We dedicate this book to older adults and their families worldwide who deserve only the best of social and health care services, and to those social workers who strive every day to help them manage their health with quality of life.

This page intentionally left blank

Preface

The leading causes of morbidity and mortality are almost all related to chronic diseases, resulting in acute episodes of illness over many years. The growing number of elderly with chronic disabling illnesses and the increasing need for rehabilitative services to support independent functioning means that patients and families will require more psychological and social assistance in order to address their problems effectively. Therefore, the goal of health care for the older adult is not only to provide state-of-the-art medicine and nursing, but must also focus on how the older person can manage his or her health with quality of life. Thus, we require state-of-the-art social work. Social workers and other health professionals with knowledge in aging will become even more essential to address the complex needs of older people and their families. Elderly people with chronic diseases and activity limitation will represent an increasing percentage of all persons helped by social workers.

Historically, the social work profession has separated the issues of aging from the fields of health and mental health. This has been most evident in social work education where we have developed specializations and concentrations in aging as distinct from those in health, mental health, and disability. However, a growing body of research has shown that social work practice with older adults and their families—once virtually the exclusive concern of social workers in geriatric sites—is increasingly becoming a major focus of care in a range of health and community-based services. For example, we know that in hospitals at least 40% of patients served by social workers are older adults and their caregivers. Given the dramatic growth in the numbers and proportion of older adults in our society, it is time to bring the concepts of aging and health care together in our educational programs, in our

practice, in our policy considerations, and in our research.

The *Handbook of Social Work in Health and Aging* is the first reference text to combine the fields of health care, aging, and social work in one concise volume. The *Handbook* was developed to address a critical gap in reference literature among these areas, which are too often treated as discrete entities. The reality is that all social workers deal with issues in health and aging on a daily basis, regardless of practice specialization. And, as the baby boomers age, the impact on practice in health and aging will be dramatic with social workers needed to meet the increasing demands of a growing aging population. Social workers who consider themselves generalists may find their clientele “graying” in the next decade. All social workers need more specialized knowledge about aging, health care, and the resources available to best serve older adults and their families.

The *Handbook of Social Work in Health and Aging* was specifically planned and designed as an all-inclusive and practical reference. It contains 100 original chapters and 13 overviews written by the most experienced and prominent gerontological health care scholars in the United States and across the world. The *Handbook* was designed to provide social work practitioners and educators with up-to-date knowledge of evidence-based best practice guidelines for effectively assessing and treating older adults and their families; new models for intervention in both community-based practice and institutional care; and knowledge of significant policy and research issues in health and aging.

PLANNING AND DEVELOPMENT OF THE HANDBOOK OF SOCIAL WORK IN HEALTH AND AGING

Planning for the *Handbook of Social Work in Health and Aging* began in May 2003 and took its lead from the *Social Workers’ Desk Reference* (Roberts, 2003). For further guidance, the editors relied on a ten-person editorial board composed of nationally known social work scholars in gerontology and health care. This board was formed in November 2003 to provide oversight and perform editorial support functions for each section of the *Handbook*. In addition, in order to ascertain which topics would be relevant to social workers in practice with older adults, Berkman and D’Ambruoso administered a national survey to over 150 gerontological social work educators

and practitioners from a database that exists thanks to the generosity of the John A. Hartford Foundation in its funding of the Hartford Geriatric Social Work Initiative, a multi-million dollar undertaking to strengthen research, teaching, and practice in gerontology and social work. The survey was inspired by a similar national survey done by Al Roberts, editor of the *Social Workers’ Desk Reference* and generated a list of substantive topics for inclusion in the *Handbook*, as well as a list of known experts in the field. Based on the findings of the survey, the editors collaborated with the editorial board to finalize the topical areas, the chapter entries, and the contributor invitations. Contributors to the *Handbook* were selected for their established breadth and depth of knowledge in a given area. We are proud that the *Handbook* includes authors of various ethnic, racial, gender, and sexual identities, reflecting the diversity of the very populations with which we work.

ORGANIZATION OF THE HANDBOOK

Following a comprehensive chapter on aging by Nancy Hooyma, the *Handbook of Social Work in Health and Aging* is organized around seven unifying parts: part A, the populations social workers serve; part B, where social workers practice; part C, how social workers practice; part D, local, state, and federal policies affecting social work practice with older adults; part E, international social work and the care of older adults; part F, social work research in aging; and part G, social work education and careers in aging.

Parts A, B, and C are subdivided into sections each of which contain chapters that focus on similar domains. Each subsection has a section editor who has written an overview of the chapters in the section. Parts D, E, F, and G are not subdivided, as we believe the chapters contained in each of these parts relate to a similar domain. Each part has an editor who has written an overview of its chapters.

This *Handbook* is planned as a comprehensive reference text that covers the major areas of social work in health and aging in one volume. The chapters in the *Handbook* present a balanced mix of current research-based knowledge and current key policy decisions, issues, and trends, as well as research needs. Each chapter has been concisely written, synthesized, and integrated in order to create an overview of the topic. In addition, heuristics are used throughout the

Handbook to engage the reader and generate quickly and easily consumed knowledge. The references contained in each chapter are invaluable and can lead the reader to locate even more in-depth knowledge. The ideal way to begin reading this text is to peruse the

table of contents, which, we believe, will give the reader a clear, comprehensive view of the field of health and aging. We hope you will be impressed and gratified as you review the depth and wealth of knowledge presented.

Acknowledgments

We must begin by thanking our editorial board, Amanda Smith Barusch, David E. Biegel, Iris Carlton-LaNey, Namkee G. Choi, Linda Harootyan, Nancy Hooyman, Amy Horowitz, Rosalie A. Kane, James E. Lubben, Deborah D. Padgett, Marsha Mailick Seltzer, and Patricia Volland. These brilliant scholars provided the guidance and support for what at times seemed like a monumental endeavor. Without their support, we doubt this book would ever have been undertaken. And, we could not have created this volume without the dedication and skills of our section editors. They worked beyond our expectations (and sometimes their own) to create this single volume knowledge base of social work in health and aging, a feat never before achieved. We also thank our contributors who wrote exceptional chapters that met our stringent guidelines for conciseness while thoroughly covering their subjects. And finally, we cannot begin to offer the appreciation we owe to the board and staff of the John A. Hartford Foundation of New York City. Their support for the Hartford Geriatric Social Work Initiative has created a rebirth of interest in social work in health and aging and generated a growing network of social work specialists in aging who, with other health professionals, will be available to meet the needs of our aging population.

Introduction

Our Aging Society

NANCY HOOYMAN

DEMOGRAPHY OF AGING

The dramatic growth of the older population is the most compelling factor underlying the importance of this *Handbook of Social Work in Health and Aging*. Given such growth, social workers in all practice arenas and with all age groups increasingly encounter older adults and their families in the child welfare system, family services, schools, mental health centers, AIDS treatment clinics, and among the homeless. In 1900, older adults formed approximately 4% of the U.S. population, less than 1 in 25. In the past hundred years, the older population increased twelve-fold, compared with a threefold increase in those under age 65; older adults now comprise approximately 35 million or 13% of the total population. Moreover, the number of people over age 65 is projected to double to more than 70 million by the year 2030, approximately 21% of the U.S. population (Administration on Aging, 2002).

With a 300% increase from 1960 to 2000 among the “oldest old,” those aged 85 and over now comprise more than 12% of the aging population. Although the young old (ages 65–74) currently form 53% of the older population, these proportions will shift to 44% young-old and 23% oldest-old by 2050. Among the oldest-old there was a 35% growth in “centenarians” from 1990 to 2000 (Administration on Aging, 2002; U.S. Bureau of the Census, 2001a). Because the oldest-old tend to have multiple physical and cognitive impairments and declining levels of functional disability, they are disproportionately represented in long-term care settings and publicly funded social and health services, where they and their families interact with social workers (U.S. Bureau of the Census, 2002).

Baby Boomers

The most striking increase in size of any age group in the 2000 census was the 49% jump in those 45 to 54 years old, prefiguring the baby boomer's entry into the 65-plus cohort, which begins in 2010. One in 26 baby boomers is expected to live to be 100 by 2025. By the year 2050, the older population (age 65 plus) is projected to comprise 20% of the U.S. population (U.S. Bureau of the Census, 2001, 2002). This significant percent increase in older adults will profoundly affect the demand for social, health, and long-term care services. With less than a ten-year window to prepare for the coming "Age Boom," the unprecedented jump in the number of older adults through the first half of this century has created a sense of a "demographic crisis" (Alliance for Aging Research, 2002).

Life Expectancy

These generational shifts are occurring because of increases in life expectancy (average length of time that one can expect to live based on the year born). Life expectancy in America has gone from 47 years in 1900 to 76.9 years currently, and is projected to reach 77.6 years in 2005 and 82.6 years in 2050. Approximately four out of five individuals can now expect to reach age 65, at which point there is a better than 50% chance of living past age 80. A five- to six-year gender difference in life expectancy is projected, with females born in 2000 expected to live to age 79.5 and men to age 74.1 (National Center for Health Statistics, 2000b; Population Reference Bureau, 2003). These projections do not, however, take into account potentially new diseases that could differentially affect mortality risks for men and women. If AIDS continues to infect younger men, the gender differential in life expectancy could increase. On the other hand, women's growing death rates due to heart attacks and stroke could narrow such gender differences over time. Most gains in life expectancy are not the result of medical advances in old age, but rather are due to better medical care and eradication of diseases at early ages (e.g., influenza, TB).

Worldwide Trends

All regions of the world are experiencing an increase in the absolute and relative size of their older populations. The number of elders in the world is expected

to grow from approximately 420 million in 2000 to 761 million in 2025. In fact, one out of every seven people in the world will be 65 years or older by 2025 (U.S. Bureau of the Census, 2001b; 2002). Differences between industrialized and developing countries are dramatic. In 2000, the population age 65 and older for most Western European countries was estimated to be greater than 15%. With the highest life expectancy in the world, Japan is experiencing the world's most rapid rate increase of the older population—from 7% in 1970 to 17% in 2000. In contrast, only 3% of the population of South Asia and Sub-Saharan Africa are elders, largely because of high fertility and mortality rates. Nevertheless, as a result of improved sanitation, nutrition, and medical care, the less-developed regions of the world expect to show a nearly fivefold increase in their oldest citizens, from 3.8% in 1975 to 17% in 2075, with the most rapid growth among the oldest old. By the year 2025, only 30% of older adults are projected to live in industrialized nations, while 70% will be in developing countries (U.S. Bureau of the Census, 2001b; Population Reference Bureau, 2003; United Nations, 2001).

Normal Aging and Disease-Related Processes

Social workers need to understand the differences between normal aging and disease-related processes. As a universal biological phenomenon that begins with birth, aging refers to changes—good, bad, and neutral—that occur throughout the lifespan. After age 30, however, all physiological systems—sensory, organ, respiratory, and cardiovascular—tend to reflect normal decline and increased vulnerability to disease. Individuals cope in different ways with this gradual accumulation of irreversible functional losses. Even with 50% deterioration in many of these systems, an older person can still function adequately by modifying their environment (International Longevity Center, 1999). Wide variation in the aging process within and across individuals results from differences in heredity, diet, exercise, socioeconomic status, and living conditions.

Health status encompasses (1) the presence or absence of disease and (2) the degree of disability in level of functioning. More than 80% of older adults have at least one chronic condition, but this does not necessarily interfere with their activities of daily living or ADLs (e.g., cooking, getting dressed, bathing, toileting). Approximately 20% of elders have a mild degree

of disability that alters daily routines, with only about 4% severely disabled and 2% confined to bed by chronic conditions (Merck Institute, 2002; NCHS, 2000a). The extent of disability, the need for help with daily activities, and the type of supports available typically determine whether older adults can remain in their own homes, or may need to move to an assisted living facility, adult family home, or nursing home (Lubben & Girona, 2003). Because of inequities experienced across the life span, older women and ethnic minorities are most likely to experience disabling illness along with poverty and inadequate housing—problems that social workers must address.

Although normal aging does not result in significant declines in intelligence, learning, and memory, the prevalence of mental disorders ranges from 5 to 45% of the older population, depending on whether samples include older residents in institutional settings (Gatz & Smyer, 2001). In some instances, these represent mental illnesses that have occurred across the life span. Depression is the most common mental disorder in late life (Blazer, Hybels, & Pieper, 2001). The likelihood of dementia, particularly Alzheimer's, increases with advancing age, with some estimates as high as 50% for those age 85 and over (Institute of Medicine, 2001). Social workers are committed to enhancing the quality of life, sense of competence, and independence of older adults, regardless of elders' extent of disability or functional health.

HETEROGENEITY OF THE OLDER POPULATION

Ethnicity and Race

The older population is becoming more ethnically and racially diverse. Currently, a smaller proportion of ethnic minorities are over 65 and a larger percent are younger adults when compared to the white population. Those 65 and older comprise 8% of African Americans, 5.6% of Latinos, 2.4% of Asians/Pacific Islanders, and less than 1% of American Indians, compared to 14.4% of Caucasians. These differences result primarily from both the higher fertility and mortality rates among the nonwhite population under age 65. However, these proportions will shift dramatically when the large percent of ethnic minority children who, unlike their parents and grandparents, reach old age. The percent of people of color over age 65 is projected to increase from approximately 16% in 2002 to 34% by 2050, faster than the rate of growth among the

Caucasian population (NCHS, 2000; U.S. Bureau of the Census, 2002). Given these demographics, it is imperative that gerontological social workers be culturally competent.

Gender

Women form the fastest-growing segment of the older population, especially among the oldest old, making the aging society both in the United States and globally primarily a female one. Because of women's longer life expectancy, they represent 55% of the population aged 65 to 74 and 71% of those over age 85 (U.S. Bureau of the Census, 2000). However, men who survive beyond age 85 are likely to be in better health and have a similar life expectancy—or even more remaining years than women (Calasanti & Slevin, 2002; Moen, 2001).

Sexual Orientation

Estimates of the number of older gay men and lesbians range from as low as 3% to as high as 18 to 20%. This translates into at least two million older lesbians and gay men, which will likely increase to over six million by the year 2030 (Cahill et al., 2001; Wojciechowski, 1998). As a result of their history of disadvantage, marginalization, and invisibility, lesbians and gay elders may encounter obstacles in both receiving and providing care, including discrimination from providers, limited access to supportive services, and lack of legal protection for their partners and other loved ones (Barranti & Cohen, 2001; Brotman, Cornier, & Ryan, 2001; Brotman, Ryan, & Cormier, 2003; Cahill et al., 2001; Clunis, Fredriksen-Goldsen, Freeman, & Nystrom, in press; Gabbay & Wahler, 2002).

Geographic Location

With regard to geographic diversity, about 52% of all adults age 65 and over live in nine states, with the greatest proportions in Florida (17.6%) and Pennsylvania (16%) and lowest in Alaska (5.7%) and Utah (8.5%). In some states, such as Florida, migration of older adults explains the increase, while in others, such as West Virginia and South Dakota, migration of young people out of the state leaves a greater proportion (15%) of older people. Residential relocation is relatively rare for older adults. In a typical year, less

than 5% of older persons move compared with 18% of people under age 65 (Administration on Aging, 2000; 2002). Approximately 23% of elders live in rural areas, 21% in cities, and the largest cohort (56%) in suburbs, reflecting the “graying of the suburbs” (AARP, 2002).

Education

Today’s older population is better educated, with 70% of those over age 65 being high school graduates compared with less than 20% in 1960. Nevertheless, racial and gender differences in education and socioeconomic status are striking. Among Caucasians age 65 and older in 2000, 74% had completed high school, compared with 51% of African American and 35% of Latino counterparts. Because educational level is closely associated with economic well-being, these differences impact poverty levels of persons of color across the life span, and particularly in old age (Elder & Liker, 2000; Stoller & Gibson, 2000).

Socioeconomic Status

Older adults comprise only 3% of the U.S. labor force, with 17% of men and 9.7% of women over age 65 reporting that they work full time outside the home, although many older adults prefer and seek part-time work (U.S. Bureau of the Census, 2002). Social Security is the primary source of income for most retired Americans; of the 90% of older adults who receive Social Security; approximately 66% rely on it for at least 50% of their income. In 2000, only 22% of elders identified earnings and 41% private pensions as primary income. In fact, Social Security benefits underlie the improved economic status of older adults. Currently, over 10.1% of elders are poor, compared to 35% in the late 1950s; another 6.3% of older adults are classified as “near poor” (Administration on Aging, 2002; Kingson & Williamson, 2001; National Center for Policy Analysis, 2003). This improved economic status as a whole, however, overlooks the growing poverty rates among older women, elders of color, the oldest old, and those living alone. Older women are nearly twice as likely to be poor as their male counterparts (13% vs. 7%), and older African American and Latino women are the poorest and most functionally disabled groups in our society. Poverty is highest among elders in central cities and rural communities (U.S. Bureau of the Census, 2002; Women’s Institute for a Secure Retirement, 2003).

LIFE COURSE PERSPECTIVE

Since the meaning of chronological age varies by culture and social class, “people as they age” may be a more useful concept than older adults. A life course perspective, rather than a focus only on elders, recognizes (1) the reciprocity or interdependence across multiple generations; (2) the presence of older adults in settings that typically serve “younger populations”; and (3) the interplay among generational influences, the larger social and historical contexts, and economic and health inequalities, which results in cumulative disadvantage across the life span for historically disadvantaged populations (Elder & Johnson, 2001).

Given social work’s mission of social justice, social workers are pivotal in addressing economic inequities and health disparities across the life span. While the likelihood of chronic illness grows with age, the origins of risk for chronic health conditions begin in early childhood or earlier (World Health Organization, 2002). Regardless of age, chronic disability magnifies the risk of poverty throughout the life course. Furthermore, this risk continues to be impacted by socioeconomic status and associated life experiences across the life cycle (Burton & Whitfield, 2003; Whitfield & Hayward, 2003). Similarly, childhood conditions explain a substantial portion of the race gap in men’s mortality, operating indirectly through adult socioeconomic achievement, not lifestyle factors (Warner & Hayward, 2002). Alternatively, gains in socioeconomic status are related to people living longer and healthier lives (Lynch, Smith, Kaplan, & House, 2000). Life course research aims to uncover the patterns of relationship among resources or “social capital” earlier in the life span and their effects on different groups within the aging population (O’Rand, 2001, 2003). The importance of interventions early in the life course to enhance quality of life in old age was articulated by the 2003 Gerontological Society of America conference theme, *Our Future Selves: Research, Education, and Service for Early Development and Childhood in an Aging Society*.

Families as They Age

About 66% of older adults live with a partner, child, or sibling, although not necessarily in a multigenerational household, and nearly 94% have living relatives (Administration on Aging, 2002; Connidis, 2001). The 6% without family ties, particularly women and elders of color, typically turn to support from friends,

neighbors, acquaintances, and community gatekeepers (Moen, Erickson, & Dempster-McClain, 2000). Nearly 60% of the young old are married and live with a spouse in an independent household, although the percent living with a spouse declines with age. Given the higher rates of widowhood among women than men, older men (83%) are more likely to live in a family setting, generally with a partner, than are women (59%). Accordingly, women represent 80% of the individuals who live alone. Although the majority of older parents do not live (and prefer not to) with adult children, they typically have at least one child nearby whom they regularly see (Administration on Aging, 2002). However, declining health, loss of a former caregiver or partner, desire for companionship, and lower income often precipitate a move to an adult child's home (Wilmouth, 2000).

