believed that human experience, like processes in the physical world, consists of a sequence of distinct indivisible momentary experiences rather than a continuous flow. The later experiences inherit from the earlier ones by including them, or, alternatively, the earlier experiences flow into the later ones. This relation is called a *feeling* or a *prehension*. The ultimate locus of subjectivity, and therefore of value, is the individual experience.

Examination of an individual, momentary experience clarifies the implications for ethics. A moment of human experience inherits extensively from predecessor

moments. For adult human beings, this is the most important relation. However, each momentary experience inherits from other sources as well, most obviously from neuronal events. These mediate both new sense data and new bodily feelings. The new occasion is an integration of what it inherits from its personal past and the new stimuli from the body.

There is not first an occasion of experience that then inherits from the past and the body. The new occasion comes into being through the synthesizing of these relations. Thus relations are prior to the entity that is synthesizing them, although the priority is not temporal, because the relations and their synthesis all come into being at once.

Whereas in substance thought relations are external, in this process vision they are internal. In substance thought, relations among substances are chiefly spatial, and their changes do not affect the nature of the substances. For process thought, relations to past occasions are internal to the one that is becoming. A human experience is largely constituted by its relations, both to other persons and to the rest of the world.

Whitehead himself may have come to this radically relational vision more from field theory than from introspection. A physical field is constituted by a multiplicity of local events. But one can conceive of the events equally well as what the field is at a locus. It does not consist of entities that could exist elsewhere. What exists elsewhere is, by virtue of its location, a different entity. Whitehead concluded that every indivisible event is what it is largely as a fresh integration of features of its given world, one unique to each occasion.

Since, in such a model, the ethical concern is to increase value, the question is how occasions achieve more or less value. The greater value is achieved by the inclusion and integration of more of what the world offers. Diversity in these offerings makes possible greater value in the integration. But since diverse elements taken by themselves are often incompatible, simple occasions are forced to exclude most of them. More complex occasions are able to convert what would otherwise be mutually exclusive into a contrast in which the diversity is retained and the whole is richer for having both the different elements and the new values acquired through contrasting them.

Whitehead thus emphasized the importance of the environment. However, each occasion also transcends what it inherits from its world. It achieves value through some flash of novelty that introduces fresh contrast. This is the basis of the vibratory character of primitive physical entities as well as of the creative elements introduced by life. What novelty is possible is determined by what is given. The novelty itself is an expression of the creativity of the universe and is derived from the eternal order of potentiality, which Whitehead called the primordial nature of God. Thus the individual creatures that make up the environment both call forth respect for themselves by their intrinsic value and also contribute to the value of human experience in two ways: first, by the intensity or richness of their own individual experience and, second, by their diversity, which provides for their perceivers the possibility of rich contrasts.

CHARLES HARTSHORNE

Charles Hartshorne (1897–2000) has been the most influential philosopher in the development and promulgation of Whitehead's philosophy. He combined his philosophical pursuits with an interest in birds, and was himself deeply concerned about such ecological matters as the loss of habitat for other species. Hartshorne was a metaphysician and philosopher of religion. He focused attention on what Whitehead treated rather briefly as the consequent nature of God.

Both Whitehead and Hartshorne believed that what happens fleetingly in the world is cumulatively real in God. Without this retention of value in the divine life, the transitoriness of all things would undercut the importance of what happens in the world. Because what we do to ourselves and to our fellow creatures we do also to God, this process tradition undergirds ethics with religious faith. Hartshorne called it *panentheism*. His ethical goal was contribution to the divine life; so he called his ethics *contributionist*.

RESPONSES TO THE ENVIRONMENTAL CRISIS

Process thinkers were prepared by their philosophical understanding to respond to the environmental crisis. Although few engaged in explicit formulation of environmental ethics, much of their writing has been permeated by environmental concerns. Noteworthy examples are Ian G. Barbour, a physicist, and David Ray Griffin, a philosopher of religion.

John B. Cobb, a theologian, drew together the implications of process philosophy for environmental ethics, and in 1972 he published *Is It Too Late? A Theology of Ecology* (revised in 1955). Meanwhile, Charles Birch, a Whiteheadian biologist specializing in ecology, was trying to get the World Council of Churches (WCC) to respond to the new concern. This effort succeeded in 1975 at the Nairobi meeting. The WCC changed the earlier call for "just and participatory societies" to ones that are "just, participatory and *sustainable*." Birch gave the plenary address hailing and explaining this move. Subsequently, Birch and Cobb teamed up to write *The Liberation of Life* (1981), in which they argue for an ecological view of living things to replace the materialist one still dominant in the sciences.

Whitehead's philosophy supports concern both for ecosystems and for individual animals. The WCC concerned itself only with the former. The Whiteheadian philosopher of religion Jay McDaniel joined Birch in organizing a WCC meeting at Annecy, France, in 1988, with an emphasis on individual animals. The report produced by this meeting had little influence in the WCC, but it led to the publication of *Liberating Life* (McDaniel 1990). McDaniel also led in the American Academy of Religion in dealing theologically with animals. Additionally, he has written extensively on ecological spirituality.

Since 1972 Cobb has worked with the Whiteheadian economist Herman Daly contributing an essay to his *Toward a Steady-State Economy*, published in 1973.

In 1994 they jointly authored *For the Common Good*, proposing that economics be rethought on different assumptions. Daly has been a leader in ecological economics.

A number of religious thinkers, influenced by process philosophy, have been prominent in ecofeminism. These include Karen Baker-Fletcher, Rita Nakashima Brock, Carol Christ, Nancy R. Howell, Carol Johnston, Catherine Keller, Sandra Lubarsky, Sallie McFague, Mary Elizabeth Moore, Rebecca Parker, and Marjorie Suchocki.

CRITIQUES

Some of these ecofeminists, other ecofeminists, ecologically concerned Buddhists, and Deep Ecologists criticize Whiteheadian philosophy for advocating a "hierarchy of values" that judges some creatures to be of greater intrinsic value than others. They hold that this is too closely connected with anthropocentric and/or hierarchical thinking, locating human beings at the top, and evaluating others according to their proximity to humans. Defenders of Whitehead's gradation of values respond that practical decisions based on such judgments are inescapable and that Whitehead's criteria for judging the amount of value are not crudely anthropocentric. Although whales resemble humans less than do monkeys, the occasions of whale experience are probably richer. There may be very different creatures elsewhere in the universe with higher grades of value. God's experience, as process thinkers imagine it, is incomparably richer.

Clare Palmer offers the most thorough criticism of Whitehead as environmental ethicist. She considers the judgment that other beings resemble humans in having subjectivity to be "dominating" or "colonizing." She argues that the generalization from human experience suppresses the difference of the other. One response is that the usual ways of describing their otherness deprive them of intrinsic value altogether, whereas Whitehead attributes intrinsic value to all.

Palmer shows that a variety of ethical approaches can find a foothold in Whitehead's philosophy, but she concludes that it is finally consequentialist. Consequentialists fail to attend to relations to the past, such as promises that have been made. Whitehead certainly encouraged the increase of value, but occasions aim at value not only in their future but also in the present. Because each occasion is composed largely of relations to the past, such relations as promise keeping are not be ignored. Cobb dealt with technical ethical questions of this sort in his contribution to Daly's *Toward a Steady-State Economy*.

Palmer finds some of Whitehead's language about nonhuman animals demeaning. Although Whitehead's basic emphasis was to reduce the difference between human beings and other species, she is right that he took human superiority for granted. She also notes rightly that Whitehead thought of civilization as pure gain. He did not appreciate the quality of life in hunting and gathering societies or their arguably superior environmental record. Overall it is true that, even though Whitehead does not emphasize evolutionary and historical progress, he did take many of the humanist assumptions of his time for granted. To follow his philosophy does not require repetition of all his judgments.

Lisa Sideris has followed the theologian James Gustavson in formulating norms for evaluating environmental ethical positions. She judges, surprisingly, that process thought fails to emphasize affective judgments. Although Whitehead used reason extensively in his arguments and considered the emergence of rationality as a great gain, his ultimate appeal was to intuition. Emotion is the primary reality and is involved in every judgment.

Sideris argues for a radically theocentric ethics and judges that process ethics is too anthropocentric. On the one hand, she objects to the view that God aims at the increase of value in the world and that faith in God contributes to well-being. On the other, she objects that whereas process thinkers oppose the sacrifice of animals for minor human gains, they would sacrifice other creatures to meet urgent human needs. This is true. Process thinkers oppose the fragmentation of thought and do not want an environmental ethics that threatens deep concern for the well-being of every human, and especially for the poor and oppressed. Their goal is a single ethic that integrates concern for the biosphere, animal suffering, and human flourishing. They give less attention to refining ethical formulations than to promoting broader changes in attitude and in spirituality. In particular, they think the theoretical changes most urgently needed are in such fields as agriculture and economics.

Q

QUEER THEORY

Queer theory, which emerged as an academic area of study in the early 1990s, is an interdisciplinary body of scholarship that attempts to understand the way power works as a productive and normalizing force that shapes personal identity, human experience, knowledge, policy making, and political movements. For example, queer theorists question the norms of gendered embodiment that make a person recognizable as a man or a woman and their relationship to sexual norms such as heterosexuality and monogamy. Though influenced by feminist theory and gay and lesbian studies, queer theory builds on the philosopher Michel Foucault's (1926–1984) insight that power is productive rather than being only restrictive and that identity and resistance are effects of societal practices that normalize certain types of behavior and bodies compared with others. As a force of normalization, power takes on the appearance of being natural and inevitable while inducing conformity in the individual. Queer theorists have used Foucault's insights about power to interrogate understandings of gender identity and desire.

The term *queer* often is used as an umbrella designation to refer to lesbian, gay, bisexual, and transgender people; however, within the context of queer theory the term is best understood as a verb. In other words, queer theory aims to queer—to question and defamiliarize—the identities, concepts, knowledge, and experiences that shape lives, values, societies, policies, and academic inquiry. Central to queer theory is a critique of heteronormativity, which is understood both as the institutionalized assumption that heterosexuality and conventional modes of being in a relationship such as marriage and monogamy are normal and natural and as the pressure and obligation to conform to those modes as a condition for respect, legitimacy, recognition, and citizenship.

Queer environmental philosophy seeks to theorize the role of assumed norms of identity, experience, and embodiment that inform the deployment of terms such as *nature*, *the natural*, *sustainability*, *future generations*, and *the common good*. These are key terms which underlie environmental philosophy, policy, and activism, but queer environmentalism recognizes and critiques their heteronormative bias. Queer environmentalism also makes visible and critiques connections between the disavowal of that which is understood to be queer and environmental destruction. There are many areas of overlap between queer environmental philosophy and ecological feminism. In order to understand the commonalities between queer environmental philosophy and ecological feminism, as well as their differences, one must first understand some of the ways in which feminism has influenced queer theory.

QUEER THEORY AND FEMINISM

Queer theory is influenced by and shares the feminist critique of the sex-gender system of oppression and compulsory heterosexuality, both of which rely on the presumed naturalness and inevitability of the connection between biological sex, gender, and desire/sexuality. Both feminism and queer theory expose the social and cultural nature of the sex-gender system and its long-standing role in rationalizing the oppression of women and sexual minorities.

Despite some feminist disagreement with the critique of identity found in queer theory, that critique

has roots in feminist interrogation of the concept of woman as well as Foucault's understanding of power and subjection. Foucault understood subjection both as the subjection of the individual to dominating force and the production of the individual as a subject. Building on that concept, queer theory characterizes all identity categories as effects of power and not as pure sites of resistance to power, and its critique of identity includes a critique of the subjects around which feminism and lesbian and gay studies have been organized: woman and lesbian and gay. In 1990 the philosopher Judith Butler used Simone de Beauvoir's famous question, "What is a woman?" as a point of departure and asked how the subject of feminism (woman) is "produced and restrained" by the power structures through which women's liberation is sought (Butler 1990, p. 2). Gender, Butler argued, is performative, the materialization of historical and cultural norms that make gender and sex visible, real, and meaningful (Butler 1990, 1993, 2004). Butler's performative theory of gender was a major contribution to feminist theory and was foundational for queer theory.

ECOLOGICAL FEMINISM AND QUEER ENVIRONMENTALISM

There also are areas of overlap between ecological feminism and queer environmentalism. For example, both are critical of gender and nature essentialism and value dualisms. Essentialism is the view that all the members of a group (e.g., women) share unchanging characteristics, an essence that is necessary for membership in that group. Queer environmentalists and ecological feminists contend that essentialist definitions do not portray gendered reality or the relationship between humans and nature accurately. Both queer environmentalism and ecological feminism have been influenced by Donna Haraway's (1991) concept of the cyborg, calling into question distinctions between human beings, nature, and technology. Chris Cuomo distinguished between ecofeminism and ecological feminism, arguing that much of ecofeminism is premised on universal, essentialist conceptions of woman, woman's connection to nature, and feminine virtues that ignore how white, wealthy women in the North benefit from globalized exploitation of the earth, poor people, and people of color (Cuomo 1992).

In the 1990 essay "The Power and Promise of Ecological Feminism" Karen J. Warren argued that a critique of value dualisms is an important contribution of ecofeminism. Value dualisms are opposites that categorize dominant conceptions of reality: man/woman, human/animal, culture/nature, mind/body, reason/emotion, and white/black, for example. These opposites are value dualisms because in each pair the second term is subordinated to the first and the meanings attached to the first term define cultural norms. In value dualisms the terms in each pair are "seen as exclusive (rather than inclusive) and oppositional (rather than complementary)," and characteristics associated with the first term are considered to be better than those associated with the second (Warren 2000, p. 46). In an attempt to bridge the gap between ecofeminism and queer theory, Greta Gaard proposed a queer ecofeminism that challenges the oppression of the erotic, an oppression shaped by "reason/erotic" and "heterosexual/queer" dualisms that define Western culture and are integral to the oppression of queers, women, indigenous people, and nature (Gaard 1997, pp. 118–119).

Queer environmentalism differs from ecological feminism in the centrality of Foucault's concept of power and Butler's performative theory of gender to its analysis of environmental problems. For instance, oppression is the predominant concept of power that fuels the ecological feminist critique of interlocking systems of oppression (e.g., racism, sexism, speciesism, classism, oppression of the earth) that support violence against all oppressed humans, nonhuman animals, and nature. Although queer theorists do not deny the existence of oppression, they consider analyses of power centered on oppression to be incomplete. When power is understood as primarily oppressive, the world is divided into those who have power (those who exercise power) and those who do not (those over whom power is exercised), and resistance becomes a matter of making visible power imbalances that characterize oppression, explaining their injustice, and seeking liberation for the oppressed. However, queer theorists in general and queer environmentalists in particular are interested in the ways in which power operates in the myriad coincidences of knowledge and power that generate norms, condition subjectivity, and increase the institutionalized management of individuals.

QUEER CRITIQUES OF ENVIRONMENTALISM

Queer analyses of environmental problems focus on the ways in which the discourse of environmentalism produces subjects that ultimately legitimate rather than undermine globalized capitalism and its role in environmental destruction. Catriona Sandilands argued that environmentalism is a "normalizing discourse" that assumes that there are limits inherent in nature (Sandilands 1999, p. 80). Consequently, both radical and mainstream environmentalism tend to focus on "self denial" as the hallmark of the environmentally responsible citizen who is implicitly juxtaposed against people and governments in the "Third World" that have failed to exercise appropriate self-discipline (Sandilands 1999, pp. 80–81). Even though many, including ecofeminists, critique specific forms of population control, Sandilands contended that

most environmentalists have not challenged population/fertility management as a goal (Sandilands 2004).

Éric Darrier (1999) also crtiqued environmental discourse, focusing specifically on the function of the concept of nature in environmental philosophy and policy. Like Sandilands, he was critical of the values and practices people are obliged to adopt in the name of "the common good," "sustainable development," or "the proper functioning of the 'ecosystem'" (Darrier 1999, p. 217). Darrier proposed a "green aesthetics of existence" rather than a green ethics of existence, a practice he defined as critically self-reflective regarding the assumed truths of nature that are used to justify environmental policies and encourage the adoption of particular values or modes of being (Darrier 1999).

Some theorists, such as Alison Kafer and Eli Clare, have examined connections between queerness, disability, and nature. Kafer argued that many environmentalist narratives about experiences with nature, including ecofeminist narratives, assume able-bodiedness (Kafer 2005). That disregard of disability, Kafer contended, contributes to conflicts between environmentalists and advocates of disability rights over issues such as the accessibility of public lands and parks. According to Kafer, many environmentalists assume that making trails and canoe launches accessible, for example, will exceed limits that are inherent in nature, as if making trails more accessible would "insert the all-too-human into the 'wilderness'" (Kafer 2005, p. 139). For Kafer the absence of the disabled body in environmentalism ultimately assumes and naturalizes a human/nature dualism that many environmentalists want to critique. As an alternative, she proposed Clare's 1999 narratives of hiking as important sources of insight into the ways in which ideas of nature can be shaped by queerness and disability. For Kafer and Clare, queering nature involves understanding that nature and disability are not mutually exclusive, that there is nothing "unnatural" about disability.

Queer environmentalism calls into question the normalization of the concepts of the human, nature, future generations, and population that inform even discourses mobilized on behalf of environmental protection. It proposes persistent questioning of the ways even well-intentioned environmental philosophy and policy can promote the exploitative interests of globalized capitalism.

R

REGAN, TOM
1938–

Tom Regan, best known as the philosophical father of the animal-rights movement, was born on November 28, 1938, in Pittsburgh, Pennsylvania. Regan taught for over thirty years at North Carolina State University, receiving emeritus status upon retirement. Major honors include multiple teaching awards, research awards, the William Quarles Holladay Medal, the Gandhi Award, and the Joseph Wood Krutch Medal. His work has focused on animal rights and on the philosophy of G. E. Moore. His major publications include *The Case for Animal Rights* (1983) and *Bloomsbury's Prophet: The Moral Philosophy of G. E. Moore* (1987). Both of these books were nominated for the Pulitzer Prize and the National Book Award. He also authored *All That Dwell Therein: Essays on Animal Rights and Environmental Ethics* (1982), edited *Animal Sacrifices: Religious Perspectives on the Use of Animals in Science* (1986), and authored *Defending Animal Rights* (2001). Of his many articles, two are major contributions to environmental ethics: "The Nature and Possibility of an Environmental Ethic" (1981) and "Does Environmental Philosophy Rest on a Mistake?" (1992). He founded the Tom Regan Animal Rights Archive at North Carolina State University. Tom and Nancy Regan also created the Culture and Animals Foundation to promote animal rights through art.

In his 1981 classic essay "The Nature and Possibility of an Environmental Ethic," Regan argued that a genuine environmental ethic is an ethic *of* the environment, not merely an ethic *for the use of* the environment. The latter sort of ethic regards the environment and the entities inhabiting it as valuable only inasmuch as they benefit humans (are *instrumentally* valuable). An ethic of the environment, by contrast, must hold (1) that nonhuman beings are valuable in and of themselves (are *inherently* or *intrinsically* valuable), and (2) that both conscious and nonconscious beings are inherently valuable. Regan then shows that arguments against the possibility of an environmental ethic rest on unjustified moral claims. Next, Regan exposes the failure of arguments attempting to establish that an environmental ethic is unnecessary for environmental protection. Finally, Regan sketches what it would mean for a being to be inherently valuable/good: Its value is independent of conscious beings, is an objective property arising from its other properties, and appropriately inspires respectful admiration and preservation. Regan concludes his prolegomena to any future environmental ethics by posing two unanswered questions: What property makes a being inherently good? How can we know which beings are inherently good?

In his seminal work *The Case for Animal Rights* (1983), Regan suggests some answers. Here Regan lays out a meticulous case for the inherent value of all "subjects-of-lives." Subjects-of-lives are experiencing, goal-directed beings with welfares. Clear cases of subjects-of-lives, Regan holds, are mammals over one year old. Such beings are rights bearers, having valid claims against moral agents. How can we know this? Regan claims that only rights theory containing the subject-of-a-life moral principle meets the criteria for a satisfactory ethical theory: consistency, scope, precision, conformity with reflective rational intuitions, and simplicity/parsimony.

It would be wrong to conclude that Regan, with the subject-of-a-life proposal, has ruled out an environmental

ethic. He explicitly leaves open its possibility by stating that being the subject-of-a-life is sufficient, but not claimed to be necessary, for inherent value. He thus grants that nonconscious beings might be inherently valuable, although he says it is "radically unclear" how this could be so (1983, p. 246). Nevertheless, Regan holds that his rights view is compatible with an environmental ethic according inherent value to individuals. An example is Paul Taylor's individualistic ethic, defended in *Respect for Nature* (1986). Regan's framework is incompatible with a holistic environmental ethic, however; such an ethic accords inherent value solely to wholes such as species and ecosystems, attributing merely instrumental value to individuals.

In 1992 Regan published another key contribution to environmental ethics, "Does Environmental Ethics Rest on a Mistake?" Here Regan argues that the emerging paradigm for an environmental ethic is fatally flawed. According to the paradigm, natural entities are due respect from moral agents because of the noninstrumental value of these entities, with different and greater intrinsic value attributed to wild beings than to domestic beings. Regan proceeds to argue that no theory of intrinsic value can meet all these requirements for an environmental ethic. A theory according intrinsic value to beings will accord them either equal intrinsic value or different intrinsic value. The first type of theory (e.g., Taylor's biocentric egalitarianism) cannot accord more intrinsic value to wild beings than to domestic beings. The second type of theory would establish a hierarchy of intrinsically valuable beings, with lower-ranking entities being sacrificed for the sake of higher-ranking ones. Such a theory cannot ground respect for natural entities, which merely occupy positions in a hierarchy. Moreover, such a theory is indistinguishable in practice from one positing a hierarchy of instrumentally valuable beings, with a top level of intrinsic value (e.g., an ecosystem, for the sake of which individuals can be culled). This second type of theory is more parsimonious than theories that attach intrinsic value hierarchically, although it too provides no grounds for respecting natural entities.

If Regan is correct, an individualistic environmental ethic, already challenged to justify its criterion of intrinsic value, must abandon the claim that wild and domestic beings have different degrees of intrinsic value. Individualists and holists rejecting Regan's approach must show that he is mistaken here.

Regan's animal-rights philosophy has received its share of criticisms from environmental ethicists. Both J. Baird Callicott (1989) and Mark Sagoff (1984) have argued that the animal-rights view would commit moral agents to protecting all rights bearers, even prey. They hold that this would have disastrous implications for the environment. A different objection has been raised by ecofeminists such as Josephine Donovan (1993). According to this criticism, moral-rights theory is based on a patriarchal worldview that enshrines reason and individualism while denigrating emotion and community, lying also at the foundations of Callicott's approach to environmental ethics. Instead of making rights and justice paramount in ethics, ecofeminists urge that care, partiality, and nature should be at the center.

Regan has replied to these and other critics in *Defending Animal Rights* (2001). He argues that moral agents do not have the general obligation to assist prey (p. 19). Nonhuman predators do not violate prey rights, since these predators are not moral agents. Moreover, there is no duty to assist prey animals against their innocent attackers, because in general they can fend for themselves. Against the ecofeminist critique, Regan argues that it is based on misrepresentation, undefended claims, false dilemmas, and the same biases embodied by patriarchal views (pp. 54–64).

Whether one thinks Regan has succeeded or failed in his criticisms of major environmental ethical theories and in his defenses of animal-rights philosophy, he has made ground-breaking contributions to the view that moral worth is not confined to humanity.

Evelyn B. Pluhar

REGIONALISM

A *region* is a portion of the earth's surface unified by a high degree of internal functional integration and formal consistency. For instance, the corn belt of the United States, which stretches from Ohio to Iowa, functions much like a vast machine, with components such as cornfields, farmhouses, county roads, feedlots, and meat-packing plants. The recurrence of these components in the landscape gives the region a uniform—some might say monotonous—appearance, smell, and sound. Because there is a perceptible consistency in the region's landscape and in the manners, customs, and culture of its people, regions are usually recognized by ordinary people, and their names are part of vernacular geography.

Regional is an adjective attached to forms (artifacts, institutions, beliefs) that are characteristic of, but not necessarily unique to, a region. We speak of a regional landscape, cuisine, dialect, architecture, or costume. In traditional human societies (folk cultures), almost all cultural traits were regional because interaction with people outside the region was limited and most artifacts and practices were adapted to the needs and opportunities of the local environment. Regional distinctiveness has been greatly reduced by modern communication and transportation technology, which increases long-distance interaction and permits functional integration on the continental and global scales.

Regionalism is self-conscious attachment to, and preservation of, regional forms. The members of a folk culture are not regionalists, and their reproduction of regional forms is not regionalism, because they reproduce regional forms out of habit and necessity. These are the only forms they know, or the forms best suited to their physical environment. Regionalism is, on the other hand, a disposition to prefer regional forms (of speech, dress, food, and architecture), when other and perhaps more cost-effective alternatives are available, simply because they are regional.

For example, in Texas, cowboy boots and cowboy hats were, originally, folk forms of dress that emerged from precedents available in the Anglo-Hispanic borderlands to meet the needs of men who spent much of their lives in the sun, with their feet in stirrups. They wore these articles because almost every other man they had ever seen wore them and because they were tools well adapted to cattle ranching in a hot climate. Today most men and women who wear cowboy boots and hats are, in contrast, self-consciously identifying themselves with the region. They are saying, "I'm from Texas and I'm proud of it!" Regional idioms, accents, foods, and the like may all become expressions of regionalism once they are used, self-consciously, as symbols of identity, pride, or defiance. Regional folk culture becomes vernacular regionalism when, and to the extent that, it is elective and expressive rather than habitual and necessary.

In addition to the vernacular regionalism of ordinary people, there is an intellectual regionalism of artists and scholars who write regional literature and history, or restore, preserve, and develop regional folkways, crafts, arts, and architecture. Intellectual regionalism is sometimes antiquarian and curatorial, an exercise in preserving the memory of a regional culture that is lifeless, however beautifully embalmed. More often, intellectual regionalists aspire to keep regional culture alive with new and creative work within the regional tradition. Their understanding of tradition has much more to do with the ideas of the poet and critic T. S. Eliot or the philosopher Alasdair MacIntyre than with Morris dancing, quilting bees, or Civil War reenactment. The best-known example of American intellectual regionalism is the work the writers, known as the Fugitives or Agrarians; centered at Vanderbilt University in the 1930s; they worked to restore pride in the southern way of life.

Vernacular and intellectual regionalism is frequently explained as a reactionary movement on the part of people who fear spatial homogenization and the universal rationality of enlightened modernity. This interpretation reveals more about the prejudices and plans of the interpreter than it does about the motives of regionalists. Its defects are the assumptions that an international style (of everything) is inevitable, that dislike and fear of modernity is irrational, and that regionalism is, at best, equivalent to throwing the covers over one's head at the sound of the bogeyman coming up the stairs. More portentously, critics of regionalism like to suggest, with very little evidence, that it is the gateway to xenophobia and fascism. Regionalism does, indeed, dispute the universal pretensions of enlightened modernity; at least in its intellectual form, however, it does so in an enlightened manner. Far from indulging in fanciful nostalgia, regionalism criticizes and challenges the core assumptions of modernity. Regionalists are not typically cowards who have thrown the covers over their head; they are, more often than not, men and women with the courage to look modernity in the eye and ask it some very hard questions.

RESOURCE MANAGEMENT

Resource management refers to decision making about how to conserve, allocate and use the goods and services available to satisfy people's value demands. Such decision making is fundamental to people's interactions with one another and with the environment, as depicted in Harold Lasswell's model of the human social process: "participants → seeking to maximize values (gratifying outcomes) → utilize institutions → affecting resources" (Lasswell 1971, p. 18). The term *resource management* often is used to refer specifically to decision making about the goods and services available from the natural world, or natural-resource management. This includes decisions about allocating the benefits and costs of resource use among current members of society and between current and future generations. To some people resource management is simply a matter of good planning: carefully making use of available resources to provide social utility while ensuring that there is enough left to meet future needs. That conception, however, masks important ethical and philosophical debates about which approach to management is most appropriate, what the goals of management should be, and whether it is even acceptable to characterize aspects of nature as resources to be managed.