With increased life expectancy, the multigenerational family has also grown. Among Americans over age 35, 80% are members of a three-generation family, and 16% of four generations (Bengtson, 2001; Bengtson, Putney, & Wakeman, 2004). Parents and children may now share five decades of life, siblings eight, and grandparents and grandchildren three or more decades that tend to be characterized by emotional closeness (Bengtson, Biblarz, & Roberts, 2002; Gonyea, forthcoming, 2006). This modified extended family, which appears to be stronger now than ever before, is characterized by moderate face-to-face contact and greater geographic distances between family members, yet high rates of communication (often electronically) and strong norms of filial obligation (Bengtson, Biblarz, & Roberts, 2002; Bengtson, Putney, & Wakeman, 2004; Navaie-Waliser, Feldman, Gould, Levine, Kuerbis, & Doneland, 2001).

Generally, families experience a pattern of reciprocal support between older and younger members, with older adults providing support to children and grandchildren as long as they are able (Silverstein, Conroy, Wang, Giarrusso, & Bengtson, 2002). Yet increased longevity also means extended years of caring for community-residing older relatives with chronic illness or disability (Bengtson, 2001; Bengtson, Biblarz, & Roberts, 2004). Families, who provide approximately 80% of such care, are a significant factor influencing whether an older adult will live in a nursing home. Paradoxically, because of reduced fertility, fewer people within each generation may be available in the future to provide care for older relatives. Caregiving is not only from younger to older generations. For example, with the increased life expectancy of adult children with developmental disabilities or mental illness,

more elders are providing care for their adult children while faced with their own declining health.

Women—daughters, daughters in law, and wives—form 80% of family caregivers of elders. In fact, nearly 40% of baby boomers are part of the “sandwich generation,” facing demands from employment, dependent children, and older relatives (Brody, 2004; Ingersoll-Dayton, Neal, & Hammer, 2001). The financial, physical, and emotional burdens (Beach, Schulz, Yee, & Jackson, 2000; Connell, Janevic, & Gallant, 2001; Polen & Green, 2001; Tennstedt, 1999) and, more recently, gains of caring for older family members are extensively documented (Kramer, 1997; Beach et al., 2000; Narayn, Lewis, Tornatore, Hepburn, & Corcoran-Perry, 2001; Sherrell, Buckwalter, & Morhardt, 2001). Children and spouses typically turn to institutionalization as a “last resort” when faced with their own illness, severe family strain, or exhaustion of resources (Seltzer & Li, 2000). Although most family caregivers do not utilize formal services, psychoeducational programs, support groups, and respite care are found to be relatively effective interventions in reducing caregiver stress, all of which have implications for social work roles (Burgio, Stevens, Guy, Roth, & Haley, 2003; Gartska, McCallion, & Toseland, 2001; Mittelman, 2002; Morano, 2000; National Respite Network and Resource Center, 2002; Schulz et al., 2002; Toseland, Peak, & Smith, 1990).

The heterogeneity of American families, within the context of greater economic uncertainties, is also increasing with the growth in divorce and blended families, numbers of people living alone, single-parent households, and never-married individuals living together in other nontraditional family arrangements (e.g., grandparents raising grandchildren, gay and lesbian families, and single parents choosing to raise children on their own). Given this diversity, it is imperative to broadly define family by interactional quality, not necessarily by members' living together or blood ties. Kinship, a matter of social definition, varies by culture and socioeconomic class. This voluntary intergenerational latent kin matrix is typically activated in times of need (Bengtson, Putney, & Wakeman, 2004). For example, grandparents as primary caregivers to grandchildren, and the extended network of fictive kin—“play relatives,” godparents, and friends—are defined as family among many ethnic minorities, and chosen or “friendship” families are a source of support for many gay men and lesbians.

The growth of the multigenerational family is illustrated by the fact that among the 80% of older parents currently, 94% are grandparents and nearly 50%

great grandparents. Similarly, approximately 96% of all persons have at least one grandparent alive when they reach age 20 (Uhlenberg & Kirby, 1998). Women may experience grandparenthood for more than 40 years, since the transition to grandparenting typically occurs in middle age, not old age (Giarrusso, Silverstein, & Bengtson, 1996; Szinovacz, 1998). Most grandparents derive satisfaction from their role and interaction with grandchildren (Davies & Williams, 2002). Grandparents have traditionally provided care for grandchildren, especially across families of color and immigrant families (Cox, 2002; Pruchno, 1999). What has changed in the past two decades is the rapid growth of grandparents (or great grandparents) who are the primary or sole caregivers for grandchildren (Fuller-Thompson & Minkler, 2001). In fact, such skipped generation households (e.g., the absence of the parental generation) are the fastest growing type (Wallace, 2001). Similarly, the number of children living in a home with both a parent and grandparent present has declined (Casper and Bianchi, 2002).

In 2000, 4.5 million children under the age of 18 lived in grandparent-headed households, and about 2.1 million were being raised solely by their grandparents with no parents present. These grandparent caregivers have been called the “silent saviors” of the family (Goodman & Silverstein, 2001), and face considerable stress and numerous obstacles when dealing with child welfare, health care, TANF (Temporary Assistance for Needy Families), and school systems (Giarrusso, Silverstein, & Feng, 2000; Green & Berrick, 2002; Minkler, 1999; Minkler, Berrick, & Needell, 1999).

AGING POLICY ISSUES

The Older Americans Act, Social Security, Medicare, and Medicaid are the primary federal policies and programs responding to these demographic, health, and familial changes. The Older Americans Act (OAA), passed in 1965, funds a wide range of programs that can help older adults remain in their homes. Services encompass access (information and referral, transportation, case management); in-home (homemaker, chore, respite, home health care); community (senior centers, meals on wheels, adult day care, elder abuse prevention, advocacy); and supports for family caregivers (respite, counseling, education) through the National Family Caregiver Support Program. Assistive technology, such as Lifeline and Life Safety Systems, voice-activated phones, and com-

puter reminders, is also a growing resource to enable elders to remain in their own homes, although available primarily to those with the ability to cover technology-associated costs. When older adults need a higher level of care, planned housing options other than nursing home care are available: congregate housing, continuing care communities, assisted living, and adult foster care/homes. Only about 5% of older adults live in a nursing home at a given point in time, although approximately 50% require such care during their lives. Because older adults and their families typically turn first to the growing number of non-nursing home options, nursing home residents are generally sicker, older, suffering from dementia, and require more intensive services than their counterparts 20 to 30 years ago. Nearly 50% of all nursing home residents are single women or widows without close family (NCHS, 2000).

While the Older Americans Act funds primarily social services for elders, Medicare and Medicaid are the primary funding sources for health and long-term care. Medicare, however, covers less than 50% of the total health expenditures of older adults, since it does not pay for long-term care and only partially for prescription drugs (Schoen & Cooper, 2003). Medicaid does pay for nursing home care, but only for those who fall below a certain income level. In recent years, most states have petitioned the federal health care authority for Medicaid waivers to provide community-based options, such as adult day care and home health aids. Ongoing cuts in Medicaid, however, are limiting services at the state level. As noted above, the crisis facing our society is not the growth of the older population per se, but increased economic and racial inequities across the life span and into old age. Inadequate public policies and programs for elders and other historically disadvantaged populations have created such life course inequities, which are now exacerbated by trends of privatization, individualization of risk, and current economic difficulties in the United States and worldwide (Parrott, Mills, & Bengtson, 2000; O’Rand, 2003).

LOOKING TOWARD THE FUTURE

Senior boomers are projected to be healthier and of higher economic status than current cohorts of elders. If the trend toward early retirement continues, they may experience up to one third of their lives outside full-time employment. Senior boomers are likely to remain productive, not necessarily in the traditional

sense of paid work, but by engaging in activities that contribute to society, whether through child care, volunteer work, leadership in organizations, and assistance to family, friends, and community members (Hinterlong, Morrow-Howell, & Sheraden, 2001). With older adults as our most underutilized societal resource, social workers can provide leadership in developing strategies to build upon elders' knowledge, wisdom, and time. Cross-generational coalitions addressing societal needs, such as Generations United and new intergenerational program models, may serve to reduce competition among age groups for limited resources. However, the increasing policy emphasis on the concepts of successful, active, vital, or productive aging can overlook ethnic minority elders and older women who lack the financial resources to sustain activities such as exercise or voluntarism in old age (Estes & Mahakian, 2001; Holstein & Minkler, 2003). Resilience may be more useful for conceptualizing elders' strengths (e.g., internal, family, community, and cultural capacities) when faced with adversity. In fact, many older adults find purpose and meaning in their lives because of adversity, not despite it, and may—even when impaired—contribute to society in diverse ways (Ryff, Keyes, & Hughes, 2003). The opportunity and challenge for the social work profession is to address both increased longevity for the majority of older adults along with life span inequities for historically disadvantaged populations. Social work, with its person-in-environment perspective and strengths-based values, is pivotally placed to foster innovative, multicultural, and cross-generational partnerships to enhance the well-being of adults and their families as they age.

**Social Work Practice and Older Adults With Chronic
Physical and Health Conditions**

This page intentionally left blank

OVERVIEW

Social work practice with older adults, whether or not specifically focused on health issues, requires knowledge of the range of age-related health conditions and physical disabilities, as well as an appreciation of the impact of these conditions on the well-being of both the older adult and their family members. This section contains eight chapters that address the major health conditions experienced in later life that affect significant subgroups of older adults. Each chapter addresses the empirical and clinical evidence base in terms of prevalence, risk factors, characteristics of the condition, treatment options, psychosocial impact on older adults and their families, considerations for social work practice, and future research needs.

Peter Maramaldi and Jonghyun Lee focus on cancer and aging and emphasize that trends in prevalence and treatment are changing the perception of cancer from an inevitable terminal condition to a chronic disease that is largely age-related. Amy L. Ai and Lynn Carrigan examine age-related cardiovascular disease, one of the most prevalent conditions of later life and a major cause of mortality in older cohorts. One of the major themes in this chapter is the close relationship between the emotional status of the older individual and the morbidity and mortality associated with cardiovascular conditions. Diabetes is also an extremely prevalent and potentially life-threatening condition in later life and, as the chapter authors Richard Francoeur and Jennifer Elkins stress, can lead to significant systemic complications, including cardiovascular problems, vision disorders, neuropathy, and cognitive impairment. Helen Miltiades and Lenard W. Kaye review the major orthopedic diseases and associated conditions, including the predictors and consequences of both falls and fear of falling among older adults. They highlight the important role that social workers can play in encouraging active lifestyles among older adults, as both a preventive approach and one that can minimize the disability associated with orthopedic problems. Cynthia Stuen clearly highlights that, though often overlooked and/or misinterpreted as involving normal aging *changes*, sensory *impairments* in later life, especially those resulting from age-related vision and hearing disorders, can have profound functional and psychological consequences for older adults. Developmental disabilities, as discussed by Elizabeth Lightfoot, and HIV/AIDS, covered by Cynthia Poindexter and Charles Emlet, are conditions not typically associated with aging. However, each has increasing relevance for gerontological social workers as increased

life expectancy in both groups has resulted in emerging populations of older adults who are aging with these health conditions. Michelle Putnam and Susan Stark look at disability in later life across conditions. They argue for the social model of disability as a situation that is as much a function of environmental conditions as it is of individual characteristics.

There are several themes that emerge from these thoughtful reviews that have implications for social work practice with older adults. First, it is clear that physical and mental health have strong, reciprocal relationships. That is, age-related health conditions and impairments place the older adult at greater risk of mental health problems, especially depression. Depression, in turn, is a major risk factor for increased disability, further morbidity, and increased mortality rates in life-threatening illnesses. Evidence is mounting that, regardless of the particular condition, attention to the psychological consequences of age-related disease and disability is a critical component of overall care.

Second, health conditions of older adults affect the entire family system. Family members sometimes suddenly find themselves in caregiving relationships with their older relatives and, as other chapters in this volume also underscore, often experience extensive stress as a result of the physical and psychological demands of caregiving. Further, families often need information and education about the nature of the condition affecting their older relative, as well as help negotiating the typically fragmented systems of acute, rehabilitative, and long-term community and/or institutional care. Social work practice with older adults with health problems is clearly a family affair.

Third, it is evident that risk is not evenly distributed and that there are significant health disparities among older adults. Although not universal, African Americans, Latinos, and other ethnic groups often have higher rates of disease and disability when compared to Caucasians. Some differences apparently have a physiological base (e.g., higher rates of glaucoma among African Americans); others are clearly a function of societal inequities in access to care, as well as socioeconomic characteristics associated with poor health behaviors (e.g., obesity, smoking) that increase risk of conditions such as cardiovascular disease and diabetes. Advocacy on the individual and policy level is a critical component of social work practice with this population.

Fourth, social work practice with older adults with chronic health conditions increasingly means working with multidisciplinary health teams and across both systems of care and service networks. That is, older

adults with health conditions often move in and out of the different sectors of the health care system—acute care, rehabilitative care, home care systems, and long-term care facilities—and not necessarily in linear fashion. Furthermore, providing care for particular subgroups often means coordinating aging network services with, for example, services available from mental health, disability and rehabilitation, and developmental disability networks.

Finally, the authors have identified directions for future research. Especially highlighted is the need for well-designed, controlled intervention studies that test service models (e.g., mental health interventions in health care settings, models to enhance self-care, family support programs) targeted to improving the care and enhancing the quality of life for older adults with chronic health conditions and impairments.

Following heart disease, cancer is the second leading cause of death in the United States (American Cancer Society [ACS], 2004a). The annual cancer projections published by the ACS indicate that more than 560,000 people will die of cancer in 2004; that is, approximately 1,500 people in the United States are expected to die from some form of cancer every day. During the same year, more than 1.4 million people are projected to be newly diagnosed with cancer (ACS, 2004b). Once diagnosed, an individual is considered to be a “survivor” for the remainder of her or his life (National Cancer Institute [NCI], 2005b). In 2001 (the most recent year for which data are available), it was estimated that 9.8 million people, or 3.5% of the U.S. population, were survivors of cancer. Of the almost 10 million survivors, 14% had been alive 20 years or longer (NCI, 2005a). For many people, especially older people, cancer has taken on dimensions of a chronic disease.

CANCER AS A CHRONIC CONDITION

Sustained public health efforts have resulted in increased participation in community-based cancer screening, improved diagnostic technology, and advances in treatment modalities. As a result, the number of cancer survivors will continue to increase, many of whom will be living with multiple chronic conditions. Although a malignant tumor can be resected and cancer cells can be destroyed through radiation therapy and chemotherapy, cancer can recur to the same site or other parts of the survivor’s body. An individual with a past cancer history is considered at risk for a recurrence of the original cancer at the same site or other parts of the body. Therefore, regardless of age, an individual with a cancer history must be diligently monitored for recurrence of a previous cancer or the occurrence of a new form of cancer. With survivors living longer, often with more than one chronic condition, some types of treatable cancer can be seen less as a terminal disease and more as a manageable chronic condition. This is especially relevant for older populations who may have perceived a cancer diagnosis as a death sentence given their early life experiences prior to the current advances in cancer control. Yet, despite advances, cancer remains a deadly and debilitating disease.

CANCER MORTALITY

National data on cancer mortality in the United States were first collected in the 1930s. These data indicated

PETER MARAMALDI
JONGHYUN LEE

Older Adults With Cancer

that death rates from cancer continued to rise steadily for more than 50 years, until epidemiological surveillance revealed something astounding in the 1990s: a decline in cancer deaths. Extensive interdisciplinary efforts to control cancer appear to have had a cumulative effect on cancer incidence and mortality. Despite these gains, however, the aging of the population will result in greater numbers of people being diagnosed with cancer because of the association between cancer and aging, even if the current cancer rates remain constant. If cancer rates follow current patterns, cancer incidence will double over the next half-century, with 2.6 million newly diagnosed cases in the year 2050. This estimate is according to a 2002 interagency report by the major institutions in cancer research and population control: the NCI, the ACS, the North American Association of Central Cancer Registries, the National Institute on Aging, and the Centers for Disease Control and Prevention, which comprises the National Center for Health Statistics and the National Center for Chronic Disease Prevention and Health Promotion (Edwards et al., 2002).

AGING AND CANCER

Older people bear a disproportionate cancer burden in the United States. As a result, cancer is now classified as a disease of older adults (Cohen, 2003; Deimling, Kahana, Bowman, & Schaefer, 2002; Ershler, 2003; Goodwin & Coleman, 2003; Kurtz, Kurtz, Stommel, Given, & Given, 1999; Nussbaum, Baringer, & Kundart, 2003; Overcash, 2004; Sacks & Abraham, 2003; Wallace, 2001). Although older individuals have the highest incidence rates of almost all cancers, they have the lowest rates of screening procedures of proven efficiency. Data from Surveillance, Epidemiology, and End Results (the SEER Program of NCI) indicate that between 1994 and 1998, 60% of all newly diagnosed malignant tumors and 70% of cancer deaths occurred in people age 65 and older. Compared with younger segments of the population, cancer incidence rates are 10 times higher for people age 65 and older (Perlich, 2002). Considering that 75 million baby boomers born in the United States between 1946 and 1964 will age into higher risk groups for various forms of cancer, incidence rates are likely to reach all-time highs.

Although increasing age is a risk factor for almost every type of cancer, little is known about the nexus between aging and cancer. The dearth of knowledge in this area is best reflected by the multidisciplinary workshop convened by the National Institute on Aging

and the NCI in June 2001 to explore the integration of aging and cancer research. As a result of this workgroup's proceedings, the National Institutes of Health (NIH) acknowledged how little is really known in this area. Geriatric and cancer research have until this point moved in separate orbits—developing significant bodies of knowledge—with little or no intersection. As a result, NIH set a cross-institute priority to bring aging and cancer research together with research programs that will span the scientific continuum from biomedical research to behavioral aspects of population control. These coordinated efforts are likely to have a favorable impact on cancer control and the quality of life for survivors.

CANCER DEFINED

Cancer is a disease characterized by uncontrolled and abnormal cell growth that often invades nearby tissue. Cancer cells can spread through the lymphatic system and the bloodstream. There are four main types of cancer: Carcinoma begins in the skin or tissues that line or cover the internal organs; sarcoma begins in the bone, cartilage, fat, muscle, blood vessels, or other connective tissue; leukemia starts in blood-forming tissue, such as bone marrow, and floods the blood system with abnormal blood cells; and lymphoma is a type of cancer that begins in the cells of the immune system (NCI, 2005b). Cancer is not a single disease but any of more than 100 diseases that can occur in almost all of the organs and anatomic sites of the human body. Certain types of cancer are more lethal than others, and each one has its own unique profile (Cohen, 2003; Hess, 1991; Roy & Russell, 1992; Wallace, 2001).

COMMON TYPES OF CANCER

The five most commonly diagnosed cancers in women age 65 and older are cancer of the lung, breast, colon, rectum, and pancreas. In older men, the five most common cancer sites are lungs, prostate, colon, rectum, and pancreas (Sacks & Abraham, 2003). Each of these cancers will be reviewed briefly, acknowledging that an entire volume could be dedicated to each.

Lung Cancer

Lung cancer is the leading cause of cancer deaths for both men and women over 60 years old (Jemal et al.,

2003), accounting for 30% of all cancer deaths in this age group (Ershler, 2003, p. 6). The incidence rate of lung cancer increases dramatically with age. Lung cancer incidence rates are 600 per 100,000 for men and 400 per 100,000 for women between ages 60 and 79.

Cigarette smoking is known to be a major risk factor for lung cancer, and the risk is significantly increased based on the duration, quantity, and age at onset of smoking. Content of nicotine and tar and the inhalation level are also significant risk factors to consider. For smokers age 75, mortality rates for lung cancer are estimated to be 1 per 100 for men and 1 per 200 for women. Although smoking cessation is beneficial at any age, the risk of lung cancer is greatly reduced by cessation at an earlier age (Haura, Blackwell, & Crawford, 2003; Oddone, Heflin, & Feussner, 2003). Environmental factors such as asbestos, radon gas, chromate, nickel, polyhydrocarbons, and alkylating compounds are also known to increase the risk of lung cancer (Haura et al., 2003; Oddone et al., 2003).

Diagnosing the stage of lung (and other types of cancer) is a highly technical procedure that is often complicated by multiple or overlapping classification systems and conflicting clinical approaches to staging at diagnosis. Although staging at diagnosis is beyond the scope of this chapter, it is important to note that survival rates are directly linked to stage at diagnosis. Advanced stage leads to lower survival rates.

Lung cancer is commonly known for its high incidence rate and poor prognosis. The 5-year survival rates for distant metastasis of advanced stage at diagnosis are only 2%, compared to earlier-stage diagnosis with 48% survival rates for those with localized tumors that have not spread (Haura et al., 2003; Oddone et al., 2003). Lung cancer is generally divided into two groups: small cell and non–small cell. Small cell lung cancer is a type of lung cancer in which the cells appear small and round when viewed under the microscope. This type of lung cancer metastasizes slowly and can be treated effectively at early-stage diagnosis. Non–small cell is a group of lung cancers that includes squamous cell carcinoma, adenocarcinoma, and large cell carcinoma. Current treatments do not cure non–small cell lung cancers. They are often found at an advanced stage due to rapid growth. They metastasize quickly, in contrast to small cell lung cancer, which tends to grow and spread slowly. Approximately 75% to 80% of all lung cancers are non–small cell cancers (Haura et al., 2003).

Early detection leads to higher survival rates. Screening tests for lung cancer are chest radiography, sputum, and low-dose spiral computed tomography,

although their effectiveness for the detection of lung cancer remains controversial. Diagnosis of lung cancer is made through sputum cytology, bronchoscopy, biopsy, and transthoracic needle therapy. Older adults appear to tolerate this diagnostic procedure well as long as they do not have a specific thyroid condition (Haura et al., 2003; Oddone et al., 2003).

Surgical resection offers the greatest chance of cure for many types of lung cancer, provided the disease has not metastasized to other parts of the body. Adjuvant chemotherapy or radiation therapy is offered to reduce reoccurrence of the disease. Preoperative chemotherapy is offered for those at more advanced stages before attempting to perform curative resection. At the inoperable stage, radiation therapy has been the most common form of treatment. It is a common treatment modality for older patients and has been recommended especially for those who display symptoms such as an intractable cough, hemoptysis, dyspnea, and chest pains. Common side effects due to radiation therapy are fatigue, loss of appetite, nausea, vomiting, and lowered numbers of blood cells. For people with a metastatic disease, platinum-based chemotherapy has been beneficial, although its benefit is often brief and has been accompanied by treatment-related toxicity (Haura et al., 2003; Krmarik, Prendergast, Ely, & Runo, 2003).

Breast Cancer

Breast cancer is the second leading cause of cancer death in women age 65 and older, with approximately 50% of newly diagnosed cases occurring in this age group (Ershler, 2003). Less than 1% of all breast cancer is diagnosed in males. Women over 65 account for as much as 67% of breast cancer mortality. The highest incidence rates for breast cancer are seen in women around age 75 (Balducci & Phillips, 1998; Partridge & Winner, 2003; Sacks & Abraham, 2003). Breast cancer incidence rates for women are 76 per 100,000 under age 65 and 441 per 100,000 age 65 and older. Breast cancer causes significant morbidity and disability, even in the case of survival (Balducci & Phillips, 1998; Oddone et al., 2003).

Risk factors for breast cancer among older women are advancing age, family history and genetic predisposition, higher estrogen levels, early age at menarche, late menopause, benign breast disease, alcohol use, number of or late pregnancies, hormone replacement therapy, and exposure to radiation. Other, less established risk factors include a high-fat diet, obesity,

and use of oral contraceptives (Balducci & Phillips, 1998; Oddone et al., 2003; Partridge & Winner, 2003; Sacks & Abraham, 2003).

Although older women are still less likely to receive mammograms or other tests for breast cancer than their younger counterparts (Eisner, Zook, Goodman, & Macario, 2002), the overall breast cancer screening rates among women 65 and over has increased from 48% in 1991 to 64% in 1998 (Oddone et al., 2003). Screening strategies for the early detection of breast cancer include self-examination, clinical breast examination performed by a health care professional without any special equipment, and mammography. When the clinical exam is combined with mammography, the accuracy of the detection rate is estimated at between 83% and 98.5%. Suspicious screening results are followed up by biopsy to confirm a positive diagnosis (Balducci & Phillips, 1998; Oddone et al., 2003; Roy & Russell, 1992).

For women age 50 and older, 5-year survival rates are 97.6% for localized breast cancer, 77.5% for metastases to regional lymph nodes, and 20.1% for distal metastases. The 5-year overall survival rate for women age 70 and older with early-stage breast cancer is about 54% (Sacks & Abraham, 2003). Although older women have lower survival rates due to differences in tumor characteristics, individual factors, health care utilization, and the existence of comorbid conditions, screening should continue throughout the life span (Oddone et al., 2003; Partridge & Winner, 2003).

There are two general types of surgery to treat breast cancer: breast-sparing surgery (also known as breast-conserving surgery) and mastectomy. For women diagnosed at an early stage of breast cancer, breast-sparing surgery combined with radiation therapy results in the same survival rates as for those who have mastectomy. Breast-sparing surgery is a procedure intended to remove the breast cancer but not the breast itself. Types of breast-sparing surgery include lumpectomy (removal of the lump), quadrantectomy (removal of one quarter, or quadrant, of the breast), and segmental mastectomy (removal of the cancer as well as some of the breast tissue around the tumor and the lining over the chest muscles below the tumor). Mastectomy is a surgical procedure to remove as much of the breast as possible (NCI, 2005c). Additionally, radiation therapy, hormonal therapy, and chemotherapy are common treatment approaches for breast cancer. Depending on the stage of the disease, its characteristics, and the individual woman's life expectancy and comorbid conditions, these treatment modalities are used separately or in combination (Balducci & Phillips, 1998; Partridge & Winner, 2003). Older women are known to tolerate breast cancer surgery

fairly well compared to younger women. Unlike their younger counterparts, they are less likely to undergo breast-conserving surgery and generally receive less aggressive treatment (Partridge & Winner, 2003). The most common adjuvant chemotherapy is a combination of cytoxan, methotrexate, and 5-fluorouracil (CMF). Despite risks and more recent controversy associated with its use, tamoxifen has been known to be effective for older women who cannot tolerate surgery (Partridge & Winner, 2003; Sacks & Abraham, 2003).

Prostate Cancer

Although the occurrence of prostate cancer is rare in men younger than 40 years, incidence rates double during each subsequent decade of life, and African American men are at the highest risk in all age groups (Hayes, 2004; SEER, 2004). Men 65 and older account for more than 80% of all prostate cancer, with those age 74 and older accounting for almost half of all prostate cancer mortality. Prostate cancer incidence rates are 50 per 100,000 for men younger than 65 years and 1,025 per 100,000 for men age 65 and older. Mortality rates are 2.6 per 100,000 for men younger than 65 years and 225 per 100,000 for men age 65 and older (Coleman, Hutchins, & Goodwin, 2004; Sacks & Abraham, 2003).

Prostate cancer starts in the prostate gland, which is located at the base of the penis, just below the bladder and in front of the rectum, and which produces seminal fluid. At the beginning stage, it does not endanger life, as the disease remains localized in the gland. The 5-year survival rate of localized prostate cancer is 80%, compared to 8% for distant metastases. Without early detection and appropriate treatment, prostate cancer can spread to other organs and cause death (Hayes, 2004; National Education Association/Health Information Network, 2004; Oddone et al., 2003). Routine screening tests such as the serum prostate specific antigen and the digital rectal examination lead to early detection. If either of these tests are suspicious, follow-up tests include sonogram (also known as ultrasound) and biopsy. Biopsy is the most invasive but most effective means of detecting prostate cancer.

The exact etiology of prostate cancer is not known, making preventive behaviors difficult to recommend. Known risk factors linked to prostate cancer include advancing age, African American race/ethnicity, family history of the disease, and a high-fat diet (Illinois Department of Public Health, 2004; Matin & Trump, 2003; Oddone et al., 2003; SEER, 2004).

In general, prostate cancer treatment is divided into three categories based on the extent of the cancer

(Matin & Trump, 2003). The first, localized prostate cancer, is potentially curable through prostatectomy and various forms of irradiation therapy. However, these treatments carry significant risks of side effects, including acute cystitis, urinary retention, impotence, blood loss, and incontinence. The second category is an advanced state of the cancer. Although prostate cancer does not spread to other tissues or organs, local metastasis in the pelvic area makes prostatectomy or irradiation therapy less effective. The third category is metastatic prostate cancer. About 30% of prostate cancers are metastatic at the time of diagnosis. Metastatic prostate cancer afflicts patients with considerable morbidity and is associated with bone metastasis and spinal cord compression (Matin & Trump, 2003). Prognosis is poor, and hormonal therapy is considered one of the best treatment options (Matin & Trump, 2003; Roy & Russell, 1992).

Colon/Rectum Cancer

Although cancer of the colon and rectum are clinically differentiated, they are discussed under the rubric of colorectal cancer (CRC). CRC is the second most common cancer for older men and women, and its incidence and mortality rates increase with age. Incidence rates are 287.8 per 100,000 for women and men age 65 and older and 450 per 100,000 for those age 85 and older. Mortality rates are 5.7 per 100,000 for men and women under age 65 and 120 per 100,000 for those age 85 and older. Additionally, among women whose age is 80, CRC exceeds breast cancer as a cause of death (Enzinger & Mayer, 2003; Oddone et al., 2003; Sacks & Abraham, 2003). Comorbid conditions such as hypertension, heart disease, and chronic obstructive pulmonary disease are found to increase with age and are associated with early CRC mortality (Enzinger & Mayer, 2003).

Eighty percent of CRC is known to develop from adenomatous polyps that take approximately 5 to 10 years to become malignant. As many as 1 in 3 people have adenomatous polyps by their mid-50s. The importance of targeting older populations for CRC screening is underscored by the incidence of adenomatous polyps reaching 50% by age 75 (Enzinger & Mayer, 2003; Oddone et al., 2003). Screening tests such as digital rectal examination, fecal occult blood testing (FOBT), sigmoidoscopy, and colonoscopy are, in ascending order, the current detection strategies of choice for colorectal cancer. FOBT is the most cost-effective and commonly used screening test for CRC. A positive FOBT should be followed by a colonoscopy.

Colonoscopy is the most expensive but the preferred screening procedure because it allows for the clinical examination of the entire colon and immediate biopsy of suspicious tissue. In addition, adenomatous polyps are removed during the screening procedure (Enzinger & Mayer, 2003; Oddone et al., 2003).

Risk factors for CRC include increased age, a personal history of CRC or ulcerative colitis (Crohn disease), a family history of CRC or familial adenomatous polyposis in a first-degree relative, and history of breast, ovarian, or uterine cancer. Approximately 75% of CRC patients had no known risk factors prior to diagnosis. Lack of physical activity, obesity, higher consumption of red meat and lower consumption of fruits and vegetables, in addition to the use of tobacco and alcohol are also risk factors that can increase the incidence (Enzinger & Mayer, 2003; Oddone et al., 2003). The best preventive strategy is to remove pre-malignant polyps. The 5-year survival rate is 90% for early diagnosis with localized malignancy. Survival drops to 64% for regional metastases and 8% for distal metastases (Enzinger & Mayer, 2003; Oddone et al., 2003).

Surgery and chemotherapy are common treatment approaches for CRC. Colorectal tumors are removed along with adjacent bowel, blood vessels, and lymphatics through en-bloc surgical resection. Adjuvant chemotherapy is offered after surgery. Postoperative chemotherapy is known to decrease recurrences and mortality by 40% and 33%, respectively. A 5-fluorouracil is offered in combination with leucovorin as the postchemotherapy for high-risk resected colorectal cancer. Although it is known that older adults receive adjuvant chemotherapy less often than younger people with the same disease, postoperative chemotherapy is as beneficial for individuals age 70 and over as it is to their younger counterparts (Enzinger & Mayer, 2003; Sacks & Abraham, 2003). Finally, a colectomy and, in some cases, a partial colectomy, results in colostomy. Colostomy is an opening to the outside of the body that provides a new path for waste material to flow. In some cases, a colostomy can be temporary to allow a remaining section of the colon to heal. In all cases, colostomy maintenance requires patient training and, in some cases, regular assistance. In older populations, colostomy maintenance should be considered an additional activities of daily living (ADL) in all levels of assessment.

Pancreatic Cancer

The pancreas is located near the stomach and the small intestine. It produces several hormones used in

regular digestion of food (Oncologychannel, 2004). Although pancreatic cancer accounts for only about 2% of new cancer cases, its high lethality accounts for about 5% to 6% of all cancer deaths in both men and women in the United States. It is the fifth most fatal of all cancer types (ACS, 2004a; Massachusetts Department of Public Health, 2002; Messenger-Rapport & Thacker, 2002). Because pancreatic cancer tends to be aggressive in nature, most cases are detected at an advanced stage, and the median survival period is approximately 5 months for individuals with the metastatic disease. As a result, the 5-year survival rate for pancreatic cancer is only 3% to 5% (Enzinger & Mayer, 2003; Messenger-Rapport & Thacker, 2002; Skinner et al., 2003).

Just as with other cancer cases, older adults account for a significant portion of pancreatic cancer patients. Most pancreatic cancer cases are detected in individuals between age 60 and 80 years, with the median age at diagnosis of 60 years (Enzinger & Mayer, 2003; Massachusetts Department of Public Health, 2002; Messenger-Rapport & Thacker, 2002). Although men show a higher prevalence rate compared to women, it is the fourth most fatal cancer for both men and women age 60 and older (Jemal et al., 2003). Despite its seriousness, little is known about this cancer.

The risk factors for pancreatic cancer are thought to be smoking, diet, medical conditions, family history, and environmental agents in addition to advancing age (Enzinger & Mayer, 2003; Massachusetts Department of Public Health, 2002; Messenger-Rapport & Thacker, 2002; Oncologychannel, 2004). African Americans show a higher rate of pancreatic cancer than other racial or ethnic groups. Although associations with the disease have not been tested, certain medical conditions, including chronic pancreatitis, diabetes, and cirrhosis, are considered to be risk factors. Higher intake of meat and fats in the diet are also associated with pancreatic cancer. Although the outcomes of various investigations have linked pancreatic cancer to environmental agents such as gasoline, asbestos, nickel and chromium compounds, and ionizing radiation, study findings are characterized as inconsistent and controversial. It is suggested that between 3% and 10% of pancreatic cancer cases are related to genetic predisposition (ACS, 2004b; Enzinger & Mayer, 2003; Massachusetts Department of Public Health, 2002; Messenger-Rapport & Thacker, 2002; Oncologychannel, 2004; Skinner et al., 2003).

Because the symptoms of pancreatic cancer are not specific, diagnostic tests are often delayed. Indi-

viduals with pancreatic cancer typically seek out medical attention due to jaundice, weight loss, epigastric and back pain, fatigue, loss of appetite, and glucose intolerance. Patients may report diarrhea, constipation, bloating, flatulence, chills, dizziness, or muscle pains (Enzinger & Mayer, 2003; Oncologychannel, 2004; Roy & Russell, 1992). Screening tests for pancreatic cancer are computerized axial tomography (CAT scan), endoscopic retrograde cholangiopancreatography (ERCP), ultrasound, magnetic resonance imaging, and biopsy. The ERCP procedure can be performed to not only detect the cancer but also to treat jaundice (Enzinger & Mayer, 2003; Oncologychannel, 2004).

Pancreatic cancer treatment includes surgery, chemotherapy, and radiation therapy. These treatment remedies are offered individually or in combination based on the degree of morbidity (Enzinger & Mayer, 2003; Oncologychannel, 2004). People with advanced pancreatic cancer usually undergo surgery to remove a small part of the pancreas. Another surgical approach is the pancreaticoduodenectomy, also called the Whipple procedure, to remove more extensive areas of the pancreas or, sometimes, the entire resection, including the distal duodenum, the proximal jejunum, the neck, head, and uncinate process of the pancreas, the gallbladder, and the distal bile duct. This is followed by postoperative adjuvant chemotherapy. This combined therapy has been considered to expand survival time. Patients with inoperable pancreatic cancer that has not spread to other organs often receive radiation therapy and chemotherapy. The most severe cases of distal metastatic pancreatic cancer are treated with chemotherapy or palliative care (Enzinger & Mayer, 2003; Roy & Russell, 1992).

PSYCHOSOCIAL CONSIDERATIONS

Understanding cancer, its treatment, posttreatment recovery, and maintenance are directly associated with an older individual's physical and cognitive ability. This is especially true for a person experiencing a cancer diagnosis for the first time. Comorbid conditions contribute to the physical and emotional impact of the cancer. If an individual is experiencing a condition with symptoms more severe than those accompanying the cancer, she or he may be less motivated to take treatment action. This is an especially important consideration in early-stage diagnosis, when relatively little or no discomfort may be experienced. Treatment delays and noncompliance with prevention, screening, and treatment regimens

introduce the risk of metastases, which may result in less favorable prognosis for cure, survival, and quality of life after treatment. The delay or noncompliance phenomenon may be exacerbated by cognitive impairments.

Clinicians must consider symptom management and possible side effects or complications related to treatments. Pain management, possible physical impairments, effects on social relationships, psychological and emotional distress, nutritional issues, and financial burdens must all be considered in the context of the patient's age and resources (Haley, 2003; Ahmed, 2004; Jepson, 1999; Badura & Grohmann, 2002; Balducci, 2003; Sharp, Blum, & Aviv, 2003; Frongillo, Valois, & Wolfe, 2003; McCarthy, Phillips, Zhong, Drews, & Lynn, 2000; Hayman et al., 2001; Ingram, Seo, Martell, Clipp, Doyle, Montana, & Cohen, 2002). Older cancer patients require considerable support to achieve positive health outcomes from the treatment as well as to achieve an acceptable quality of life.

PHYSICAL/COGNITIVE FUNCTIONING

Impaired physical and cognitive capacities may complicate the treatment of older people with cancer. Some older people may experience chemotherapy as intolerable and require special medical attention (Ershler, 2003; Goodwin & Coleman, 2003). Cancer treatments must be established through careful individualized assessments that reflect comorbid and other physical conditions (Balducci, 2003; Yanick, Ganz, Varricchio, & Conley, 2001). Malnutrition, anemia, and neutropenia can result from the negative effects of chemotherapy and require careful attention and monitoring. Other types of chronic conditions, such as diabetes, arthritis, and respiratory problems, are also common conditions that may complicate treatment (Balducci, 2003; Cancer Care, 2003). Older patients' physical impairments, including of hearing, speech, and literacy, may influence their daily living activities, such as cooking, dressing, bathing, shopping, taking medications, and visiting hospitals for treatment, and therefore directly affect prognosis (Balducci, 2003).

Older patients with cognitive impairments may be unable to convey their needs and physical condition to health care providers: physicians, nurses, social workers, and other, informal caregivers. The inability to assess and/or convey one's own physical condition may have a direct outcome on diagnosis, treatment, and maintenance (Badura & Grohmann, 2002). Pain management is one of the great challenges for treating older patients because the cancer is often accompanied by

acute and chronic pain (Balducci, 2003; Soscia, 2003). Cognitive impairments may interfere with the accurate assessment of older patients' experiences of pain. Pain assessment is a critical component of cancer care and quality of life. In addition to behavioral observations, clinicians should use pain assessment tools for people with cognitive impairments (Badura & Grohmann, 2002; Balducci, 2003; Ferrell, 2003; Soscia, 2003).

EMOTIONAL/PSYCHOLOGICAL RESPONSES

Cancer produces a range of emotional and psychological distress, often related to specific functional impairments. Fear, anxiety, sleep disturbance, depression, and avoidance often surface due not only to symptoms and side effects of treatment, such as surgery and chemotherapy, but to the looming fear of recurrence or death that is prevalent in older patients (Deimling et al., 2002; Ersher, 2003). Pain is a predictor of depression (Badura & Grohmann, 2002), and many cancer treatments, especially surgery, are extremely painful.