RESOURCES

A basic utilitarian definition of a resource might be "something that can be used by humans." Anthropocentric thinking of that type dominates Western models of natural resource management, although there have been dissenting voices through the years, such as George Perkins Marsh, Henry David Thoreau, John Muir, and Aldo Leopold. Critics of anthropocentrism object to the implication that the value of the nonhuman world lies solely in its ability to satisfy human desires. They point to the many failures of attempts to control or dominate nature and argue that treating the natural world as a collection of resources that can be manipulated and used to achieve human ends is misguided and arrogant.

Alternatives to anthropocentric resource management draw on a variety of philosophical traditions that posit a more equal relationship between humans and the natural world, including the worldviews of some aboriginal societies, in which humans are considered part of nature and there is an emphasis on respect for the nonhuman world; the land ethic of Aldo Leopold, in which humans are members of a broader community of the land and "a thing is right when it tends to preserve the integrity, stability, and beauty" of that community (Leopold 1949, pp. 224–225); the "democracy of all God's creatures" promoted by Saint Francis of Assisi (White 1967, p. 1206); and the more recent human-nature egalitarianism of deep ecology. In those alternative conceptions treating elements of nature as resources to be managed or assigning value to nature solely on the basis of instrumental considerations makes little sense.

Whether or not nature has intrinsic value, humans do make use of and derive benefits from the natural world. In addition, as the claims of the critics of anthropocentrism demonstrate, human values and attitudes toward nature are multidimensional, ranging from an emphasis on use and dominion to aesthetic appreciation and moral concern about natural rights. When resources are defined more broadly to include anything that provides value, resource management can encompass decisions about providing the full spectrum of those values, including protecting wilderness areas for moral reasons as well as managing other areas for recreation or consumptive use. Furthermore, it is not just elements of the natural world that are at stake; cultural, heritage, spiritual, and other human resources often are included in modern understandings of resource management, and managing human behavior can be as important as managing nature.

The physical characteristics of resources also have implications for management because those characteristics dictate the ways in which particular resources can be used or allocated to provide value. Some resources provide materials or inputs for human activities, whereas others have the capacity to assimilate and process wastes or outputs. Some resources are bought and sold in markets and have readily identifiable prices that provide an indication of their value to humans. Others, known as nonmarket resources, do not have easily determined monetary values, making it more difficult to assess their importance relative to goods and services that are

exchanged in the market. Some resources, such as forests and fisheries, are renewable because when they are harvested at an appropriate rate, they can regenerate and provide a continuing supply in the future. In this sense renewable resources form a stock that can be maintained while a flow of benefits is withdrawn. Other resources, such as oil and gas, metals, and most other minerals, are nonrenewable because they cannot be regenerated within human time scales once they are consumed or converted.

Two other key characteristics of resources for management are subtractability, which indicates whether use by one person reduces the capacity of the resource to provide goods or services to others, and excludability, which indicates how difficult it is for users or managers to exclude additional users. When resources are subtractable and nonexcludable (common pool resources), they are likely to be overused unless rules or other institutional structures limit access and exploitation.

APPROACHES TO RESOURCE MANAGEMENT

Approaches to resource management have varied with the scarcity and physical characteristics of resources and have evolved with changes in values, knowledge, and technology. For example, when the American West first was occupied by settlers of European descent, resources seemed highly abundant and the principal management concerns were to allocate those resources in a fair manner and ensure that they were used to encourage settlement and economic development. Accordingly, the Western system of water rights was built on principles of "first in time, first in right," and "use it or lose it," which determine priority among users and help ensure that water is put to use but pay little attention to conservation or the effects of extraction on other users or other components of the system. Similarly, land was allocated for free to those who would homestead and farm, grazing of cattle and sheep was permitted on public lands without charge, and mining and timber rights were granted to encourage the exploitation of those resources.

With the closing of the frontier in the second half of the nineteenth century the supply of free land dwindled, and this, together with evidence of the damage caused by overuse—such as the effects of sheep ranching in the Yosemite area, the impacts of extensive land clearing and logging throughout the West, and the crashes of prominent wildlife populations—fostered the development of two main competing streams of conservation-oriented thinking about resource management. The preservationist philosophy championed by John Muir called for setting aside entire regions of the landscape to protect wilderness values, provide sanctuaries for wildlife species, and preserve examples of wild nature. Preservationists pushed for the protection of Yosemite and other national parks, and this philosophy continues to inform the management of protected areas in both terrestrial and marine environments. In contrast, the progressive conservation of Gifford Pinchot advocated scientifically informed use of resources to maximize the benefits for all: "Conservation means the greatest good to the greatest number for the longest time" (Pinchot 1947, p. 325). This utilitarian philosophy, which often is applied to the management of a single resource, informed sustained yield management policies for forests and fisheries and has become ingrained in many resource management agencies.

Management for a single use does not deal with the interactions of the different demands that humans make on their environment or the effects that utilizing one resource may have on other aspects of the environment and other people's values. In response to increasing pressures and conflicts among demands such as recreation, water supply, ranching, agriculture, and forestry, the concepts of multiple-use and integrated resource management evolved.

Under a multiple-use approach resources are managed to provide multiple benefits for a variety of users, with the overall objective of maximizing human utility. The overlap between multiple use and sustained yield is evident in legislation such as the Multiple Use Sustained Yield Act of 1960, which requires management of U.S. national forests for a sustained yield of products and services, including uses such as range, outdoor recreation, timber, and wildlife. Although multiple-use management involves a degree of integration, the idea of integrated resource management has been extended and interpreted much more broadly to mean coordinated management of social, ecological, and economic systems toward goals such as sustainable development and sustainability.

Approaches to resource management that are explicitly systems-oriented became more prevalent near the end of the twentieth century. For example, in the early 1990s many federal and state land management agencies embraced ecosystem management. The principles of ecosystem management may include managing ecological systems holistically to maintain their integrity, taking account of the disturbance regimes in which those systems evolved, managing adaptively to accommodate and learn from change, and involving the public and incorporating social considerations in management. Ecosystem-based management is a close relative of ecosystem management, which emphasizes management on the basis of ecosystems rather than management of ecosystems. Another important application of systems-oriented thinking to resource management is found in the work of C. S. Holling and his collaborators on panarchy theory, which considers the adaptive cycles and interactions of multiple economic, social, and ecological systems operating at different

temporal and spatial scales and encourages management to "maintain ecological resilience as well as the social flexibility needed to cope, innovate, and adapt" (Holling 2001, p. 404). As with other contemporary models of resource management, systems-based approaches often encourage public participation and the use of traditional ecological knowledge in decision making.

GOALS OF MANAGEMENT

Underlying this diversity of management approaches is an equally diverse array of goals toward which resource management can be directed. Among the more prominent goals are the following:

- Maximizing the extraction and use of a single resource in the short term;
- Maximizing the yield of a single resource that is sustainable over the longer term;
- Maximizing the sustainable benefits of multiple resources at the same time;
- Preserving natural landscapes or systems;
- Reducing harmful pollution or achieving an economically optimal level of pollution;
- Internalizing the positive and negative externalities caused by human activities;
- Protecting human health;
- Preserving charismatic or otherwise highly valued species;
- Preserving biodiversity;
- Maintaining ecosystem health or land health;
- Maintaining ecological integrity or ecosystem integrity;
- Maintaining the resilience and adaptive capacity of systems;
- Maintaining ecosystem functions;
- Keeping systems within their historical range of variability;
- Sustainable development;
- Sustainability.

Since the report of the World Commission on Environment and Development in 1987, the goals of resource management often have been tied to the concept of sustainable development—or sustainability—of social, economic, and ecological systems. Definitions of sustainability vary, however, from sustaining the combined stocks of natural and human-created capital, to sustaining the stock of natural capital separately, to managing within safe minimum standards, which may entail precautionary management to avoid crossing thresholds and causing irreversible change.

Throughout history humans have sought to manage resources, in some cases more successfully than others. Different approaches to resource management reflect different understandings of the appropriate relationship between humans and the natural world. Whether people attempt to manage resources actively toward particular goals or manage their own behavior to allow natural systems to operate without extensive human influence, experience suggests that failure to respect the limits on the capacity of natural systems or to recognize and adapt to changes in that capacity over time can be disastrous.

RIO DECLARATION

The United Nations Conference on Environment and Development (UNCED), the Earth Summit, held in Rio do Janeiro in June 1992, produced a short document titled *Rio Declaration on Environment and Development*. This document was to be named the *Earth Charter*, but developing nations objected that such a name focused too much on the earth and nature, and not enough on people and development, so the title was changed. It was renamed the *Rio Declaration* for the lack of any consensus about a title with more explicit reference to its contents. The declaration states twenty-seven principles, most given in a sentence or two, while a few form short paragraphs. Although it was only six pages long, there were lengthy arguments during the proceedings over nuances of phrasing. Toward the close of the conference a document was produced, and this has since been signed by almost every nation. The United States signed, with some protests about possible misinterpretations of the language of the declaration.

Even before the conference started, developing nations had already made it clear that they did not want an earth charter. In the discussion, a First World country delegate suggested an earth charter, a short creed, that "should be framed and put in the room of every child of the world." The retort from a Third World delegate: "Not every child has a room, maybe not even a bed!" Representatives of developing nations argued that direct concern for nature was an elitist luxury of First World nations, an inhumane overlooking of human poverty. "Ecologists care more about plants and animals than about people," complained Gilberto Mestrinho, governor of the Brazilian state of Amazonas. Or concern for saving the Earth was insincere, critics objected, unless accompanied by large donations from the wealthy nations to those in developing nations being asked to preserve nature.

"Human beings are at the centre of concerns for sustainable development," so the *Rio Declaration* begins in principle 1. It goes on to say that people are entitled to "a healthy and productive life in harmony with nature." Alternative language, which was rejected, read, "Human beings are entitled to live in a sound environment, in dignity and in harmony with nature for which they bear the responsibility for protection and enhancement." Principle 4 reads, "In order to achieve sustainable development, environmental protection shall constitute an integral part of the development process and cannot be considered in isolation from it." Development is clearly the dominating motif, with environmental conservation subsidiary to it.

Principle 7 reads, "States shall cooperate in a spirit of global partnership to conserve, protect and restore the health and integrity of the Earth's ecosystem. In view of the different contributions to global environmental degradation, States have common but differentiated responsibilities. The developed countries acknowledge the responsibility that they bear in the international pursuit of sustainable development in view of the pressures their societies place on the global environment and of the technologies and financial resources they command."

Environmental ethics with any direct concern for animals, plants, species, or ecosystems was essentially stripped from the draft language for the declaration. Its ethics was much more subdued than had been anticipated, because the rich-poor controversy became so unexpectedly intense. "Changes in life styles of the rich to those that are less polluting and wasteful is essential to reaching sustainable development." So proposed the developing nations in a draft text that the developed nations rejected. The objection was not so much to eliminating waste and pollution as to the suggestion that poverty in the South (the developing nations) was the fault of overconsumption in the North (the wealthy nations).

There were widespread complaints that world population growth was insufficiently addressed in the *Rio Declaration*, as well as overall at the Earth Summit, due to ideological and religious objections. The motivations suppressing attention to population control were as often implicit as explicit: that population reduction is an effort to reduce the number of non-Western (or non-Northern) people in the world, or that population control is an easier route than sharing unequally distributed resources, or that population control violates human rights or national sovereignty, or that the large populations of the poor really consume less than the limited but extravagantly consuming populations of the wealthy nations. The *Rio Declaration* mildly says, "States should . . . promote appropriate demographic policies" (principle 8). Developing nations were much more anxious to thrust blame on the developed countries for their overconsumption.

The *Rio Declaration* contrasts, tellingly, with a much earlier UN document called the *World Charter for Nature*. This charter begins, "Every form of life is unique, warranting respect regardless of its worth to man" (United Nations General Assembly 1982). A total of 112 nations endorsed this charter, though the United States vigorously opposed it. This statement was largely aspirational; few took it to require any serious changes in policy. In contrast, the *Rio Declaration*, coupled with the massive *Agenda*

21, which accompanied it, was expected to produce changes in behavior. The diplomatic negotiations formulating the document became a kind of morality play of developed nations versus developing nations, North versus South, rich versus poor, development versus conservation.

Disappointment in the *Rio Declaration* led original advocates of an *Earth Charter* to continue their efforts, and such efforts continued during the decade following the United Nations Conference on Environment and Development. A version was completed in March 2000 at The Hague, Netherlands, and efforts to gain subscribers continue. Thousands of organizations have endorsed it, including the United Nations Educational, Scientific, and Cultural Organization (UNESCO), but not yet the United Nations General Assembly. The first principle of the *Earth Charter*, ''Respect Earth and life in all its diversity,'' states, ''Recognize that all beings are interdependent and every form of life has value regardless of its worth to human beings.'' The latter phrasing recalls that of the *World Charter for Nature* and was inserted with an eye to the adoption of the *Earth Charter* by the United Nations General Assembly.

The *Rio Declaration* contains some key themes that are working their way into law: the principle that the polluter pays, responsibility for spillover damage from one country to another, intergenerational equity, public participation, a precautionary approach, environmental-impact assessments, differential responsibilities, healthy environments. Despite its shortcomings, the *Rio Declaration* serves a useful purpose as a negotiated multinational instrument that can serve as an icon for environmentally responsible development.

Holmes Rolston III

RISK ASSESSMENT

In an uncertain world most important choices involve a risk of losing something of value. Risk assessment is a process of discovering the possible adverse effects of decisions and figuring out what to do about them. People try to identify and measure the likelihood of adverse effects, put a value on them, and compare them with the costs and benefits of alternatives. This is an important part of any process of rational decision making.

TYPES OF RISK ASSESSMENT

The relative importance of a decision (and the importance of the risks involved), including the expected costs and benefits of accepting, reducing, or eliminating risk, can determine whether the appropriate way to assess risk is through a quick and intuitive judgment or through a more formal and often more technical and costly process. A rational person might do a quick and intuitive risk assessment to help decide when to buy new tires for a car; the same person is likely to take more care, think more formally, and get more information and advice before deciding whether to undergo a risky medical procedure to diagnose or treat a possible cancer. Businesses assess risk before deciding whether to invest in a new venture, and governments perform risk assessments to decide whether to introduce a new program or regulation. In any risk assessment the aim is to decide whether it is most reasonable to introduce or create a risk in exchange for a benefit, try to eliminate or reduce the cause or mitigate the effects of an identified risk, or accept a risk or adapt to the bad consequences if they occur.

RISK ASSESSMENT IN PUBLIC POLICY

Although risk assessment is something individuals and businesses do more or less explicitly or formally every day, the term has acquired a special sense in the context of its use in justifying and explaining decisions that involve public policy. Risk assessment has been part of government activities for as long as governments have been concerned about threats to public and environmental health from disease, pollution, war, and technologies. However, risk assessment for public policies developed as a formal discipline in the 1960s, a period when there was broad support in the United States and other industrially developed countries for regulations aimed at protecting humans and their environments.

Between 1965 and 1980 the U.S. Congress enacted more than thirty major laws aimed at protecting health and the environment that established or strengthened at least a dozen regulatory agencies. Those laws set the agenda and the process for most environmental regulations for several decades. Explicit attention to the

complicated nature of environmental risks led to the growth and influence of research into risk assessment as some advocacy groups lobbied for stricter regulations and others responded to newly promulgated regulations by arguing that they went too far and cost too much. All that activity prompted scientists and engineers to continue to develop formal methods of risk assessment that could improve the quality and acceptability of complex regulatory decisions. In the process the methods and use of formalized risk assessments themselves became subjects of ethical and political concern.

One reason for these controversies in environmental policy making is that different parties to the debates have different political agendas and also may have fundamentally different attitudes toward human responsibilities to nature. Risk assessments tend to disaggregate the problems people face and present them as far as possible in terms of their effects on human health and welfare. The advocates of risk assessment often encourage people to monetize or quantify the components of problems to make the various factors comparable and then aggregate those components into an overall evaluation of the alternative prospects. Some people regard this process as exemplifying the idea of rational decision making, whereas others regard it as being designed to blind people to some of the most important concerns and thus distorting important values.

HOW SAFE IS SAFE ENOUGH?

One of the stimulants to developing risk assessment techniques was the controversy over the safety of nuclear power plants in the United States in the 1970s and 1980s. Nuclear power was turning out to be an expensive and at best marginally profitable source of electricity, and the newly established Nuclear Regulatory Commission, responding to concerns about the safety of large reactors, considered promulgating new regulations that would have added to the costs of producing electricity. Some risk assessors and nuclear engineers began to argue that reactors were already safe enough and that further safety measures were unnecessary and too costly to be justified. Those assessors admitted that any nuclear reactor presents an inevitable small risk of a serious accident but argued that the level of risk was socially acceptable. Their conclusion was based on studies that examined the levels of risk the public accepted in other areas of life and how much the public seemed to be willing to pay to reduce a risk to life, health, or the environment. Critics of the status quo argued that because the consequences of a major nuclear accident were potentially so catastrophic, the probability of an accident must be reduced to very close to zero for that technology to be socially acceptable.

As this controversy developed, the question for risk assessment became: How safe is safe enough? The proponents of nuclear power wanted to look at risk in a general

ECOLOGICAL RISK ASSESSMENT

The Preamble to the National Environmental Protection Act establishes a U.S. "national policy which will encourage productive and enjoyable harmony between man and his environment . . . [and] promote efforts which will prevent or eliminate damage to the environment and biosphere and stimulate the health and welfare of man . . . " The U.S. Environmental Protection Agency (EPA) was established in 1970 to oversee the enforcement of this and other environmental laws. In the first two decades of its existence, however, the EPA focused almost exclusively on protecting human health and welfare from nature while ignoring the need to protect ecosystems from the impact of human activity. This tendency was exacerbated by the rising influence of human health-based risk assessments in guiding EPA policies. In an attempt to correct this imbalance, the EPA around 1990 developed Ecological Risk Assessment (ERA) guidelines, initially for use in its Superfund program.

The aim of ERA is to evaluate potential adverse effects that human activities have on the living organisms that make up an ecosystem. An ERA is supposed to identify stressors that will produce an adverse effect on an ecosystem. A stressor is any physical, chemical, or biological agent that can induce changes in organisms. Stressors may be physical (e.g., dams, construction, etc.), chemical (e.g., pesticides, effluents, etc.), or biological (e.g., introduced species or pathogens). Adverse effects are those that are considered potentially harmful to the healthy functioning of an ecosystem.

ERAs so far have had only limited impacts on environmental policies. Part of the reason is that ecosystems are complex and often harder to understand than human health effects. There is more disagreement about what is good or bad for an ecosystem and about which ecological entities are most important to protect.

and uniform way and see the problem as determining a general value of a probabilistic increment of the risk of death, illness, or environmental loss. The critics insisted that some risks are different from others and that it is necessary to consider the qualities of the different risks involved as well as the measure of a probability-weighted outcome to determine what is socially acceptable.

HOW PEOPLE JUDGE RISK

The question is partly empirical. It involves issues that are economic as well as issues that are psychological and may involve other cultural factors as well. Research that examined how people thought about this question had several important findings. First, most people find it very difficult to think clearly and consistently about risk and probability. People find it especially hard to compare different risks directly in a coherent way. It is easy to be confused, especially when experts disagree, about the significance of low levels of exposure to harmful substances. For these and other reasons, some experts on risk question the value of using economic data on consumer willingness to pay to reduce some increment of risk through the use of optional safety features in, for example, automobiles or preventive medicines, to support conclusions about social preferences for generally acceptable trade-offs among risks, costs, and benefits. To interpret consumer behavior as revealing a preference for trading off risks, costs, and benefits, it is necessary to assume that consumers are aware of the risks involved, are factoring that knowledge into their economic choices, and are behaving consistently. Research on the psychology of choice casts doubt on those assumptions.

Psychologists and anthropologists have shown that people are influenced by features of a risk other than the magnitude of harm and the probability that it will occur when they judge whether particular risks are acceptable. Social scientists have identified a number of factors that may explain, for example, why many people find the risks posed by nuclear power plants unacceptable but show little concern about technologies or products that pose a much greater likelihood of death or harm. These findings and the debates they generate suggest that any answer to the question "How safe is safe enough?" requires answering more basic questions about whether the goal of risk assessment in public policy should be primarily to protect public health and the environment or instead to determine what will satisfy public values. Risk assessment thus becomes entangled with moral and political issues.

RISK ASSESSMENT AND RISK EVALUATION

As the role and methods of risk assessment came to be seen as more complex and controversial, several expert studies sponsored by the independent National Academy of Sciences (NAS) tried to offer guidance. The main advice in those studies was to separate the scientific aspects of risk assessment, which the NAS sometimes referred to as risk estimation, from the more inherently controversial and value-laden activity of risk evaluation. The idea was that risk assessment should be able to provide useful advice that is free from the moral and political considerations that are part of making important decisions about public policy. The hope behind those recommendations was that experts in risk assessment might focus on the objective and measurable components of risk while the subjective and value dimensions could enter at a later stage of evaluation or political deliberation.

As some of the experts who helped write those NAS reports were aware, however, it is not easy to make risk estimation value-free. A risk assessment must begin by identifying which risks to study and what to count as a risk, an exercise that often requires making value judgments. Suppose, for example, that one is interested in reducing occupational risk and learns that exposure to a certain chemical acts synergistically with tobacco smoke to produce cancer rates in workers exposed to both that are higher than the aggregate of the two independent risks. One must decide whether this risk should be included in an assessment of occupational risk or whether it is acceptable to ignore it in a study because it is a risk to smokers who make a personal lifestyle choice and thus is not a risk to workers in general. Any choice one makes here involves an ethical judgment.

A second class of issues that cause problems in separating the scientific from the value-laden determinants of risk assessment has to do with how to treat different kinds of uncertainty. In the absence of direct epidemiological evidence of the risk of low levels of exposure to many carcinogenic substances, for example, risk assessors must rely on studies conducted on animals that involve exposure to high levels of the substances involved. Experts disagree about the proper way to extrapolate from high risk to animals to low risk to humans. The NAS studies recommended dealing with those uncertainties by reporting results as ranges rather than single numbers or point estimates of risk. This solution is not always available, however, and it does not get to the problem of determining how conservative or precautionary one should be in selecting a number or describing a range. This is another way in which simply identifying and estimating risk involves making value judgments.

The problems involved in understanding and communicating about uncertainties are among the most difficult issues that risk assessment must confront, especially in areas involving important environmental risks. This is the case because uncertainty can be of different kinds and can

be relevant in different ways. Some of these issues are well illustrated in risk assessments of global climate change. In 1988 the United Nations organized the Intergovernmental Panel on Climate Change (IPCC), a group of thousands of leading scientists around the world, and as stated in the "Principles Governing IPCC Work," assigned it the task of reporting on "the scientific basis of risk of human-induced climate change, its potential impacts and options for adaptation and mitigation" (1998, p.1).

UNCERTAINTY

The IPCC published four reports that reflected the consensus of the world scientific community on those questions. Each report indicated that there is much uncertainty about human-induced climate change, but the nature of that uncertainty has changed dramatically during the two decades of IPCC reporting. In its First Assessment Report, published in 1990, the IPCC reported that global climate change could be observed but that there was no way to determine with certainty whether human activities were contributing significantly to it. By 1995 the IPCC scientists could agree that "the balance of evidence suggests a discernable human influence on global climate," but that language still supports uncertainty about the amount of the human contribution. In its fourth report, published in 2007, this uncertainty was removed. The IPCC concluded that the evidence now showed that "[m]ost of the observed increase in globally averaged temperature is very likely due to the observed increase in anthropogenic greenhouse gas concentrations."

This is as close as scientists ever get to stating that a conclusion is certain in a complex world, but in light of the conservative language, the degree of certainty (which the report explains means greater than 95 percent confidence) can be appreciated only by comparing this statement with the earlier IPCC conclusions. Moreover, many other uncertainties—about more localized changes and about which areas and populations will be hurt the most and which may even benefit from climate change—are left untouched or even increased by research that virtually eliminates uncertainty about what is happening on a global scale. These remaining and shifting uncertainties create many problems for risk evaluation.

One issue illustrated by those uncertainties involves the way the distribution of risk can interact with both the perspective taken in a risk assessment and the sometimes different perspectives on determining what does and should matter most to people. Consider a situation in which an average individual in an exposed population has a $1/n$ chance annually of suffering an adverse consequence. This level of individual risk can be distributed across a population in different ways. To take two possibilities, $1/n$ individuals in the population will with certainty suffer the consequence each year but the identities of those individuals cannot be known in advance; alternatively, there is a $1/n$ chance that the entire population will suffer the consequence in any specific year. Those risks can seem identical from an individual's perspective, but from the perspective of the population as a whole the two ways of realizing the risk can be quite different. The former possibility involves no risk at all, but the latter might involve a catastrophic risk. It is clearly an important ethical consideration to determine whether and how risk to the group is to be balanced against risk to an average individual within the group or to a particular group among a larger population. Attempts to balance the risks as seen from more than one perspective also can require changing the level of risk exposure to the individual or the group.

ETHICAL ISSUES

It is not possible to eliminate the possibility of adverse consequences from activities that are deemed socially desirable. Many of the ethical issues surrounding risk assessment can be seen as asking how people should measure and respond to those risks, but at least one concern raises a different sort of question. Some people are bothered by the assumptions of most risk assessments that all values are comparable and can be measured on a single scale. This concern is especially significant when the chosen scale is money and the determinant of value is an aggregation of individuals' willingness to pay for things or changes in human welfare. In these assessments the value of human life and health and the value of natural treasures and healthy ecosystems are treated as commodities or goods with a price. The worry of some critics of this approach to thinking about complicated questions of policy and social values is not whether ethical judgments must be made in the process of risk assessment but whether ethical issues are involved even in considering some possibilities as appropriate subjects of formal risk assessment.

RIVERS

Rivers are the blue ribbons of the earth. Over geological time they have shaped the lay of the land through erosion, flooding, and meandering—carving sinuous paths from headwaters in the mountains to estuaries at the mouth. They are the perfect mediators between aquatic and terrestrial ecosystems, providing habitat for land and water species alike. Carrying and depositing sediments, they form intricate complex landscapes with fertile floodplains at the center of their basins. The basin or watershed comprises the entire catchment area that drains surface water into a river, which carries it to the ocean. Connecting land, air, and ocean, rivers play a crucial role in the hydrological cycle: Evaporated from the ocean and transported through the atmosphere, water returns to land as snow or rain and, seeping through soil into streams, it ends up in a river, again on its journey back to the ocean.

Every river has a distinctive flow pattern, determined by the size of its basin and features such as topography, geology, climate, and vegetation. The flow is a crucial driver for the health of the river system, determining the conditions for animal and plant life. Over the course of the year, rivers might have very different flow signatures, depending on snow melt and seasonally variable rain. The Mekong River, for example, carries fifty times more water in the summer monsoon period than in its long dry season. Although it is the seventh-longest river in Asia, the twelfth-longest in the world (4,180 km), and the tenth-largest by *annual average* volume, it has the highest flow variability and, when swollen by summer rains, it turns out to be the third largest by volume, surpassed only by the Amazon and Brahmaputra.

The Amazon is by far the largest river: It delivers more freshwater to the ocean than any other river, 20 percent of the global river discharge. Its drainage area, the Amazon Basin, is enormous: 6.5 million square kilometers, almost 40 percent of South America. Its annual average discharge is 219,000 cubic meters per second. In comparison, the Nile, with its 6,695 kilometers, is the longest river (300 kilometers longer than the Amazon's 6,387 kilometers), but it discharges on average a mere 2,830 cubic meters per second. During certain periods of the year, no water at all reaches the mouth of the Nile at the Mediterranean Sea, revealing the most recent and influential driver of river flows nowadays: humanity. During some seasons all the Nile's water is taken for irrigation.

RIVERS IN CULTURE

Throughout recorded history humans have shaped rivers for irrigation, navigation, and flood protection. The ancient Sumerian culture and, later, the Assyrian civilization (2400 B.C.E.) flourished in the Fertile Crescent, an area whose astounding fecundity was due to its main river systems, the Tigris and Euphrates. These peoples constructed elaborate irrigation and flood-control projects that led to the emergence of cities and sophisticated tax-based economic and legal systems. Like most irrigation-based societies, their civilizations collapsed because of soil depletion, salinization, and a high vulnerability to invasion. By the time the Greek historian Herodotus (c. 484–c.425 B.C.E.) visited the area—parts of present-day Turkey, Syria, Iran, and Iraq—the Persians had established their rule. "Rivers . . . they revere," he wrote about the Persians. And he continued, "They will neither urinate nor spit nor wash their hands in them, nor let anyone else do so" (Herodotus, Book 1, Chapter 138, Section 2).

The only irrigation-based ancient civilization that proved to be sustainable was that of the Egyptians. Their secret lay in the fact that their method of irrigation was basin-based—that is, it made use of the natural rise and fall of the Nile's seasonal fluctuations and hydrology. The river's yearly flooding rejuvenated the land not only with water but also with a new layer of soil—a rich layer of sediments. This annual flood-deposition cycle continued until the Aswan High Dam disrupted the natural flow pattern of the Nile in the twentieth century. A famous bas-relief from 3100 B.C.E.—showing one of the ancient kings ceremonially holding a hoe for cutting an irrigation ditch—testifies to the existence and importance of irrigation waterworks going at least back to that time. For at least 5,000 years the peoples of Egypt maintained an irrigation-based culture.

The flooding of the Nile precipitated the development of mathematics: The world's first numerical system was invented in order to apportion the land after floods and sediment depositions had obliterated boundaries (*geometry* literally means "land measurement") and to determine planting and harvesting schedules. Herodotus rightfully called Egypt "the gift of the Nile." Many Egyptians worshiped Hapi, the god of the Nile; although he was the father of all gods, he was depicted with breasts, a symbol of his capacity to nurture with life-giving fluids.

Rivers are revered in many traditions. Along African rivers one finds small offerings like a bowl of fruit or a bundle of flowers; rivers are of vital importance in Africa, the world's most arid continent. For Hindus in India, rivers are goddesses. The doorways of early Hindu temples were decorated with images of the two main rivers: Ganga rode on a crocodile and Yamuna on a tortoise. "Mother Ganga"—known internationally by its Anglicized name, Ganges—is still the most sacred river in India. Her generative and purifying powers are invoked in various initiation rites and bestow longevity on the one who drinks of her waters. Pilgrims visit her banks for daily ritual bathing, which heals the weak and sickly and washes away sins. People give the bodies of the dead to the river or spread their ashes over her, and she carries them in a last transition to the land of their ancestors.

In many cultures rivers represent the capacity for transformation. The most definitive transition is the one between life and death, symbolized in Greek mythology by the rivers Styx and the Lethe. Indeed, the latter washes away human memories so one can begin anew the afterlife. At the dawn of Greek philosophy, Heraclitus used the image of a river to symbolize the ever-changing flux of nature. In many traditions time is represented as a river. In various literary texts we also find river symbolism. In Dante's *Inferno* ice—not fire—is at the center of hell, and frozen stasis is its most severe punishment. Small rivulets—trickles thawed out of ice—symbolize the narrow path to renewal and hope.

Rivers have been anchors of civilization and bones of contention (the word *rival* is cognate with *rivulet*). They cover great distances and connect a wide diversity of people and places, from high-altitude snowy mountains to lowland deltas. They are rich ecological and cultural corridors. Many cities have arisen at the bank of a river or at a confluence of two rivers. Such rivers have shaped a valley and at a strategic site a city arose: the bottleneck, the valve, of flows of sediments and trade material, in and out of the valley—hence a center of commerce.

In the early 1500s Leonardo da Vinci and Niccolò Machiavelli furtively conspired to mastermind a diversion of the Arno River from the city of Pisa. It would have deprived the city of water, thereby giving victory to Florence after a ten-year war. The plan, if successful, would have turned Florence into a world power with access to a seaport. For various reasons the plan fell apart, inspiring Machiavelli to compare fortune to a river—something that is unpredictable, violent, and irresistible. Even though that scheme to divert the Arno did not come to fruition, the underlying paradigm of the control of fortune through a powerful combination of economic, engineering, and strategic forces was a precursor of modern river management.

RIVERS IN THE MODERN ERA

In early modern times rivers were relegated to the industrial and mercantile back regions of town and turned into functional arteries for transport, for harbors, and for other economic purposes. Or they were exiled underground; or turned into open sewers, carrying diseases; or dried, paved over, and turned into roads to make space for traffic.

Since the Industrial Revolution most of Europe's rivers have been treated as cheap waste transportation to the sea. Heavily polluted, they have harmed human health and degraded the quality of coastal and marine waters. The biodiversity of thousands of kilometers of waterways was affected. The same happened in the United States, culminating in a famous incident in 1969: A thick layer of oily industrial pollutants on the Cuyahoga River in Cleveland, Ohio, caught fire from the sparks of a passing train. Even the revered Ganges and Yamuna rivers turn into open sewers after they pass through Delhi and Varnassi, respectively. Each enters a city alive and leaves nearly dead, soiled by sewage and other waste, anaerobic with a zero dissolved-oxygen level as gaseous sludge rises from the bottom and floats to the surface.

Along the Mississippi River farming and logging on a massive scale had caused immense erosion by the early twentieth century. Vast amounts of topsoil were washed

down the river into the Gulf of Mexico, a trend that had a disastrous impact on impoverished farmers. The Tennessee River is a major tributary of the Mississippi. The Tennessee Valley Authority (TVA) was created in 1933 as a federally owned corporation to provide the residents of the Tennessee River watershed, one of the areas most severely affected by the Great Depression, with a regional development plan based on modernizing the area's economy and society. The complex plan for flood control and electricity generation involved the creation of twenty-nine dams and 1,050 kilometers of navigation channels. It is today the largest public power company in the United States.

Dam building has been promoted as the prime technological approach to riverine development. It was at the heart of President Franklin Roosevelt's program of New Deal public works, which, during the Depression years of the 1930s, provided jobs for masses of unemployed Americans. FDR, however, was only carrying on in the tradition begun by his elder distant cousin and predecessor, President Theodore Roosevelt, who had initiated the twentieth-century American modernization paradigm in 1901: "Great storage works are necessary to equalize the flow of streams and to save the flood waters," he proclaimed (Postel and Richter 2003, p.1). In the same spirit of progress, Prime Minister Nehru of India honored dams in the 1940s as "the Temples of Modern India"; India went on to build some 3,600 dams.

The twentieth century saw an unprecedented impact on rivers, mainly through dam building, leaving a legacy of approximately 800,000 dams worldwide, of which 48,000 are 15 meters or higher, with almost half of these large dams built in China. The collective weight of the harnessed water and trapped sediments in the reservoirs has caused a measurable change in the angle of the earth's axis and the speed of its orbital movement. One-fourth of the global sediment ends up in reservoirs behind dams instead of nourishing floodplains and estuaries. Silt's color accounts for the names of the Yellow River and the Colorado River (Colorado is Spanish for "colored"), but dams have robbed them of the significance of their names: As released from the major dams on these great rivers, the water is as clear as glass. Some of the smaller reservoirs behind dams have silted up to form marshy plains.

Dams provide almost 20 percent of the world's electricity supply. The massive dam at Itaipu (built from 1975–1991), for example, on the mighty Parana River between Brazil and Paraguay, provides Sao Paolo (a city of 11 million people) as well as Rio de Janeiro (a city of 6 million) with energy and furnishes 20 percent of Brazil's electricity and 93 percent of Paraguay's. The Itaipu dam shifted the course of the seventh-biggest river in the world. Echoing Nehru in a secular fashion, the American Society of Civil Engineers called the dam one of the seven wonders of the modern world.

Dams come at high costs. They profoundly disrupt long-established ecological, hydrological, and cultural systems. Dams have displaced 40–80 million people, either by forced eviction or because of the loss of their traditional livelihood as a result of dam-induced environmental change. The stagnant waters of the reservoirs breed mosquitoes and are infested with freshwater snails that carry parasites, generating diseases such as Schistosomiasis (also known as *bilharzia*, or snail fever), commonly found in Asia, Africa, and South America. Snail fever, endemic to Egypt, is exacerbated by the Aswan High dam and associated irrigation projects along the Nile.

Dams have triggered protests all around the world. Modern communication technologies—email, blogs, YouTube videos—have facilitated global networks supporting local communities, social movements, and nongovernmental organizations organized to oppose dams. Influential advocacy groups, such as International Rivers, question the conventional or modern "development" model that dams epitomize. Among other things, they research other ways of meeting people's needs for water, energy, and protection from damaging floods. In 1997 the World Commission on Dams (WCD), an independent panel to review large dams, was created, led by the International Union for Conservation of Nature (IUCN), and the World Bank. The Commission initiated a broad-based research process resulting in its 2000 report, *Dams and Development: A New Framework for Decision-Making*, which acknowledges the important benefits of dams for human development but also judges that the price paid—both socially and environmentally—is unacceptable (WCD 2001).

Once widely regarded as a symbol of progressive technology, dam building is now commonly viewed as a threat to the earth's ecosystems. Nevertheless, major dams are still being built and planned. A series of dams are planned for the headwaters of the Ganges River in India. The Tehri Dam, which began to fill in 2004, already affects the flow of the Ganges River from the Himalaya Mountains. Sunderlal Bahuguna, Indian activist and philosopher in the tradition of Mahatma Gandhi, has gone on many hunger strikes to stop the Tehri Dam Project, and was forcibly moved to a government issued home upstream. A leading Indian scientist, G. D. Agarwal, former dean of the Indian Institute of Technology at Kanpur, has decided to go on a fast unto death against the damming of the River Bhagirathi "to oppose the destruction of this ecological marvel and the epitome of Hindu cultural faith" (Agarwal 2008).Where for Nehru the dam was the temple, now the river is the religious center of attention.

At the beginning of the twenty-first century, one in ten of the world's major rivers no longer reached the sea for part of the year because of upstream use of their waters, mainly for irrigation. The Nile, the Yellow, the Indus, the Rio Grande, and the Colorado rivers, along with many others, now end in sand, sometimes hundreds of kilometers before they have a chance to reach their mouths and fertilize their deltas to maintain ecologically rich estuarial ecotones that mix sweet and salt water into one of the most productive kinds of ecosystems on Earth. The number of foreshortened rivers may increase during the twenty-first century. Although irrigation already accounts for 70 to 80 percent of human use of freshwater, more and more countries are pushing their water resources, including rivers, to the limit in order to increase food production.

Many rivers are thus but a shadow of their former selves. The blue lines on the map are often tokens of faded glories. Whereas rivers once symbolized transition, they are now themselves in transition.

RIVERS IN TRANSITION

In German romanticism the Rhine and Danube—with their castles, vineyards, and associated ancient legends—loomed large in the cultural imagination. This popular veneration did not spare the rivers from pollution and other forms of environmental degradation. A renewed environmental consciousness, however, is transforming cultural attitudes toward rivers. Human and ecosystem water needs ought to be balanced, according to the water experts Sandra Postel, director of the Global Water Policy Project, and Brian Richter, director of the Freshwater Initiative of the Nature Conservancy (Postel and Richter 2003). More than 60 percent of the world's 227 largest rivers have been fragmented by infrastructures such as dams and diversions. Rivers are turned on and off instead of flowing by natural rhythms. Their main functions are providing hydroelectric power, irrigation for agriculture, and shipping routes for trade; their traditional ecological functions and services have been systematically undermined. With great efficiency the periodic floods of untamed rivers shaped river channels and redistributed sediment, creating habitats essential to fish and other riverine life. Because floodwaters are no longer getting cleansed by floodplain wetlands, more pollution is reaching inland and coastal seas. Hence in many parts of the world, the harnessing of rivers for economic gain is causing more harm than good.

In 2000 the European Parliament adopted a water-policy framework, the European Community Water Framework Directive (the WFD), an unprecedented attempt to design a regime for managing water quality and instream flow for each watershed, thus creating a basic geographic unit for resource planning. The WFD aims to manage whole watersheds or river basins in a holistic manner (a strategy referred to as integrated water-resources management [IWRM]) at the basin or watershed level in order to integrate land and water—upstream and downstream water, surface water, groundwater, and coastal water. A more transparent and participatory transnational governance alternative has thus replaced a politically fragmented, top-down management approach. In an effort to achieve multiple-stakeholder consensus, hydrological and engineering expertise has been complemented by ecological concerns along with urban, agricultural, industrial, and recreational interests. Because water connects all elements of society, an integrative water ethic becomes essential, one that views local problems of water quality and quantity in transregional and global political contexts.

The major water laws were created in an era of economic control of rivers. The emerging new paradigm is based on the concept of ecological health. This radical shift calls for a dislodging of entrenched laws and policies. Around the globe, in areas as diverse as Australia, South Africa, Europe, and Texas, governments are implementing policies that establish allocation of water for ecosystem support—mainly minimum instream flows to maintain environmental quality and sustainability.

Because rivers are the anchors of cultures, many cities are revitalizing communities and ecosystems by reconnecting them to the rivers that run through them. Rivers are resurfacing in the public imagination as cultural and ecological corridors, creating a cultural rejuvenation. Although some of these projects are driven solely by economic motives, most of them stimulate awareness of the river's ecological, cultural, and economic wealth and inspire public education about local water issues. Some of them explicitly aim for increasing stewardship of the river and engaging communities in river-related projects. New urban river projects—such as river-walk promenades, theaters, cafés, and restaurants along old quays—are beginning to appear in many places. This trend often comes with a gentrification of dilapidated harbor neighborhoods as old warehouses turn into high-priced riverfront housing developments.

For example, the Los Angeles River is about to be unlocked from its concrete ditch and restored by means of a riparian-community-based process meant to create a blue ribbon along housing developments, parks, and walkways, thus revitalizing river and community alike. New Orleans plans "RiverSphere" as a forum for art, science, and technology focused on the Mississippi. In an era of fluvial imagination, river festivals burst forth: there is the Brisbane River Festival in Queensland, Australia; the Hudson River Festival in New York City; London's Thames Festival; and Danube day throughout southeastern Europe. New urban water cultures are emerging that celebrate

The Concrete Channel of the Los Angeles River. *The Los Angeles River was once the primary water source for the Los Angeles basin, but frequent flooding led some to search for a sollution to control the unpredictable river flows. Since the late 1930s, the river has been primarily a flood control channel. Environmentalists and others hope that the river can soon be returned to its more natural state.* **PHOTO BY IRENE KLAVER.**

rivers as part of a deepening appreciation of waterways and growing involvement in river basins. The "One River Mississippi" festival celebrates the river along the Father of Waters (which is what "Mississippi" means in the Cherokee language) at various places, all at the same time.

Also in rural areas river restoration is underway: Remeandering—done by many of the same engineering firms that straightened them fifty years ago—gives floodplains back to the rivers. And there is a movement to learn to live with the floods—riparian restoration and nurturing wetlands to take out pollutants, fertilizers, and pesticides before the water drains back into the river.

With the combined application of interdisciplinary engineering, hydrological expertise, and ecological sensitivity, the twenty-first century promises a renewal of river cultures, perhaps even a respect approaching the ancients' reverence for these great waterways. New management regimes are seeking to work with, not against, the great rivers to enhance their flow and allow them the freedom of flood in a natural cycle of renewal and rejuvenation for humans and the entire manifold of life that flows into and out of these vital arteries the earth.

Rivers are archives. They record deep and shallow time, revealing what happened a million years in the past as well as a moment ago upstream. Rivers are the sinews of the world; without them life unravels

ROLSTON, HOLMES, III
1932–

Holmes Rolston III was born in the Shenandoah Valley of Virginia on November 19, 1932. His father was a rural pastor. Rolston grew up with the Blue Ridge Mountains on the horizon; from his earliest years he recalls wandering the woods and swimming the creeks of his native landscape.

Rolston's formal education included a B.A. in physics from Davidson College (1953), a Ph.D. in theology from Edinburgh University (1958), and (after several years' service as a pastor back in Virginia) an M.A. in the philosophy of science from the University of Pittsburgh (1968). At each step Rolston felt dissatisfaction with the reigning concepts of nature and with people's mistreatment of nature itself. He especially disliked the common insistence that nature was value-free. He came to realize the need for an environmental philosophy that could undergird a richer appreciation of life on earth. His forty-year career in the Philosophy Department at Colorado State University, beginning in 1968, was largely devoted to creating such a philosophy.

Rolston's 1975 article, "Is There an Ecological Ethic?" helped to jump-start interest in environmental ethics in academic philosophy. In 1979 he helped to found the first journal in the field, *Environmental Ethics,* and as of 2008 remained an associate editor. During this time he was developing his own nonanthropocentric environmental ethics, first in articles later collected in *Philosophy Gone Wild* (1986) and then in a systematic presentation in the book *Environmental Ethics* (1988).

Rolston is best known for his sustained, ingenious, and uncompromising advocacy of the idea that values inhere objectively in nature. He holds that individual organisms, biological species, and ecosystems may all possess intrinsic values—values based on what they themselves are—in addition to their instrumental values to human beings. These intrinsic values ground duties to treat nature with respect and use it with restraint. Rolston insists that human beings are sometimes morally required to put values discovered in nature above their own preferences or self-interest.

In addition to defending nature's intrinsic values, Rolston attempts to enrich our account of nature's instrumental values to humans (including life-supporting, economic, recreational, aesthetic, scientific, and spiritual values). He also argues for nature's "systemic value": the creative capacities of the earth's ecosystems to generate intrinsic and instrumental values over evolutionary time. Rolston's goal is a comprehensive and accurate account of the way in which nature ought to be valued, one that not only does justice to human beings' uniquely complex and important roles on earth and to the new values brought forth by consciousness, but that also appreciates nonhuman nature for what it is.

Rolston's value arguments are built upon detailed, scientifically informed descriptions and an appreciation of the natural entities in question. They have been so influential that casual observers often define environmental ethics as the position that nature has intrinsic value, or equate environmental ethics with nonanthropocentrism. Strictly speaking, this is false, since one can consistently hold an anthropocentric environmental ethics. Rolston, however, finds such ethical outlooks to be inadequate, either as guides to practice or as complements to a modern scientifically informed worldview.

Rolston has also worked to specify what respect for nature might mean for policy issues such as protected-areas management, endangered species and biodiversity conservation, wilderness preservation, sustainable development, corporate environmental responsibility, and population policy. *Conserving Natural Value* (1994) provides a comprehensive, nuanced account of Rolston's positions on many of these issues. Throughout his writings he places a premium on reining in human consumption in order to preserve wild nature.

In addition to his efforts to formulate an environmental ethics, Rolston has endeavored to overcome the modern split between science and religion. Motivation for this project goes back at least to his time as a pastor to evolution-fearing but nature-loving southern farmers. This work, also widely influential in philosophical circles, led to his invitation to give the Gifford Lectures at the University of Edinburgh in 1997–1998, later published as *Genes, Genesis, and God* (1999). In 2003 he was awarded the John Templeton Prize in Religion, the money from which he used to endow a chair at his alma mater, Davidson College. Rolston has been university distinguished professor at Colorado State University since 1992.

Often referred to as "the father of environmental ethics" and later sometimes as its "grandfather," Rolston lectured on all seven continents. He strongly influenced environmental ethics through his six books, fifty authored chapters, and more than one hundred articles; his many generous efforts to help philosophers, theologians, and scientists further their own work; and his practical conservation efforts at the local, state, federal, and international levels.

ROMANTIC POETRY, ENGLISH

The Romantic period of the late eighteenth and early nineteenth centuries has historically been seen as a time of a renewed interest in the natural world, and many attitudes, ideas, and landscapes that writers of the period celebrated in their poetry have endured in contemporary environmental thinking. Influenced by such European writers as Jean-Jacques Rousseau, the English poets of the period saw nature as a means of resisting and opposing the artifice and corruption of many aspects of culture. Indeed, one of the signal ideas of the Romantic period is that nature and culture are opposed rather than conforming, as Alexander Pope and other Enlightenment figures had thought. A central motivating idea for the Romantics was that human nature was perfectible in nature and made corrupt only by culture. Thus such early Romantic poets as Charlotte Smith, William Wordsworth, and Samuel Taylor Coleridge wrote lyric poems featuring the poet fleeing various instances of culture (cities, crowds, families) and seeking the isolation of various forms of wilderness.

INDIVIDUAL IMAGINATION AND THE NATURAL WORLD

In this version of the Romantic lyric, the speaker returns to spiritual health by finding in the natural world solace and wholeness. The most influential example of this is Wordsworth's "Lines Composed a Few Miles above Tintern Abbey," a poem that is also a kind of manifesto for how the natural world can make the individual a better person, morally, spiritually, and physically. Many poems by Smith and Coleridge make the same point. Coleridge's pronouncement in "The Eolian Harp" (1796) that the "one Life within us and abroad" is the source of all solace is a succinct encapsulation of a quintessentially Romantic and environmental idea. The key arguments here are that the harmony and beauty of the natural world point to a fundamental reality obscured and even destroyed by much human activity and that nature is imbued with, or is a manifestation of, a powerful spirit, consciousness, or force to which human consciousness may return.

Wordsworth developed these ideas in dozens of poems, including his epic autobiography *The Prelude*, which argues that an early and sustained connection to the natural world is necessary for the development of a healthy and creative imagination. Indeed, literary criticism of the early twenty-first century has heralded Wordsworth as the father of the nascent ecological vision of Romanticism (Bate 1991; Buell 1995), and also as the originator of a key myth of modern environmentalism, or at least one of its deepest and perhaps most unscrutinized ideologies: the idea that the natural world is a source of health and that cities and other forms of human culture produce pollution and disease, both physical and spiritual.

The Romantic poets did not think of themselves as belonging to a school or movement, however, and each had distinctive ideas about the natural world. Indeed, their belief in the sanctity of the individual imagination almost guaranteed much diversity of thought. The emphasis on the individual's encounter with the natural world is also a central feature of much environmental writing by such later figures as Ralph Waldo Emerson and Henry David Thoreau in the mid-nineteenth century, and as Robinson Jeffers, Edward Abbey, Aldo Leopold, and many others in the twentieth. There are two connected ideas here: that nature offers places of solitude in which to discover one's individuality and that the true quality of nature can only be appreciated and understood by the solitary observer.

ANIMAL ETHICS AND THE ROMANTIC PERIOD

Although Coleridge would give up both poetry and his idealization of nature to become a philosophical idealist by the early 1800s, the extraordinary popularity of his *Rime of the Ancient Mariner* has earned him a perhaps outsized influence on environmental thought. This self-consciously mysterious and symbolic poem tells the story of the mariner's apparently random killing of a beautiful and companionable animal and the revenge enacted upon him by both the natural and supernatural worlds. The poem has been read variously as revealing humanity's crimes against nature (and nature's ultimate revenge), as arguing for sympathy and kindness toward animals, and as revealing a deep and hidden moral (or amoral) order in the physical world—all of which ideas resonate with environmental thought.

Concern for the status and well-being of animals is a consistent and important feature of Romantic-period environmental thought. Such early Romantic poets as

Anna Barbauld and Robert Burns wrote popular poems that seem to condemn cruelty to animals, and the young Coleridge's "To a Young Ass," much mocked at the time, asserted solidarity with animals. Though, as a radical and apocalyptic Christian, William Blake generally valued human imagination over the necessarily fallen and corrupt physical world, his poetry brilliantly and consistently sees animals, and human treatment of them, as symbolic of actual sin and potential redemption. The "peasant poet" John Clare is remembered today in part for the careful description of birds and mammals in his poetry, and for his powerful evocation of sympathy for the well-being of animals and the ecosystems that support them. Clare is important too for decrying the privatizing of public grazing lands and for extolling the virtue of careful and sustained observation of animals and landscapes, as opposed to the rare moments of epiphanic insight celebrated by most of the other Romantic poets.

Probably the most committed animal-rights poet and most radical environmental thinker of the Romantic period was Percy Bysshe Shelley, who wrote two tracts on the "necessity" of vegetarianism, in which he developed the radical view of meat eating (and the production and slaughter of livestock) as the "root of all evil." His argument, ultimately about the interconnectedness of things, is that how and what we eat, for instance, affects our physical environment as well as our moral being. Though Shelley's thinking often overreaches, the daring and vigor of his imagining of the relationship between consciousness, culture, and the physical world anticipates much contemporary environmental thinking the most of all the Romantic poets.

Shelley is simultaneously a radical materialist and a radical idealist. Important poems such as "Mont Blanc," "Ode to the West Wind," and *Prometheus Unbound* argue that the laws of the world are ultimately those of nature, which have long been obscured by the corrupting cycles of human development. Shelley seems to have been the only Romantic poet aware of the deep implications of the new science of geology: that the Earth was far older than the Bible stated and also that humankind may be insignificant in the vastness of geologic time. Shelley was invigorated by the thought that if natural forces, rather than human forces, were primary, then human culture (which Shelley saw as producing predominantly violence and pain) was ultimately a veneer and could be replaced, through the forces of nature and healthy human imagining, by the kind of ecological utopia imagined at the end of *Prometheus Unbound*: a place of permanent spring and renewal.

JOHN KEATS AND LORD BYRON

Though John Keats and Lord Byron (George Gordon Byron) have long been seen as important figures of the English Romantic period, their contributions to environmental thinking, relative to the other four central figures, have been less obvious. Both poets were more interested in the nature and value of poetry and in the life of the poet than in the natural world as an end in itself. Though Byron wrote memorably about the natural world in many poems, he did so in the mode of ironic posing as a late Romantic. Yet his descriptions of his love of animals, and the centrality of physical passion to human nature, are central and powerful. He would no doubt be surprised and pleased that his most influential contribution to environmental thinking is his comic nihilistic poem "Darkness" (1816), which imagines a world in which the sun dies, and human morality and then human life are slowly extinguished: "The World was void, / The populous and the powerful was a lump, / Seasonless, herbless, treeless, manless, lifeless— / A lump of death." The poem was probably written in response to the abysmally cold summer of 1816, caused by the massive release of ash by the explosion of the Indonesian volcano Tambora the year before. Now the poem has powerful resonances with nuclear winter and catastrophic climate change.

Keats managed to absorb much of the spirit of the period and to reflect it in some of the most beautiful and powerful verse ever written. His "Ode to Autumn" (1819), one of the most perfect nature poems of the period, revels in the ability of language to reproduce the experience of observing and being content with the natural world. The poem is also tinged with the recognition that the bliss and contentment of a harmonious relationship with nature is threatened by winter and death. Indeed, Keats's awareness of mortality, of the inevitability of change, provides a necessary correction to the Wordsworthian idealization of the natural world as static and harmonious, due primarily to Wordsworth.

Though the Romantic poets produced an astonishing variety of ideas about the natural world, their belief that writing about the natural world could itself be significant and beautiful has had the most profound effect on later writers. Romanticism virtually invented nature writing as we know it today.

ROMANTICISM

There are two main traditions of Romantic literature and philosophy with significant implications for environmental philosophy. The emergence of Romanticism as a dominant school of thought in Germany toward the end of the eighteenth century marked a significant change in conceptions of nature and the natural sciences. British Romanticism developed slightly later, from similar sources, and was predominantly a literary movement. The German Romantics, by contrast, were as concerned with the scientific study and depiction of nature as with its portrayal in art, and indeed considered these two realms of human activity to be inseparable. As a result of the emphasis of German Romanticism on the beauty and freedom of nature, its philosophy and literature played an influential role in the worldwide inception and development of environmental preservation, appreciation, and ethics. British Romanticism too, with its focus on the relationship of humans to nature, fostered new ways of viewing and valuing the natural world.

ORIGIN OF THE CONCEPT OF ROMANTICISM

Although the Romantic period was commonly contrasted with the Neoclassical period that preceded it, the specific sense of the term *Romantic* as it began to be used in the early nineteenth century was conceived in 1800 by Friedrich Schlegel (1772–1829) to evoke a "return to the Romans" (1982 [1800], p. 89) and the Italian medieval romance (1991 [1798–1800], p. 31), both of these as part of a projected urbanity that could embrace a multitude of styles and genres while retaining a universal and progressive significance. The term *Romanticism* also refers to the idea of a *lingua romana*, or a language of (all) the people. Romanticism evolved in reaction to what were conceived to be the negative consequences of Enlightenment thought, especially its association with the industrialization and homogenization of Europe. Despite their reaction against scientific conceptions that envisioned and depicted nature mechanistically, Romantic thinkers were not antiscientific, and indeed they made significant contributions to the philosophy of nature and the natural sciences.