Lack of social support and restrictions on activity are other factors that cause emotional and psychological distress among older cancer patients. The disruption of social support is another consideration in treatment planning for older patients. It is not uncommon for patients to consider themselves disfigured or maimed by surgery. Older women are less likely to receive reconstructive surgery after breast cancer. A colostomy patient may live in horror of leakage, especially during the initial stages of adjustment. Cavalier attitudes about appearance or self-consciousness not mattering to an older person should be monitored and addressed by clinicians at every juncture of service provision in the medical setting and the patient's community.

Older cancer patients may be twice as old as their providers. It is important for providers to be sensitized to the vitality of older people. A younger provider approaching an older cancer patient as someone who has lived out her or his years is behaving inappropriately, unethically, and potentially detrimentally to a patient's prognosis. The despair of older women experiencing surgery for breast cancer should not be minimized because of their age. Neither should providers minimize an older man's concerns about side effects of prostate cancer treatment (Kurtz et al., 1999; Sharp, Blum, & Aviv, 2003). Emotional and psychological assessments and appropriate support must be offered to meet the emotional and psychological needs of older cancer patients.

SOCIAL/FINANCIAL RESOURCES

Limited social and financial resources may influence treatment decisions and outcomes among older people with cancer (Balducci, 2003). Financial burdens become a critical issue for older adults with cancer, due to their out-of-pocket medical expenses. Even a minimal copayment may present a real or perceived barrier for an older patient living on a fixed income. Visiting the treatment site, securing outpatient medications, receiving home care, and obtaining needed medical supplies are formidable tasks and additional worries for the older patient (Haley, 2003). Treatment planning must include accessible services, including a visiting nurse, community supports, and financial assistance; are all critical aspects of treatment for older cancer patients (Cancer Care, 2003).

Social support has a direct impact on the effectiveness of treatment (Koretz & Reuben, 2003; Kurtz et al., 1999). Without some form of social support, older adults may face very serious problems that interfere with their overall daily functions. Family members or caregivers are an important emotional resource that can offer various supports to older adults with cancer (Overcash, 2004). A caregiver is someone who has a personal connection and commitment to a cancer survivor. They provide care in activities of daily living, household chores, administering medication, visiting the treatment site, and managing side effects (Haley, 2003; Overcash, 2004).

Many of the services provided to cancer survivors by caregivers, 80% of whom are women, were once performed in hospitals or health facilities. Services now provided at no cost by caregivers are estimated to be worth over \$300 million annually. Additionally, most people in this role do not identify themselves as caregivers. Caregivers of older cancer patients often have competing responsibilities and roles, such as partner, parent, and employee. Many experience high levels of stress as they face difficult end-of-life issues related to treatment decisions and procedures (Haley, 2003). Caregivers experience significant psychological, physical, and economic burdens in relation to the cancer patient (Haley, 2003; Hayman et al., 2001; Jepson, McCorkle, Adler, Nuamah, & Lusk, 1999; Query & Wright, 2003). Caregivers' own stress influences the quality of care that they can offer (Koretz & Reuben, 2003).

Clinicians should provide caregivers with information, emotional support, and case management advice. Focus should be on maintaining the well-being of both the cancer survivor and the caregiver (Haley, 2003).

An example of an important clinical intervention with caregivers is some form of respite service. The amount of respite can range from 1 or 2 hours to attend to personal matters or recreational activity such as a movie, to as much as days or weeks for other responsibilities or a vacation with family or friends. Caregivers should also be encouraged to request case management assistance from their insurance company to provide efficacious care for the cancer survivor. The cost benefit of effective case management provides social workers with strong leverage when advocating for services. Finally, when the caregiver is a family member, the Family and Medical Leave Act requires companies employing 50 or more people to allow up to 12 weeks of unpaid leave for an employee who must care for a family member. When considering this provision, the lack of income must be carefully weighed against the benefit of job protection.

SOCIAL WORK

Clinical social workers can provide older cancer survivors and caregivers comprehensive clinical case management designed to complement the medical, environmental, and economic conditions during initial diagnosis, treatment, and discharge into the community. At various stages of the cancer continuum, psychosocial treatment plans encompass patient and caregiver needs during diagnosis, treatment, survivorship, and, when the disease cannot be cured or controlled, palliative care. As members of interdisciplinary teams specializing in specific cancer types, clinical social workers' expertise in all aspects of the disease, including side effects of treatment, pain management, and assessment of self-care needs, helps patients navigate the complex medical terrain and bridge the gap between the biomedical and psychosocial aspects of the disease.

A comprehensive oncology social work approach will provide older cancer patients, families, and caregivers with an overview of services and resources available. Social workers are uniquely situated to help patients communicate with medical oncologists, to understand the disease and treatment options, and to explore emotional and social issues related to the specific cancer in the patients' psychosocial circumstances. Conversely, the social worker communicates the patient's situation, understanding of the disease, and treatment options back to the interdisciplinary team. Geriatric considerations, particularly as they relate to quality of life in survivorship, are particularly

important. When appropriate, social workers help the patient and caregivers negotiate the complex medical, financial, and community health care systems introduced by the cancer diagnosis, treatment, and survivorship. In cases where the disease prognosis is poor, options for palliative care must be explored as well.

SUMMARY

During their youth, older individuals may have lived through a time in history when a cancer diagnosis was virtually a death sentence. Technological advances in cancer screening, diagnosis, and treatment have resulted in unprecedented cancer survivorship. So great are the numbers of survivors and the duration of survivorship, that cancer—in some cases—can be reframed as a chronic condition. This should not confuse the fact that a cancer diagnosis assaults every aspect of a person's being—especially older people. Unless a patient is significantly debilitated by a comorbid condition, other physical conditions must not interfere with continued cancer screening, treatment, and maintenance. The notion that the older individual has lived a full life and is ready to die is both false and potentially dangerous. Finally, older cancer patients require special consideration to help them understand the disease and its treatment, to remove barriers to treatment and maintenance, and to monitor not only the disease but also patients' physical and cognitive functioning during survivorship.

Older Adults With Age-Related Cardiovascular Disease

2

According to the U.S. Census Bureau, 40 million Americans will be age 65 or older in 2010 (cited in AHA, 2005). This population-aging trend will considerably increase the incidence of chronic diseases, especially age-related cardiovascular diseases (CVD). Social workers must enhance their knowledge of CVD to improve their practice with the elderly. This chapter describes the immense impact of age-related CVD on society, older persons, and the disadvantaged, its important mental health comorbidity, particularly depression, and related social work practice.

THE SIGNIFICANT IMPACT OF CVD ON SOCIETY AND AN AGING POPULATION

According to the World Health Organization (WHO), 16.7 million of the global population die of CVD each year; about one-half of all deaths (8.6 million) are women (cited in AHA, 2003). CVD has been the leading cause of death in Europe each year and in the United States since 1900. Incidence of CVD is now higher in India and China than in all developed countries combined. With the global population aging, CVD will become the leading cause of death in developing countries by 2010 (American Heart Association, 2003).

In the United States, the estimated cost of CVD and stroke was \$393.5 billion in 2005, nearly \$175 billion more than the estimated cost of all cancers and HIV infections (AHA, 2005). More than 1 of 4 Americans were affected by CVD in 2001 (AHA, 2003). It is the leading cause of premature death for men and women of all racial/ethnic groups. CVD claimed 1,400,000 lives, that is, 1 of every 12.6 deaths in 2002. Each year, CVD claims as many lives as the next five leading causes of death combined (i.e., cancer, chronic lower respiratory diseases, accidents, diabetes mellitus, and influenza/pneumonia). Over 83% of CHD deaths occur in people age 65 and older (AHA, 2005). Since 1984, more women have died of CVD than men, and this gap continues to increase dramatically (American Heart Association, 2003).

Regarding incidence, 1 in 3 individuals age 65 or older has suffered some form of heart disease or stroke (AHA, 2003). Studies have found that average annual rates of first major CVD event rose from 7 per 1,000 men at ages 35 to 44 to 68 per 1,000 at ages 85 to 94 (American Heart Association, 2005). The comparable rates occur 10 years later for women, but the gap between men and women narrows with advancing age. After age 75, the prevalence of CVD is greater in women than men (AHA, 2003). CVD such as coronary heart disease (CHD), ischemic attack in brain

(stroke), high blood pressure (hypertension), irregular heart beat (arrhythmia), and congestive heart failure (CHF) are related to aging. Women after menopause are 2 to 3 times more likely to have CHD than are women of the same age who are premenopausal (AHA, 2005).

Regarding mortality, CHD is the single largest killer of Americans among all CVDs (National Academy on an Aging Society, 2000a). Of Americans who die of CHD, 83% are age 65 and older (AHA, 2005). After age 70, lifetime risk of CHD is 35% for men and 24% for women. CHD is the leading reason for short-stay hospitalization, of which 58% was for older persons (American Heart Association, 2003). Of people age 70 and older, those with heart disease are more likely to use prescription drugs and social services such as a social worker, adult day care, rehabilitation, transportation, and Meals on Wheels than their younger counterparts. CHD is the most debilitating type of CVD. Among adults with CHD, about 33% of those age 51 to 61 and about 50% of those age 70 and older have difficulty with one or more activities of daily living (ADL), and 40% require assistance. Family members provide 65% of their in-home help and 70% of their instrumental ADL needs. So, older persons with CHD are likely to experience early retirement and low satisfaction with retirement (National Academy on an Aging Society, 2000a).

Resulting from narrowing coronary arteries that causes insufficient blood and oxygen supply to the heart, CHD causes angina pectoris (chest pain), myocardial infarction (MI or heart attack), and sudden cardiac arrest. In the United States, the average age of a person experiencing a first MI is 65.8 for men and 70.4 for women. After suffering a recognized MI, 25% of men and 38% of women will die within a year. Because women tend to have MI in older age, they are more likely to die within a few weeks of the occurrence. After surviving an MI, the risk of another MI, sudden death, angina pectoris, heart failure, or stroke remarkably increases. In such survivors, within 6 years, nearly 22% of men and 46% of women will be disabled with heart failure. CHD is the leading cause of premature, permanent disability in the U.S. labor force and accounts for 19% of Social Security disability insurance payments (American Heart Association, 2003 (AHA, 2005); National Academy on an Aging Society, 2000a).

CVD, including CHD, strike many workers in the lower social strata, who are often served by social workers. In the United States, monthly earnings for workers with heart disease, especially older adults with ADL limitations, are considerably lower than for other workers (National Academy on an Aging Society, 2000a). The premature death rate from CHD for male

manual workers (e.g., builders) is 58% higher than for nonmanual workers (e.g., lawyers). The comparable rate for female manual workers is more than twice as high than for their nonmanual counterparts (American Heart Association, 2003). In developed countries, people with lower socioeconomic status (SES) have a higher incidence and higher mortality of CVD, including CHD. The burden of CHD will shift to the low-SES group in developing countries as a CVD epidemic matures along with economic transition, urbanization, industrialization, and globalization that bring about lifestyle changes there.

DIFFERENTIAL RACE AND ETHNICITY IMPACTS OF CVD

Rates of CVD are higher in non-Hispanic Blacks than in non-Hispanic Whites in the United States (American Heart Association, 2005). In people age 65 and older, rates of new and recurrent MI are higher in non-Black men than in Black men, but lower in non-Black women than in Black women. This discrepancy seems not to be explained simply by genetic factors. Other socioeconomic contributors may also need to be taken into account. Blacks are more likely than Whites to die from heart disease. This gap between Blacks and Whites has widened since the 1980s (Centers for Disease Control and Prevention, 1998). The incidence of CHF approaches 1% of Americans age 65 and older (American Heart Association, 2005). CHF rates are higher in Black men than in other men only in the subgroup of ages 75 to 84, and higher in Black women than in other women in ages 65 to 84. Stroke is a leading cause of serious, long-term disability in the United States, and about 88% of stroke deaths occur in people age 65 and older. Rates of stroke in older persons increase with age, from 2.7% to 3.6% in men and 1.6% to 4.1% in women. In ages 65 to 85, racial and ethnic minority populations have a higher relative risk of stroke death (American Heart Association, 2003). This disparity can be understood only through more research on the SES of aging in conjunction with race factors in the United States.

Around the globe, 600 million people with hypertension are at risk of MI, stroke, and CHF, according to WHO (American Heart Association, 2003). Among people older than age 60, as many as 50% in some populations are hypertensive (AHA, 2003). Nearly one in three Americans has hypertension, but 30% of them are unaware of it because no symptoms are present (AHA, 2005). Of Americans diagnosed with hypertension, nearly 66% are age 55 and older, of whom 42% are covered by Medicare and 12% by Medicaid.

Among those age 70 and older, nearly all are publicly insured, and 63% are women (National Academy on an Aging Society, 2000b). Rates of hypertension are higher in Blacks (41.8%) and Mexicans (34.5%) than in Whites (32.2%). In Blacks, especially women, hypertension is a particularly powerful risk factor for CHD. Blacks with hypertension are more than twice as likely to suffer health-related work limitations than are other Blacks (American Heart Association, 2003).

Black and Mexican American women have more CVD risk factors than do White women with comparable SES. Most CVD risk factors that tend to increase with lower SES are preventable. Rates of tobacco smoking are exceptionally higher in American Indian and Alaska Native men (32.0%) and women (36.9%) than in White men (25.2%) and women (20.7%). The prevalence of high total cholesterol levels is greater in Mexican American men (54%) than in other racial and gender groups, except in White men (51%). Yet, the rate of total cholesterol levels higher than 240 mg/dL is even greater in Asian American, Pacific Islanders, American Indians, Alaska Native, and Hispanics (25.6%–28.6%) than White and Black populations (10.6%–19.9%). Black and Hispanic men and women, as well as Asian American women, have higher physical inactivity rates. Defined as a body mass index of 25.0 Kg/m and higher, overweight and obesity in people age 60 and older is much more common in Black women (77.2%) and Mexican American men (73.1%) and women (71.7%) than in non-Hispanic White men (69.4%) and women (57.2%). Finally, another CVD risk factor, diabetes mellitus, is almost twice as common in Mexican Americans and non-Hispanic Blacks than it is in non-Hispanic Whites (American Heart Association, 2005).

THE MENTAL HEALTH COMORBIDITY OF AGE-RELATED CVD

According to the National Institute of Mental Health (2005), depression affects more than 18.8 million adults in the United States. However, depressive symptoms are often missed by health care professionals. Depression is one of the most common complications of every chronic condition, including CHD, MI, and stroke (National Academy on an Aging Society, 2000c). Particularly in the past decade, numerous studies have shown depression and anxiety as major CVD comorbidities (Hemingway, Malik, & Marmot, 2001; Pignay-Demaria, Lesperance, Demaria, Frasure-Smith, & Perrault, 2003; Rozanski, Blumenthal, & Kaplan, 1999).

Over the past 10 years, mounting evidence has shown depression to be an important predictor of

CHD morbidity and prognosis. Research finds an increasing prevalence of depression in various CHD conditions, including unstable angina, CHF, MI, and coronary catheterization or angioplasty (Burg & Abrams, 2001; Frasure-Smith, Lesperance, Juneau, & Talajic, 1999; Krantz, Sheps, Carney, & Natelson, 2000; Lane, Carrol, & Lip, 2003; Scheidt, 2000; Severus, Littman, & Stoll, 2001; Smith, 2001). Depending on the sample and instrument used, the prevalence of major depression is estimated to be 16% to 23%, and that of clinically significant depressive symptoms 31.5% to 60% (Musselman, Evans, & Nemeroff, 1998). Current meta-analyses have linked depression with CHD-related mortality, especially 3 years after an initial assessment (Barth, Schumacher, & Herrmann-Lingen, 2004), and with post-MI mortality and CV events (van Melle et al., 2004). Anxiety also was shown to influence CHD prognosis and mortality (Kubzansky, Kawachi, Weiss, & Sparrow, 1998; Rozanski et al., 1999) and to be an independent predictor for post-MI cardiac events and health care consumption (Strik, Denollet, Lousberg, & Honig, 2003).

Mental health symptoms manifest in the process of and affect the outcomes of advanced cardiac surgery treatments for heart disease. From 1979 to 2002, the number of cardiac procedures (e.g., diagnostic cardiac catheterization, percutaneous transluminal coronary angioplasty or PTCA procedures, cardiac pacemaker procedures, endarterectomy procedures, coronary artery bypass graft procedure or CABG, and heart valve procedures) increased 470% in the United States (American Heart Association, 2005). Through vasculization of coronary arteries, CABG surgery has achieved impressive long-term clinical efficacy in terms of symptom relief. Although coronary bypass graft and valve replacement can save life and improve cardiac function, all patients must be fully informed before the operation about related side effects and risks (Ai, Peterson, Tice, Bolling, & Koenig, 2004). Research has shown that distress in the waiting time prior to surgery may account for the variance in recovery indices (Pirraglia, Peterson, Williams-Russo, Gorkin, & Charlson, 1999). The majority of CABG patients experience psychosocial effects before the surgery, from psychological complications to impaired social functioning.

The cost of cardiac surgery strains some social factors (e.g., financial resources and other support) that may intensify the stressful situation preoperatively (Ai, Peterson, & Bolling, 1997). However, studies have found that age is inversely related to preoperative distress in cardiac surgery patients (Plach, Napholz, & Kelber, 2003). Among patients undergoing cardiac surgery, the incidence of depression varies among studies between 7.5% and 47% preoperatively and 19%

and 61% postoperatively, depending on instruments used (Pignay-Demaria et al., 2003). Depression symptom levels remained stable before and after surgery (Andrew, Baker, Kneebone, & Knight, 2000; Pignay-Demaria et al., 2003) and even predicted mental status 1 year after operation (Boudrez & DeBacker, 2001). Several follow-up studies have indicated that depression is a major risk factor for readmission, new cardiac events, poorer quality of life, and especially cardiac mortality in patients undergoing cardiac surgery (Baker, Andrew, Schrader, & Knight, 2001; Ben-Zur, Rappaport, Ammar, & Uretzky, 2000; Pignay-Demaria et al., 2003).

Until recently, however, no major attempt has been made to influence routine screening, prevention, or treatment of depression among patients with MI or CHF or undergoing cardiac surgery (Richardson, 2003; Scheidt, 2000). Yet, even if symptoms were identified in these patients, pharmacological treatment of depression under a surgical or MI circumstance would be difficult, given the complex pathophysiology involved (Pignay-Demaria et al., 2003). For instance, selective serotonin reuptake inhibitors (SSRIs) are currently the most widely prescribed antidepressant drugs because of their good safety profile, but some SSRIs may interact with cardiovascular drugs.

Researchers have recommended the combination of SSRIs with cognitive-behavior therapy as the most effective treatments of depression in CHF (Guck, Elsasser, Kavan, & Barone, 2003). A review of available research, however, reveals that current treatment for depression has not necessarily improved cardiac event-free survival in post-acute-MI patients (Carney, Freedland, Veith, & Jaffe, 1999; Louis, Manousos, Coletta, Clark, & Cleland, 2002).

One large-sample clinical trial, Enhancing Recovery in Coronary Heart Disease, compared the cognitive-behavioral intervention for depression and social isolation to usual care. Despite reduced depression, the treatment showed no effect on post-MI reinfarction or mortality. One explanation was that depression was not related to increased post-MI mortality, a finding inconsistent with other studies (The ENRICH Investigators, 2001). In another large clinical trial, the Sertraline Antidepressant Heart Attack Trial (Shapiro, Lesperance, & Frasurre-Smith, 1999), although antidepressant use reduced depression, it did not affect left ventricular ejection fraction and ventricular arrhythmia. In addition to these two clinical trials, inconsistency has been noted in the association between post-MI prognosis and negative emotions from various observational studies (Lane et al., 2003). Therefore,

interdisciplinary research is now focusing on multiple psychophysiological pathways between mental and cardiac health and mechanisms in these associations. These include health-related behaviors, negative emotions, acute stress, autonomic nervous system regulation, platelet activation, hypothalamo-pituitary-adrenal axis activity, and inflammatory processes.

Without a singled-out "cure," the key to the prognosis and the quality of life in CVD patients with depression or anxiety may lie in the appropriate multidisciplinary management. To play a significant role in this team approach, social workers need to understand psychosocial protectors in CVD patients in current research. Lower SES contributed to greater depression, whereas social support, adaptive coping, and exercise may improve symptomatology and well-being (Ai, Dunkle, Peterson, & Bolling, 1998; Ai et al., 1997; Pirraglia et al., 1999; Sykes, Hanley, Boyle, & Higginson, 2000; van-Elderen, Maes, & Dusseldorp, 1999). In middle-aged and older cardiac surgery patients, social involvement and lack of finding comfort in religion were significant predictors of mortality (Oxman, Freeman, & Mannheimer, 1995). Using prayer for coping contributed to better mental health postoperatively (Ai et al., 1998).

There is also evidence that positive attitudes predicted better outcomes in CVD patients. Following a first MI, optimism was related to fewer hospital readmissions, whereas pessimism predated subsequent death. Among patients undergoing CABG, optimism was associated with better quality of life, a faster rate of physical recovery during the period of hospitalization, a faster rate of return to normal life activities subsequent to discharge, and better postoperative quality of life at 6 months. Within 6 months following the first PTCA procedure, patients at lower risk for a new cardiac event (e.g., CABG, PTCA, MI, or disease progression) were those who responded to their illness by perceiving control over their future, having positive expectations about their future, and having a positive view of themselves, as measured in a previous study (Helgeson & Fritz, 1999). A study of larger samples has linked hope with the survival advantage of stroke patients (Lewis, Dennis, O'Rourke, & Sharpe, 2001).

IMPLICATIONS FOR SOCIAL WORK ASSESSMENT AND INTERVENTION

Given the importance of mental health and socio-cultural factors in CVDs, gerontological social work can play a significant role in future cardiac care. Social

workers may contribute to the outcome of CVD in the aging society through policy analysis, advocacy, community intervention, and psychosocial care. For example, in the policy arena, the lack of sufficient health insurance coverage results in the failure of nearly 1 in 5 Medicare beneficiaries with hypertension to purchase the recommended prescription drugs (National Academy on an Aging Society, 2000b). The national debate about health care reform and funding for prescription drug coverage, Medicare, and Social Security is an opportunity for social workers to pursue policies that will provide needed assistance for their clients. Social workers in geriatric and community care should voice the needs of these older CVD patients and help them obtain comprehensive and supplemental health insurance, other state or federal health program benefits, discounted drugs direct from pharmaceutical companies, or other resources to prevent the worst outcomes, such as MI, stroke, and sudden cardiac arrest. These consequences are mostly likely to increase the expensive use of emergency care and the chance of disability, resulting in great socioeconomic burden for individuals, their family members, and the society.

Because of the complexity of CVD impact on individuals and families, care of older cardiac patients must be interdisciplinary. New research suggests that their mental health and social needs remain largely unmet (Anderson et al., 2001). Social workers should assume various responsibilities in preventive and clinical cardiac care (Anderson et al, 2001; Proctor, Morrow-Howell, Li, & Dore, 1999–2000; Sulman & Verhaeghe, 1994; Thurlow, 1995). Because most types of CVD are both treatable and preventable, gerontological social workers should in general promote the awareness of and prevention strategies for CVDs among older clients. These should include both the promotion of health behaviors that can prevent the CVD-related functional decline and the treatment of mental health symptoms that can contribute to poor prognosis of CVDs.

To assist older patients and families to cope with acute and chronic cardiac conditions, gerontological social workers must first engage in an in-depth exploration of responses to cardiac events in hospital and community-oriented care. Assessment involves multiple elements and their interrelationships: socioeconomic factors, access to health care services, prescription drug coverage, mental health symptoms, coping behaviors, daily activity level, functional abilities, adjustment to illness, social support, family dynamics, financial resources, sexual concerns, and legal issues of competency, advanced directives, and durable

power of attorney for health care. Risks such as obesity, physical inactivity, smoking, chemical dependency, and abuse or neglect must also be explored. Family members should be interviewed to determine their understanding of care needs and their ability to support the patient in constructive and concrete ways. Assessing existing involvement with community agencies and the need for additional support to meet basic living and medical requirements is a key aspect of developing a treatment plan, as is the readiness, willingness, and ability of the patient and family to accept new services.

Using standardized measurements can enhance comprehensive biopsychosocial assessment and help practitioners gauge patients' perceptions of their health status in the treatment process. The MacNew Heart Disease Health-Related Quality of Life questionnaires (Hofer, Lim, Guyatt, & Oldridge, 2004) assess three primary domains—physical limitations, emotional function, and social function—as well as physical symptoms (chest pains, shortness of breath, fatigue, dizziness, aching legs). Such tools allow social workers to be aware of the multilevel impacts of heart disease from the patient's perspective. With an in-depth assessment, the social worker can develop effective action plans with patients to address their needs, including the complex interplay of depression symptoms in all three domains. Social workers are then prepared to contribute as an effective team member for multidisciplinary intervention.

Social workers assisting CVD patients must include families in treatment planning, not only as therapeutic allies, but also in regard to the multiple stresses that caregivers experience (Lim & Zembrack, 2004). In addition to evaluating the patient's coping methods, gerontological social workers need to assess the impact of shifting roles and responsibilities on family members, who often suffer great disruptions in their daily routine and quality of life as they are called on for help in care coordination. Stressors include the degree of caregiving demands, patient impairment, the duration and intensity of care, ADL dependency, caregiver overload, recurrence of illness and problem behavior in the patient, and lack of assistance in caregiving. Family members who are older, isolated, or with prior health or disability problems have been found to have more difficulty in their attempts to assist with care. Loss of physical strength and its impact on the caregiver's self-esteem is associated with lower quality of life, as is lower income and a distressed relationship with the patient.

CVD, especially MI and stroke, can occur in seemingly healthy persons in their most productive years,

causing sudden death and permanent disability that leave unprepared families in devastation. Assistance with family communications and decision making around critical events is a very important part of the social work service. Support for acceptance of limitations, personal self-care, and the possible need for additional help can reduce conflict around the potential burden of caregiving. Family members also need ongoing education to aid them in formulating realistic perceptions of caregiving in relations to the dynamic processes of disease, treatment, and recovery or decline. Because hospitalization from CVDs creates major social and individual costs, in their assessment social workers should pay special attention to identify older cardiac patients at risk for readmission. Advanced age increased risk of readmission within 3 months after discharge, as did living alone and coping difficulties (Berkman, Millar, Holmes, & Bonander, 1991). Social and environmental factors, such as the adequacy of home care, have been found to be critical for preventing hospital readmission. One study attributed 40% to 50% of CHF readmissions to social problems and lack of community services (Proctor et al., 1999–2000). Risk factors for readmission included sicker conditions during the first 2 weeks postdischarge, inadequate compliance with prescribed medication regimens, and insufficient home care. The key to preventing readmission thus lies in the quantity and quality of home care supports. Gerontological social workers in hospital and home care must take an integrative approach to the posthospital care assessment and discharge planning. Central to this plan is to identify a helper or programs for assisting with specific ADLs: preparing meals, helping with toilet functions, managing medications, and encouraging or supervising appropriate levels of exercise for rehabilitation.

For effective psychosocial intervention with CVD patients, geriatric social workers can provide individual and family support, treatment for depression and anxiety, crisis intervention, prevention and health promotion workshops, and psychosocial cardiac education. They can also facilitate interdisciplinary teamwork, offer grief counseling, and make referrals and community connections to address needs of patients and families. In addition, social workers may need to help patients and families navigate systems of insurance and drug coverage, disability income, and subsidized housing, assisted living, or nursing home care. Advance planning for expected further deterioration or a terminal event is recommended if the patient or family is amenable. A discussion about health care directives or funeral planning can be linked to the value

of self-determination and decision making, which is most effective when not crisis-driven.

The role of gerontological social workers in assisting patients and families with durable powers of attorney for health care, living wills, and decisions regarding resuscitation and its various components cannot be overstated. Families need help understanding the difference between these documents, when each go into effect, and how to ensure that all health care providers, family members, and emergency personnel know the wishes of the CVD patient.

As noted, disease burden associated with CVD falls disproportionately on several racial/ethnic minority populations (American Heart Association, 2003; 2005). Other than their disadvantaged SES, the high prevalence of risk factors, such as higher cholesterol levels, obesity, inactive lifestyles, unhealthy food, smoking, and diabetes mellitus are major contributors to this disparity. Medical professionals, however, tend neither to be aware of cultural-related problems, nor to pay attention to health disparity issues.

Geriatric social workers can become valuable team members by incorporating culture-sensitive assessment and interventions into health care for minority CVD patients (Galambos, 2003; Panos & Panos, 2000). They should obtain the cardiac and self-care information about diverse populations and understand the particular socioeconomic and political environment that directly affects the incidence of comorbidity in minority CVD patients. Medical and community social workers must develop awareness of institutionalized oppression and their own cultural values, biases, and beliefs that may influence clinical practice. Culturally competent practice may improve compliance with medical care. It is thus critical to develop communication skills that adequately demonstrate respect for and address cultural orientation, primary language, level of acculturation, historical trauma, and community involvement in care for minority, older cardiac patients.

In the development of treatment plans, geriatric social workers must be prepared to challenge prevailing medical models that may pathologize culturally based behavior. They should consider and incorporate patients' beliefs about health, disease, service utilization, and culture-bound healing systems. Community-based collective experience and values may preempt cardiac patients' decision making regarding roles and relationships, expectations of functioning, and determinants of quality of life. Illustratively, traditional risk factors in the disproportionately high incidence of CHD among native Hawaiians were found to be compounded by barriers in the health care system.

The high costs of medications and care, isolated communities, and lack of culturally compatible practitioners and indigenous healing practices reduced the acceptability of Western health services. Culturally responsive strategies (e.g., lower-cost nutrition programs, outreach to *traditional* clubs, health education involving traditional foods, sliding fee scales, and encouragement of family involvement in decision making) appeared to enhance disease management in this population (Mokuau, Hughes, & Tsark, 1995).

Finally, the heart is related to mind and spirit in many cultural legacies. In Oriental medicine, the heart is highly sensitive to abrupt emotional stress; it was believed to be “an organ of the mind.” In the West, French philosopher Blaise Pascal in his famous *Pensées* stated: “The heart has its reasons which reason does not know.” (An American poet, Henry Wadsworth Longfellow, wrote, “The heart hath its own memory like the mind, And in it are enshrined the precious keepsake, into which is wrought the giver’s loving thought” (cited in Ai, 1996). Given the positive role of spirituality and expectations in cardiac care, social workers should be keenly attentive to the spirituality of older patients. They should help them to identify and mobilize such resources as faith strength, deepest values, disciplines, and positive attitudes (hope and optimism) in their coping with difficulties in the cardiac disease process (Anandarajah & Hight, 2001; Fallot, 1998). As team members, gerontological social workers may need to educate older patients and other health care professionals about the importance of a contextual biopsychosocial-spiritual approach to cardiac care. The integration of culturally sensitive clinical models of care, with awareness of structural, political, and economic disparities and advocacy for equal access to care, is a challenge to which we must rise in conventional medical care to promote the quality of life for cardiac patients.

NOTE

The cardiac study of Amy L. Ai was supported by National Institute on Aging Grant 1 RO3 AGO 15686-01, National Center for Complementary and Alternative Medicine Grant P50 AT00011, a grant from the John Templeton Foundation, and the Hartford Geriatric Faculty Scholars Program. Older Adults With Diabetes and Complications

3

The American Diabetes Association (ADA; 2004a, pg. S5) defines diabetes mellitus as “a group of metabolic diseases characterized by hyperglycemia resulting from defects in insulin secretion, insulin action, or both.” Type 1 diabetes mellitus (T1DM) accounts for approximately 5% to 10% of all diagnosed cases of diabetes; it is also referred to as insulin-dependent diabetes or juvenile-onset diabetes. Type 2 diabetes mellitus (T2DM) is the most common form of diabetes, accounting for approximately 90% to 95% of all diagnosed cases, and is frequently referred to as non-insulin-dependent diabetes or adult-onset diabetes. Whereas individuals with T1DM need insulin injections to survive, this is not true for individuals with T2DM, who can control hyperglycemia through a careful diet and exercise regimen and oral medication (ADA, 2003). Older age, obesity, and minority race/ethnicity are among the most significant risk factors for T2DM (ADA, 2004b).

According to the ADA (2003), approximately 8.6 million adults age 60 years or older were affected with diabetes in 2002. By 2050, the largest increase (336%) in prevalence of diagnosed diabetes will be in individuals 75 years or older (Boyle, Honeycutt, Narayan, Hoerger & Geiss, et al., 2001). Older adults with diabetes are at especially high risk for developing cardiovascular complications, kidney damage, vision problems, neuropathy, foot problems, and cognitive impairment (Croxson & Jagger, 1995; Fletcher & Dolben, 1996; Gregg, Engelgau, & Narayan, 2002; Howard, Cowan, Go, Welty, & Robbins, et al., 1998; Nilsson, Fastbom & Wahlin, 2002; Sinclair, Bayer, & Girling, 2000; Smith, Savage, Heckbert, Barzilay, & Bittner et al., 2002). Diabetes can exact a devastating toll on an older adult’s biopsychosocial functioning and, if left undetected or untreated, can have life-threatening consequences (DeCoster, 2001).

Social workers frequently provide services to older populations and as a result, will regularly encounter individuals coping with diabetes. Social workers in health care settings, hospitals, nursing homes, assisted living communities, home health care agencies, and senior centers are most likely to work on a regular basis with older adults with diabetes. Social workers in other settings may be less likely to work with older adults, or with older adults diagnosed with diabetes; even so, they are likely to provide services to individuals in social support networks involving older adults, such as friends, relatives, and caregivers.

It is essential that every social worker become more knowledgeable about the impact of diabetes and its complications in older populations, as this will allow social workers to provide more appropriate and

effective services not only directly with older adults, but indirectly through family and friends. This chapter discusses complications associated with diabetes, including the medical, psychological, and social risk factors. Treatment and intervention approaches relevant to social work practice are reviewed, and implications for social work practice are highlighted at the conclusion of the chapter.

COMPLICATIONS AND RISK FACTORS ASSOCIATED WITH DIABETES

Medical Factors

Cardiovascular disease (CVD) represents perhaps the most life-threatening complication for individuals with diabetes. An adult diagnosed with diabetes carries the same cardiovascular risk as someone who already has had a heart attack. Statistics show that approximately 2 out of every 3 people with diabetes die from heart disease or stroke (Centers for Disease Control and Prevention [CDC], 2003). Erlinger, Pollack, and Appel (2000) found in a nationally representative general population of older adults that almost 90% of individuals over age 65 had one or more nutrition-related cardiovascular risk factors. Not only are women with diabetes at a higher overall risk for CVD, but diabetes also appears to have a greater negative impact across individual risk factors for CVD in women (Howard et al., 1998).

Treatment and control of cardiovascular risk factors tends to be less than ideal in a general population of older adults, and this is much more the case for older adults with diabetes (Smith et al., 2002). Unfortunately, despite being at highest risk for stroke, older adults are the least likely to be able to identify even one risk factor or warning sign (Pancioli et al., 1998). Therefore, it is particularly important for social workers, along with other members of the multidisciplinary treatment team, to focus on recognizing and educating older adults in general and older adults with diabetes about the early warning signs and risk factors for CVD.

Microvascular complications of the smallest blood vessels constitute the second category of medical complications prevalent in older adults with diabetes. Microvascular complications include retinopathy (damage to the small blood vessels in the retina resulting in vision loss), nephropathy (kidney disease, preventing removal of waste and excess fluid from the bloodstream), and peripheral neuropathy (painful

nerves in the feet, legs, and hands). Most microvascular complications can be prevented, delayed, or even reversed with appropriate glycemic control (Beers & Berkow, 2004).

The strongest predictor for development and progression of retinopathy is the duration of diabetes (Fong et al., 2004). Up to 21% of individuals with T2DM have retinopathy on initial diagnosis, and most will develop some degree of nonproliferative retinopathy (NPR). And although T1DM is less common than T2DM, nearly all individuals who have T1DM for over 20 years will develop NPR (CDC, 2003). Similar to younger and middle-aged adults, control of diabetes is as important in older adults and one of the most important factors in preventing progression of retinopathy (Morisaki, Watanabe, Kobayashi, Kanzaki, & Takahashi, et al., 1994). Diabetic retinopathy progresses from mild NPR, also known as background retinopathy, which does not significantly alter vision, to moderate to severe NPR, and finally to proliferative retinopathy (PR), which can result in blindness. Other eye complications with disproportionately high prevalence in individuals with diabetes include glaucoma and cataracts.

Due in large part to the growing trends in obesity, a significant risk factor for diabetes, T2DM is increasingly diagnosed at younger ages (Maahs & Zeitler, 2004). As part of a larger 25-year longitudinal study on health in Pima Indians, the risk for retinopathy and nephropathy in individuals diagnosed with T2DM at younger ages (before 20 years) and individuals diagnosed at older ages was examined while accounting for duration of the disease (Krakoff, Lindsay, Looker, Nelson, & Hanson, et al., 2003). The investigators found that the incidence of nephropathy increased with duration and was equal in all age groups, whereas incidence of retinopathy was significantly lower in the young-onset group and in all duration categories compared to older-onset groups. Although development of retinopathy was somewhat lower in the young-onset group, a significant percentage still went on to develop complications. By an average age of 30 years, 57% of individuals with young-onset diabetes were diagnosed with nephropathy and 45% with retinopathy (Krakoff et al., 2003).

Diabetic nephropathy (DN), which is associated with kidney disease, is less common, with 10% to 21% of all people with diabetes developing kidney disease (CDC, 2003). Older adults with diabetes are twice as likely to be hospitalized for kidney infections compared to their healthy counterparts. The most severe form of DN is end-stage renal disease, which requires

kidney dialysis and even transplant. Following ADA (2004d) treatment guidelines for detection of DN at an early stage by testing annually for microalbuminuria is critical to preventing more severe kidney damage. End-stage renal disease is much more common in African Americans, Native Americans, and Mexican Americans than in non-Hispanic Whites (CDC, 2003).

Social workers and other health professionals can look to the promising research of the Diabetes Control and Complications Trial (DCCT) and the Epidemiology of Diabetes Interventions and Complications (EDIC) study, which demonstrated that early intensive treatment of individuals with T1DM reduces the risk of microvascular complications over a long-term period (DCCT/EDIC Research Group, 2003; EDIC Research Group, 1999). Early intensive treatment and prevention of T2DM and its complications is particularly important if we consider the growing trend toward T2DM diagnosis in children and adolescents.

About 60% to 70% of individuals with diabetes will develop mild to severe forms of DN (CDC, 2003). Severe forms of neuropathy affecting the nerves in the spinal cord and brain are much less common than milder forms of neuropathy affecting the feet, legs, and hands, which can still be very painful. Symptoms of neuropathy include loss of feeling, numbness, prickling, tingling, burning, aching, and sharp jabs of needlelike pain (ADA, 2003). Diabetes is the most common cause of neuropathy, yet at least one study found that neuropathy caused by diabetes was more common in young-old (65–79 years) patients than it was in old-old (over 80 years) patients (Verghese, Bieri, Gellido, Schaumburg, & Herskovitz, 2001). If true, social work practice and research needs to be more careful in accounting for age differences among older adults.