In addition, Romanticism allied itself with progressive political thought, in particular, the ideals of equality and freedom espoused by the French Revolution. The philosophy of Jean-Jacques Rousseau (1712–1778) postulated that humans in the state of nature are neither good nor evil and that it is society that corrupts humans or cultivates good citizens. His educational theory emphasized the role of the study of nature in properly educating citizens. These two aspects of his thought thus provided a link between the study of nature and progressive politics. Rousseau's last published work, *The Reveries of the Solitary Walker* (1782), expressed the need for humans, even in a fully realized civil society, to reconnect with the natural environment to actualize fully their human essence.

PHILOSOPHICAL FOUNDATIONS OF GERMAN ROMANTICISM

Romantic philosophy of nature was deeply influenced by the philosophy of Immanuel Kant (1724–1804) and the literary and scientific studies of Johann Wolfgang von Goethe (1749–1832), both of whom, in different ways, advocated intertwining science and art. In his *Critique of Judgment*, Kant describes a "technic of nature," by which he meant that for scientific explanations to systematize all the discrete laws and regularities arrived at through observation of nature, humans must go beyond empirical cognition and think of nature in an artistic manner. This necessity of conceiving nature as a unified whole is an a priori demand that our faculty of judgment carries within itself, and cannot be justified objectively. Nonetheless, Kant argues, without what he calls the "fiction" of the theoretical construct of the unity of nature, scientists will never rest content with their results. Kant postulated the organism, a self-regulating natural being, as the most satisfying metaphor for describing nature as a totality. This conviction led to the Romantic conception of nature as an organic whole. In addition, Kant's description of the sublime aesthetic judgment contributed to the Romantic fascination with wild landscapes depicted in visual art and poetry.

As a natural scientist, Goethe insisted on a more empirical approach to nature than Kant's articulation of the transcendental conditions for the possibility of making and unifying judgments, although the primal phenomena that Goethe identified in nature attributed spirituality to nature. This attribution inspired the Romantic philosophy of nature, which saw nature as a kind of subject in its own right. Goethe identified what he considered to be the two

great driving forces of nature: polarity, on the one hand, and enhancement or intensification, on the other. Polarity, according to Goethe, is a property of nature insofar as it is thought of as natural, and intensification is a property of nature insofar as it is spiritual. He called polarity "a state of constant attraction and repulsion," and intensification "a state of ever-striving ascent." These two forces affect mind and body equally, and are interdependent for their existence. Goethe argued that phenomena like magnetism and metamorphosis are "originary," in the sense of strictly belonging neither to the realm of matter nor to that of spirit.

LITERARY FORMS OF GERMAN ROMANTICISM

These originary phenomena were named "potencies" by Novalis (the pseudonym of Friedrich Leopold, Freiherr von Hardenberg; 1772–1801), the Romantic poet, novelist, scientist, and mathematician. Novalis called Romanticism a "qualitative potentization" (1965–2005, vol. 2, p. 545), or an elevation to a higher level of potency, by which he meant that when one elevates ordinary experience to the mystical level, the finite to the infinite, the known to the unknown, or the material to the spiritual, one is romanticizing it. The idea behind Romantic thought was that by re-enchanting nature through art, a closer affinity might be created between humans and nature—an affinity that in turn might lead to an increase in knowledge without destruction of nature. The natural world was not to be conceived of as a machine to be harnessed and manipulated for practical purposes, nor as an object upon which one could experiment without compunction, but rather as an organism whose needs and endeavors could oppose or complement, but always affect, those of humans.

The word *organic* was first used around 1799 by the Romantic poet Friedrich Hölderlin (1770–1843) to project onto nature the peculiarly human activities of "self-action," art, and reflection; to attribute to the whole of nature systematic form (1988 [1794–1800], p. 54). While Hölderlin's poetry can be read as a continuation of the Romantic project of re-enchanting nature by creating art to reinstill a sense of beauty, magic, and wonder in nature, he viewed the human desire for a unification with nature as ultimately unfulfillable. Organic nature is nature as appropriated and thus inevitably transformed by humans. Standing in opposition to organic nature is what Hölderlin designated as "aorgic" nature, nature prior to human intervention, a realm of being that precedes the subject/object distinction and that is thus not conceptualizable or knowable (1988 [1794–1800], p. 53). The difference between the aorgic and the organic is akin to the difference between an unlimited striving and a series of constraining forms that bring nature into presence. According to Hölderlin, these two forces are continually in tension with each other, and humans will never know nature as it is in itself, however much they may wish to.

FRIEDRICH SCHELLING

Friedrich Schelling (1775–1854), who made nature the central focus of his systematic thought, was perhaps the best-known German Romantic philosopher. In his philosophy of nature, Schelling combined the Romantic quest to integrate the diverse areas of human inquiry, Kant's critical philosophy and insights into how to overcome the gap between nature and human freedom, Goethe's emphasis on grounding all theoretical philosophy of nature in experience, and the idealist perspective of Johann Gottlieb Fichte (1762–1814), as well as the most radical scientific theories of his day.

Schelling not only insisted, like Kant, that theories of nature must reflect a unified conceptualization of nature, but also expressed complete confidence that nature agrees with the maxims of reflective reason (1988 [1797], p. 41). Schelling set out to show that nature in itself is, in fact, systematic, and that its purposiveness is not simply limited to the form of our cognition. Calling his philosophy of nature a "speculative physics," Schelling argued that nature is in fact the realization of an overarching rationality. What Georg Wilhelm Friedrich Hegel accomplished for the moral world, customs, social life, politics, and history, Schelling first outlined for the physical world of nature. In nature, spirit should recognize itself.

After 1801 Schelling turned away from a Fichtean preoccupation with the centrality of the "I" and of freedom as the highest principle of all philosophy, toward the philosophy of nature. This change of direction arose directly out of his reading and discussion of the chemical theories of Antoine-Laurent Lavoisier, his attendance at the lectures of Karl Friedrich Hindenburg on experimental physics in Leipzig, his reading of Carl Kielmeyer on organic powers and Alexander von Humboldt on electrophysiology, and his research into the theories on biology and medicine of John Brown, as well as his enduring allegiance to Kant's speculative scientific theories on force, life, and matter.

Schelling broke with Fichte on the nature of the absolute ego. For Fichte, nature is nothing more than the pure negative, the illusory "not-I," of the absolute ego. Originally, Schelling emphasized the power of mind or spirit (Fichte's absolute ego) to expand outward, to be determined or restricted only by the negative force of consciousness, or the not-I (rather than the in-itself of Kant, which lay outside of the mind). In contrast to Fichte, Schelling argued that the limitation or restriction came from the absolute ego's striving to know itself, and that the natural world arose through the interaction of

the creative ego and the constrictive formative force. Schelling stated that his philosophy of nature, or speculative physics, regards active nature (*natura naturans*)—as opposed to passive nature (*natura naturata*), which empirical science takes as its object—as a subject in its own right and the proper focus of all theory (2004 [1799], p. 202). Schelling's assertion of an independent philosophy of nature as active put him at the center of German Romanticism.

Although Schelling accorded active nature a kind of freedom, it was a freedom within the bounds of law, in contrast to the theory of vital force of Johann Friedrich Blumenbach (1752–1840), which Schelling believed illegitimately implied the complete self-determination of nature. Following Kant, Schelling asserted that the behavior of nature can be scientifically accounted for only as law-governed, and that such lawful freedom can hold only if we take the organism to be a fundamental concept, not only in biology, but also in chemistry and physics. He thus moved beyond the logical analysis of the a priori conditions for the lawfulness of nature toward the real experience of the organism as a freely self-motivated natural entity.

There seems to be a fundamental correspondence between the systematizing power of the human (and divine) mind and the organization of nature. This structure can be seen in the simplest of organized forms. Schelling set his philosophy apart from pure idealism by insisting that two distinct types of philosophy are equally necessary: a transcendental philosophy that understands nature as the visible organism of our understanding and a philosophy of nature that explains the ideal as arising from and explainable from the real.

Schelling called nature the "original duplicity" in its character as both subject and object, and claimed that the opposite tendencies that pervade nature through magnetism, electricity, and sexuality manifest this duplicity (both mechanically and vitally) in nature's productivity (1867, p. 201). The process of the conflict of forces in this expanded sense can be experienced through the senses both in the realm of the inorganic, through magnetism, electricity, and chemical processes, and in the realm of the organic, through sensibility, irritability, and metamorphosis. Schelling argued that the heart of natural science was the experiment, since in the experiment "nature [is] compelled to act under certain definite conditions, which either do not exist in it at all or else exist only as modified by others" (2004 [1799], pp. 196–197). Only through such acts is it possible to gaze into the internal structure of nature.

In his essay "On Human Freedom," Schelling, following Jakob Boehme (1575–1624), described nature as effecting the self-revelation of the divine itself. God, according to Schelling in this essay, enters freely into a relation of *love* with nature. It is this relation that allows the self-manifestation of the divine, of human freedom, and of ethics. Here Schelling outlines a modified, dynamic Spinozan pantheism in which nature provides the ground for not only human freedom and divine actualization, but also evil. Schelling insists that nature, as God's ground, remains eternally separate from God, but he also accords a kind of freedom to nature because of its origin in the divine (1987 [1809], pp. 251–252). The separation of nature as ground and nature as existence in God, and the dual beginning that springs forth from this difference, also allows for personal existence, love, and human freedom. Such a loving relationship extends not only to the relationship between God and nature and between God and humans, but also and essentially to the relationship between humans and nature, whose intimate interconnectedness can be seen in the analogous structure of organism and system.

BRITISH ROMANTICISM

British Romanticism emerged out of German Romanticism. The poet Samuel Taylor Coleridge (1772–1834) in particular was strongly influenced by the philosophy of Schelling, as well as by Kant and Fichte. Coleridge's poetry and theoretical writings express the belief that a new conception of self in its relation to nature might emerge through consideration of the relation of words as "living powers" to thought and being. William Wordsworth (1770–1850) and Coleridge together initiated a new way of considering and responding to the natural world, often along the themes of journey and return through self-transformation—themes borrowed from the metaphysics of German Idealism. Wordsworth celebrated the spiritual power of raw natural beauty as a resource for self-renewal and education. John Keats (1795–1821) also used poetry to celebrate the beauty of nature and the eternal solace that nature can offer in the midst of human suffering. In contrast, William Blake (*Jerusalem*), Percy Bysshe Shelley ("Ozymandias"), Mary Shelley (*Frankenstein*), and Lord Byron ("Darkness") offered nightmarish visions of the results of human destruction or false manipulation of nature.

INFLUENCES OF GERMAN ROMANTICISM ON ENVIRONMENTAL PHILOSOPHY

The American Transcendentalists Ralph Waldo Emerson (1803–1882) and Henry David Thoreau (1817–1862) were influenced by German Romanticism in their articulation of the fundamental unity and harmony of humankind and nature, and the essential spirituality of all creation. They shared in the post-Kantian acceptance of a tempered convergence of religion and science.

Emerson, following Kant, strove to see in the beauty of nature a reconciliation of the realms of science and freedom, and like Schelling, he accorded a kind of morality to nature. The organism and the organic principle of form were central concepts for Emerson and Thoreau in their reflections on nature and writing. John Muir (1838–1914), the American naturalist, shared the Romantic conviction that there is a divine presence in nature, and he translated his concern for wilderness and appreciation of the sublime in nature into an initiative for nature preserves and the first U.S. national parks.

ROOSEVELT, THEODORE
1858–1919

Born in New York City on October 27, 1858, Theodore Roosevelt was the twenty-sixth president of the United States, a historian, a naturalist, a big-game hunter, and a cofounder of the Boone and Crockett Club. Roosevelt's presidency is noted for its support for the conservation of natural resources. Roosevelt withdrew from development a total of 234 million acres of public lands and set them aside as national monuments and parks, national forests, and federal wildlife refuges. He created or empowered federal agencies to manage that land on an unprecedented level. Roosevelt died on January 16, 1919, in Oyster Bay, New York.

POLITICAL CAREER

Roosevelt's childhood interest in natural history and ornithology led him to consider becoming a zoologist. He published two ornithology books while in college, the

first of his three dozen books on a variety of topics. Instead of becoming a zoologist, he graduated from Harvard and enrolled at Columbia Law School, though he entered politics without getting a law degree. He served in the New York State Assembly from 1882 to 1884. In 1883, he purchased a cattle ranch in what is now North Dakota and worked it on and off for the next five years. The experience taught him about life and the environment in the semi-arid Western frontier region.

In 1887 Roosevelt co-founded the Boone and Crockett Club, a gentleman hunter's club with a strong interest in the preservation of large game animals. It fought for the preservation of Yellowstone Park, contributed to the passage of the Forest Reserve Act in 1891—the basis of the national forest system—and helped found the Bronx Zoo in 1895.

Roosevelt served on the U.S. Civil Service Commission (1889–1895) and the New York City Police Board (1895–1897) and became assistant secretary of the U.S. Navy (1897–1898). When the Spanish-American War began in April 1898, he resigned to form the First United States Volunteer Cavalry regiment, better known as the Rough Riders. He returned a war hero and was elected governor of New York in 1898. In 1900 he was elected vice president of the United States, and in September 1901 he became president after the assassination of William McKinley.

Theodore Rooselvelt with John Muir, 1903. *President Roosevelt and John Muir often camped together at Glacier Point in Yosemite National Park, having lengthy talks about conservation. Although he supported the protection of natural wonders, Roosevelt rejected the impractical idea of of eliminating all development in wild areas.* **THE LIBRARY OF CONGRESS.**

ACHIEVEMENTS AS A CONSERVATIONIST

Besides trustbusting, Roosevelt remains in the American political consciousness for his strong support of the conservation movement. Shortly after becoming president, Roosevelt asked Gifford Pinchot of the Division of Forestry and Frederick Newell of the U.S. Geological Survey to help craft an integrated program for federal management of natural resources. Like them, Roosevelt feared letting private industry continue to exploit public lands without federal regulation and believed that only federal scientific management could save American natural resources and, by extension, democracy from industrial monopolies and their wastefulness.

During his first term in office Congress passed the Newlands Reclamation Act in 1902, bringing nearly three million acres of semiarid land in a dozen states under irrigation and making settlement there feasible. After the 1904 presidential election Roosevelt made conservation a central domestic issue.

Roosevelt supported both preservation and conservation. He favored the preservation and protection of natural oddities and wonders but rejected as impractical the preservationists' idea of eliminating development in all natural or wild areas. He urged Congress to pass the Antiquities (or National Monuments) Act of 1906, which allowed the president to set aside scientifically or historically important areas such as the Grand Canyon for protection. He also established the first federal wildlife refuges and reservations to protect wildlife and its habitats. At the same time Roosevelt promoted utilitarian conservation and planned natural resource development. In 1905 Congress transferred the sixty-three million acres of federal forest reserves to the Department of Agriculture and created the U.S. Forest Service to manage the national forests for timber and watershed protection.

Roosevelt appointed commissions and held conferences to highlight his conservation agenda. In 1907 he appointed the Inland Waterways Commission to examine multiple-purpose development of river basins. His Governors Conference on Conservation in 1908 inspired individual states to establish state forests, forest services, and conservation boards. Roosevelt also expanded conservation to include the health of children, waste in war, and civic beautification. The Country Life Commission, for example, attempted to stop the disintegration of rural life, which some social critics considered of vital

importance for the political survival of the nation. Congress, however, resented the expansion of executive power and cut off funding.

After leaving the presidency in 1909, Roosevelt undertook an African expedition to collect specimens for the Smithsonian Institution. After his defeat in 1912 as a third-party candidate for president, he explored a newly discovered river in Brazil. The trip nearly killed him, but his party mapped the river and collected specimens. In Roosevelt's honor, Brazil renamed the river Rio Roosevelt. His last years were spent writing articles and reviews for various publications. Among his many accomplishments, Roosevelt's conservation work may be his greatest legacy.

RUSKIN, JOHN
1819–1900

The Victorian art and social critic John Ruskin was born in London on February 8, 1819. Among his primary concerns was the accurate description of nature. His 1834 essay in *Loudon's Magazine* discussed, as an example, the causes of the color of the Rhine. That commitment to exactness and curiosity about nature, articulated explicitly or implicitly within the terms of natural theology, defined his thought throughout his life. In the first half of his career, Ruskin's principal intellectual preoccupations were with the moral testimony of art, particularly art representing nature. Ruskin understood the best art as art that, first, respected the empirical truths of nature through accurate representation and, second, embodied a great artist's interpretation of the moral truths of nature. To see the natural world properly, in this respect, was an act of love and a way of understanding ethical teaching. The five volumes of Ruskin's *Modern Painters* (1843–1860) offered a detailed account of the English painter J. M. W. Turner as an ideal artist, faithful in the representation, and wise in the interpretation, of nature. They proposed as a general conviction that to "see clearly is poetry, prophecy, and religion,—all in one" (vol. 5, p. 333).

Ruskin's close observation of nature contributed to his exceptional drawings and watercolors. In the early 1850s he supported, with equivocation, the principles of the Pre-Raphaelite Brotherhood to represent the natural world faithfully. His concern with the representations of art gradually expanded into a preoccupation with the condition of the world in which artists worked. *Unto This Last* (1860) marked, at least as Ruskin saw it, his formal turn to economics and politics. Inseparable from his political arguments were new questions about the meaning of nature and how industrial modernity treated it. Although Ruskin had rejected his evangelical Christianity in 1858, only for the briefest moments thereafter did he lose faith in the divinely inspired meaning of the natural world. In the 1860s, looking for new ways to discuss what human beings could learn from the natural world, he explored mythological readings of nature, including Greek myth in *The Queen of the Air* (1869). Ruskin's late scientific textbooks—*Love's Meinie* (1873–1881), *Deucalion* (1875–1883), and *Proserpina* (1875–1886)—endeavored to draw the best wisdom from such mythological approaches to nature.

Politically, Ruskin in the 1870s paid attention to rural communities and the contamination of the natural world, which he regarded as a betrayal of humanity's God-given duty of care. The public letters of *Fors Clavigera* (1871–1884) developed plans for an alternative agrarian community—the Guild of St. George—that privileged hand labor over mechanical labor, and that, in its statement of principles, required a basic commitment to respect life and beauty: "I will not kill nor hurt any living creature needlessly, nor destroy any beautiful thing, but will strive to save and comfort all gentle life, and guard and perfect all natural beauty, upon the earth" (vol. 28, p. 419). In his last years, Ruskin's impatience

with industrial pollution prompted frequent statements admonishing the nation and recurrent private lament. In 1878 he entered into an angry argument with the Corporation of Manchester, which was trying to turn the lake of Thirlmere into a reservoir. Elsewhere he mourned the loss of humbler natural sites that he had personally valued (see the elegy for Croxted Lane in *Fiction—Fair and Foul*, pt. 1 [1880]). Most dramatically, in his public lectures *The Storm-Cloud of the Nineteenth Century* (1884), he argued that a "plague wind" was infecting England (vol. 34, p. 31). That wind, he said, suggested an approaching environmental calamity born of divine displeasure. From many years of observation, Ruskin adduced evidence for the palsied behavior of nature: "blanched Sun,—blighted grass,—blinded man" (vol. 34, p. 40). He concluded that natural disorder confirmed moral gloom. His lectures, the most extreme development of Ruskin's reading of nature's lessons for human beings, offered prototypes of early-twenty-first-century rhetoric of environmental apocalypse.

Ruskin's legacy in environmental matters was significant in his own century. Alongside William Morris, he influenced the development of the arts and crafts movement, with its favoring of traditional industries and nonmechanical labor. His initiation of the Guild of St. George lay behind later back-to-the-land movements and socialist utopias (see, for instance, the work of Edward Carpenter). The development of the Garden City initiative, late Victorian campaigns for clean air, and the foundation of the National Trust owe inspiration to Ruskin's writings, which continue to be cited as protoenvironmentalist and prescient in its strong commitment to the organic harmony of living things.

Francis O'Gorman

RUSSIA AND EASTERN EUROPE

Environmental ethics in the Commonwealth of Independent States and East European countries was initially formed under the strong influence of Russian science, Russian culture, and, up to the early 1990s, Marxist ideology. For a variety of geographical, historical, and political reasons, Russia was the dominant intellectual center in Eurasia. Even after the 1990s, East European countries and the Commonwealth of Independent States remained under the influence of Russian high culture, which depends not only on the spread of the Russian language and the popularity of Russian literature and philosophy but also on the unprecedented development of theoretical and scientific thought in the Soviet Union in the twentieth century. Scientific schools, emanating from the Soviet Academy of Sciences or the leading universities of Russia, still function more or less successfully in all of these countries.

Russian scientists—among them Vladimir I. Vernadskii, Nikita N. Moiseev, Vladimir N. Sukachev, Nikolai V. Timofeev-Resovskii, and Alexander L. Yanshin—made fundamental contributions to the development of ecology in the twentieth century. Because of this strong tradition, the Soviet scholarly community was receptive to the ideas of environmental ethics developed by Albert Schweitzer and the Italian industrialist and economist Aurelio Peccei.

PHILOSOPHICAL UNDERSTANDING OF HUMAN INTERACTIONS WITH NATURE

During the Soviet period, ecological literature that analyzed the state of the environment paid special attention to the role of sociopolitical factors, which were considered primary for understanding and resolving emerging ecological problems. The view was that only in the capitalist world do ecological catastrophes arise.

Under socialism, the ecological relation between humans and nature was explored from the vantage point of dialectical materialism. According to this concept, the interaction between humans and nature is a natural historical process, the concrete contents and movement of which depend on the level of development of productive forces and on the class that controls the means of production. In other words, the relation between humans and nature is not constant and natural, but is determined by social factors. Humans are related to nature through practical activity and material production. This relation is one not of abstract observation of nature, but of interaction through labor and practical activity.

Under presocialist socioeconomic institutions, there is spontaneous interaction between society and the natural environment. Under socialism, however, society has transitioned from spontaneous interaction with nature to guiding nature and being responsible for its future course. The view was that real guidance of the interactions between society and nature is possible only with public ownership of the means of production, sociopolitical unity, and humane social relationships.

Initially, on the basis of these philosophical and methodological considerations, the Soviet socioecological literature even attempted to claim that there was no ecological crisis under socialism, since socialism engaged in planned, predictable development of the economy. Yet socialism needed more theoretical development, particularly for working out the practical, legal, socioeconomic mechanisms for harmonizing the interaction of society and nature. Unfortunately, this need was not fully understood and put into practice by the authorities of the Soviet Union and other socialist countries. Thus, under socialism, these counties were unable to resolve the contradictions inhering in interactions between nature and society, contradictions that increased with technological progress.

ENVIRONMENTAL PROBLEMS AND DISASTERS

The high concentration of industry in cities during the Soviet period degraded the environment around them and spawned a variety of health problems. No less than 10 percent of Russian cities have high levels of soil, air, and water pollution. Almost every city with a population of over 1 million people has ecological problems. Many of these and other environmental problems, as cataloged by William Carter and David Turnock (1993), are a legacy of the Soviet era. Areas of environmental degradation include the region around the Aral Sea (in Kazakhstan, Uzbekistan, and Tukmenistan), the former Semipalatinsk nuclear test site in Northern Kazakhstan, and the industrial zones of Donbass in Ukraine and of the Kola Peninsula and the South Urals in Russia.

During the period of glasnost in the 1980s, new nongovernmental organizations began engaging the state on environmental issues, but the collapse of the Soviet Union and other communist states and the economic crises that ensued effectively terminated these discussions. Since the early 1990s, clear improvement in the environmental situation has not occurred. This failure was a result in part of the transition to market economies, in which protection of the environment had low priority. While more progress was made in the relatively richer East European countries, several problems require urgent attention. These include uncontrolled management of dangerous waste, unreliable treatment of waste water, deterioration of air quality in highly populous urban and industrial areas, and contamination and damage to the soil by pesticides and overcultivation. In addition, multinational oil corporations have motivated Kazakhstan, Uzbekistan, and Azerbaijan to allow large-scale drilling in the shallow waters of the Caspian Sea, at the risk of destroying vulnerable ecosystems.

By far the worst environmental damage resulted from the accident at the Chernobyl nuclear power plant on April 26, 1986, when a breakdown of the fourth reactor resulted in the release of a large amount of radioactivity into the environment. The explosion released thirty to forty times the combined fallout from the atomic bombing of Hiroshima and Nagasaki. Belarus (the European part of the Russian Federation) and Ukraine suffered the most, with Belarus receiving about 60 percent of the fallout. A year after the disaster, the radiation across most of the European territory of the Soviet Union primarily involved long-lived cesium isotopes. In areas closer to the disaster, strontium-90, various isotopes of plutonium, and several other highly radioactive elements continue to pose hazards. By 2005, 56 direct deaths had occurred, and the expectation is that there will eventually be as many as 4,000 cancer deaths among the 600,000 most exposed and as many more among the 6 million people living nearby. Ten-year forecasts of the continuing pollution of European territories have been made. Most of the pollution will largely disappear between 2006 and 2016, but in the Bryansk region pollution will remain until 2092.

ADDRESSING ENVIRONMENTAL PROBLEMS

As of 2008, several groups are seeking to address these environmental problems. For example, the Regional Environmental Center for Central and Eastern Europe, which publishes the quarterly magazine *Green Horizon*, seeks to assist in solving environmental problems in this region by providing information on the environment, promoting public participation, and encouraging cooperation among environmental stakeholders.

Western countries eventually overcame their neglect of the environment. Several characteristics of nonsocialist societies played a role in that process. These characteristics include transparency, public availability of environmental information, the emergence of mass environmental movements, and advocacy by ecologically oriented political parties leading to the adoption of environmental laws. As a result, under constitutional states, environmental problems started to be resolved more effectively than under socialism because needed laws were rapidly adopted and enforced.

A NEW ENVIRONMENTAL ETHIC

Socioecological literature of the Soviet period included serious theoretical works arguing that contradictions in the interrelations between society and nature are inevitable quite apart from the socioeconomic structure of society. This argument was based on an analysis of how the system of society and nature functions under the laws of nature, particularly the conservation laws of physics and chemistry, which preclude the destruction of matter and energy. This literature concluded that contradictions are inevitable for such systems because a society cannot develop without using natural resources and producing

Brown Bear, Kamchatka, Russia. *The brown bear (*Ursus arctos*), shown here crossing a stream in the Valley of the Geysers, Kronotsky Zapovednik Reserve, is found in many parts of the world, but the species is most populous in Russia. Over the last century, habitat encroachment and hunting by humans has dramatically reduced the number of brown bears globally; in most populations they are considered endangered or threatened. Conservation efforts are fighting to increase the numbers of brown bears in Russia and elsewhere.* **IGOR SHPILENOK/NATUREPL.COM.**

waste and this reliance sooner or later leads to specific ecological collisions. In coming to these conclusions, the scientific literature, unlike the ideological literature, did not idealize Eastern socialist economies and did not bow before the received notion that the presocialist societies of the West would inevitably break down.

Environmental ethics in the Soviet philosophical literature was logically divided along the following perspectives toward nature: theoretical, practical, aesthetic, and ethical (Tugarinov 1978). The practical attitude toward nature focuses on processes that produce goods and services and enable humans to live. Through these processes, the human forces at work in society are revealed. These practical and material economic arrangements determine, in accord with dialectical materialism, the theoretical and ideological structures of society, including society's attitude toward nature

The aesthetic attitude toward nature can be seen in the human need to observe the beauty of natural phenomena and various landscapes, and to engage in artistic reflection on observable forms, such as space and light. Natural elements enrich figurative artistic exploration of reality. In turn, the aesthetic attitude toward nature contributes to the formation in mass consciousness of the idea of an empathetic approach toward nature.

In the second half of the twentieth century, the importance of an ethical attitude toward nature grew significantly. Inculcating a love of nature and the need to preserve plant and animal species and their habitats became one of the most important tasks of moral education. The point was not to resurrect animistic feelings, but to understand that the surrounding flora and fauna are necessary for humans (for both their physical existence and spiritual enrichment) and that some limits on the transformation of nature are needed even under conditions of socialism. Ethical indifference toward nature was to be replaced with a clear understanding that destruction of nature is immoral and intolerable. More and more people understand that nature is a support for

human life, a source of beauty, and the ground of an ultimate good. It thus became commonplace to include in the sphere of moral relationships some aspects of the relationship between humans and nature, along with traditional considerations of person-person and person-society relationships.