Plummer and Albert (1996), in a retrospective review of all charts for patients referred to a foot care service over a 2-year period, found that 56% of those with diabetes had peripheral neuropathy. Foot problems are another consequence of complications from DN. A significant number of older adults with diabetes, even those with risk factors for foot complications, do not have the recommended annual foot exams (Fletcher & Dolben, 1996). Older adults also can have difficulty completing simple and/or routine foot care advice (Plummer & Albert, 1996; Thompson & Masson, 1992). Medical complications can also interact with and exacerbate this problem. For example, an older adult with vision problems will have greater

difficulty recognizing foot ulcers. Although we might initially dismiss foot problems as minor in comparison to other problems, when left untreated, they could result in more severe consequences, such as lower limb amputations. Therefore, it is critical that both the providers and the patient receive education regarding preventive foot care.

Psychological Factors

Because the number of severe and sometimes fatal complications associated with diabetes can be overwhelming to individuals living with the disease, it should come as no surprise that, like other chronic diseases, diabetes is associated with disproportionately high risk for psychological disorders. One of the consequences of comorbid diabetes and psychological disorders, such as depression, is that it can complicate an individual's ability to self-manage diabetes, which can, in turn, result in even more medical complications associated with diabetes (Araki, Murotani, Kamimiya, & Ito, 2004; Black, 1999; Kinder, Kamarck, & Baum, 2002; Rubin & Peyrot, 2001; Williams et al., 2002). The physical limitations associated with the medical complications described earlier can exact a devastating psychosocial toll on the lives of older adults. But is this always the case?

In a nationally representative sample, Blaum, Ofstedal, Langa, and Wray (2003) found that 25% of individuals 70 years or older with diabetes reported high functional status and fewer comorbid conditions. At least one study suggests that depressive symptoms are related more to the degree to which diabetes intrudes in an individual's life than the number of complications an individual might have (Talbot, Nouwen, & Gingras, 1999). Assessment of quality of life is an important aspect of the management of chronic diseases in general, and diabetes specifically (Ragonesi, Ragonesi, Merati, & Taddei, 1998). But what exactly does the term "quality of life" encompass? Frequently, it is measured in terms of functional disabilities and role limitations. A recent study (Egede, 2004) found that individuals with both diabetes and depression have more functional disabilities in comparison to individuals with diabetes or depression alone. Other studies have likewise found that the effect on functional disabilities of both diabetes and depression is greater than the effect of having only one condition or neither condition, suggesting that detecting and ameliorating mental health symptoms may offset the risk

of developing functional limitations (Fultz, Ofstedal, Herzog, & Wallace, 2003).

In a study comparing older and younger adults with diabetes, Treif, Wade, Pine, and Weinstock (2003) found that, although older adults report more physical problems leading to greater role limitations, they also report less diabetes-specific emotional distress and are better at coping with and more readily accept diabetes-related lifestyle changes. The authors suggest that “coping skills, social relationships or other factors may act as buffers and prevent high levels of distress that often accompany diabetes” (p. 617). This study contradicts some others by suggesting that, although quality of life factors can lead to depression, they do not always do so. Understanding the psychological impact of diabetes in older adults can be complicated, and as such, social workers need to be careful in their assessment process to guard against making too many generalizations or assumptions. At the same time, however, it is important to be aware that the psychological and social problems associated with diabetes have the potential to adversely affect the quality of life of older adults with the disease (Ragonesi et al., 1998).

Many studies have confirmed the relationship between diabetes and depression, anxiety, eating disorders, loneliness, distress, and use of antipsychotic medications (Adams & Ball, 2000; Araki et al., 2004; Black, 1998, 1999; Feldman, Hay, Deberdt, Kennedy, & Hutchins, et al., 2004; Peterson et al., 1998; Rubin & Peyrot, 2001). Rubin & Peyrot and DeCoster (2001) are excellent sources for social work professionals interested in a more detailed review of psychological issues. Yet, despite this link, we cannot determine definitively the causal pathways between diabetes and depression. However, at least two recent longitudinal studies have demonstrated that individuals with depression are significantly more likely to develop diabetes (Golden, Williams, Ford, Yeh, et al., 2004; Williams & Paton Sanford, et al., 2002). Golden et al. found that individuals with the most severe depressive symptoms were more likely to develop T2DM 6 years later. However these findings are far from conclusive, and the authors point out that these findings might be partially confounded by low socioeconomic status and obesity.

All this being so, psychological disorders are so common in individuals with diabetes that screening for depression is a standard component for all older adults during a diabetes evaluation (ADA, 2004; California Healthcare Foundation/American Geriatrics Society, 2004). Why is living with diabetes so often linked to psychological complications? One explanation may be that

the regimen for diabetes is probably the most complex and demanding of any common disease . . . [including] complex nutritional practices, weight management, frequent monitoring of blood or urine glucose, foot care, special procedures in the event of common maladies such as cold or flu, and, in many cases insulin injections. (Fisher, Delamater, Bertelson & Kirkley, 1982, p. 993)

Rood (1996, p. 730) reports that “even with meticulous attention to detail, things may go wrong and wrong things often lead to blindness, nerve damage, kidney failure, and amputation.” Common emotional reactions to diabetes include denial, stress, fear, sadness, anger, guilt, frustration, being fed up, and feeling overwhelmed (DeCoster, 2001, 2003; Fisher et al., 1982; and Rubin & Peyrot, 2001). It is important that social workers do not overlook these common emotional reactions when working with older adults with diabetes.

Social Factors

It is important to understand factors representing barriers to prevention of complications and integration of optimal self-care recommendations. Examples of barriers include lack of financial resources, lack of access to affordable health care, lack of education about diabetes, improperly treated pain, and discontinuity in care (Bazargan, Bazargan, & Baker, 1998; Piette, Heisler & Wagner, 2004; Roubideaux, Buchwald, Beals, Middlebrook, et al., 2004; Schoenberg & Drungle, 2001). Frequently, barriers to optimal self-care and prevention of complications are influenced by factors such as race/ethnicity, education, income, and social support. Several studies have suggested that the barriers in diabetes care for individuals living in rural areas are more difficult to overcome than for those in urban areas (Andrus, Kelly, Murphey, & Herndon, 2004; Zoorob & Mainous, 1996). Barriers specific to preventive care in rural areas include lack of adequate insurance coverage, lower income, lack of transportation or greater travel distance to a primary care provider, inadequate screening and preventive services, and poorer compliance with standards of care of the ADA (Andrus et al., 2004; Zoorob & Mainous, 1996).

Schoenberg and Drungle (2001) examined barriers to optimal self-care in older women with T2DM, focusing primarily on three areas: financial challenges, lack of access to quality self-care, and pain and

disability. They found that 35% of participants had difficulty obtaining medical appointments, 20% experienced logistical barriers, and impaired vision represented a major problem for many (25% of the entire sample) along with the inability to check their feet on a regular basis. Generally, the authors found that being African American, less educated, and poor was associated with increased barriers to optimal self-care. Although this study focused exclusively on non-Hispanic Whites and African Americans, there has been increasing focus on the impact of diabetes across different racial/ethnic groups.

On average, African Americans, Hispanic/Latino Americans, and Native Americans are 1.6, 1.5, and 2.2 times more likely, respectively, to have diabetes than non-Hispanic Whites; native Hawaiians and Japanese and Filipino residents of Hawaii are approximately 2 times more likely to have diabetes than White residents of Hawaii (CDC, 2003). How do we interpret these numbers? If we consider the fact that diabetes prevalence increases with age and that African Americans, Hispanic/Latino Americans, Native Americans, and some Asian Americans are also at particularly high risk for diabetes, it demonstrates the need to prioritize social work assessment and interventions tailored to working with older adults in minority populations.

One way this can be accomplished is by gaining a better understanding of culturally specific knowledge regarding diabetes. For example, the literature informs us that African American and Native American women tend to report significantly greater concern with developing diseases, such as diabetes, compared to their non-Hispanic White counterparts (Wilcox, Ainsworth, LaMonte, & DuBose, 2002); older minority individuals, particularly African Americans, persistently underutilize medical/health services (Bazargan et al., 1998); the cultural definition of an “elder” in the Native American community typically refers to individuals at ages much younger than 65 years (Roubideaux et al., 2004); and Mexican Americans are more likely to be active in self-care if they perceive their own behaviors as causes of diabetes (Hunt, Valenzuela, & Pugh, 1998). The ADA Web site is an excellent resource for culturally specific resources, education, interventions, and materials written in different languages.

Perhaps the most comprehensive example of culturally competent research in this area, however, is the Diabetes Prevention Marketing Study (CDC, 1997). In this study, a total of 27 focus groups were conducted in populations disproportionately affected by diabetes. One of the goals of the study was to com-

municate how Native Americans (from various tribes), African Americans, Hispanics/Latinos (from Mexico, Central America, and the Dominican Republic), and Asian Americans (Korean, Filipino, Chinese, and Vietnamese) live with diabetes in various communities. Key focus group findings are summarized in Table 3.1. A literature review across these populations was also conducted. The literature review, focus group findings, and references (CDC, 1997) may be downloaded at <http://www.cdc.gov/diabetes/pubs/focus/index.htm#contents>.

Among the findings from the literature review, notions of attribution, though similar in some respects, pose important differences regarding whether diabetes is considered a cause or a result of bodily disturbance, or whether preventive care or behavior modification is likely to be considered. For instance, Native Americans consider diabetes to be a disease imposed by a social environment altered by contact with Whites and loss of traditional lifestyles. Hispanic/Latino populations consider illnesses such as diabetes to be a punishment by God that requires stoic endurance. A strong present orientation among many African Americans may not be compatible with preventive care, and Asian Americans may be receptive to modifying behaviors because cultural beliefs about food and illness relationships are based on principles of bodily energy balance involving polarities of hot and cold, male and female, or yin and yang. The summary of key findings from this literature review, together with the findings from the focus groups, provide an excellent start to realizing culturally sensitive social work practice with older adults.

TREATMENT APPROACHES AND INTERVENTIONS

Rood (1996, p. 739) points out that the frequent frustration on the part of the medical community when working with patients with diabetes is related to how difficult it is for the patient to change, and that education frequently leads to “knowledgeable noncompliant patients.” Social workers have the opportunity to play a prominent role in the lives of older adults coping with diabetes, particularly in addressing some of the gaps in treatment that can lead to professional frustration and generalizations or stereotypes about older adults diagnosed with diabetes. DeCoster (2001, p. 30) does an excellent job of explaining how the unique contribution of social workers’ “behavioral science background; ability to work with individuals,

TABLE 3.1. CDC Diabetes Prevention Marketing Study Focus Group Findings

Native American Populations

- Many participants expressed intense feelings of shame about having diabetes. They felt that they would be stigmatized in their communities if other people found out. This perception seemed quite prevalent among the men.
- Some of the women who lived on a reservation bemoaned the fact that although one of the best ways for them to exercise is walking, they fear attack from stray dogs.
- Although participants want to follow a diet regimen that will help them control their diabetes, they said that foods such as fresh fruits and vegetables and leaner cuts of meat are not affordable. Government commodities—often high in fat and sugars—constitute a significant portion of their diet.
- Some participants expressed a longing for continuity in their health care. They said that through the Indian Health Service, they may see a particular doctor only once or twice and are unable to establish a longer-term relationship.
- Some participants who use nontraditional treatment methods for diabetes said that they rarely tell their doctors for fear of being ridiculed. Others do not share the information with doctors because the methods are considered sacred.
- Most participants felt that the ethnicity of the treating physician did not need to be the same as the patient with diabetes. However, they did feel that a Native American doctor would put a Native American patient at ease, would take more time with the examination, and would be more patient and thorough in answering questions.

African American Populations

- No one felt prepared for the life changes that followed the diagnosis of diabetes.
- Participants attributed high incidence of diabetes to stress in the community, lack of information, a preponderance of other serious illnesses, and dietary preferences. Some participants described a perception of stress related to social ills, citing crime, work layoff, lack of transportation, lack of resources, AIDS, racism, and lack of communication between family members.
- Many said that because African Americans tend to put off seeking health care, diabetes may be discovered late.
- Participants in all groups expressed concerns about the financial burden of diabetes. Many participants voiced appreciation for health care providers who were flexible about payment for services.
- Many sources of information were mentioned, including print material from health care providers; workshops, classes, other presentations at hospitals and clinics; and the American Diabetes Association. In general, participants were satisfied with the information they receive but said that it needs to be disseminated more widely among young adults.
- Participants did not express a strong preference for African American health care providers, but some said that providers' knowledge of the cultural significance of diet would be useful.
- Several participants said that diabetes does not get the same attention in the African American community as do cancer, high blood pressure, and stroke.

Hispanic/Latino Populations

- Several participants said they typically forgo buying needed medication, glucose-testing strips, or both until they can afford them or a family member buys them.
- Among male participants' concerns about the complications of diabetes, one of the most important is the fear of sexual dysfunction. Many admitted that their experience with impotence negatively affected their self-esteem.
- Some participants said they believe that the onset of diabetes results from a strong emotional reaction to a good or bad event (e.g., winning the lottery, being robbed, witnessing a suicide).
- Some participants said they feel inhibited about asking their physicians diabetes-related questions because they feel ashamed of taking up too much of the doctors' time and are afraid that the doctors will become angry.
- Most participants said that their community offers them little support in managing their diabetes.
- When discussing why some Hispanics/Latinos might not manage their diabetes well, participants pointed to a lifestyle that emphasizes the joys and pleasures of eating.

Asian American Populations

- Women were concerned about injections.
- Many Chinese participants stated that both Western doctors and Chinese herbal doctors participate in their health care. The herbal doctors were valued by participants in part because they speak the same language and understand their culture and eating habits.
- Some believed that doctors try to control patients by doling out information a little at a time and discounting the value of non-Western treatment.

(continued)

TABLE 3.1. CDC Diabetes Prevention Marketing Study Focus Group Findings (*continued*)

-
- Participants said that diabetes is caused by a combination of factors, including intense emotional stress, consumption of sweets, and hereditary disposition.
 - Participants said that illness is more manageable if the mind is peaceful and positive.
 - Chinese participants felt that their diet did not lend itself to developing diabetes, stating that they consumed foods low in fat and low in sugar. However, the Korean participants believed that there is a high incidence of diabetes among their cohorts. They spoke of the Korean diet, pointing to an emphasis on meat and spicy foods.
 - Family support was particularly important among the Asian participants.
 - Several worried about the impact that diabetes could have on their interactions with others. They explained that among Asian people, there is a strong focus on the group's harmony and well-being, as opposed to an individual's well-being. Thus, Asians do not want to stand out from the crowd. To do so would create embarrassment, said participants. They also pointed out that they do not want to embarrass their hosts by not eating what is served at social gatherings.

groups or families; cultural competence; and ecological approach can be useful to patients and diabetes programs.”

Ideally, treatment is team-based, and professionals should have expertise in the field of diabetes and/or gerontology. Members of this team can include primary care doctors, diabetes educators, registered dietitians, eye doctors, podiatrists, dentists, exercise physiologists, and mental health professionals. Continuity of care is one of the most critical components for successful diabetes care. Going beyond this team-based approach to diabetes care, Jack, Airhihenbuwa, Namageyo-Funa, Owens, and Vinicor (2004) describe a collaborative care management approach, which involves the patient as a member of the team, and a transdisciplinary approach, which further involves the community as a member of the team. Although their work is geared to an audience of primary care providers, the authors convey the importance of approaching diabetes care from a strengths-based, empowerment, and ecological approach, making it a valuable tool for social workers collaborating with health care professionals who may not specialize in gerontology or diabetes or be familiar with social work concepts.

Social workers are integral to the case management and brokerage between all the providers and the patient. Consequently, they must be familiar with the current standards and components of diabetes care. The ADA Web site has a link to these recommendations. Another recent publication, “Guidelines for Improving the Care of the Older Person with Diabetes” (California Healthcare Foundation/American Geriatrics Society, 2003), containing evidence-based guidelines specific to older adults, is also an excellent resource. The basic goals in treatment of diabetes are

not much different for older than for younger adults (e.g., glycemic control, weight and exercise management, medical nutritional therapy, treatment of macrovascular and microvascular complications, self-management), but some modifications are necessary. It is also important that social workers tailor their interventions to the setting they are in and whether they have the opportunity to provide short- or longer-term treatment.

Effective treatment of diabetes and its associated macrovascular and microvascular complications is critical, but not to the exclusion of the numerous psychosocial complications, many of which may precede or exacerbate these vascular complications. As discussed earlier, psychological complications associated with diabetes can be considerable. Likewise, there is mounting evidence that social and emotional support can have a positive effect on diabetes care, prevention of complications, and well-being in older adults (Bertera, 2003; Seeman & Chen, 2002; Treif, Grant, Elbert, & Weinstock, 1998). For example, in a sample of older Chinese adults with T2DM, Cheng and Boey (2000) found that support outside the family played a more important role than family support in adaptation to the disease.

Group interventions are one method of enhancing social and emotional support. They have the benefit of being cost-effective and provide older adults with needed socialization and support. Robison (1993) describes a 12-week training and support group for older adults with diabetes. Not only did participants successfully meet the goals (to improve compliance with diet plans and lower their weekly peak glucose levels) in comparison to a control group, but these results were maintained at 12- and 24-month follow-ups. Although this study had several significant

limitations, the intervention is well described and could easily be replicated by social workers in the field. A second example is a year-long group intervention with the goal of solving psychosocial problems associated with diabetes (Alley & Brown, 2002). It is based on a task-centered model. The results were mixed, but it is important to note that the setting for this study was an HMO, and the study describes how some of the barriers and politics of starting a group were addressed.

Social workers should take into consideration any factors that might impede an older adult's ability to learn or to attend a group that might be associated with aging and/or diabetic complications (Beers & Berkow, 2004). Telephone-, Internet-, and home-based interventions are several recent approaches to circumvent some of these complications (Barrera, Glasgow, McKay, Boles, & Feil, 2002; Huang, Wu, Jeng, & Ling, 2004; Sacco, Morrison, & Malone, 2004). One study is particularly promising. Barrera et al. (2004) focused on enhancing social support through Internet-based interventions focused on diabetes. Participants receiving the social support interventions had significant improvements in their perceptions of social support in comparison to those receiving information-only interventions. Considering the growing number of adults familiar with and comfortable using computers and the Internet, this intervention has a lot of potential in the diabetes field.

The participatory action research (PAR) model is an excellent example of a culturally sensitive, evidenced-based approach to community intervention. People are seen as experts in their own lives, and the strengths of local people are used to plan action for change. Giachello et al. (2003, p. 311) define PAR as pursuing "research objectives (knowledge, understanding) with the meaningful involvement of community members (stakeholders) and an ultimate focus on social action leading to improvements in social conditions." The authors outline the community-based PAR approach they used to reduce the impact of diabetes in an underserved minority neighborhood and describe how that process led to increased awareness of the complexities of diabetes and readiness for system reform.

These approaches also tend to be more effective in minority racial/ethnic communities. Samuel-Hodge et al. (2000) examined culturally based psychosocial issues and other factors influencing behaviors of African American women with diabetes. Spirituality, general life stress, multiple caregiving responsibilities, and psychological impact emerged as important fac-

tors in adjustment, coping, and management of the disease. Likewise, these authors recommend family-centered and church-based approaches to diabetes care interventions in this population. McNair and Smith (1998) stress the importance of engaging natural supportive networks within the community, particularly in churches. Finally, two very important components of diabetes education, exercise and diet/nutrition, provide an excellent example of how interventions can be tailored to the community in which a social worker practices. Providing dance classes or adapting recipes in cooking classes to accommodate working in Asian American, African American, Hispanic/Latino, or Native American populations is as important for social workers as educating and preparing older adults and their family members for the myriad complications associated with diabetes.

CONCLUSION

Social work practice with older adults who have diabetes will vary depending on the setting. Social workers in health care settings are more likely to focus on enhancing psychosocial factors that can affect compliance with diabetes care; social workers in community-based settings are more likely to focus on education, prevention, and screening for diabetes in high-risk groups (Bertera, 2003). Due to the growing epidemic of obesity and increases in T2DM in the United States, family- and community-centered interventions arguably have the most potential for preventing diabetic complications in older adults, in the delay or even reversal of complications with T2DM in younger adults, children, and adolescents, and in creating large-scale change.

Social work research should focus on addressing knowledge gaps that hinder social workers from capitalizing most effectively on their unique role on the health care team and in the community. We highlight two critical areas here. First, there is a need to test whether earlier screening and intervention with at-risk adults could prevent or reduce depressive symptoms that can lead to poor glycemic control, diabetic complications, stroke, and dementia. Arguably, interventions for depression, such as cognitive-behavioral treatment, should begin *before* depressive symptoms escalate to major depression ("Diabetes and Depression," 1999). Social work research on psychosocial and physical symptoms in diabetes should make better use of ongoing support groups and the Internet to

conduct these screenings and interventions. Second, there are important research gaps about specific cultural beliefs, illness attributions, behaviors, and practices in various older, ethnic populations. How widely held are the cultural beliefs, attributions, behaviors, and practices that we assume to be common? Which are the most strongly held, amenable to change, or diffuse within underserved, ethnic elder populations?

As the population ages and lives longer, the so-called baby boom generation has placed particular demands on our society and brought dramatic changes as they pass through the various changes in the life cycle. As this generation approaches the age when T2DM becomes a serious risk, and if the statistics for onset of T2DM remain the same or even decrease somewhat, the numbers of people needing treatment for T2DM will dramatically increase, putting extreme pressure on those who provide services to older T2DM patients. It is essential that the infrastructure to deal with this likely increase be in place before the problem becomes a crisis. In addressing this issue, of all the professionals working in the area of diabetes, social workers are perhaps the most uniquely suited to lead the effort to provide education, prevention, and screening for diabetes and to implement effective interventions across multiple systems with the individual, the family, the treatment team, in local communities, and statewide.

NOTE

Older Adults With Orthopedic and Mobility Limitations

4

This chapter considers the major orthopedic diseases and associated conditions that older adults face and the challenges they pose for them, their families, and the social workers and other health care professionals that work with them. Recommendations are offered for social work practitioners who are likely to work with older adults with orthopedic diseases and who are at risk for falls, fractures, and joint replacements.

OSTEOPOROSIS

Osteoporosis is a systemic skeletal disease characterized by low bone mass and deterioration of bone tissue, with a consequent increase of bone fragility and susceptibility to fracture. It is estimated that between 13% and 18% of older women (Looker et al., 1995; “Osteoporosis among Estrogen-Deficient Women,” 1998) and between 3% and 6% of older men (Bilezikian, 1999) have osteoporosis. Osteoporosis has been historically associated with menopause and hence thought of as a “women’s” disease. The prevalence of osteoporosis is higher in Caucasian women, women 65 or older, and women with a low body mass index (“Osteoporosis among Estrogen-Deficient Women,” 1998). Women with lower socioeconomic status and limited access to health care are less likely than women with resources to report a diagnosis of osteoporosis (“Osteoporosis among Estrogen-Deficient Women,” 1998). This is most likely due to lack of knowledge regarding osteoporosis, not a lower incidence of osteoporosis.

Several risk factors have been linked to osteoporosis. Age, low calcium intake (Bauer et al., 1993; Marcus, Feldman, & Kelsey, 2001), family history (Bauer et al., 1993), vitamin D deficiency (Marcus et al., 2001), hypogonadism in men, steroid use for inflammatory conditions, alcoholism, smoking (Orwoll & Klein, 1995), and diabetes (Nicodemus & Folsom, 2001) all increase the risk of developing osteoporosis. The consequences of osteoporosis are severe. More than 1.5 million osteoporotic fractures occur each year (Riggs & Melton, 1992). Loss of height and curvature of the spine (Hofman, Grobbee, de Jong, & van den Ouse-land, 1991) lead to limited mobility and pain (Roberto & Reynolds, 2001).

Osteoporosis is often undiagnosed and undertreated. Missed diagnosis and undertreatment may be due to poor physician-to-physician communication, a lack of awareness that osteoporosis is prevalent in older men and premenopausal women, and adverse reactions to prescription osteoporosis medication

(Neuner, Zimmer, & Hamel, 2003). Older adults and their caregivers need to be encouraged to advocate for osteoporosis testing. Unfortunately, many men and women are unaware of their risk of developing osteoporosis (B. Williams, Cullen, & Barlow, 2002).

Older women with osteoporosis report changing their daily life and social interactions due to mobility restrictions caused by osteoporosis (Roberto & Reynolds, 2001). These changes include slowing daily activities, such as cooking, and restricting social engagements. A special issue to be addressed in working with women with osteoporosis is their fear of becoming increasingly dependent, falling, and losing the ability to maintain their own home (Roberto & Reynolds, 2001).

It is important to be aware of the fact that osteoporosis is preventable (McCoy, 2001). Calcium and vitamin D supplements are the first line of defense (McCoy, 2001). Weight-bearing exercise and resistance training have been shown to be effective in maintaining and/or increasing bone mass (Klesges et al., 1996). The importance of social support to encourage proper exercise and nutrition is vital to healthy aging. Encouraging women to join an osteoporosis prevention program can help them maintain healthy levels of bone density. Treatment of the condition is crucial. The hallmark of osteoporosis treatment for postmenopausal women is hormone replacement therapy (HRT; McCoy, 2001). HRT has been shown to increase bone mineral density and reduce the risk of fractures. Even so, the risks and benefits of HRT should be weighed by patients considering this treatment.

For further information, the National Osteoporosis Foundation (1998) has published guidelines on osteoporosis prevention, diagnosis, and treatment (see Table 4.1).

ARTHRITIS

Arthritis refers to 100 different diseases that affect the joints. Arthritis and rheumatoid arthritis are characterized by joint inflammation; the latter is considered an autoimmune disorder. Both are associated with joint stiffness, swelling, and pain. Arthritis is the most common self-reported condition among older persons today. The prevalence of arthritis increases with age. The prevalence rate of arthritis in the United States is projected to range between 43 and 60 million in 2020, with activity limitations associated with this condition projected to affect 11.6 million people (Cen-

ters for Disease Control and Prevention [CDC], 1999). Higher prevalence rates for arthritis are associated with lower educational levels (Dunlop, Manheim, Song, & Chang, 2001), lower socioeconomic status (Hill, Parsons, Taylor, & Leach, 1999), female gender, and obesity (CDC, 2002).

Arthritis is the leading cause of disability for middle-aged and older persons. People with arthritis can have varying degrees of difficulty in walking, lifting and carrying items, climbing stairs, and generally maintaining their household. In a study using Medicare data pooled over 6 years, Porell and Miltiades (2001) found that arthritis was consistently associated with increased risk of functional decline and reduced the chances of functional improvement in older adults with activities of daily living (ADL) and instrumental activities of daily living (IADL) disability. The odds of disability are higher with age, for women, for non-Whites, and for those with comorbid conditions (Peek & Coward, 1999).

Even though activity limitations associated with arthritis have been reported to be higher for African Americans, the use of medical services remains higher for Whites than for Blacks (Mikuls, Mudano, Pulley, & Saag, 2003). Mayer-Oakes and all (1992) found that Whites with arthritic-like conditions were more likely to see a physical or occupational therapist than were Blacks. Ibrahim et al. (2003) discovered that African Americans and Whites report perception of pain associated with osteoarthritis differently; they posit that this may lead to undertreatment of rheumatoid conditions for African Americans.

Due to the pain associated with arthritis, many older adults withdraw from social and physical activity. Persons who experience severe arthritis are most likely to cease social participation. Persons with an active social network are more likely to remain engaged (Kaplan, Huguet, Newsom, & McFarland, 2003). Inactivity has serious physical and psychological consequences. Depression appears to be quite prevalent among persons with arthritis (DeVillis, 1995). Other health risks include increased dependence, poor health, loss of joint motion, and diminished quality of life (Hill et al., 1999; Kaplan et al., 2003; Penninx et al., 2001; G. Wang, Helmick, Macera, Zhang, & Pratt, 2001;). Comorbid conditions are also known to be associated with arthritis. Most important, the risk of institutionalization has been shown to increase with arthritis, most likely due to decreased functioning of the lower extremities (Hughes & Dunlop, 1995). It is unfortunate that half of arthritis sufferers associate the disease with normal aging and do not believe that their symptoms can be alleviated.

TABLE 4.1. Where to Turn for More Information

The Arthritis Foundation is the only national not-for-profit organization that supports the more than 100 types of arthritis and related conditions with advocacy, programs, services, and research. http://www.arthritis.ca/custom%20home/default.asp?s=1
The Arthritis Society is Canada's only not-for-profit organization devoted solely to funding and promoting arthritis research, programs, and patient care. http://www.niams.nih.gov/
The mission of the National Institute of Arthritis and Musculoskeletal and Skin Diseases is to support research into the causes, treatment, and prevention of arthritis and musculoskeletal and skin diseases, the training of basic and clinical scientists to carry out this research, and the dissemination of information on research progress in these diseases. Their Web site on osteoarthritis is. http://www.niams.nih.gov/hi/topics/arthritis/oahandout.htm
The Arthritis Research Campaign, founded in 1936, raises funds to promote medical research into the causes, treatments, and cures of arthritic conditions. This site also provides over 80 downloadable publications on arthritis and related conditions. http://www.aoa.gov/eldfam/Healthy_Lifestyles/Art_Ost/art_ost.asp
The U.S. Administration on Aging's Web site has links to information on arthritis and osteoporosis. http://www.nlm.nih.gov/medlineplus/osteoarthritis.htm
Medline Plus provides news, research, and consumer information on osteoarthritis. http://www.oarsi.org/
OsteoArthritis Research Society International is a nonprofit, scientific organization promoting and encouraging fundamental and applied research to permit better knowledge of osteoarthritis and its treatment. http://www.rheumatology.org/index.asp?and=mem
The American College of Rheumatology is the professional organization of rheumatologists and associated health professionals. http://www.fallprevent.com/Index.htm
The goal of fallPREVENT is to provide community- and institutional-based health professions with a one-stop-shopping Web site, a place where individuals can learn about falls in older people and what strategies are available to prevent falls. http://www.nof.org/
Established in 1984, the National Osteoporosis Foundation is solely dedicated to osteoporosis and bone health.

It is generally recognized that an exercise regimen is an important vehicle for maintaining physical functioning among elders with arthritis. Tai Chi (Gallagher, 2003), aerobic and resistance training (Penninx et al., 2001), and fitness walking (Hughes et al., 2004) all show promise in decreasing the pain and stiffness associated with arthritis. In fact, women who believe they can control their exercise behavior do have higher levels of functional performance (Gaines, Talbot, & Metter, 2002). An effective treatment for pain in the later stages of osteoarthritis is joint replacement (discussed further in this chapter).

FALLS

Falls are a frequent occurrence among older adults. Thirty percent of community-dwelling elders fall once a year (O'Laughlin, Robitaille, Boivin, & Suissa, 1993); the rate is 3 times higher for hospitalized and/or institutionalized older adults (American Geriatrics Society, British Geriatrics Society, and the American Academy of Orthopaedic Surgeons Panel of Falls Prevention [AGS], 2001). Women are more likely than men to experience a fall (Baker, 1992; Tromp, 1998). Over 130 risk factors for falls have been identified

(Myers, Young, & Langlois, 1996). A combination of environmental, physical, and psychological factors increases the likelihood that an elder will fall. The AGA identified 11 of the most common risk factors. Lack of balance control significantly increases risk of falling (Lord, Sherrington, & Menz, 2003), as does impaired gait (Tideiksaar, 2002). Other risk factors include increased age (Samelson, 2002), arthritis (Huang, Gau, Lin, & Kernohan, 2003), cognitive impairment (Tromp, 2001; van Doorn et al. 2003), history of falls (Nevitt, Cummings, & Hudes, 1991), muscle weakness (Moreland, Richardson, Goldsmith, & Clase, 2004), use of assistive device (Kiely, Kiel, Burrows, & Lipsitz, 1998), visual impairment (Legood, Scuffham, & Cryer, 2002), ADL impairment (Kiely et al., 1998), and depression (Lipsitz, Jonsson, Kelley, & Koestner, 1991). Diabetes (Hanlon et al., 2002) and polypharmacy (Flaherty, Perry, Lynchard, & Morley, 2003) also increase the risk of falls.

Falls have serious health consequences. Between 10% and 30% of falls are injurious to the extent of requiring hospitalization, decreasing mobility, and increasing chances of mortality (King, & Tinetti, 1995; Sterling, 2001). Falls are the leading cause of accident mortality among older adults (Murphy, 2000). Approximately 3% to 5% of falls result in fractures (Stalenhoef,

Crebolder, Knottnerus, & Van der Horst, 1997; Wilkins, 1999); 95% of hip fractures are caused by falls (Nyberg, Gustafson, Berggren, Brannstrom, & Bucht, 1996).

A major health concern, even among older adults who have never fallen, is the fear of falling. Between 33% and 50% of community-dwelling adults fear falling (Cumming, Salkeld, Thomas, & Szonyi, 2000; Yardley & Smith, 2002), and 46% of nursing home residents fear falling (Frazoni, Rozzini, Boffelli, Frisoni, & Trabucchi, 1994). In addition to the health risks of falling, many older adults fear the social embarrassment of falling and the loss of functional capacity. Dependence on others is another fear; in 50% of nonfatal fall cases, fallers require assistance to rise (Tinetti, Lui, & Claus, 1993). Falling and fear of falling lead many older adults to restrict their activities (Fletcher, & Hirdes, 2004). Consequences include increased social isolation, depression, development of physical limitations, and increased dependence on caregivers (Stel, Smit, Pluijm, & Lips, 2004). Fear of falling has been shown to predict institutionalization, even among older adults who have never fallen (Cumming et al., 2000).

Caregivers play an important role in reducing an older adult's chances of falling and providing emotional support. Older adults who have emotional and instrumental support are less likely to fear falling and restrict their activities (Fletcher & Hirdes, 2004). Family members are likely to provide the majority of beneficial social support. Faulkner, Cauley, Zmuda, Griffin, and Nevitt (2003) found that family networks are more likely than friendship networks to offer a protective effect against falls. They hypothesize that family members are more likely than friends to offer physical help and emergency care and to express concern about an older adult's safety. Caregivers may help with tasks such as grocery shopping and housekeeping, thus limiting fall-producing circumstances (Andrew, 1993).

It is important to note that caregiver responsibilities and anxiety may increase after a fall. The majority of older adults who experience fall-related fractures and other injuries have yet to recover their prefall functional levels 1 year later (Kempen et al., 2003). This can be expected to increase dependence on caregivers and consequently increase caregiver stress.

Although a single best preventive method may not yet have been identified, most falls are preventable. Various comprehensive checklists and measures of physical ability exist to assess the risk of falls (Tideiksaar, 2002). The Get-Up and Go test is the simplest measure of balance and is recommended as an initial

screening tool (AGS, 2001). Older adults are asked to get up from a chair, walk 10 meters, return, and sit down in the chair (Mathias, Nayak, & Isaacs, 1986). The Home Fall Hazard Assessment Tool (Clemson, Fitzgerald, Heard, & Cumming, 1999) is used to assess environmental conditions inside and outside the home that potentially contribute to falls. Tinetti, Richman, and Powell (1990) developed a 10-item scale to assess confidence in performing ADLs without falling. This scale is beneficial in understanding the anxiety associated with completing daily life tasks.

A multifaceted approach to interventions is the most effective method of fall prevention. The American Geriatrics Society has established guidelines for fall prevention (AGS, 2001). Tai Chi, an exercise that emphasizes balance stability and postural control, has been shown to increase self-efficacy and reduce the risk of falling and fear of falling (Wolf et al., 2003). Up to one-half of falls occur around the home environment (Wilkins, 1999). Creating a slip-free and clutter-free environment is essential to reducing falls. Interventions that include home hazard assessment and environmental modifications have been shown to be effective in reducing falls (Nikolaus & Bach, 2003). A review of medications to identify side effects such as dizziness and, if possible, to reduce the number of medications taken could also prevent falls (Ray & Griffin, 1990). Regular visits by volunteers to assess general health have also been shown to be effective in reducing falls (Carpenter & Demopoulos, 1990). Use of health and social services, such as home health care and Meals on Wheels, provides social support and help with daily living. Unmet need for personal assistance services has been associated with falls (LePlante, Kaye, Kang, & Harrington, 2004). It is important to encourage older adults to see a health care provider for disease management, particularly health conditions related to falls. Older adults should also be encouraged to supplement their diet with calcium and Vitamin D to maintain healthy bones.

FRACTURES

More than 500,000 hospitalizations occur each year from fractures (NHDS, 1998); by 2040, the number of hip fractures alone is expected to be 500,000 (Cummins, 1990). Hip fractures and vertebral fractures lead to mobility restrictions, increased dependence, and a lower quality of life. In a study that examined recovery from various fracture types, hip and wrist fractures had the greatest impact on IADL and ADL

disability a year later (Scaf-Klomp, van Sonderen, Sanderman, Ormel, and Kempen (2001)). Mortality rates are highest for hip fractures (Woolf & Akesson, 2003). Among older adults, fracture rates are 3 times higher for women than men (Praemer, Furner, & Rice, 1999).

One out of six women will experience a hip fracture (Melton, 1995). Men are less likely than women to experience a hip fracture because they possess fewer risk factors (Walter, Lui, Eng, & Covinsky, 2003). Risk factors for hip fracture include age, White ethnicity, cognitive decline, difficulty transferring, and ADL and lower body limitations (Walter et al., 2003; Wolinsky, Fitzgerald, & Stump, 1997). Nursing home residents who are able to transfer independently are more likely to experience hip fractures (Gregg, Pereira, & Caspersen, 2000). Similarly, studies have shown that older adults who wander are more likely to fall (Cesari et al., 2002). This creates a challenge for caregivers, who must balance an older adult's right to autonomy with the need to create a safe environment. Overprotective caregivers may foster learned helplessness. Additionally, restricting movement causes muscle atrophy and increased dependence (Campanelli, 1996).

The average length of hospitalization for a hip fracture is a week. Forty percent of hip fracture patients are discharged to a residential facility; estimates show that a year later, 25% to 33% are still in a nursing home (Magaziner, 2000). After an approximately 8-week rehabilitation period, older adults who are not in residential facilities are discharged home. However, the majority of hip fracture patients do not regain their prefracture levels of mobility (Kempen, Scaf-Klomp, Ranchor, Sanderman, & Ormel, 2001). Another complication of hip fracture is incontinence (Palmer, Baumgarten, Langenberg, & Carson, 2002), a distressing condition that limits an older adult's social engagement.

Caregivers of older female hip fracture patients underestimate caregiving activities related to continence, length of mobility impairment, and the pain levels associated with hip fracture recovery (M. A. Williams, Oberst, Bjorklund, & Hughes, 1996). Non-spousal caregivers report the greatest difficulty with caregiving tasks (M. A. Williams et al., 1996). Social support through an older adult's primary network has been shown to positively influence long-term recovery (Kempen et al., 2001). Even phone contact appears to have a positive benefit on 1-year recovery rates (Magaziner, Simonsick, Kashner, Hebel, & Kenzora, 1990). Instrumental support, such as help with gro-

cery shopping and transportation, also has a positive impact on recovery (Oh & Feldt, 2000). These studies indicate that caregivers' emotional and physical assistance are most instrumental in assisting an older adult's recovery from hip fracture.