In the past, the specific content of these different human attitudes toward nature were considered to depend significantly on the socioeconomic structure of society and on the various social relations and value configurations that emerged in a given historical situation. Yet since the 1990s, through social connections, the surrounding environment has obtained universal significance for people, satisfying their different needs—from simple physical ones to spiritual ones. In Russia, East European countries, and the Commonwealth of Independent States, environmental ethics is now understood to depend on the formation of an environmental consciousness and an environmental culture, based on continuous environmental education and ecological enlightenment.

SUSTAINABLE DEVELOPMENT

Undoubtedly, the concept of sustainable development adopted by the 1992 U.N. Conference on Environment and Development (Rio de Janeiro) provided a new impulse for environmental ethics to go in that direction. In Russia, the concept of sustainable development reflects the increase of social, economic, and ecological problems on our planet, on the one hand, and also our overall level of scientific understanding of nature and society, on the other. The concept of sustainable development seems to be the point of convergence of several philosophical and sociological teachings and several theories in the natural sciences and mathematics.

Simply put, humankind has to transition to sustainable development for the survival of humanity and preservation of the biosphere—the thin sphere of life enveloping the geosphere. Needed is a transformation of all spheres of human activity in the direction of diminishing pressure on the biosphere. Without doubt, sustainable development should be characterized by economic effectiveness and social justice, as well as a general reduction of anthropogenic pressure on the biosphere.

The Russian approach to understanding ecological problems and sustainable development is connected with Vladimir I. Vernadskii's teachings about the biosphere and noosphere. The concept of a noosphere, a sphere of mind, reflects a belief in the power of reason and its unlimited creative capabilities. The notion was developed by the French scientists Edward Leroi and Pierre Teilhard de Chardin, as well as by Vernadskii, though their several ideas about the noosphere are significantly different from one another. According to Vernadskii, the epoch of the noosphere will be characterized by the following basic traits:

- Humankind settles the whole planet; connections between various peoples and countries intensify.
- The geological role of human activity prevails over natural geological processes taking place in the biosphere.
- The borders of the biosphere expand; humankind enters outer space.
- New sources of energy are found.
- People of all races and religions are discovered to be equal.
- The role of the masses in solving the problems of domestic and foreign policy grows.
- Wars are excluded from social life.
- The welfare of working people grows; a real opportunity emerges for the elimination of hunger, poverty, and disease.
- The original planetary biosphere is reasonably transformed to satisfy all the material and spiritual needs of a growing global population.
- Scientific thought and inquiry are liberated from the pressures of religion and politics, and state and society create conditions favorable to the realization of this intellectual freedom.

The philosophical connections between Vernadskii's vision and the later concept of sustainable development are striking. For instance, the concept of sustainable development means, among other things, a movement of humankind into the sphere of reason, where society and nature harmoniously interact with each other.

Since around 2005, there has been a generalization of the concept of sustainable development. Under this generalization, sustainable development is understood not simply as ecologically secure development, but also as stability in the social and political spheres of social life, based on respect for human rights, democratic principles, the rule of law, and norms of international law. Such sustainable development unites the environmental, economic, and sociopolitical domains into a single unified system. Moreover, it connects reason and morality. Historically, the achievements of reason, torn asunder from moral elements, have sometimes acquired a malevolent and antihuman character. To limit rational but inhumane social development, spiritual values and norms of morality are needed.

Transition to sustainable development means changing both the substance and form of the material and spiritual culture of civilization. This transition cannot be

achieved by means of conventional thinking or traditional ideas and values. It requires working out new scientific and philosophical approaches to complex problems, corresponding not only to postmodern reality but also to the prospects for civilization in the third millennium.

Realizing sustainable development that affirms the intrinsic value of nature and ethical attitudes toward it is of utmost importance. Former strategies, oriented only to economic development, need to be replaced with a strategy of integrating the human economy into the natural economy and patterning the design of artificial systems of energy production and agriculture on the model of ecosystems, in accord with the concept of sustainable development. The modern way of life, with values formed in the previous half millennium, needs to undergo radical changes in order to meet the challenges of the new millennium.

In Soviet and post-Soviet cultural literature, the ecology of the biosphere is basically treated as the new means of reconciling humans and nature on the basis of knowledge about and understanding of nature. By knowing the modalities, depth, and scale of interaction between humans and nature, biospheric ecology can play a significant role in the formation of environmental thinking, reorienting all spheres of human life toward solving environmental problems. The main paradigm of the Russian environmental outlook and the main thrust of biospheric ecology is understanding that people do not exist on the earth simply for themselves, that they also perform specific ecological functions. The most important characteristic of Eastern European environmental ethics is a rejection of naive anthropocentrism and a transition toward a system of beliefs built on biospheric centrism. Such an environmental ethics is the conceptual basis of a new biosphere-centered culture. By concentrating attention on the problems of the biosphere, biospheric environmental ethics creates the preconditions for actions oriented toward preserving and developing the well-being of humans and nature.

Like most environmental ethics, Eastern European environmental ethics cares about the natural conditions of existence of future generations. Orientation toward the future, which presupposes also caring about the present, distinguishes environmental ethics from traditional ethics.

Sustainable development can be understood as development that satisfies the needs of the present without endangering the ability of future generations to satisfy their own needs. This orientation can be considered the main ethical regulator of interaction between people and the natural environment. In place of anthropocentrism, there emerges a new approach to reality based on biospheric centrism. The biospheric approach introduces a fundamentally new perspective into the moral experience of humankind, hitherto based on a traditional dichotomy of good and evil. Vernadskii (1988) claims that ethics can be approached scientifically if it proceeds from knowledge of the biosphere. Environmental ethics demands that we act responsibly toward future generations when making decisions affecting the environment.

Post-Soviet environmental literature suggests that sustainable development is possible, not under conditions of socialism, but only under a biosphere-centered culture that reproduces through sustainable development. Hence, the notions of biosphere-centered culture and sustainable development reflect different aspects of the same process: harmonizing the relations between society and nature.

GLOBALIZATION

The post-Soviet environmental literature since around 2005 increasingly focuses on issues of globalization. As Vernadskii predicted, humankind lives in an era of the formation of a new world outlook, the basic content of which is, to a large extent, global. The complex, multifaceted process of globalization is defined by a number of factors, including integrative trends in the economic and political spheres, synthesis of the natural sciences and humanities to present an integrated picture of reality, and development of information and communication technologies so as to change not only the human way of life and perspective on the world but also human consciousness. The emerging danger posed by global climate change requires reconsidering the entire system of our basic social values (such as ethical norms, attitudes toward nature, and the character of production to satisfy human needs and wants).

In relation to controlling the processes of globalization for sustainable development, the premises and conditions of the formation of global consciousness become extremely topical. The contents of global consciousness should be determined less through broadening traditional perceptions and thought than through forming fundamentally new perspectives based on emerging ideas for global integration.

In each era, humankind, relying on the current level of knowledge in various fields, regulated to varying degrees its relations with the natural environment. At the beginning of the twenty-first century, however, we face the greatest challenge of our time, perhaps of all time: harmonizing the development of the socioeconomic sphere and the biosphere. The task is to realize an environmentally sound revolution in human lifestyles, to environmentalize the human way of living.

EDUCATION

Meeting this challenge is unthinkable without a corresponding transformation of social consciousness, without each individual understanding the meaning of the coming

changes. For this reason, the problems of education come to the foreground. Needed is a global change of orientation in educational systems toward the theory and practice of sustainable development. This transformation requires a search for forms and means of embedding environmental knowledge and imperatives into different levels of education.

In Russia, East European countries, and the Commonwealth of Independent States, a commonly accepted ideal is the need to deploy a multilevel system of environmental education that embraces all elements of preschool, primary, secondary, and higher education, as well as executive courses, retraining, and popularization of scientific knowledge. Such an education should be the main thrust for developing environmental consciousness and forming environmental responsibility. An environmental education is a precondition for the emergence of an environmental culture and for society's transition to sustainable development.

In Russia, environmental education should be a top priority in that country because one can especially feel a strong dependence on the material and spiritual forces of nature. Russia is not only the biggest country in the world and the richest country in terms of energy resources; it is also the coldest country, where permafrost covers more than half of its territory and an extreme natural environment dominates. Fortunately, in Russia the birthrate has been dropping catastrophically in recent years, thus relieving human pressure on the biosphere.

Education for sustainable development is integrative and multifaceted. It is directed toward solving a number of interrelated problems and thus cannot be reduced to ecological education alone. It must define strategic goals and develop the spiritual, intellectual, scientific, and technological means for achieving them. As is evident, education for sustainable development should ascend to the level of an integrated environmental education.

S

SALMON RESTORATION

As anadromous fish dependent on the oceans for feeding and fresh water for spawning, salmon are vulnerable to a wide range of human activities. Pacific salmon were indigenous to the north Pacific in coastal regions and rivers from Japan, through Russia, and across the Pacific from Alaska south to California. Atlantic Salmon on the eastern coast of North America were indigenous from Long Island through the Atlantic Provinces of Canada to Greenland, Iceland, Scandinavia, the British Isles, western Russia and south in Europe as far as Portugal. In both the Atlantic and Pacific these geographic ranges are as of 2008 significantly reduced. Historically and ecologically, the long and precipitous decline of wild salmon stocks in the United States is traceable to a constellation of factors, the most important of which are habitat destruction and over-harvesting.

Both of these factors prevail in direct proportion to increased human population density along the coastal waterways and inland river basins where salmon migrated and spawned. On the East Coast of the United States, primarily Maine, the situation of Atlantic salmon is so dire that restoration of the species is highly dubious. According to the National Oceanic and Atmospheric Administration (NOAA) Fisheries and the U.S. Fish and Wildlife Service, "The number of wild Atlantic salmon in Maine rivers is at an all-time low, placing them in danger of extinction" (NOAA Fisheries 2007, p. 1).

On the West Coast of the United States, the status of salmon—which includes Chinook (King), Coho (Sliver), Sockeye, Chum, and Pink varieties—is much more variegated, depending on the region. Salmon stocks in Alaska, for example, are usually more stable and healthy, whereas salmon stocks in California are seriously threatened or endangered. A classic example of the complex and often contentious nature of salmon recovery is the early 2000s effort to restore salmon in the Columbia River Basin, which, according to some estimates, once had the largest number of returning salmon of any river in North America—between 10 and 15 million.

Salmon restoration as a formal strategic attempt to recover salmon on the West Coast began in earnest during the 1990s, when a number of wild seasonal spawning runs of salmon, identified as evolutionarily significant units (ESUs), were rapidly listed as either threatened or endangered under the federal Endangered Species Act (1973). An important tipping point was a report issued in 1991 by Nehlsen, Williams, and Lichatowich called "Pacific Salmon at the Crossroads: Stocks at Risk from California, Oregon, Idaho, and Washington." Their research showed that of 214 wild runs of salmon, steelhead, and sea-run cutthroat trout, 101 were in extreme risk of extinction, 58 at moderate risk, and 54 of concern. They identified 106 runs that had already become extinct. It was with this background that the National Marine Fisheries Service (later known as NOAA Fisheries) was mandated by the Endangered Species Act to develop salmon and steelhead recovery (or restoration) plans.

Salmon restoration encompasses a dizzying array of stakeholder groups that can add up to a bureaucratic and policy conundrum (Lackey, Lach, and Duncan 2006; Kolmes and Butkus 2006). Although it would be unwieldy to list all those involved, a short list includes the following: federal agencies, state governments, regional and municipal governments, Native American tribes, commercial and

sport fishing associations, the hydroelectric power industry, the Northwest Power and Conservation Council, several environmentally oriented NGOs in favor of salmon recovery, and a number of industry and agriculture (e.g., irrigation) NGOs who favor the status quo. The primary entity responsible for creating salmon restoration plans and mediating the conflicts among various parties is NOAA Fisheries. The recovery process, however, is not beyond political maneuvering at the very highest levels of the federal government.

The contentious nature of salmon recovery was highlighted by the 2002 struggle in the Klamath River Basin, where competition over water between farmers and fishers (commercial and tribal) took a toll not only on community good will but also a significant number of adult salmon. In September 2002, nearly 34,000 adult salmon returning to spawn were killed when low water in the Klamath River created lethally warm conditions, causing the fish to succumb to fungal infection. The scenario in the Klamath Basin is an example of the clash of social values over salmon restoration and a notable case study in environmental ethics. It is also an example of how the abandonment of good science and the mismanagement of water resources in the Klamath River led to a conflict that nearly erupted into violence.

NOAA restoration plans have incorporated a vision of salmon recovery (reducing the risk of extinction for any population to 5% over the next hundred years) that is considered by some to be a narrow interpretation of the term *recovery*. Focused on preventing extinction and achieving the delisting of salmon as an endangered species, NOAA's approach to salmon restoration appears incongruous with the more generous vision of what "broad-sense recovery" means to most people. The shifting biological opinions and restoration plans produced by NOAA, struck down one after another by federal courts as inadequate, have raised questions about the capacity of NOAA Fisheries to carry out reliable salmon restoration planning. The attempt of NOAA Fisheries to count industrially produced hatchery fish, known to be genetically deficient and lacking the local evolutionary adaptations vital to population viability, has intensified the conflict between NOAA Fisheries on the one hand and environmental groups and locally based salmon-restoration efforts on the other (Meyers et al. 2004). In the view of some environmental activists, NOAA Fisheries has taken a view of salmon-recovery planning metrics that focuses excessively on fish population numbers to the exclusion of habitat issues or fish characteristics. Seeking to count hatchery fish to achieve stability of fish numbers, it has eschewed critical habitat requirements—and the attendant political implications for human land-use practices—that are essential for long-term salmon survival.

The issue of salmon restoration can also be addressed from the environmental-ethical perspective expressed in this question: Do human beings have a moral obligation to prevent the extinction of salmon and to commit time, money, and energy to the effort to restore the species? The answer to this question depends in large part on how one values salmon and salmon restoration. At one extreme there are those who do not value salmon at all and see salmon restoration as a major hindrance to the economic values of the industrial economy. In the middle—where the majority of people in the Northwest reside, based on opinion polls—are those who are in favor of salmon restoration and hold a variety of human values for salmon, including aesthetic, recreational, nutritional, culinary, cultural, scientific and spiritual At the other end of the spectrum are those, such as tribal peoples, who, for cultural and religious purposes, see salmon as sacred and others who believe salmon have intrinsic value apart from their utility to humans.

An interesting layer of analysis was added to the ethical assessment of salmon when, in 2001, the Roman Catholic bishops within the Columbia River Basin issued a pastoral letter entitled "The Columbia River Watershed: Caring for Creation and the Common Good." This international document surveyed the problems of the basin and provided a theological-ethical foundation for ecological and social responsibility. Grounding this idea in the concept of biblical stewardship and concern for the common good, the bishops of the region sought to create an ethical framework for action by offering ten ethical norms called "Considerations for Community Caretaking." On one of these principles, "Conserve and Protect Species of Wildlife," a critical norm for salmon restoration, the bishops state:

> The presence and health of wildlife is in many ways a sign of the health of our ecosystems, of the well-being of the people and communities dependent on the ecosystems for their livelihood, and our respect for God's creatures and creation. The presence and health of salmon and other species in the Columbia-Snake system, in particular, is a sign of the health of the entire region.

The ethical imperative to restore wild salmon is directly linked—scientifically, philosophically, and theologically—to the value of a species' life other than our own and to the generative, creative evolutionary process that produced it. The primary issue is that anthropogenic extinction inevitably curtails the evolutionary process that produces life. In the view of Holmes Rolston III, "Every extinction is an incremental decay in this stopping of the flow of life, no small thing. Every extinction is a kind of superkilling. It kills forms (species), beyond individuals. It kills 'essences' beyond 'existences,' the 'soul' as well as

the 'body'" (1988, p. 144). Accordingly, the ethical duty to preserve and restore a species is, in Rolston's words, "a categorical imperative to living categories." In other words, the obligation to recover salmon from extinction is a moral duty without exception.

Prospects for the restoration of Atlantic salmon on the East Coast of the United States are bleak. Pacific salmon, however, have better prospects because of population density and the extent of commercial development in their historic breeding range. There are runs in California (e.g., the longstanding decline of the Sacramento River winter run of Chinook) where restoration is probably not realistic. The Sacramento River spring Chinook run suffered a dramatic population crash in 2008. Other runs of Pacific salmon, from Oregon to Alaska, can be restored or preserved in healthy condition if human activities detrimental to salmon survival are sharply curtailed to enhance water quality and reduce habitat alterations, riparian deforestation, genetic dilution of previously adaptive populations caused by hatcheries, and overfishing. If human beings in salmon-bearing areas are willing to embrace and implement an ethic of sustainability—a balance between the needs of humans and the legitimate ecosystem needs of wild salmon—then there are good prospects for restoration in areas where the habitat remains viable.

SARO-WIWA, KEN
1941–1995

Kenule Beeson Saro-Wiwa, best known as Ken Saro-Wiwa, was born in Bori, an Ogoni village, on October 10, 1941. The Ogoni are an indigenous community of about 500,000 in the oil-rich Niger Delta of southeast Nigeria. He attended Government College, Umuahia, and later the University of Ibadan in western Nigeria. Saro-Wiwa became the community's spokesman in its battle against the environmental devastation caused by the long-time oil exploration and extraction activities of foreign oil companies, especially Shell.

Saro-Wiwa was a graduate assistant in English at Ibadan when a national political crisis broke out in 1966 in the form of a spate of coups d'état that pitted eastern and northern Nigerians against each other. As an easterner, Saro-Wiwa was obliged to leave Ibadan. He took up another assistantship at the University of Nigeria, Nsukka. When civil war erupted in 1967 and the Igbo declared the Republic of Biafra, he returned to his Ogoni homeland. There he taught secondary school, became a businessman, and campaigned for a federal Nigeria. In September 1967 he joined the University of Lagos as a teaching assistant.

In November 1967, at the age of twenty-six, Saro-Wiwa was appointed administrator for Bonny Island in Rivers State. After six months at that job, he returned to Lagos but soon went back to Rivers as commissioner, holding various portfolios for six years.

From 1973 until his death, Saro-Wiwa gradually moved from private life into the eye of a public storm. An Ogoni nationalist, Saro-Wiwa explained his outlook in his

prison diary: "My worry about the Ogoni has been an article of faith, conceived of in primary school, nurtured through secondary school, actualized in the Nigerian civil war in 1967–70 and during my tenure as member of the Rivers State Executive Council, 1968–73" (1996, p. 75). From his youth onward, Saro-Wiwa had witnessed his people's plight as an oil-rich but exploited minority. He became committed as a leader of their struggle for survival against the exploitation of their natural resources and the destruction of their environment, with all the economic benefits accruing to the foreign oil companies. In 1977 he failed in his attempt to win election as a member of the Constituent Assembly that had been mandated by the Babangida military regime to fashion a new constitution that, in Saro-Wiwa's opinion, established an even stronger central government that further marginalized the minorities.

His writing output, both creative and critical, expanded as he became more and more engrossed in the Ogoni struggle. Among his over twenty books are: *Sozaboy* (1985); *Songs in a Time of War* (1985); *Prisoners of Jebs* (1988), and *Genocide in Nigeria* (1992). Penguin published his detention diary, *A Month and a Day*, in 1995. The Ogoni's oil, discovered in the 1950s, fast became a curse: Incidents of oil spillage, consistent gas flaring, and ecological devastation became the daily travails of the Ogoni fishing community. Saro-Wiwa believed in the political and economic autonomy of every nationality in the Nigerian federation, particularly the minorities such as the Ogoni, which were powerless in an overcentralized system controlled by the three major ethnic groups (Fulani-Hausa, Igbo, and Yoruba). It is therefore significant that Saro-Wiwa collaborated with other Ogoni leaders in 1990 to found the Movement for the Survival of the Ogoni People (MOSOP) that would soon become a major platform for his nationalist and environmental activities. As he traveled internationally to promote the movement and became popular and controversial, he drew the ire of both Ogoni elders and the military government.

Accusations of violence were rejected by Saro-Wiwa and his followers. He always preached nonviolence and claimed the late Martin Luther King Jr. as his model of activism even though King fought for inclusion and integration whereas Saro-Wiwa was an avowed separatist who sought "to establish a government of Ogoni people by Ogoni for Ogoni people in Ogoni within a confederal Nigeria" (Saro-Wiwa 1996, p. 111).

The Royal Dutch/Shell oil company was the main target of Ogoni protest; these protests led to the company's decision to abandon exploration and exploitation in the area. Significantly, the Nigerian government maintained that Shell was "a partner in progress" despite the environmental degradation caused by oil spillage and gas flaring, conditions that adversely affected the health of nearby residents. The Ogoni composed a song that featured the lyric, "The flames of Shell are hell, we bask beneath their light." The international community's failure to respond to issues alien to their economic interests did not help the Ogoni cause. For instance, the United States, Nigeria's main oil client, did nothing to interfere with Shell's oil extraction. Although Shell got away with a slap on the wrist, with official warnings and token fines, for its destructive actions in Nigeria, similar actions in Europe and North America were being heavily punished.

Protester in South Africa Recalls Ken Saro-Wiwa's Struggle for Justice. *Protesters in Johannesburg call for democracy in Nigeria, the native country of Ogoni activist Saro-Wiwa. Saro-Wiwa spoke out against human rights and environmental abuses inflicted on his people, most notably by Shell Oil Company. Saro-Wiwa was executed by the Nigerian military in 1995, along with eight other activists.* **AP IMAGES.**

On January 4, 1993, Saro-Wiwa organized Ogoni Day, announcing a bill of rights calling for the autonomy of the Ogoni people within a Nigerian confederation. Authored by Saro-Wiwa, the bill had been signed in 1990 by representatives of five of the six Ogoni kingdoms. In partial response the military began a "pacification" of the Ogoni that consisted of the repression or elimination of any dissidents. When four reactionary Ogoni leaders were murdered in May 21, 1994, the government fingered Saro-Wiwa as the hidden hand behind the act. He was arrested, with eight other associates, on May 22, 1994.

Despite the indifference of the United States government, Saro-Wiwa had many supporters among European

and North American intellectuals and activists. The British author William Boyd advised him to contact Amnesty International and Greenpeace. Interaction with these organizations influenced him into drafting an addendum to the bill of rights titled "An Appeal to the International Community" and the establishment of the Ethnic Minority Rights Organization of Africa in 1993. Saro-Wiwa met with many nongovernmental organizations and filmmakers such as Kay Bishop who made the Ogoni documentary *The Heat of the Moment* (1992). Despite these gestures of support, on October 21, 1995, a special tribunal condemned Saro-Wiwa and his comrades to death by hanging. Notwithstanding calls from home and abroad for leniency, all were hanged on November 10, 1995.

Saro-Wiwa was nominated for the 1995 Nobel Peace Prize. In that year he won the Right Livelihood Award, known as the Alternative Nobel Prize. His exclusivist stance perhaps diminished the success of the Ogoni struggle. Perhaps Saro-Wiwa would have achieved more if he had championed the environmentalist and anti-exploitation cause on behalf of all or several Niger Delta groups. Nonetheless, his commitment to Ogoni rights and sovereignty as a minority, and to the well-being of the environment, still serves as a benchmark for activism in Nigeria. Since his execution, other groups, such as Movement for the Emancipation of the Niger Delta, have sprung up. Regarding the protection of the environment, one is tempted to believe that Saro-Wiwa's concern was more in terms of the particularity of the Ogoni, and less of the generality of nature's ecological well-being. Outside the Ogoni struggle, he would probably not have taken much interest in the environment.

SCANDINAVIA

This entry contains the following:

I. DENMARK AND SWEDEN

Scandinavia is a region of Northern Europe defined by geography, history, and language as including the countries of the Scandinavian Peninsula—Norway and Sweden—as well as Denmark. Some authorities advocate the inclusion of Finland because of economic and cultural connections, and Iceland and the Faroe Islands because their populations speak Northern European tongues closely related to Swedish and Norwegian. The region is often associated with nature-friendly attitudes and strong traditions of nature management, outdoor life, and environmental education. Danish and Swedish environmentalism share an ecological worldview, a critical view of technology, and a call for participatory democracy in environmental policy making.

Danish environmentalism, which encompasses a cosmological dimension, has emerged from a political culture of participatory democracy and a decentralized, small-scale economy. It speaks to civil society and encourages personal commitment to environmental goals. Swedish environmentalism is influenced by a centralized state administration emphasizing systemic solutions to environmental and developmental challenges.

Environmental controversies and debates in Denmark and Sweden have focused on genetically modified organisms (GMOs), animal welfare, the use and storage of pesticides and herbicides in the chemical and transport industry, the building of a fixed link across the Öresund (the strait that separates the Danish island Zealand from the southern Swedish province of Scania), the radioactive fallout from the nuclear accident in Chernobyl in 1985, and the question of environmentally friendly energy and nuclear power.

THE NUCLEAR ENERGY CONTROVERSY

Strong movements of opposition to nuclear energy have arisen in both Denmark and Sweden, but they took different forms in each country because of the countries' differing political cultures. Swedish antinuclear environmentalism has been mostly assimilated into previously existing governmental and nongovernmental institutions, although it has generated some new organizations. In 1980 the national nuclear-energy referendum resulted in the two more positive lines defeating the anti-nuclear line. Three months after the referendum the Swedish Parliament decided to phase out all nuclear reactors before the end of 2010. Many radical antinuclear activists considered this measure a setback because of its extended time frame. The antinuclear movement was scattered, and the issue was rapidly further institutionalized with the formation of the Swedish Green Party in 1981.

In Denmark the antinuclear movement engaged in critical debates with the political establishment, critical scientists, and journalists. As a result of these joint discussions, in the 1980s the Danish government repudiated nuclear energy, a decision made in a context of a small-scale, decentralized economy that aimed to develop alternative energy sources through increased research, local developments, and commercial incentives. The differences between Danish and Swedish environmentalism can be traced to the two countries' contrasting traditions of environmental law, policy making, environmental research, and environmental ethics and philosophy.

THE LEGAL AND POLICY DIMENSIONS OF SWEDISH AND DANISH ENVIRONMENTALISM

Allemansrätten (the right of public access) is a unique Scandinavan and Swedish regulation that protects the public's right to move freely in nature. This right also includes a responsibility not to destroy and disturb the environment. This is an example of how Swedish representative democracy, with its top-down institutionalized culture of environmental politics, governs public access to land.

In Denmark the culture of participatory democracy has engendered dialogues between the political establishment and the environmental movement. One important result of these dialogues has been the establishment of consensus conferencing that seeks to include the public in decisions concerning the environment and development issues. In 1986 one of the world's most rigorous precautionary laws on genetically modified organisms was passed as a result of this public-consultation procedure. In the late 1990s NGOs and the public argued that the issue of commercialization of GMO crops implied that precautionary principles should include ethics and value judgments. On the other hand, the experts and the industry continued to treat risk in a scientific and physical sense. Thus the issue of commercialization of GMO crops challenged this consensus.

In Sweden, because of the rapid incorporation of environmentalism into parliament (such as the Centre Party), administration (such as the Environmental Protection Board [1967]), and nongovernmental organizations (such as the Swedish Society for Nature Conservation) in the 1960s and 1970s, Swedish environmental policy making is largely the result of parliamentary work in which staff members from NGOs often serve as expert consultants. This process has resulted in predominantly large-scale solutions to environmental problems, including the incorporation of environmental concerns into the existing economic and corporate culture.

In Denmark, as previously noted, environmentalism has not been as easily channeled into official governmental bodies. Instead, the country's heritage of citizen participation and cooperation has played a vital role in creating alternative ways of enhancing public environmental awareness. The grass-roots movement NOAH, founded in 1969, refers to "the first environmental activist who fought for the species" (Jamison et al. 1990, p. 120). NOAH has played a significant role in discussions about alternative technologies. NOAH was formed by environmental activist students who dramatically revolted against NOA (a natural history society at the University of Copenhagen) at a NOA annual seminar in 1969.

Educational institutions have played an important role in the development of environmental awareness in both Sweden and Denmark. As far back as 1940, Elisabeth Tamm (1880–1958) and Elin Wägner (1882–1949) argued for the importance of integrating environmental and development concerns with education and women's emancipation—an argument that predates concepts such as sustainable development and education for sustainable development by thirty to fifty years.

The Swedish school system has long been responsible for instilling social values and instigating social change. The guidelines and regulations put forward by the United Nations Educational, Scientific and Cultural Organization's (UNESCO) Decade of Education for Sustainable Development (DESD) are, for example, implemented at all levels of the Swedish educational system, emphasizing critical reflection, pluralism, and democracy.

The People's High Schools have promoted the development of environmental activism and ecological awareness in the rural population of Denmark. The minister, poet, and educator N. F. S Gruntwig (1783–1872) is considered to be the father of these schools, which became arenas for alternative-technology workshops and

the promotion of alternative ecological lifestyles in the 1970s and 1980s. Like the Danish People's High Schools of the 1980s, the Swedish implementation of the United Nations' Education for Sustainable Development (ESD) since 2000 has gone beyond traditional pedagogy to teach values and critical reflection

ENVIRONMENTAL RESEARCH AND PHILOSOPHY

The largest and most ambitious environmental research program in the humanities in Scandinavia, Man and Nature (Menneske og nature) (1992–1997), was based in Denmark at Odense University. In Sweden the best-known program is Roads to Sustainable Development (1996–2002) (Vägar till uthållig utveckling-beteenden, organisationer, strukturer).

The Swedish and Danish natural environments have influenced both countries' environmental research and philosophy. The lack of wildlife in mainland Denmark, the fact that Denmark is densely populated, and Denmark's history of decentralized and small-scale economy has inspired experimental and pragmatic environmental research and philosophy. This pragmatic take on nonhuman nature includes the view of nonhuman nature as a workshop. This view, in contrast to the Swedish theoretical view, was typical of Tycho Brahe (1546–1601) and Hans Christian Ørsted (1777–1851), who combined romantic and utilitarian views of nonhuman nature in his research.

In Sweden the heritage of Carl Linnaeus's (1707–1778) theoretical classifications approach to nonhuman nature, along with the need to understand and manage large areas of wilderness, has given birth to an almost imperialistic relationship to nonhuman nature. Nevertheless, empirical studies of Swedes' views of nonhuman nature reveal strongly nonanthropocentric, biocentric, and ecocentric attitudes.

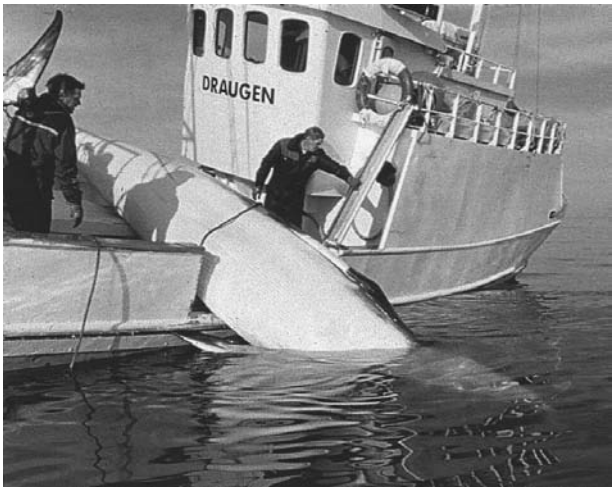
II. NORWAY

In Scandinavia the ideas of ecophilosophy, ecosophy, and ecopolitics have been a staple of debates on issues related to environmental ethics. Norway has been a hotbed of these ecologically informed philosophies, which offer unique perspectives on living in harmony with the environment. Key Norwegian thinkers include the coauthor of *The Limits to Growth* (1972), Jørgen Randers; the founder of Deep Ecology, Arne Naess; the chair of the World Commission on Environment and Development, Gro Harlem Brundtland; the politician and diplomat Rolf Edberg (1912–1997); and the peace researcher Johan Galtung.

The development of environmental ethics and philosophy gained real momentum in Scandinavia only after the 1960s. It was environmental concerns that arose abroad that triggered Norwegians into action and reflection. Rachel Carson's famous warning against pesticides in *Silent Spring* (1962) was immediately translated into key Scandinavian languages, and it inspired many people to adopt an ecological perspective. Equally important were the environmental writings of Lynn Townsend White Jr. (1907–1987) and Jacques Yves Cousteau (1910–1997), and the reflections on the technological



Whalers off the Coast of Norway, 1999. *Whale blubber was once a hot commodity in Norway, used in a wide range of products. Today the price is so low that even hunters believe its not worth the cost of hauling to land. Environmentalists around the world criticize the whaling practice for violating animal rights; Norway defends it as being sustainable.* **AP IMAGES.**

standardization of human life and nature by the Finnish philosopher George Henrik von Wright (1916–2003).

Scholars active in the International Biological Program (IBP; an effort, from 1964 to 1974, to coordinate large-scale ecological and environmental studies) mobilized a series of students and philosophers throughout Scandinavia to rethink the human condition in the natural world. This program, initiated by members of the International Union of Biological Sciences, focused mainly on problems related to food production and management of natural resources in view of a rapidly increasing human population and widespread malnutrition in the world. In Scandinavia the program was active between the mid-1960s and the mid-1970s, and fully in effect between 1967 and 1972. The managerial benefits of ecological research were, at least initially, stressed in all the Scandinavian countries. The managerial perspective gave way to a biocentrism that accorded intrinsic value to the environment as a whole. The ecologists who dominated the program pledged to deliver scientific and philosophical methods that could generate useful knowledge about the consequences of various modes of land use. Most of their research sought to achieve an energy balance between species, as articulated by the American ecologist Eugene P. Odum (1913–2002). This methodology assumed the desirability of a steady-state economy of human beings that would be in balance with steady-state economy of nature.

ECOPOLITICS VS. ANIMAL RIGHTS

The hegemony of the ecological approach may explain why the protection of individual animals failed to capture public attention in Norway. The few vocal defenders of both animal liberation and animal rights have not been successful in translating philosophical points into political or legal achievements. A case in point is the issue of whaling, which is defended by Norwegian politicians, scientists, and environmental philosophers alike from an ecological point of view. The Norwegians have only been hunting mink whale, which, according to Norwegian marine ecologists, are not endangered. Despite criticisms from environmentalists around the world who more often than not focus on animal liberation or rights, Norwegian environmentalists thus tend to defend whaling as sustainable.

Many of the scientists involved in IBP were deeply concerned about environmental problems. For example, the Norwegian ecologist Ivar Mysterud argued that politics should be put on a secure ecological footing, and in 1970 he suggested the term *ecopolitics* to demarcate managerial environmentalism from an approach to politics based on the science of ecology. The term was quickly adopted not only by fellow ecologists but also by many scholars, activists, and students who questioned the practices of technocracy and industrialism. Much of this criticism had, since the mid-1960s, been informed by populist agrarian socialism, which persisted under the new label ecopolitics from 1970 onward.

Ecopolitics aims at developing a steady-state social economy that would mirror the steady-state balance of the economy of nature. One of many students inspired by steady-state reasoning was Nils Christian Stenseth, who later became a key figure in international ecological research. His first article, published at the age of twenty-three, was about ecopolitics. In it he argued that "all biologists should work for a *steady-state society* in place of the *growth society*," and one should limit the human population growth to zero (1972, p. 118). Ecological modeling represented the way forward, for simulation models could determine exactly when and how to achieve a steady state.

Ecologists began to arrange seminars and various outreach activities to engage scholars in the political and social sciences and philosophy. As a result, the environmental debates in Scandinavia were often framed in terms of ecological methodologies and perspectives. In Sweden, for example, the politician and diplomat Rolf Edberg wrote several popular books about the need to take care of the environment. He described the need to achieve a more harmonious relationship to nature through the science of ecology.

Beginning in the late 1960s, there was a growing concern in Sweden about the effect of airborne industrial pollution originating elsewhere in Europe on the nation's forest industry, a topic brought to international attention

at the United Nations Conference on the Human Environment that took place in Stockholm in June 1972. At the heart of the Swedish agenda was not only raising international awareness but also presenting analytical tools that could address environmental issues. One such tool was socioeconomics, an academic field with strong intellectual ties to the socialist-inspired economies of all the Scandinavian countries.

ECOPHILOSOPHY

In Norway many philosophers were impressed with the ecologists, and they would attend their lectures and participate in their seminars. The Norwegian philosopher Sigmund Kvaløy organized a Coworking Group for the Protection of Nature and the Environment inspired by the ecologists. Those with a philosophical bent met in the Ecophilosophy Group, a subsection of this loose association. Kvaløy was granted a four-year Ph.D. scholarship in philosophy starting in 1967, which he used to explore ecological thinking. He had been Arne Naess's student and assistant since 1961. In 1969 he took over Naess's introductory seminar to epistemology, "Nature and Humans," and quickly turned it into a workshop for his group's work in "ecophilosophy" (a word Kvaløy coined).

Kvaløy's students and followers were fond of quoting Karl Marx's famous saying, "The philosophers have only interpreted the world in various ways; the point, however, is to change it." Turning words into action, the Coworking Group became an effective, hard-hitting student association that targeted hydropower developments. Most dramatic was their attempt to save the Mardøla River, which included Norway's highest waterfall, during the summer of 1970. Naess joined the Mardøla demonstration, and he decided afterward to resign his professorship so that he could devote himself fully to the environmental cause.

At the same time Naess started to attend his own "Nature and Humans" seminar, where Kvaløy was now in charge. Apparently, Naess was one of the few who took notes, and in the spring of 1971 he transformed them into a lecture series titled "Ecology and Philosophy." In these talks he introduced, for the first time, his

> ecosophy ... as a type of philosophy that takes its point of departure from an identification with all life in this life-giving environment. It establishes in a way a classless society within the entire biosphere, a democracy in which we can talk about justice not only for humans but also for animals, plants, and minerals. And life will not be conceived as an antagonism unto death but an interaction with surroundings, a life-giving environment. This represents a very strong emphasis on everything hanging together and emphasizes that we are only *fragments*—not even parts. (Naess 1971, p. 54)

ECOSOPHY

The Mardøla experience and the discussions at the "Nature and Humans" seminar radicalized the thinking of Kvaløy, the charismatic leader. After the Mardøla experience he adopted from ecology the idea that a complex ecosystem is more robust than a simple one in the face of environmental changes. Inspired by Herbert Marcuse, he argued that a complex human society would have a better chance of surviving the environmental crisis than one based on the "one-dimensional man" of industrial society.

Many of the ecophilosophers, including Naess and Kvaløy, were active members of the Norwegian Alpine Club, an organization devoted to technical climbing. Among their many activities, they made several visits to the high mountains of Pakistan. It was during a trip in 1964 that Naess first formulated what later became known as the ecosophy formula. He explained his "thriving" in Pakistan's mountains as a mixture of pain and excitement in the following mathematical terms: $T = G^2/(L_S + Å_s)$. In this equation T, *trivsel,* (thriving) equals G^2, *glød*, (excitement squared) divided by L_S, *legemlige smerter*, (bodily pains) plus $Å_S$, *åndelige smerter* (spiritual pains). This formula would later serve as a key explanation of the meaning of self-realization in Naess's "Ecosophy T," with the T standing for "thriving." The "T" could also be short for Tvergastein, the name of Naess's cottage, or also "Tolkning" (interpretation) as this was important to his early philosophy. There is, however, only circumstantial evidence for these readings.

Equally important to his ecosophy was Mohandas Gandhi's (1869–1948) teaching of nonviolence, which came to the forefront of Naess's thinking after his first visit to Pakistan in 1950. Back in Oslo he gave a lecture series about Gandhi's political ethics that resulted in a book he coauthored with the young sociologist Johan Galtung that was published in 1955. In 1960 Naess followed up with a popular version of this work, which was translated as *Gandhi and the Nuclear Age* in 1965. Here he argued that people from the Europe and North America had much to learn from Gandhi given the threat of nuclear Armageddon.

DEEP ECOLOGY

Naess introduced the concept of Deep Ecology in a paper at the World Future Research Conference in Bucharest in early September 1972. The conference was organized by the World Futures Studies Federation. What dominated future studies in 1972 was *The Limits to Growth* report for the Club of Rome written, among others, by the twenty-seven-year-old Norwegian solid-state physicist Jørgen Randers. At the time Randers was entirely unknown. It was therefore a shock to Norwegian environmentalists to see him rise to world fame through a

report that came to dominate environmental debate at the United Nations' conference in Stockholm. Though *The Limits to Growth* predicted that there would be limits to natural resources, it did not predict limits to existing political systems. The MIT group behind the report was, in this respect, part of a larger trend of environmentalists looking for solutions to ecological problems within established social structures.

For Galtung and Naess the time was ripe in Bucharest to hit back at what they saw as a "shallow" technocratic analysis of the environmental situation. Galtung spoke first with his paper "*The Limits to Growth* and Class Politics" (1973), a head-on attack on the lack of social analysis in the report. When it was Naess's turn to mount the rostrum in Bucharest, he, too, took an anti-class posture in presenting "The Shallow and the Deep Ecology Movement" in Norway. Upon returning to Oslo Naess used his notes to compile a summary which he published as "The Shallow and the Deep, Long-Range Ecology Movements" in 1973.

Ironically, the long-range ecology movement Naess spoke of faded upon his return to Oslo, as the Coworking Group for the Protection of Nature and the Environment was infiltrated and taken over by Marxist-Leninists. The group dissolved in 1973 after a period of internal cleansings and futile debates about the value of democracy. Its last unified stand came with the national referendum on membership in the European Community at the end of September 1972. The group was decisively opposed to joining, arguing that "this industrial-serving mega-society seeks to break apart the established *diversity* of sturdy self-governed and heterogeneously, traditional-colored local communities and replace them with a uniform system of government that presupposes uniform social units and a uniform culture: a simplification that increases vulnerability, according to the science of ecology" (Samarbeidsgruppa 1972, p. 91). They made their case: Norway voted against EU membership but could not decide on what to do next. As a result, the ecophilosophers split into socialist and ecological wings. Kvaløy and Naess regretted this leftward turn in the politics of ecology because it undermined the broad science-based environmentalism they sought to mobilize. They subsequently continued with their activities outside the academic realm in various environmental organizations where they, among other things, mobilized people to save the Alta River in the north of Norway.

GRO HARLEM BRUNDTLAND

When the young and politically inexperienced feminist Gro Harlem Brundtland became minister of the environment in 1974, she faced the ecophilosophers in various heated debates and rough conflicts. They used every opportunity to show that the ecological steady-state society was not an herbal-tea party but a revolutionary break with industrial growth. As a medical doctor, she took a strictly anthropocentric stand against them and the ecologists claiming to speak on behalf of nature, arguing in favor of bureaucratic rules and democratic procedures instituted by humans to the benefit of humans and especially the working class she represented as the head of the Labour Party. In offering resistance to her views, both the ecophilosophers and the ecologists forced Brundtland to reflect more deeply on social aspects of environmental affairs, as she later did in *Our Common Future* (1987).

CONCLUSION

Norwegian ecologists' and environmental activists' concerns for the environmental future mobilized a series of students and philosophers to rethink the human condition in the natural world. Their innovative thinking about ecophilosophy, ecosophy, and eco-politics became part of the international debate.

Peder Anker

SCHUMACHER, ERNST FRIEDRICH
1911–1977

Ernst Friedrich Schumacher was an economist, policy adviser, and essayist who was born in Bonn, Germany, on August 16, 1911. His most famous work, *Small Is Beautiful* (1973), sold millions of copies and helped spark the "intermediate" or "appropriate technology" movement. Schumacher died in Switzerland on September 4, 1977.

EDUCATION AND EARLY WORK

E. F. Schumacher studied economics from an early age, eventually becoming a Rhodes Scholar, and traveled to England to study at New College, Oxford. Throughout the late 1920s and early 1930s Schumacher's life and work were overshadowed by the struggles in his Germany to cope with a series of economic and political crises that led to the rise of Adolf Hitler and the Nazis. At the outbreak of World War II Schumacher was interned in England as an enemy alien and later was forced to work as an agricultural laborer. That experience fostered his interests in farming, soil management, and Marxist socialism that were to influence his future activities.

At the end of the war Schumacher—now a British citizen—was made a member of the Strategic Bombing Survey, which examined the impacts of bombing on Germany; he later became a member of the British Control Commission in Germany. After his return to England he became the economic adviser to the National Coal Board, where he stayed until his official retirement in 1971. His early interests in the postwar period revolved around reconstructing Germany and the attempt to establish an international financial and trading system (the World Bank and the International Monetary Fund).

In 1955 Schumacher was invited to go to Burma for a short term as an economic adviser, an event that resulted in an essay published in 1955 titled "Economics in a Buddhist Country," later revised as "Buddhist Economics." The essay drew on his experience of a country whose core way of life was completely different from the world he had inhabited. Schumacher was astonished at the happiness of a people living in poverty. In that essay and in later works he ascribed their contentment to a series of approaches to life: (1) minimizing wants; (2) work as a means of enhancing life; and (3) a spiritual understanding of human beings. The enrichment of life was seen as the purpose of economics. In this way Schumacher rediscovered in Burma a buried British tradition (sometimes referred to as the Third Way) of economic socialism that derived from John Ruskin, William Morris, and R. H. Tawney and was instrumental in creating Gandhi's spiritual economics.

PHILOSOPHY AND LATER WORKS

Schumacher's new interest in the problems of developing countries led him to India, where the vast distance between the high-technology future planned by the government with the assistance of international economic advisers and the poverty of the population led him to push for intermediate technologies that would enhance the work people were doing through the application of appropriately considered improvements.

Small Is Beautiful: Economics as If People Mattered (1973) is a series of overlapping essays. "Nuclear Power—Salvation or Damnation" not only attacks the economics of nuclear power but also points out in detail the intransigence of the waste problem. "Development" articulates the emerging problem of rich elites in developing countries as enclaves of westernization in a sea of poverty. "Social and Economic Problems Calling for the Development of Intermediate Technology" puts forward a diagnosis and a work agenda that would be followed by the Intermediate Technology Development Group (ITDG). The most famous chapter, "Buddhist Economics," set out the essentials of ecological economics long before anyone gave it a name: Schumacher makes clear the distinctions between renewable and nonrenewable resources and the folly of living off capital rather than interest. "How to obtain given ends"—the dignity of the human—"with minimum means" is Schumacher's version of what a Buddhist economics should be; as opposed to a system driven by a goal of maximum consumption. *Good Work* (1979) is a complementary series of speeches and short essays published after Schumacher's death that includes an indictment of dependence on oil.

Guide for the Perplexed (1977), which was written after Schumacher's conversion to Catholicism, is an attempt to put forward a more extensive philosophy and theology. It is essentially an updated version of medieval Christianity based primarily on the thought of Saint Thomas Aquinas and argues that contemporary philosophies are "horizontal" (concerned only with the material world), whereas a "vertical" approach is more appropriate to beings who ascend from mere physical life, the mineral, through plants, to consciousness, and then to self-awareness. The book claims that people need an adequate level of response to the problems at each level.

SCHWEITZER, ALBERT
1875–1965

Albert Schweitzer, theologian, philosopher, concert organist, and physician, was born on January 14, 1875, in Kaisersberg, Alsace-Lorraine. In 1912 Schweitzer left his position as professor of theology at the University of Strasbourg to become a mission doctor at Lambaréné in what later became Gabon.

Schweitzer is best known for his philosophy of reverence for life, which he developed in response to the sense of cultural crisis that was widespread in Europe in the late nineteenth and early twentieth centuries. Schweitzer argued that the failure of ethics to provide an orientation to life rests on trying to base ethics on a worldview that claims that the world itself is structured by and oriented toward ethical values. Rejecting any such metaphysical project, Schweitzer called for an ethics based on a view of life as practical action within the world.

Schweitzer's development of his ethical view of life is a form of life-philosophy (*Lebensphilosophie*), a nineteenth and twentieth century development that put life and will at the center of philosophical thought. His orientation is explicitly existential: How can an individual give positive meaning to life, starting with the will to live as each individual immediately experiences it. Ethics has the task of giving the human will to live a focus that frees it from alienation and pessimism. "Deepened affirmation of world and life consists in this: that we have the will to maintain our own life and every kind of existence that we can in any way influence, and to bring them to their highest value" (Schweitzer 1987 [1923], p. 278).

Schweitzer says that when human beings affirm both their own inner will to live and the will to live in all forms of life, they experience contact with something much deeper: "Reverence for life means to be in the grasp of the infinite, inexplicable, forward-urging will in which all Being is grounded" (Schweitzer 1987 [1923], p. 283). Schweitzer argues that this mystical experience is necessary for a genuinely positive orientation toward life.

The principle of reverence for life has important implications for human relations with animal and plant life (see Schweitzer 1988 [1919]). Our world is "a ghastly drama of the self-estrangement of the will to live. One existence makes its way at the cost of another; one destroys the other. . . . I can do nothing but hold to the fact that the will to live in me manifests itself as will to live that desires to come to harmony with other will to live" (Schweitzer 1987 [1923], p. 312).

Recognizing that injury to life is necessary for sustaining human life, Schweitzer asked how it is possible to lead a concrete life of reverence for life. While causing unnecessary suffering and harm is strictly forbidden, Schweitzer acknowledged that reverence for life has an unavoidably subjective or personal dimension. One person may conclude that reverence for life requires one to be vegetarian; another that eating animal flesh is permissible. Each, in making this subjective decision, may be showing reverence for life, but if one decides to eat meat, one has the objective obligation to ensure that animals live and die without unnecessary suffering. However one decides this question, one always lives at the expense of other life, and to this extent one is always guilty.

While Schweitzer's thought has been influential in animal-welfare movements, it has had less impact on environmental thought. But his insistence on reverence for all life, in whatever form, makes his philosophy a potentially important resource for biocentric thought, and reverence for life is a clear relative of Edward O. Wilson's notion of biophilia.

Schweitzer's philosophy of reverence for life presents two major problems for contemporary thought. First, his mysticism concerning the infinite will to live will be foreign to many people, though the experiential nature of this mysticism will make it accessible to some. He insists that his mysticism is not an abstract worldview, but rather a concrete attitude toward life. One may want to ask, however, whether this mysticism successfully avoids the problems Schweitzer sees in abstract mysticism. Second, Schweitzer's emphasis on the guilt that inevitably results when a moral agent lives in a world in which life lives at the expense of other life may strike some readers as a version of original sin. One may want to ask whether a moral life that lives at the expense of other life is possible without guilt.

SEED BANKS

Seed banks are facilities for conserving seeds, either by continually replanting and harvesting them in the places in which they were bred (in situ) or by placing them in some form of remote storage (ex situ). Seed banks play a key role in crop improvement and in the conservation of biodiversity. There are more than 1,500 government, private-sector, and nongovernment-organization seed banks around the world with more than 6 million accessions—different landraces or varieties—in storage.

Modern agricultural practices have dramatically reduced the number of landraces, or traditional regional varieties that are grown by local farmers. Farmers who continue to plant the varieties of their forebears conserve tremendous the genetic variation that has been created over thousands of years of artificially—as opposed to naturally—selected mutations, natural hybridizations, and chromosomal aberrations. Genetic diversity is also being destroyed by other human activity and global climate change. The Food and Agricultural Organization (FAO) estimates that in 1949 there were 10,000 wheat varieties grown in China. In the 1970s that number had shrunk to 1,000 varieties (1997).

Seed banks also provide a reservoir of genes and cultivars (a variety of plant that originates and persists under cultivation) that can be used by research scientists and farmers. There are instances in which catastrophic events such as wars or hurricanes have destroyed the seed of an important traditional variety and the seed bank material was used to reestablish the cultivar. Following the Rwandan civil war in 1994, several international organizations helped to reintroduce more than 275 bean varieties back to Rwandan farmers, thus helping to restore food security.

Plant breeders are the major users of the genetic material stored in seed banks. Cultivars, landraces, and wild populations stored in the seed banks provide the genes and genetic resources needed by plant breeders to develop new cultivars with increased yield, pest resistance, and other valuable traits. Plant breeders will screen large numbers of accessions from seed banks to identify new genes for biotic and abiotic stresses, including insects, diseases, temperature, and soil. They will also look for other genetic traits, including growth habit, nutrition, color and quality. Wild germ plasm can also be used by plant breeders to improve yield and other important traits of agricultural crops.

Seed banks only store the genetic material, whereas farmers who plant landraces or allow plants to grow in their natural habitat will continue to create new genes and gene combinations. Both biotic and abiotic stresses help to select new genes that will then be available to the plant breeders. Creating new genes through mutation is important as climate change continues to influence plant production. In situ cultivation over thousands of years is what has produced the genetic variation that we have today. The ideal way to store genetic diversity is in situ. This method allows the population to continue to create additional genetic diversity. The Convention on Biological Diversity (CBD) states that ex situ conservation should complement in situ conservation. The CBD (1993) enhanced global awareness of the importance of conserving, using, and sharing the benefits of genetic diversity.

Doomsday Vault, Norway. *The Svalbard Global Seed Vault, known as the "doomsday" vault, was officially opened in February 2008, to protect millions of food crops from climate change, wars, and natural disasters in the remote Arctic location. Several seed banks exist around the world, in order to protect against an accidental loss of genetic diversity.* **AP IMAGES.**

A seed bank (the Svalbard Global Seed Vault) has been built in northern Norway, 696 miles from the North Pole. It will hold more than 3 million samples at minus 18 degrees Celsius. Opened in February 2008, this seed bank will preserve seed from the world's major and minor food crops. It was built by the Norwegian government and will be operated by the Global Crop Diversity Trust.

SHEPARD, PAUL
1925–1996

Paul Howe Shepard was born on July 12, 1925, in Kansas City, Missouri. His life-long fascination with natural history and evolution led to research in many fields of inquiry in the sciences and social sciences. He is credited with synthesizing this far-ranging view into a human ecology that explicated the relationship of humans to the whole of nature.

Shepard acknowledged that his theory was informed by his boyhood experiences, first in collecting and keeping animals as a child, and later in youth, through hunting, fishing, trapping, and falconry. His original view of human ecology was culminated, at the age of fifty-seven, in *Nature and Madness* (1982). In this psychohistory, Shepard explains attenuated development and maturation in humans, examines our puzzling estrangement from nature, and proposes the proper rearing of children close to nature.

Nature and Madness followed years of seeking the origins of nature perception in humans. In 1950, after graduation from the University of Missouri and a brief stint as field representative of the Missouri Wildlife Federation headed by Charles Callison, Shepard entered a Master's Conservation Program at Yale University, co-directed by renowned plant ecologist Paul Sears and evolutionist G. Evelyn Hutchinson. Focusing on the relationship of art to ecological perception in pioneer America, Shepard plunged into the study of the Hudson River School painters of the 1830s and 1840s. He broadened this study in an interdisciplinary doctoral program that culminated in his dissertation, "American Attitudes Towards the Landscape in New England and the West, 1830–1870."

During his graduate studies and his first academic appointment at Knox College, Shepard was a grassroots activist in his summer employment as a seasonal state and national park ranger. At Big Spring State Park in Missouri and at Olympic National Park in Washington, he was a whistleblower, publicizing the illegal logging of old growth forests, which led in both cases to administrative and policy changes. As conservation chairman of the National Garden Clubs of America, he initiated letter-writing campaigns supporting the creation of the Arctic National Wildlife Refuge and opposing the use of pesticides and the building of a dam in Dinosaur National Monument. In his first teaching position at Knox College, he transformed old mine tailings and pits into a biological field station, Green Oaks, restoring one meadow to tall-grass prairie. During this period of his life he was married to Melba Wheatcroft Shepard and they had three children, Kenton, Margaret, and Jane.

Shepard's studies on the influence of landscape aesthetics on nature perception were presented in 1967 in his book, *Man in the Landscape: A Historic View of the Esthetics of Nature*. This book, along with the anthology *The Subversive Science*, co-authored with Daniel McKinley, were important to developing ecologists and used as popular readers for burgeoning environmental studies programs. Published posthumously in 2003, *Where We Belong* is a collection of essays on landscape and place also written by Shepard during this period.

After living in Massachusetts and holding several teaching positions in the East, in 1973 Shepard and his second wife, Ruth Attwood Shepard, moved to California where he was named Professor of Human Ecology and Natural Philosophy at Pitzer College, one of the Claremont Schools.

Years of writing and research on nature perception led Shepard at this time to an unexpected conclusion: Landscape art and literature, rather than drawing us to nature, distance us from it and creates a world of observers rather than participants. It was then that he turned to anthropology. Soon after arriving at Pitzer College, Shepard published his much acclaimed *The Tender Carnivore and the Sacred Game* (1973), a celebration of our primal hunter and gatherer forebears. However, his assertion that domestication turned humans away from a harmonious foraging way of life drew strong criticism.

Enthralled by animals from an early age, Shepard believed that humanity emerged in close association with

animals and cannot be complete without them. He explored this connection in three books. *Thinking Animals: Animals and Human Development* (1978) shows how animals have been and still are integral to human thought and language. *The Sacred Paw* (with Barry Sanders, 1985) establishes the significance of the bear to northern hemisphere peoples in art, mythology, and literature. And in *The Others: How Animals Made Us Human*, published posthumously in 1996, Shepard explores the relationship of humans to animals in diverse cultural contexts throughout history.

Shepard retired from teaching at Pitzer College in 1994. He died at home in Salt Lake City on July 16, 1996, as his last book, *The Only World We've Got*, a reader, was published. In *Coming Home to the Pleistocene* (1998)—edited by his third wife, Florence Krall Shepard, and published posthumously—he summarized and clarified his most important insights into our human ecology and development. He believed that carried deep in our DNA is an integrated person who knows how to live ethically and ecologically on Planet Earth.

SHIVA, VANDANA
1952–

Vandana Shiva, who was born in Dehra Dun, India, in November 1952, is one of the leading environmental scholars and activists in the world. Originally trained in physics, she completed a doctorate in the philosophy of science in 1978. She is the author and editor of fifteen books and has published more than three hundred articles in addition to lecturing worldwide. In 1982 she established the Research Foundation for Science, Technology and Natural Resource Policy in India, which supports local environmental struggles, promotes biodiversity, and protects indigenous knowledge. Shiva has developed an activist platform for "earth democracy" that is opposed to life-destroying corporate globalization and demands local sovereignty over food systems, water systems, and biodiversity systems.

Shiva's critique of corporate globalization identifies the multiple ways in which Western economic development strategies and technological incursions destroy not just nature but native knowledge and social relations as well. In *The Violence of the Green Revolution* (1989) she identified the destruction caused by first world corporations in their efforts to increase crop productivity and profits. For many, the Green Revolution brings to mind advances in agricultural development that allowed greater food production to feed an ever-increasing human population, particularly after years of catastrophic famines. Shiva's discussions reveal a darker side in which high-yielding seeds brought environmental, economic, and social disasters. Corporations that developed and owned the new technologies turned biologically diverse and sustainable local farms into monoculture plots that were dependent on corporate products and World Bank loans for funds to purchase the products. When a crop failed, there was nowhere to turn, and in communities that had changed their farming practices a bad year meant economic and social collapse. In addition, the toxic pesticides and chemical fertilizers that were necessary for "advanced" methods of farming destroyed native plants and depleted soils.

Building on her earlier criticisms of the development of industrialized agriculture, Shiva is an outspoken critic of genetically modifying foods and patenting life, which she addressed in *Biopiracy: The Plunder of Nature and Knowledge* (1997). When corporations claim ownership of the earth and the living things on it, the value of

nature and those who work with nature is diminished. Bidiversity and sustainability are sacrificed for profit.

As both a writer and an activist, Shiva uses her scholarly analyses to develop ecologically sustainable alternatives. For example, to combat the problems associated with the intervention of corporate agribusiness in Indian farming and the increasing destruction of globalized food production, Shiva formed an organization, Navdanya, whose name means ''nine crops'' that represent India's collective source of food security. Navdanya supports local organic farming, rescues and protects seeds and plants that are threatened with extinction, and defends native knowledge and food security.

Most of the farmers who produce most of the food in the third world are women, and Shiva is aware of the way in which ecological destruction disproportionately affects women. From her early days as part of the Chipko movement, which was made up of Himalayan women dedicated to the protection of the environment, through her critique of ''maldevelopment'' in *Staying Alive: Women, Ecology and Development* (1988), to the formation of an international coalition of women to respond to globalization called Diverse Women for Diversity, Shiva's environmentalism has been linked to the struggles of women.

Shiva has argued that the masculine way of thinking, doing science, and defining progress as controlling wealth and property dehumanizes women as well as men and ultimately will destroy the earth. This destructive force of patriarchy requires harnessing the creative power of women and nature. To accomplish this, those in positions of economic and epistemic power relegate women and nature to the realm of the passive. Once something is made passive or inert, Shiva argues, it can be used and commodified more readily. The health of the planet demands that women's labor and knowledge and the earth itself not be used in these ways, and thus she sees feminism and environmentalism as powerful political partners. This partnership can provide liberation from the life-destroying systems that currently threaten women, particularly third world women, and the planet.

Some have criticized Shiva's stance against global corporate techno-culture as over-simplified. Critics claim that she has underestimated the value of technological advances in saving lives. Shiva's stance is not anti-technology, however. She advocates democratic, community participation in the decisions to use and control technology and raises cautionary concerns about the long-term effects of technological incursions into social relations and our delicate relationship with the Earth. Recently she has issued warnings about the dangers of rushing to replace oil with biofuels, or fuels derived from corn, soya, and other common food crops. She argues that this quick fix solution will negatively impact the lives of poor people who will not be able to afford food.

SHRADER-FRECHETTE, KRISTIN
1944–

Kristin Shrader-Frechette was born on September 14, 1944, in Louisville, Kentucky. She got her B.A. in mathematics from Xavier University, earned a Ph.D. in philosophy from the University of Notre Dame, and held postdoctoral fellowships in biology (community ecology), economics, and hydrogeology. As of 2008 she is O'Neill Family Professor of Philosophy and Concurrent Professor of Biological Sciences at the University of Notre Dame. She is the author of more than 350 articles and 15 books, much of this work focused on ethical and methodological issues that arise in connection with technological risks to humans and the environment, the actual consequences of various technologies, and related governmental regulatory efforts. She also writes on ethical theory and the scientific method.

Shrader-Frechette's work has regularly addressed problems related to nuclear technology. She has written extensively on the proposed permanent nuclear-waste

repository in Yucca Mountain, Nevada. Because of the nature and extent of the scientific uncertainty regarding whether such waste could be safely housed there (or anywhere) for 10,000 years—a number that is, in any case, problematically arbitrary—she claims that the Department of Energy should delay determination of the site's suitability and store waste for a century in numerous regional, monitored, retrievable facilities while the option of permanent interment is further studied. She has criticized federal regulations governing releases of radiation from the site, arguing that the U.S. Environmental Protection Agency's suggested radiation-exposure limits, which are twenty-three times higher for the distant future than for the near future, fail the demand for equal protection, indefensibly entailing that we merit more protection than our descendents in spite of the fact that we, not they, profit from the power for which the waste was generated. Furthermore, she holds that the agency should not assess compliance with these regulations according to mean and median doses of exposure across the affected population, since both of these approaches are capable of sanctioning lethal doses for many people. Instead, compliance should be assessed according to whether any individual faces an exposure dose over a certain amount. She has also written on the siting of uranium-enrichment facilities, the effects and cleanup of low-dose ionizing radiation from above-ground nuclear-weapons testing, and safety regulations in the nuclear-workplace environment.

Shrader-Frechette has consistently defended the use of cost-benefit analysis in environmental-policy decision making, albeit only where such analysis is conceived of and conducted in ways she sees as appropriate. She believes that while its use may be necessary for rational societal decision making, it is not sufficient, since considerations such as who is responsible for creating the risk, who benefits from the risk, whether the risk is involuntarily imposed or voluntarily chosen, what moral and legal rights affected parties have, and so on, can override narrow cost-benefit judgments. She maintains that assessments of policy-related gains and losses must be scientifically well informed—a demand to which economists have traditionally been somewhat insensitive. Such analysis must treat risk assessment as not purely subjective, that is, not as matters purely of value rather than fact. However, she argues, this does not mean that risk assessment or the resultant determination of costs and benefits should be conceived of as a purely scientific process in which only expert analysis counts. Rather, public deliberation is critically important. The appropriateness of lay persons' involvement is based in the stake that we all have in the outcomes of these policy decisions, in the very idea of democracy, and in the fact that scientific judgments are often unavoidably plagued by uncertainty. Thus, Shrader-Frechette makes a much smaller role for technocrats in regulatory decisions than do some others (perhaps most notably Cass Sunstein).

Shrader-Frechette has also produced writings central to the development of the environmental-justice movement and been involved on the ground in environmental-justice efforts around the world. In the Congo, for example, she worked with the World Council of Churches to advise locals on how to avoid having toxic waste shipped to their land from developed countries. And with her students, she helped the predominantly African-American community of Scarboro, Tennessee—one with high numbers of children suffering from respiratory and pulmonary ailments—assess local levels of exposure to pollutants, including beryllium, lead, ionizing radiation, mercury, and polychlorinated biphenyls. She has advised the United Nations, the World Health Organization, numerous foreign governments, as well as the president of the United States, the U.S. Congress, and various federal and state agencies. She was the first female president of several prestigious scholarly associations and societies.

SIERRA CLUB

The Sierra Club has influenced environmental thought and policy in the United States for more than one hundred years. The club's original regional focus has gradually enlarged to the point where it now has a global presence, with more than 1 million members. This shift has been accompanied by an evolution of the organization's goals, methods, and overall philosophy. With a history intertwined with that of the National Park

Service, the Sierra Club has a strong tradition of both conservation and recreation.

As its name suggests, the Sierra Club was inspired by the Sierra Nevada mountain range of California. Revered today as a patron saint of not only the Sierra Club, but also of the conservation movement as a whole, John Muir (1838–1914) articulated an early statement of purpose. Even before the organization was founded, Muir, along with the editor Robert Underwood Johnson (1853–1937), lobbied Congress successfully for the creation of Yosemite National Park in 1890. On May 28, 1892, a coalition of prominent San Francisco Bay area residents, including professors from Stanford and the University of California, joined Muir and Johnson in founding the Sierra Club. They wanted to defend and enlarge Yosemite but also sought to formulate larger scientific and recreational goals for California.

The Sierra Club found its voice in Muir, whose writing was published by the organization in its journal, the *Sierra Club Bulletin*. Muir's enthusiasm was infectious, fostering opportunities for others to visit the mountains. By 1901 the Board of Directors approved summer excursions. That first year nearly a hundred people went to Tuolumne Meadows in Yosemite. The numbers of participants in outings grew rapidly, along with membership totals.

In 1914 the Sierra Club organized a final trip to Hetch Hetchy Valley. Considered by many to be Yosemite Valley's equal in beauty, Hetch Hetchy was the subject of a long fight between conservationists and the city of San Francisco, which sought to dam the valley for its municipal water supply. This controversy tested the young Sierra Club and drove a permanent wedge between two groups of conservationists that previously held a shaky truce: on one side were the "preservationists," whom the Sierra Club fully embraced, and on the other were the utilitarians, or "conservationists," headed by the first chief of the United State Forest Service, Gifford Pinchot (1865–1946). Preservationists argued for retaining natural lands with minimal management, while utilitarians believed that wild lands can be productively used for multiple purposes. The Sierra Club failed to preserve the valley: In 1913 Congress approved the damming of Hetch Hetchy.

Following that defeat the Sierra Club won a victory with the passage of the National Park Service Organic Act of 1916, which created this new government agency and appropriated federal funding in its support. Utilitarians such as Forest Service Chief Pinchot thus saw their influence eroded in the national parks. Efforts to develop and make accessible places such as Yosemite were a major focus of the next several decades. Hiking trails were built, and Sierra Club members began pioneering new ways to explore the mountains. Mountaineering and rock climbing techniques opened up previously inaccessible areas. Lightweight hiking and camping gear made these expeditions more enjoyable and popular. The 1920s saw major road-building efforts, and the automobile brought ever-increasing numbers of tourists to the expanding park system.

The recreational successes that the Sierra Club was enjoying began to clash with the group's ecological goals. Development of the most scenic areas in the country was so rapid and overwhelming that the parks were in danger of being destroyed by overuse. As Michael Cohen notes, the organization's statement of purpose was amended in 1951 to read "explore, enjoy, and preserve" instead of "explore, enjoy, and render accessible" (1988, p. 100). Working with other groups such as the Wilderness Society, the Sierra Club was no longer satisfied with national park designations unless they were backed by an ecological vision.

The early 1950s brought many changes and fights to the Sierra Club, both internal and external. David Brower (1912–2000) became the club's first executive director in 1952. His leadership, along with a proposal to dam the Colorado River in 1951 at Echo Park and flood Dinosaur National Monument, spurred the Sierra Club to employ more aggressive tactics. One strategy was full-page newspaper ads to lobby against the proposed dam; these ads brought the Sierra Club to the Supreme Court when their tax-exempt status was threatened. Meanwhile, the organization brought tens of thousands of new visitors to Dinosaur, many of whom experienced the area by rafting the Colorado. The club's tradition of making previously unknown places accessible proved successful in this case: The proposal to dam the river at Echo Park was thwarted in 1956, although construction began for the Glen Canyon Dam. The Sierra Club continued to publish books in support of its mission and branched out into filmmaking. The organization decided to avoid losing its tax-exempt status, however, by not directly lobbying the government.

The Sierra Club now had a national presence yet retained a regional focus through its local chapters. This local presence was enhanced when the club's tax-exempt status was revoked. Fighting against a proposal to dam parts of the Grand Canyon, the Sierra Club took out several full-page advertisements in national publications. Their most famous ad, published in 1966, proclaimed, "Should we also flood the Sistine Chapel so tourists can get nearer the ceiling?" Membership skyrocketed. April 22, 1970, the first Earth Day, sparked a rise in awareness of environmental issues that brought the Sierra Club still more members. However, this wave of members came without Brower, who resigned as executive director in 1969 after several years of clashes with board members.

Sierra Club Ceremony, Johnson City, Tennessee. *Members of a local Sierra Club chapter stage a "funeral" for four ancient beech trees cut down to make way for development in 2005. The organization, with John Muir as its patron saint, has been around since the early twentieth century.* **AP IMAGES.**

Through the 1970s the Sierra Club's platform became more wide-ranging. The group addressed issues such as overpopulation, arguing that birth rates in the United States are too high; the club, however, does not take a position on immigration or issues it sees as disconnected from conservation. Brower, after reconciling with the Sierra Club, led a faction that argued for a public position against immigration in 2000, but the club's moderate elements steered official club policy towards a more compromising stance. Notably, younger conservation and environmental organizations have criticized the Sierra Club as being too willing to compromise and make deals with Washington. These groups argue for grassroots activism and suggest that the Sierra Club has strayed too far from John Muir's originary vision.

Despite criticism, traditional conservation causes remain important to the Sierra Club. For example, it has repeatedly lobbied to keep the Arctic National Wildlife Refuge closed to oil drilling and has worked to create new wilderness areas. Global and urban issues also attracted the Sierra Club as the group passed its centennial in 1992. Climate change and renewable energy became major policy issues, as have clean urban spaces and environmental justice. The Sierra Club has evolved into a comprehensive conservation group that has managed to keep local chapters small and dedicated to excursions. Nevertheless, it maintains a national presence and wields considerable influence in Washington, D.C. These efforts to be local yet global, to protect yet promote, have created a flexible and lasting organization.

SINGER, PETER
1946–

Peter Singer was born in Melbourne, Australia, on July 6, 1946. He completed undergraduate studies in law, history, and philosophy at Melbourne University and did graduate work in philosophy at Oxford, where he received a bachelor of philosophy degree in 1971.

His primary appointments have been as a professor of philosophy at Monash University in Australia and a professor of bioethics at the Center for Human Values at Princeton University; he also has held visiting positions at universities around the world. Singer addresses timely and provocative moral issues, has a clear and accessible writing style, and is a socially engaged public intellectual. He is said to be among the most influential philosophers alive (Specter 1999).

PRACTICAL ETHICS

Singer's most important contributions have been in practical ethics. He helped establish the applied ethics movement in which philosophers turned their analytical and argumentative skills toward matters of moral significance and public interest. He has focused primarily on "relevant" issues that "any thinking person must face" (Singer 1993, p. v).

Singer has argued vigorously for challenging, usually unorthodox positions on the treatment of nonhuman animals; the obligations affluent people have to people living in absolute poverty; the ethics of globalization; environmental protection, including measures to reduce climate change; and major issues in bioethics, including

euthanasia and abortion. His works offer a critique of the doctrine of the sanctity of life.

ANIMAL LIBERATION AND ANIMAL RIGHTS

In *Animal Liberation,* first published in 1975, Singer challenged the morality of using nonhuman animals for food and scientific experimentation. He maintained that it is inconsistent to use animals for purposes for which people would not consider using a human being, even an infant or a person whose mental level is similar to that of an animal. He argued that such uses are wrong because they result from an unjustified prejudice against other species, which, adopting a term coined by Richard Ryder, he called *speciesism*.

Singer has defended the "fundamental principle of equality," the demand that equal moral consideration be given to comparable interests regardless of whose interests they are, by arguing that that principle best explains why racism and sexism are wrong. In the human case it generally is agreed that women's and minorities' educational, political, and economic interests are comparable to those of white men, and so their interests should be given equal consideration.

In the case of animals Singer argues that many animals also have interests both in avoiding pain and suffering and in experiencing happiness. *Animal Liberation* uses photographs and vivid descriptions to show how animals' interests are given little or no consideration by agribusiness and research industries. That treatment violates the principle of equality and therefore is wrong.

Animal Liberation sold hundreds of thousands of copies and helped start a worldwide animal protection movement. It has been referred to widely as the Bible of the animal liberation movement. In *Practical Ethics,* first published in 1979, Singer supplemented his equality-based defense of animals with a utilitarian defense, arguing that the overall harms produced by these uses of animals typically outweigh the benefits.

In *Practical Ethics* Singer also discussed the major issues in biomedical ethics. His sanctity of life doctrine holds that all human life, regardless of its subjective quality, is equally valuable and thus deserves equal treatment. Singer has argued for an ethic sensitive to relevant details, for example, whether the individual is conscious, is in pain and suffering, has expressed a preference for how her or his life should end, the medical prognosis, and the family's wishes. He has argued that those factors can make it permissible or even obligatory to let a human being die and even be killed actively. Singer thus argues that abortion, voluntary euthanasia, assisted suicide, and even infanticide can be morally permissible and often are.

POVERTY AND MORAL OBLIGATIONS

Singer has applied the principle of equality and utilitarianism to questions about people's moral obligations toward the billion or more people living in and dying from absolute poverty. He has argued that affluent individuals and nations are morally obligated to provide generous assistance to people in poverty, with an immediate response to famines and natural disasters and, more important, long-term development aid. In his essay "Famine, Affluence, and Morality" (1972) Singer defended his conclusions by referring to a simple case: Someone sees a small child fall into a pond and realizes the child is in danger of drowning. She could save the child, but her clothes would get muddy. Is she morally obligated to save the child? Most people would think that she is. Singer argues that this principle best explains why if one can prevent something very bad from happening at an insignificant cost to oneself, one is obligated to do so. By analogy and by appeal to that principle Singer concludes that people are obligated to help prevent the daily needless deaths of tens of thousands of children: Those deaths are very bad, and people can prevent them at only minor costs to themselves.

In *One World,* first published in 2002, Singer applied the principle of equality to climate change and globalization. Affluent nations enjoy their prosperity at significant costs to the environment: Their development and energy-consumptive lifestyles contribute to climate change that threatens the future of life on the planet. There is a scientific consensus on predictions for increased hurricanes and storms, droughts and floods, tropical diseases, rising sea levels, and disruption in food production resulting from climate change. That change probably will affect poor nations the most because they lack the resources to move people from affected areas, store food, and fight disease.

Singer argues that industrialized nations must reduce their greenhouse gas and carbon emissions in an attempt to curb climate change. The principle of equal consideration of interests requires a new global ethic in which leaders of developed nations consider the effects of their policies on all the people affected by them, not just the people of their own nations. He argues that on a variety of plausible theories of fairness and justice, the refusal of the United States to commit to a plan to address atmospheric change, for example, the Kyoto Protocol, is self-serving and ethically indefensible because the United States has 5 percent of the world's population but produces 30 percent of the climate-changing emissions. Because the developing nations' contributions of greenhouse gases will not equal the built-up contributions of the developed nations until about 2038 and, per capita, for at least a hundred years,

Singer argues that industrialized nations should bear the initial burdens; he proposes a cap and trade program to give developing countries incentives to keep their emissions low.

ENVIRONMENTAL ETHICS

In regard to the environment Singer's ethic is an extension of the dominant Western ethics to include all sentient beings. It attributes no intrinsic value to nonsentient entities such as plants, ecosystems, wilderness, species (apart from individual members of a species), endangered species, and nature generally. Singer argues that if an entity lacks or is incapable of subjective experience, it lacks interests that need to be considered. He rejects developments in environmental ethics, such as holism, Deep Ecology, and the land ethic, that posit intrinsic value beyond conscious beings and their experiences.

Singer has argued that his ethic provides strong environmental protection. Many human beings value natural spaces for recreational, scientific, aesthetic, and spiritual purposes: Destroying wilderness, which is irreplaceable, thwarts those interests. Because future generations of humans probably will have such interests, short-term economic benefits from destroying nature should not outweigh this loss to an indefinite number of future humans.

SNYDER, GARY
1930–

Poet, essayist, teacher, Buddhist practitioner, and community activist, Gary Snyder has lived a colorful and storied life. Many readers became familiar with Snyder through his fictionalized representation in Jack Kerouac's 1958 novel *Dharma Bums*, in which his prowess as an outdoorsman and mountain climber is highlighted. Others are particularly fascinated with Snyder's ten-year immersion in Buddhist philosophy and practice from the late 1950s through the late 1960s, during which he lived in various Zen monasteries in Kyoto, Japan, developing habits and affinities to which he continued to adhere into the twenty-first century. And, of course, most people know Snyder through his many important works of poetry and nonfiction, ranging from *Riprap* (his first book of poetry, published in 1959), to his Pulitzer-prize-winning collection *Turtle Island* (1974), to more recent volumes such as *No Nature: New and Selected Poems* (1992), *Mountains and Rivers Without End* (1995), and *Danger on Peaks* (2005). The most compendious edition of his work is *The Gary Snyder Reader: Prose, Poetry, and Translations, 1952–1998*, which appeared in 1999.

Of particular relevance to environmental ethics and philosophy are Snyder's profound engagement with and articulation of the experience of physical labor, his application of Buddhist ideas to the conceptualization of the human relationship with nature, and his personal involvement with local, regional, and global political issues associated with environmental responsibility. The poems in *Riprap* and such later collections as *Myths & Texts* (1960), *Riprap and Cold Mountain Poems* (1965), and *The Back Country* (1967), among others, vividly evoke the presence of a human speaker immersed in the sensory qualities of outdoor experience. One poem from *Riprap*, titled "Mid-August at Sourdough Mountain Lookout," for instance, recalls the poet's seasonal work as a fire lookout in the North Cascades of Washington State, immersing the speaker in the physical realities of the job ("Down valley a smoke haze /... Swarms of new flies. // Drinking cold snow-water from a tin cup / Looking down for miles / Through high still air"). Philosopher Jack Turner writes bitterly in *The Abstract Wild* (1996) that "Science, including economics, tends to reduce nonhuman life to trash...We need to find another way of describing the world and our experience in it" (p. 65). He points specifically to Snyder's work—using an excerpt from *Mountains and Rivers Without End* as an example—to demonstrate the language of engaged non-abstraction.

Many of Snyder's poems resonate with echoes of his Buddhist training, but perhaps one of the most powerful applications of this philosophical tradition to the poet's artistic vision occurs in "Ripples on the Surface," the final poem in *No Nature*. This poem explores how the human mind knows nature, seeking to read it as a text, to apprehend it as if it were a "performance." He concludes by erasing the distinction between nature and human culture, stating "No nature // Both together, one big

empty house." Despite the frequent immersion in the physical world that occurs in Snyder's poetry, this Buddhist angle presents an opposing viewpoint: The phenomenal world is not the essence of reality and essential Truth cannot be perceived or articulated. This idea directly echoes the *Diamond Sutra*. This sacred text, dating back to ninth-century China, explores the fundamental notion of reality and the importance of nonattachment and is a central text in the Mahayana Buddhist tradition.

Despite his Buddhist skepticism toward the ability of humans to apprehend nature, Snyder took a practical stance in late-twentieth-century debates about the meaning of wilderness in American culture. In the essay "Is Nature Real?" (collected in *The Gary Snyder Reader* [1999]), he both acknowledged the validity of contemporary deconstructions of "wilderness" by scholars such as historian William Cronon ("So we understand the point about wilderness being in one sense a cultural construct, for what isn't?") and sharply criticized the political naiveté of such critiques. He states: "The attacks on nature and wilderness from the ivory towers come at just the right time to bolster global developers, the resurgent timber companies . . . and those who would trash the Endangered Species Act" (p. 388).

Patrick D. Murphy begins his 2000 study, *A Place for Wayfaring: The Poetry and Prose of Gary Snyder*, by recalling that when Snyder was a small child, his family moved to Lake City, Washington, an area that had been devastated by clear-cutting. "The significance of this land having been clear-cut for Snyder's psychological and environmental-ethical development should not be underestimated," Murphy argues (p. 1). The poet himself remarked in *The Practice of the Wild* (1990): "I suspect that I was to some extent instructed by the ghosts of those ancient trees as they hovered near their stumps" (p. 118). Later, Snyder directed his social concerns toward the militaristic ambitions of the U.S. government and its allies, noting in his 2003 essay "Ecology, Literature, and the New World Disorder" in *Back on the Fire* (2007) that "we have entered a period in which global relations are defined by new nationalisms, religious fundamentalism, developed world hubris, stepped-up environmental damage, and everywhere expanding problems of health and poverty" (p. 22). Snyder's poetry, too, reflects his sense of social commitment—commitment, that is, to the larger community of life. In "For All," collected in *Axe Handles* (1983) and later in *No Nature,* he laughingly declares his true loyalty: "I pledge allegiance // I pledge allegiance to the soil / of Turtle Island, / and to the beings who thereon dwell / one ecosystem / in diversity / under the sun / With joyful interpenetration for all." This single brief poem captures the essence of the essays collected in the opening section, titled "Ethics," of his 1995 collection of essays, *A Place in Space: Ethics, Aesthetics, and Watersheds*. The "Watersheds" section of that volume includes several essays that explain in detail what it means to live responsibly in a particular community in a particular place, with a long-term (sustainable) vision of that place; essays such as "Reinhabitation" and "Coming into the Watershed" probe the author's essential concepts of community and bioregional governance.

In his 2006 essay "Writers and the War Against Nature" (collected in *Back on the Fire*), Snyder points to "Song of the Taste" (initially published in *Regarding Wave* in 1969) as his "first truly ecological poem" and an exploration of "the essential qualities of human foods" (p. 68). As he explains in this essay, the poem goes "straight to the question of conflict between the ethics of *ahimsa*, nonviolence, 'respect for all beings,' and the lives of necessity and subsistence of indigenous peoples and Native Americans I had known." People who derive their existence from the bounty of nature, he continues, "can enter into the process with gratitude and care, and no arrogant assumptions of human privilege. This cannot come from 'thinking about' nature; it must come from being *within* nature" (p. 69). From his trim, haiku-like meditations on the physicality of human engagement with nature to his Buddhism-inspired reflections and his political critiques, Gary Snyder's work resonates with the implications of a life lived "within nature" and, at the same time, within community.

SOCIAL CONSTRUCTIVISM

Social constructivism is a group of connected claims about how perspectives, knowledge, and perhaps more concrete objects arise through social processes. Most important for environmental ethics, though, are four similar ideas:

1. First, and most important, social constructivists draw attention to the ways in which scientific knowledge does not simply reflect nature, but instead stems from work done by groups of people to describe nature. That work shapes the knowledge produced; therefore, our ideas have social histories. There is no direct path from nature to our ideas about it.
2. Second, not only is scientific knowledge socially constructed, but so are values and meanings (Macnaghten and Urry 1998). People's understandings of nature and wilderness are deeply shaped by their cultures, by their economic positions, by political struggles over environmental issues, and by more idiosyncratic factors such as personal histories. To one person a forest might be a beautiful and fragile piece of wilderness needing protection. To another it might be a resource waiting to be sustainably exploited. To yet another it might be a forbidding and terrifying source of dangers to be contained. All of these meanings stem from particular cultural, economic, and political contexts. If meanings of particular natural objects are socially constructed, so are general environmental values, especially those for which philosophers argue.
3. Third, more materially, much of physical nature itself is socially constructed because many of the environments and landscapes that we take to be natural have themselves been affected by many generations of human actions (Cronon 1995). Forests in North America once looked like pristine wilderness, but even before Europeans logged and cleared them, Native Americans were managing some of those forests through controlled fires. Many of the places that modern urban dwellers most appreciate as natural refuges from the built world have been profoundly affected by human activity and even deliberately shaped for recreation.
4. Finally, what we might call "strong" social constructivism is the claim that how people understand the world *is* the world. This is the claim that with their knowledge of it people shape the world directly. Although there is a philosophical case to be made for strong social constructivism, it is controversial, and we can set it aside here.

THE CASE FOR THE SOCIAL CONSTRUCTION OF SCIENTIFIC KNOWLEDGE

The case for the social construction of scientific knowledge has been made repeatedly in science and technology studies (STS) (Sismondo 2004), and in postmodern philosophy. There is a common saying that "data do not speak for themselves." This point, which denies that data are a sufficient foundation of knowledge, might illustrate justifications for social constructivism about scientific knowledge. Data need to be interpreted before they can have any meaning. There are no absolute rules for interpretation. Instead there are practices, tools, and innovations, all of which have to be acceptable or justified to expert communities. More deeply, the choice of data to be gathered is determined by the questions posed or the hypotheses to be tested; by the means or lack thereof for acquiring data, such as satellite imaging technology or transportation to a remote site; and by the resources for purchasing equipment, conducting surveys, or paying graduate students.

The widely held view that knowledge cannot be absolutely or even solidly grounded is known as *antifoundationalism.* Antifoundationalism is important not only to STS, but also to postmodern philosophy—and even to much modern philosophy. Postmodernists argue and emphasize that people's access to nature is always mediated because there is no direct way to know nature as it is in itself (Smith 1999). They further argue that there are no stable foundations for any values or institutions; therefore, knowledge and values are constructed.

Science and technology are thoroughly social activities. They are social because scientists are always members of communities, enculturated into those communities and necessarily working within them. Communities, among other things, set standards for inquiry and evaluate knowledge claims; there is no abstract, ideal, and logical scientific method apart from the best practices of scientists. In addition, science is an arena in which rhetorical work is crucial because scientists always have to convince their peers and others (including funding sources) of the value of their ideas and plans. Scientific actors have investments in skills, prestige, knowledge, and specific theories and practices. Thus many different types of ideologies and values are important components of research; even conflicts in a wider

society may be connected to conflicts within science and vice versa.

Thousands of empirical case studies have shown that scientists have choices about how and where to look for data, how to interpret that data, what can count as good models and theories, and how to interpret and use those models and theories. To take only one important and well-studied example: The general circulation models (GCMs) that provide our best evidence of human-induced climate change are extremely complicated computer programs that combine models and data in innovative ways (Demeritt 2001; Edwards 2001). The models, and the ways in which the models are applied and programmed, differ from one GCM to another, although they are often related by descent and by cross-fertilization (models typically share ancestors; when researchers can, they use good ideas that they see in other GCMs). The models are corrected by factors that bring them into line with existing data and expectations; this kind of correction is an art. Even the data are not raw, but corrected and smoothed, to take account of the fact that they are collected differently at irregularly spaced weather stations and satellites. Every aspect of a GCM is shaped by choices; communities of experts decide what the acceptable choices are.

Scientific knowledge is produced when the socially sanctioned expert communities, or important parts of them, are satisfied with claims. For uncontroversial claims, the experts might agree very quickly, accepting the authority of the researchers making those claims or the reasonableness of the claims given other things known. Controversies can arise, however, prompting the examining and challenging of many of the choices and arguments, the competence of researchers, and the reliability of equipment. Such controversies can expose the social construction of scientific knowledge. Eventually, minority views are marginalized and excluded from the debates, and the result is a rough consensus.

OPPOSITION TO SOCIAL CONSTRUCTIVISM

The idea that our knowledge is socially constructed may appear obvious. There is, however, another set of connected claims and perspectives, typically going under the label of *realism,* that opposes the views of social constructivism. For realists, our best scientific knowledge is true to nature. Realists claim that social processes do not significantly shape scientific knowledge but instead faithfully record nature's nature and that the emphasis of social constructivism is therefore misplaced (Crist 2004). On this view, scientific knowledge, the meaning of nature, environmental values, and even "natural" spaces may be shaped socially, but they are also shaped by nature. Not only is science shaped by nature, but it must also be approximately true to nature because it is so successful—at contributing to technology, for example. In other words, scientific knowledge passes the pragmatic test of truth: It works.

A further case against social constructivism is that its emphasis makes environmental politics difficult (Soulé and Lease 1995). A focus on the social processes by which scientific knowledge is made tends to undercut that knowledge because it implies that other social circumstances would have produced different knowledge and because confidence in science is based on its reliance on formulaic methods for uncovering truths of nature. Social constructivism, in this view, cripples the ability of science to serve as a solid foundation for environmental politics. Likewise, somebody who claims that wilderness is valuable for its own sake wants to assert that claim as objectively true, not merely as one culturally bound "story" among many possible "stories." Social constructivism, however—in this case, the social construction of values and meanings—does not allow environmental values to trump other factors in political disputes. Even the third, material, form of social constructivism—the observation that some landscapes normally thought to be natural are shaped by people—poses problems for environmental politics because it raises questions about how much and why we should value those landscapes.

SOCIAL CONSTRUCTIVISM AND ENVIRONMENTAL POLITICS

We might think that at least part of the debate about social constructivism and environmental politics hinges on a theoretical clash between social constructivism and realism. If realism is right, and science and philosophy provide natural and ethical truths that mirror the way things are, then environmental politics can rest securely on those truths. If social constructivism is right, and science and philosophy provide only contingent natural and ethical truths, then environmental politics can rest only insecurely on those truths.

In practice, however, these theoretical debates are not important to environmental politics or even to most environmental arguments—not just because the theoretical debates are far removed from the action but also because practical and down-to-earth versions of social constructivism and realism often play roles in environmental disputes. The practical versions make the theoretical ones less relevant.

Environmental politics often pits experts against one another. On the one hand, experts typically try to present their own views as entirely constrained by nature and rationality so that there is no room for disagreement. On the other hand, those same experts find ways in which

opposing arguments are open to challenge. Scientific knowledge laden with choices is not hidden, a truth seen not only by people working in STS or postmodern philosophy; it is regularly rediscovered in disputes. For example, the authority of studies on climate change through GCMs has been continually challenged, both substantively and as a basis for policy (Demeritt 2001). The result is that political expertise in other domains has often played a larger role in energy policy than has climate science.

Values are even more open to challenge. Therefore, environmental politics (and any other kind of politics) is already a constructivist arena. If the stakes are high enough, the pronouncements of experts do not go unchallenged. It is well established in studies of public controversies that as long as the social and political issues are being actively disputed, so will be the scientific issues. In rough terms, all the issues have to be resolved at once.

If the above argument is right, then for science (and philosophy) to play a larger role in politics, they should become more engaged, not less. Since expertise will be ''deconstructed'' during controversies; knowledge should be constructed with controversy already in mind. The authority of science cannot depend on an incorrect formal picture of itself that is open to periodic debunking. The social-constructivist view brings to the fore the complexity of real-world science and therefore can contribute to its success. Successful science in the public sphere can be the result of the ''coproduction'' of science and politics (Jasanoff 2004); science can more easily solve problems in the public domain if scientific knowledge is carefully adjusted to its public contexts and attuned to knowledge that non-scientists have. Perhaps the third, material, form of social constructivism can give us a hint about how environmental politics can thrive in the absence of foundations. A landscape does not have to be a wilderness to have value—although enough people have to be convinced of its value, even in the absence of pure naturalness, for this claim to carry weight. Similarly, scientific and philosophical claims do not have to be indisputable to gain respect—although their authority hinges at least in part on a sufficient number of people being convinced of their value. Social constructivism, then, tells us we have to live without foundations.

SOCIAL CONTRACT THEORY

Social contract theory is generally considered to be one of the most significant contemporary political theories. While early forms of the theory are found in views attributed to Protagoras in the fifth century BCE and expressed in Plato's dialogue *Crito* (c. 350 BCE) and summarized in his *Republic*, as well as by Manegold of Lautenbach (1080), most commentators consider Thomas Hobbes's *Leviathan* (1651) to be the first fully developed statement of social contract theory. For Hobbes, a fictional state of nature illustrated the necessity of political authority. People are equal, in the sense that everyone can be killed by others, and therefore some kind of agreement is necessary in order for people to live together in peace: The social contract is essentially a life preserver. After Hobbes, John Locke, and Jean-Jacques Rousseau were the most prominent proponents of this theory. These thinkers differed from Hobbes in asserting that there are certain irreducible moral notions, based on a natural equality of moral status. Rousseau's *Discourse on Inequality* (1754) affirmed that self-preservation and pity are prior to reason and that the duty not to harm others is based not on rationality but on sentience, the capacity to feel. Thus animals have the natural right not to be mistreated by human beings. Locke, in his *Second Treatise of Government* (1689), saw humankind in the state of nature as inherently social and relatively peaceful, but as prone to conflict over property. Locke's view, in which private ownership of property preceded the social

contract, foreshadowed many conflicts between private property and the public good.

In the twentieth century, John Rawls's *A Theory of Justice* (1971) emerged as the most influential statement of social contract theory. Rawls adopts Immanuel Kant's position that persons are able to reason from a universal point of view. Rawls's premise is that principles of justice are those which rational self-interested persons would agree to in an ideally fair situation, which he termed the "original position." Rawls's original position, unlike the state of nature in some earlier contractarian theories, is not supposed to be an actual historical situation, but rather a fiction that can help us think well about justice. Rawls proposed that those in the original position were behind the "veil of ignorance," meaning that they do not know their gender, race, and socioeconomic position in society, their natural talents or endowments, or their own conceptions of the good.

Rawls argued that those in the original position would agree on two principles of distributive justice. The first principle is that each person is to have a right to the most extensive liberties compatible with the same liberties for all others. The second principle is that social and economic inequalities are to be arranged so that they are to the greatest benefit of the least advantaged and attached to offices and positions open to all under conditions of fair equality of opportunity.

Rawls's theory has evoked opposition, due in part to the exclusion of nonhuman animals and the environment from the sphere of those entitled to justice. Tom Regan argues that Rawls's theory is not impartial, since while at key points Rawls indicates that mentally disabled humans, who are relevantly like animals, are owed duties of justice, he maintains that we have only indirect duties to animals. For Regan, the veil of ignorance should veil knowledge of the eventual species of the contractor. Regan is joined in his view by Paola Cavalieri and Will Kymlicka in "Expanding the Social Contract" (1996). Mark Rowlands in "Contractarianism and Animal Rights" (1997) makes a similar point in claiming that rationality is an undeserved quality, just as are race and economic class. Peter Singer, in the revised *Practical Ethics* (1993), argues that social contract theory should be rejected for the above reasons and also for its exclusion of future generations and of poor nations from the sphere of those to whom justice is owed. J. Baird Callicott maintains that positing reason as the origin of the moral community, even in a hypothetical manner, is contradicted by what is known of the evolutionary development of ethics.

Some commentators have offered revisions that could be incorporated into Rawls's theory. For example, the idea of what constitutes the basic goods to which everyone is entitled could be expanded to include clean air and water. Another proposal is to include behind the veil of ignorance to what generation the contractor will in fact belong.

Other revisions involve the basic premises of Rawls's theory. For example, many feminist thinkers reject, as male-biased, the idea of the original position as made up of rational and self-interested humans. They argue on the contrary that humans are fundamentally social, concerned for others as well as themselves, and mutually dependent. Avner de-Shalit points out in *The Environment: Between Theory and Practice* (2000) that Rawls's theory requires those in the original position to be without identity, including without a place in the world and without moral values that affirm the environment.

Many thinkers reject reciprocity between equals as a necessary component of justice. For these thinkers, rather than being limited to agreements between equals, justice is owed to all individuals who have morally weighty interests that are in need of protection. Mary Midgley, in *Animals and Why They Matter* (1983), argues that in many cases, such as those of the mentally handicapped, animals, plants, and rivers, our duties are noncontractual.

Rawls addresses this issue by stating that we have direct moral duties to animals, but these are duties of compassion and humanity rather than duties of justice. Rawls also states that social contract theory does not comprise all of moral theory. Martha Nussbaum and others object that this strategy of separating justice from compassion tends to trivialize animals, mentally disabled humans, and the environment, due to the heavy emphasis on justice in Western moral theory.

In contrast, some have held that nonhuman animals and the natural world are active communicators who are in fact participants in the contract with humanity. Bernard Rollin (1992) argues that domestication is an implicit social contract humans have made with animals, which is violated by factory farming. Michel Serres, in *The Natural Contract* (1995), acknowledges the earth itself as a partner. He interprets a contract in terms of the relationships, the "cords" between humans and the world. For Serres, we live in a play of energies, as participants in our entire community.

SOCIAL ECOLOGY

It is difficult to separate Social Ecology from the work of the social theorist Murray Bookchin. Having elaborated its philosophical foundations in a dozen books and many essays, he is considered by many to be the founder of the field. Bookchin drew on history, anthropology, philosophy, political theory, and ecology to formulate a comprehensive analysis of the relationship between humanity and nature, the causes of the ecological crisis, and the pathways humanity could reinstate to create an ecologically sustainable and just world (Bookchin 1982, 1986, 1995, 2003).

DEFINING THE TRADITION

The Social Ecologist John Clark has argued that although Social Ecology is associated closely with Bookchin's work, it is part of a long philosophical tradition (Clark 1998). Clark creatively traced—or, as Andrew Light (1998) described it, creatively invented—the intellectual tradition that preceded Social Ecology. Among its forerunners was the anarchist Petr Kropotkin with his emphasis on the significance of "mutual aid" among animals and humans and model of a human society organized in communities founded on cooperation and free from central government (Kropotkin 1987). The geographer and anarchist Elisée Reclus, a colleague of Kropotkin's, prefigured ideas of Social Ecology in envisioning the reorganization of societies into communities embedded within their ecological and geographic regions (Clark and Martin 2004). The historian and social theorist Lewis Mumford may be regarded as an early Social Ecologist for his analysis of the way mechanization and domination lead to the dissolution of human ties to the natural world (Mumford 1967). Bookchin contributed the most elaborate articulation of Social Ecology: His argument, which continues to stand as the central pillar of Social Ecology, is that the destruction of nature originated in hierarchical and class-structured social domination among humans (Bookchin 1982).

WHAT IS SOCIAL ECOLOGY?

Clark's description of Social Ecology as "the awakening earth community reflecting on itself, uncovering its history, exploring its present predicament, and contemplating its future" highlights its general threads and calls attention to its predilection for theorizing nature and society as a unity (Clark 1998, p. 416). More specifically, key themes and arguments of Social Ecology include the following:

- Viewing nature and society as emerging through an evolutionary unfolding toward increasing diversity, complexity, freedom, and consciousness by means of processes that foundationally involve interconnection, complementarity, and cooperation;
- Understanding the relationship between nature and society as a holistic unity in diversity and seeking to discover why this relationship has gone awry; regarding social conditions and structures as the causes of the detrimental impact of humanity on nature;
- Critiquing institutionalized forms of dominance, both hierarchical and class-based, not only from a social-justice perspective but also for being causally implicated in ecological destruction;
- Privileging social-structural explanations of ecological disruptions over biological and/or psychospiritual explanatory frameworks such as human population growth and human chauvinism;
- Assessing the capitalist market economy as the major force behind intensifying ecological problems;
- Identifying capitalism as an economy, way of life, and thought style that has colonized every aspect of human life and the natural world;
- Agitating for the revolutionary abolition of all forms of domination rather than seeking reformist solutions to social and ecological problems or encouraging individual spiritual transformation;
- Urging the realization of freedom for both people and nature;
- Providing a vision of the ecological society to counter the dominance of the economism (the hegemony of the market economy) that is destroying the biosphere.

Slum District in Manila, Philippines. *A group of children in the district of Baseco in Manila play near their shanty house, which contrasts sharply with the homes being built by Habitat for Humanity aid workers behind them. According to principles of Social Ecology, ecological problems cannot be separated from social inequality and economic exploitation. In a similar vein, Social Ecologists would say that ecological destruction cannot be evaded until hierarchy and class structure are abolished.* **JOEL NITO/AFP/GETTY IMAGES.**

According to Social Ecologists, the human-nature relationship is formed through the structural and conceptual relations that predominate in any society. The drive to dominate nature originated in and is perpetuated by the human domination of humans. Social domination is organized along lines of hierarchy and class stratification: Hierarchy involves the valorization and institutionalization of human differences (gender, race, ethnicity, etc.), and class divisions are based on unequal ownership or control of material wealth and means of production. Both forms of domination underlie the destruction of nature, for it is only when differential status, master-servant relationships, and economic exploitation emerge in the social world that human beings direct related ideas and actions to the world of landscapes, animals, and plants. Ecological problems never have been separate from social inequity and economic exploitation, and the ecological crisis cannot be resolved without a revolutionary restructuring of society on the economic, political, cultural, and value levels.

In making the case for the causal primacy of social structure in the way nature is treated, Social Ecologists echo a long-standing sociological predilection for viewing social patterns as being projected onto nonsocial domains, especially the realms of gods and nature. Within any society all its dimensions are aligned through the structural and ideological mappings that the sociologist Max Weber characterized as manifesting ''elective affinity.'' Thus, societies stratified through systems of domination project a blueprint of stratification onto the natural world, representing it as a domain inferior to humanity. That projection makes nature available for many forms of physical domination: destruction of habitats, conversion of ecosystems, ownership of land,

exploitation of life forms, and experimentation on animals as well as the overarching constitution of the nonhuman world as a realm for instrumental use.

The upshot of this analysis is that ending ecological destruction hinges on abolishing domination in society. This analysis may explain why the contemporary environmental movement, along with the earlier work of Henry David Thoreau and John Muir, has been unable to turn things around. From a social-ecological standpoint, the creation of an ecological society requires nothing less than the emergence of an emancipated humanity that abandons hierarchical valuations and economic inequalities, charting instead a new historical course for both humans and nature into realms of creativity and freedom.

Although the destruction of nature did not originate with industrialism but has roots in the earliest forms of hierarchy (especially patriarchy), Social Ecologists indict the market economy as the major force behind the ecological crisis. Steven Best stated that for Social Ecology "environmental problems emerge from a long history of hierarchical social relations that culminate in a class-ridden, profit-driven, accumulation-oriented capitalist society" (Best 1998, p. 337). In its addiction to limitless growth the market economy, especially "the horror of economistic-technocratic globalism" (Clark 1998, p. 429) that it has turned into, is jeopardizing the integrity of the biosphere as a whole.

From the point of view of Social Ecology, economic expansionism is leading to the colonization of all worlds: natural, social, cultural, and personal. Economism homogenizes and impoverishes the natural world while degrading human relations and experiences into commodities. Economism also has co-opted the Enlightenment concept of progress as social development that unfolds through competition and expansionism rather than through cooperation and balance. Social Ecologists do not regard the negative impact of industrialism as stemming from either technological development or cultural-ideological contrivances such as commodity fetishism that sustain overproduction but instead from an economic system founded on the "the universal reign of limitless buying and selling, indeed, of limitless growth and expansion" (Bookchin 1986, pp. 28–29). This imperative renders capitalism nearly impervious to ethical considerations and unmasks the idea of "greening capitalism" as an oxymoron if not an Orwellian smoke screen (Bookchin 1993).

Diagnosing socioeconomic forms of domination as the source of ecological destruction presents Social Ecology with the task of envisioning an alternative way of life: the ecological society. The future ecological society is portrayed as organized in ecocommunities that will be egalitarian, democratic and participatory, and semiautonomous but interconnected. Such networked communities will live in balance—both knowledge-based and heartfelt—with their ecological regions. In the ecological society people will integrate ethical considerations into their energy choices, forms of land use, and treatment of animals. Economies will be human-scaled. In the creation and exchange of objects craft will be valued over mass production, durability over constant turnover, and simple lifestyles over consumption (Biehl 1998).

The ethos of the ecological society is envisioned as cooperative with respect to people, animals, and the land. Because cooperative relationships are ontologically primary in evolutionary, ecological, and social processes, the ecological society is conceived as a realizable and actionable vision rather than a utopian will-o'-the-wisp. The creation of a social world rooted in the praxis and ethic of mutualism is theorized as restoring the primal and ever-present, even when repressed and marginalized, ground of being (Clark 1998).

THE COSMOLOGICAL FOUNDATIONS OF SOCIAL ECOLOGY

Even as Social Ecology has problematized material relations within economic, political, and sociocultural systems of domination, it has articulated a cosmological context for the emergence of humanity within an evolving universe and biosphere; the rupture between humanity and nature that has culminated in the ecological crisis is scrutinized in the same context. The materialism of Social Ecology is thus a far cry from the materialism of European and American Marxist and anarchist traditions, which shy away from theorizing the universe at large and the Earth in particular as manifestations of a cosmos of intrinsic integrity, beauty, and order. Bookchin in particular elaborated those cosmological foundations for Social Ecology, relying on dialectical naturalism to represent society as an emergent of nature and redeem the human-nature relationship (in its original unity and future potential) as complementary, harmonious, and mutually supportive. The framework of dialectical naturalism allowed him to tap into an established philosophical tradition while signaling his divergence from Hegel's Christian idealism and Marx's anthropocentric materialism.

Bookchin portrayed natural history as grading into social history without sacrificing the distinctive qualities of either domain. Everything that is characteristically or quintessentially human, from the development of science and technology to the creation of cities, the invention of writing, and the composition of music, has been eons in the making (Bookchin 1993). The peculiar qualities of human beings, such as the capacity for reason and self-consciousness, sophisticated language, the aspiration to freedom, and the power to innovate and intervene, have

emerged through and as a form of biological evolution. Social Ecology thus affirms nature and society as a continuum, or a "differentiated unity" (Bookchin 1996): This perspective opposes lifting humanity into a realm above the natural world but also objects to conflating society and nature by discounting the unique features of humanity.

Bookchin coined the terms *first nature* (the natural world) and *second nature* (human society) to underscore their similarity and divergence. The rise of domination within second nature has had dire repercussions for first nature and for society's relationship with it: The schisms and alienation created within society echo a human schism and alienation from the natural world, and the abuses inflicted on people are all easily directed at nonhumans. By overcoming the distortions arising from social domination, a dialectical unfolding can lead humanity and nature into a higher synthesis, a liberated coexistence that Bookchin called free nature (Bender 2003).

In remaining vague about the meaning of free nature, Bookchin skirted an important issue: the substantive contours of the relationship between second nature and first nature in the ecological society. Clark endeavored to correct this by unpacking Bookchin's free nature in connection with the issues of biodiversity and wilderness protection:

> The social-ecological conception of freedom as spontaneous creative order points to the need for a larger sphere of wild nature so that biodiversity can be maintained and evolutionary processes can continue their self-expression, not only in human culture and humanized nature, but also in the natural world substantially free of human influence and control. A Social Ecology therefore implies the necessity not only for wilderness preservation but also for an extensive expansion of wilderness (and relative wilderness) areas where they have been largely destroyed. (Clark 1998, p. 430)

This passage points to the attempt to harmonize free nature with key themes of environmental thought; it also represents an attempt to begin reconciling social-ecological and deep-ecological perspectives.

Human society is born out of the natural world in a biological sense but also in the ancient and originally egalitarian structuring of human relations along kinship lines, a sexual division of labor, and rights and obligations of different age groups (Bookchin 1982). Although all human qualities exist in inchoate form in first nature, second nature has evolved an unparalleled potential aptitude for rationality, self-consciousness, and intentionality. For Bookchin the deepest realization of these abilities requires freedom, but freedom has been stifled by social domination in all its forms: status distinctions, patriarchy, racism, tribalism, economic exploitation, discrimination against minorities, and state oppression. The future of both humanity and the biosphere depends on establishing the freedom within which the highest human qualities can become actualized. Bookchin tends to echo a Nietzschean assessment of human beings as an unrealized but promise-filled species hovering between ape and superman: grown beyond unselfconscious animal but not yet nature rendered self-conscious.

Bookchin attempted to sustain first nature and second nature as a continuum while honoring the qualities that make the human phenomenon unique. By underscoring positive features of humanity such as the celebration of freedom, the cultivation of reason, and the aspiration to self-consciousness, he seems to have had a twofold goal: to preempt a conscious or subterranean response of misanthropy to the ecological damage human beings have wrought and to highlight the human qualities that can be actualized after the relational and mental shackles of domination are undone and the way to the ecological society is opened.

CRITICISMS

The social-ecological preoccupation with human uniqueness has been criticized, especially by Deep Ecologists, as an expression of human chauvinism or anthropocentrism (Bender 2003). Passages in Bookchin's work in which he draws sharp lines between human nature and all other animals invite that critique. To get a theoretically tidy distinction between first nature and second nature, Bookchin tended to oversimplify animal life as one of fixed instincts and genetic programs while exulting humanity as epitomizing the achievements of reasoning, self-consciousness, intentional planning, and behavioral plasticity. However, a dualistic frame of this type is empirically problematic because it ignores advances in behavioral ecology and cognitive ethology that reveal the complexities of animal life and ethically problematic because it underwrites a human-supremacist argument.

The motive behind such dualistic maneuvers is to avoid naturalizing the ecological crisis by anchoring it in biological programs or regarding it as a consequence of Darwinian processes. After hypostatizing the distinction between human beings and animals, Bookchin and other Social Ecologists exorcise terms such as *hierarchy, domination, competition,* and *slavery* from animal relations. When that terminology is applied to the natural world, domination of people and nature (and ultimately human colonization of the biosphere) can appear legitimated as an extension of biological basics. Thus, Bookchin's attempt to distinguish humanity from the rest of the animal kingdom allowed him to pathologize domination as a pure sociocultural phenomenon and at the same time

exonerate first nature from the vices of inequity, exploitation, oppression, and subservience.

Although Bookchin's critics often deplore the sharp line he drew between humans and animals, they rarely give him and other Social Ecologists credit for defending the natural world against its historical and recent constructions as blind, mute, cruel, selfish, competitive, and stingy. Countering the ideological fiction of nature as "demonic and hostile" (Bookchin 1986), Bookchin insisted on an understanding of the natural world as creative, pregnant, fecund, participatory, relational, and wondrous (Bookchin 1986, Clark 1998).

Social Ecology propounds a philosophy of all phenomena as interrelated, jointly enhancing, and mutually forming through symbiotic and cooperative processes. Within that framework the destructiveness of domination is conceived of as fortuitous, a possible historical trajectory but not an essential or necessary characteristic of the world. The cosmology of Social Ecology is thus openly spiritual in offering a vision of the good and goodness as primary forces and in affirming evolutionary emergence in the universe and the biosphere as a creative, awe-inspiring process, though not one conceived as either supernaturally designed or with a predetermined telos. As Clark noted about the implications of this cosmology for a possible future, "the ecological society that is the goal of Social Ecology is found to be rooted in the most basic levels of being" (Clark 1998, p. 421). For Social Ecologists, in a just and ecologically harmonious world, humanity will return to a primordial condition, but this will involve the restoration of the original essence and potential of humankind, not the reinstatement of the Stone Age or the Pleistocene.

THE CLASH BETWEEN SOCIAL ECOLOGY AND DEEP ECOLOGY