A hip fracture is more likely than other medical conditions to cause long-term functional impairment. Impairment in ADLs, IADLs, and lower and upper body limitations are common and long-lasting (Wolinsky et al., 1997). Various factors influence recovery from a hip fracture. Factors that positively influence recovery include good overall physical health, younger age (Parker & Palmer, 1995), and higher levels of functional ability prior to fracture (Roberto, 1992b). There is evidence that positive mental outlook speeds recovery (Parker & Palmer, 1995). Older adults who expect to recover experience greater gains in ambulating than older adults who do not have recovery expectations (Borkan & Quirk, 1992). Depression and anxiety are negatively correlated with recovery (Oh & Feldt, 2000). Older adults who have cognitive impairment (X. Wang & Emery, 2002) or comorbidity (Roberto, 1992a) experience limited functional recovery. Pain is another barrier to recovery (Oh & Feldt, 2000). Rehabilitation efforts may be thwarted if an older adult feels excessive pain.

Multiple interventions exist to prevent hip fractures. Use of hip protectors in nursing homes has been shown to reduce the incidence of hip fractures (Meyer, Warnke, Bender, & Muhlhauser, 2003). Fall prevention is crucial to reducing hip fractures (Woolf & Akesson, 2003). Exercise that strengthens muscles and improves balance and gait stability reduces falls and subsequently hip fractures (Wolf et al., 2003). Increasing bone mineral density through calcium supplementation, Vitamin D, and nutrition also reduces hip fractures (Woolf & Akesson, 2003). HRT for menopausal women has been encouraged to promote bone density (Reginster, 2004); however, recent findings from the Women's Health Initiative point to the need to weigh the risks and benefits of HRT.

JOINT REPLACEMENT: HIP AND KNEE

Joint replacement is the treatment of choice for end-stage arthritis for the hip or knee (Fortin et al., 1999). Pain and disability are the leading reasons to elect primary arthroplasty (Holtzman, Saleh, & Kane, 2002). In contrast, revision arthroplasty is a procedure done to replace a failing joint implant, and thus is not an elective procedure. One of the few epidemiological

population-based studies of Medicare beneficiaries found that 61,568 patients had a primary hip replacement and 13,483 had a revision hip replacement in one year (Mahomed et al., 2003). Medicare patients most likely to undergo a primary hip replacement are older, female, and Caucasian and have higher incomes (Mahomed et al., 2003). A nationally representative sample of community hospitals revealed that 254,370 primary and 23,180 revision knee replacements occurred among Medicare beneficiaries in 1997 (Hervey et al., 2003). The Medicare beneficiaries were primarily Caucasian (70%) with an average age of 69; 63% of persons undergoing primary arthroplasty were female, but only 58% of Medicare beneficiaries undergoing revision arthroplasty were female. Beneficiaries undergoing revision arthroplasty had higher levels of comorbidity. The average length of hospital stay was 4 to 5 days. Discharge dispositions were similar for both groups: Almost 50% were discharged to a short-term hospital or other facility, 30% were discharged home, and 20% were discharged home with home health care.

Various factors influence recovery. Older adults in poor preoperative health who have functional ability impairments, such as walking and IADL limitations, and moderate to severe pain do not reach the same postoperative level of functional ability as older adults who are less severely impaired (Holtzman et al., 2002; Fortin et al., 1999); however, the gains in improvement surpass the gains made by older adults in good preoperative health (Holtzman et al., 2002). Mahomed et al. (2003) found that increased age, revision hip arthroplasty, male gender, low income, Black ethnicity, comorbidity, and a diagnosis of rheumatoid arthritis were all associated with adverse outcomes and/or mortality. In a recent comprehensive review of the literature, Ethgen, Bruyere, Richey, Dardennes, and Reginster (2004) concluded that hip and knee arthroplasty improves health and physical functioning. Older age was not a barrier to functional improvement.

Spousal caregivers of older adults who undergo joint replacement require assistance with the changes in social roles and the health care complexities of recovery (Showalter, Burger, & Salyer, 2000). Increased dependence and the need for ADL and IADL assistance are common immediately after knee or hip replacement, but often abate after rehabilitation. Because individual healing trajectories vary, older adults who undergo knee or hip replacement often underestimate the pain and length of recovery time. Older adults express insecurity and impatience with the healing

process; their caregivers express difficulty balancing increased household and personal assistance tasks (Showalter et al., 2000). The social worker will want to be aware that the dynamics of caregiving under these circumstances may be different from many other situations where the presence of chronic conditions, by definition, precludes full recovery and a return to independent functioning by the older adult.

Education on postoperative functional abilities and explanation of the rehabilitation process has been shown to reduce length of stay and decrease medication use and anxiety (Daltroy, Morlino, Eaton, Poss, & Liang, 1998). Adaptive and assistive devices that allow older adults to manipulate the environment and regain independence ease the recovery transition period (Showalter et al., 2000). Participating in rehabilitation programs and exercise has been shown to hasten functional recovery and decrease stiffness and pain (Moffet et al., 2004). Self-efficacy, the belief that one can perform the rehabilitation exercises, increases compliance and speeds rehabilitation (Moon, 2000).

IMPLICATIONS FOR GERONTOLOGICAL SOCIAL WORK PRACTICE AND RESEARCH

Social workers can and should play a significant role in addressing the social, psychological, emotional, and environmental consequences of the physical diseases and conditions discussed in this chapter during the course of their work with older adults and their caregivers. A basic knowledge of the symptoms, risk factors, treatment approaches, and information and referral sources available can improve your practice and benefit your clients significantly. The special challenges and responsibilities associated with orthopedic diseases and conditions for social workers who work with older adults and their families have been highlighted throughout this chapter. In summary, the following are recommended:

1. Gerontological social workers should have a basic understanding of orthopedic diseases, injuries, and procedures, including accompanying symptoms, available procedures and treatments, and their role as a member of the health care team. Social workers should maintain or have access to others who have the necessary health care resources, referral sources, and specialist contacts that their older clients and caregivers can turn to in times of need.

2. Older adults need to be encouraged to take responsibility for maintaining their own health and well-being, staying active, and being in touch with their own bodies. Older adults must be encouraged to see their primary care practitioners on a regular basis and to feel more comfortable expressing their concerns about health issues with medical professionals and engaging generally in open exchange during patient-physician encounters.
3. It is important that both social workers and family members not be overprotective in their helping and caregiving efforts. Overprotectiveness has the potential to foster excessive dependency or learned helplessness among older adults, whereas undue restriction of movement can contribute to muscle atrophy.
4. Helping older adults and their caregivers minimize the socially isolating and emotionally demoralizing effects of orthopedic infirmities and procedures is critical. Strategies for helping older adults maintain a positive spirit, deal with depressive reactions, stay active, and maintain their opportunities for social contact and interactions even in the face of significant functional impairment is a high priority of your work.
5. Older adults need to be helped to understand that they are at risk but that many orthopedic conditions are preventable. Safe mobility practices, smart home design, healthy lifestyles, regular testing, and prompt treatment can make enormous differences in preventing, reversing, or alleviating the negative impact of orthopedic diseases and injuries.
6. Family, friends, and neighbors of elders with orthopedic-related impairment or at risk for such conditions should be kept informed of the risk factors and issues surrounding the disease so that they may serve effectively as an additional line of defense and support. Family members suddenly thrust into the role of caregiver may need crisis counseling and intense support when they are called on to respond unexpectedly to an older relative who has suffered an accident, fallen, or otherwise experienced an unexpected and disabling fracture.

Practice research is needed to help us reach a better understanding of the unique challenges and needs of spouses and other family members called on to assist relatives with orthopedic conditions, especially those who need to transition to the role of caregiver unexpectedly or engage in such functions for time-

limited periods during the older adult's recovery period. Social workers would also benefit from research that seeks to better understand the emotional and psychological dimensions of living with orthopedic disease and related conditions and the implications such knowledge has for more informed practice.

ELIZABETH LIGHTFOOT

Older Adults With Developmental Disabilities

5

Developmental disabilities are a diverse group of physical and/or mental impairments that begin anytime up until 22 years of age and are usually life-long. Developmental disabilities limit a person's capacity to engage in major life activities, such as independent living, mobility, language, learning, working, decision making, and self-care. In the United States, there is a precise federal definition of a developmental disability (Table 5.1). Common diagnoses that often fall under the definition of developmental disabilities include intellectual disability (Table 5.2), autism, cerebral palsy, hearing impairment, vision impairment, and attention-deficit/hyperactivity disorder (ADHD). There are currently about 4 million people in the United States with a developmental disability. Although the definition of developmental disability is broad, this chapter primarily focuses on issues faced by older people with intellectual disabilities.

The issues surrounding aging with a developmental disability have received more attention in the past decade due to both the increased longevity of people with developmental disabilities and an increased focus on the rights and quality of life issues of people with disabilities overall. In 2000, there were approximately 641,000 adults with developmental disabilities over the age of 60 in the United States (Heller, Janicki, Hammel, & Factor, 2002). By the year 2030, it is estimated that the number of older people with developmental disabilities in the United States will almost double to approximately 1,242,800 (Heller et al., 2002). The size of the baby boom cohort partially explains this growing figure, but as important is the growing life expectancy of people with developmental disabilities. In 1930, the average life span for a person with an intellectual disability in the United States was only about 20 years (Carter & Jancar, 1983). However, by the late 1990s, the life expectancy for people with developmental disabilities had risen dramatically. People with Down syndrome now have an average life expectancy of around 60 years, and people with other types of developmental disabilities now have a life expectancy approaching 70 years (Janicki, Dalton, Henderson, & Davidson, 1999; Warren, 1998).

In the late 20th century a major paradigm shift commenced in service provisions for people with developmental disabilities. Services used to be provided primarily in institutions, with professionals making the primary decisions on where and how a person would live. Now services are becoming more consumer-driven and community-based. Growing numbers of people with developmental disabilities are living in the community in their own homes, working

TABLE 5.1. U.S. Federal Definition of Developmental Disabilities

The term “developmental disability” means a severe, chronic disability of an individual 5 years of age or older that:¹

- 1) Is attributable to a mental or physical impairment or combination of mental and physical impairments
 - 2) Is manifested before the individual attains age 22
 - 3) Is likely to continue indefinitely
 - 4) Results in substantial functional limitations in three or more of the following areas of major life activity:
 - (i) Self-care
 - (ii) Receptive and expressive language
 - (iii) Learning
 - (iv) Mobility
 - (v) Self-direction
 - (vi) Capacity for independent living
 - (vii) Economic self-sufficiency
 - 5) Reflects the individual’s need for a combination and sequence of special, interdisciplinary, or generic services, supports, or other assistance that is of lifelong or extended duration and is individually planned and coordinated.
-

in real jobs for real wages, and participating in leisure activities of their choice. The concept of *person-centered planning*, which involves supporting people with developmental disabilities to make choices about how they live their lives, has increased their self-determination. Although supports for community living have not developed at the same rate as the desire for community living, there are now greatly expanded community-based options for people with developmental disabilities.

Likewise, the roles of social workers and social service organizations have changed dramatically in the field of developmental disabilities. Social workers are moving away from their previous role of primary assessor of needs and decision maker for services and are now becoming more involved in supporting individuals with developmental disabilities to make their own choices, helping to coordinate or broker services,

and assisting in individual and systems advocacy for appropriate services. Social service organizations providing services to people with developmental disabilities are moving away from being primarily institution-based service providers and are becoming more likely to be community support organizations—providing supports to individuals with developmental disabilities to live, work, and interact in the community (Lightfoot, Hewitt, & Sauer, 2004). This trend toward community-based supports and person-centered planning fits with the social work values of self-determination and respect for the dignity of all people (National Association of Social Workers, 1996).

The new paradigm in developmental disabilities has not lessened the complexity of the developmental disabilities field. Effective social workers need to be knowledgeable about the various federal and state

TABLE 5.2. Language Matters

Intellectual Disability

The terminology in the field of developmental disabilities has been continuously changing in an attempt to increase both respect and preciseness. The term “intellectual disability,” used internationally, has recently been adopted by many U.S. advocacy, research, and governmental agencies as a more appropriate and respectful synonym for “mental retardation.” However, many federal and state programs in the United States are still currently using the older term. Developmental disability and intellectual disability, though similar, have slightly different definitions.

People-First Language

The most important aspect in the use of language is to try to avoid labeling individuals (e.g., “He is blind”) or using words with negative connotations (e.g., “stroke victim”) or words regarded as slurs (e.g., “handicapped”). In the United States, many people with disabilities advocate using “people-first language.” People-first language puts the person before the disability, and it describes what a person has or uses, not what a person is (e.g., “person with an intellectual disability” rather than “mentally retarded person”; “he uses a wheelchair” rather than “he is confined to a wheelchair”; “people with disabilities” rather than “the disabled”).

laws and policies that protect the rights of people with developmental disabilities and provide funding for services (Table 5.3), the various program options that allow people with developmental disabilities to receive adequate supports, and the organizations that work to enact progressive legislation and to provide information and support to individuals and families (Table 5.4).

SOCIAL WORK PRACTICE WITH OLDER PERSONS WITH DEVELOPMENTAL DISABILITIES

The underlying social work issues surrounding *aging* with a developmental disability are not dissimilar from social work practice in the general area of aging. Social workers support older people to age with dignity, maintain a good quality of life, meet their basic needs, have their rights respected, access appropriate health care, and deal with the physical and emotional changes associated with aging. Until recently, there have not been strong linkages between the aging service network and the developmental disabilities service network as they relate to addressing the needs of persons aging with a developmental disability. However, in the past decade there has been a growing collaboration between the fields of aging and disability.

The general issues surrounding aging are similar for people of all abilities, but there are some different areas of emphasis that social workers need to be aware of when supporting older people with developmental disabilities. This chapter discusses some of the important issues that social workers will encounter

when supporting older people with developmental disabilities. In particular, to practice effectively and ethically with older persons and their families, social workers need to know about:

- Health concerns
- Community participation and retirement
- Residential options
- Family caregiving issues
- Later-life planning
- Loss and grief
- Assistive technology and environmental interventions
- Rights and advocacy

HEALTH CONCERNS

Social workers in the area of developmental disabilities need to be aware of health concerns associated with aging with a developmental disability. These include not only the normal health trajectory of older people with developmental disabilities, but also access to health care and the promotion of a healthy lifestyle. One of the reasons for increased life expectancy for people with developmental disabilities is the vastly improved medical care available to them in childhood and early adult years. As people with developmental disabilities are living much longer, they are now experiencing age-related health conditions similar to other older people. Our medical knowledge is still limited about many of the particularities of these age-related health concerns (Evenhuis, Henderson, Beange, Lennox, & Chicoine, 2000), though there are

TABLE 5.3. Major U.S. Federal Disability Laws

Americans with Disabilities Act of 1990 (ADA)

Prohibits discrimination on the basis of disability in employment, state and local government, public accommodations, commercial facilities, transportation, and telecommunications.

Section 504 of the Rehabilitation Act of 1973

Prohibits discrimination on the basis of disability in programs that receive federal funds.

Developmental Disabilities Assistance and Bill of Rights Act

Provides federal funding to developmental disabilities councils, protection and advocacy agencies, and university centers on excellence in developmental disabilities.

The Fair Housing Act Amendments of 1988

Prohibits discrimination in housing on the basis of disability.

The Civil Rights of Institutionalized Persons Act (CRIPA)

Authorizes the U.S. attorney general to investigate conditions of confinement at state and local government institutions, including institutions for people with developmental disabilities.

TABLE 5.4. Organizations Serving Older People With Developmental Disabilities

Administration on Developmental Disabilities

The federal organization responsible for implementation of the Developmental Disabilities Assistance and Bill of Rights Act.

<http://www.acf.hhs.gov/programs/add/>

American Association on Mental Retardation (AAMR)

Promotes progressive policies, sound research, effective practices, and universal human rights for people with intellectual disabilities.

<http://www.aamr.org/>

The ARC

A national organization providing information, support, advocacy, and research for people with developmental disabilities and their families, including older people.

www.thearc.org

Canadian Association for Community Living

National Canadian organization for people with intellectual disabilities and their families.

www.cacl.org

Foundation for People with Learning Disabilities (UK)

Provides research, develops projects, and provides information on people with intellectual disabilities (called learning disabilities in the United Kingdom).

<http://www.learningdisabilities.org.uk>

International Association for the Scientific Study of Intellectual Disabilities

An international scientific organization that promotes worldwide research and exchange of information on intellectual disabilities and has a special interest group on aging.

<http://www.iassid.org/>

Rehabilitation Research and Training Center on Aging with Developmental Disabilities, University of Illinois at Chicago

Conducts research and provides technical assistance and information on aging with developmental disabilities.

<http://www.uic.edu/orgs/rrtcamlr/index.html>

Self-Advocates Empowering Ourselves

A national organization of self-advocates that provides training, information, and support for individuals and self-advocacy organizations.

<http://www.sabeusa.org/>

United Cerebral Palsy

A national organization dedicated to improving independence, productivity, and full citizenship of people with cerebral palsy.

<http://www.ucp.org/>

numerous medical studies under way that will aid in our knowledge (Seltzer, 2004)

One area in which aging-related health knowledge has progressed is dementia and people with Down syndrome. People with Down syndrome appear to have more significant age-related health concerns, particularly with the high prevalence and early onset of dementia (Janicki & Dalton, 2000), as well as other age-related health issues such as adult-onset epilepsy, sensory losses, hip disease, and thyroid disorders (Dinani & Carpenter, 1990; Janicki, Heller, Seltzer, & Hogg, 1996; Puri, Ho, & Singh, 2001; Van Allen, Fung, & Jurenka, 1999). For other people with developmental disabilities, there are some early indicators that prevalence rates of dementia, one of the most serious

age-related health concerns, are roughly equal for adults with and without developmental disabilities (Zigman et al., 2004).

Social workers need to advocate for access to appropriate health care for older people with developmental disabilities. There are a number of barriers these individuals face in the health arena that may limit their access, including bureaucratic barriers, such as extraordinarily complicated health care financial reimbursements, which can limit medical professionals' desire to take on such patients. Further, few medical professionals have received training on working with older people with developmental disabilities, and thus many are not familiar with their typical health and functioning issues (Messinger-Rapport & Rapport,

1997). There are few valid health assessment tools that can assist medical professionals in diagnosing some age-related conditions in this population, which may be difficult to diagnose because of their cognitive ability (Shultz et al., 2004). People with developmental disabilities may also be resistant to receiving medical care due to poor previous experiences with untrained medical staff (Seltzer & Luchterhand, 1994). A final barrier is health rationing, which sometimes negatively affects older people with developmental disabilities. Due to limited resources, there is often a need to ration or prioritize medical treatment. Many people with developmental disabilities have been denied access to some forms of medical care, most notably access to organ transplants, because of their disability (National Work Group on Disability & Transplantation, 2004).

Social workers also have a role in promoting a healthy lifestyle for older people with developmental disabilities. Along with improved medical care, a healthier lifestyle associated with living in the community has helped to improve life expectancy for these individuals. However, people with developmental disabilities are still more likely to have sedentary lifestyles and poor nutrition (Braunschweig et al., 2004; Heller et al., 2002). Health promotion activities can help them avoid age-related conditions related to poor fitness and nutrition, such as Type II diabetes, osteoporosis, and coronary heart disease. Studies are showing that people involved in fitness and health education training programs have improved attitudes toward exercise (Heller, Hsieh, & Rimmer, 2004).

COMMUNITY PARTICIPATION AND RETIREMENT

Adults with developmental disabilities are becoming increasingly involved in their communities, including working and participating in leisure activities. As these individuals age, they vary on how they wish to continue their community involvement, whether through continued work, retirement, or volunteer activities. The concept of retirement is relatively new for older persons with developmental disabilities. As many are still not working at jobs with competitive wages, retirement may signify a shift in activities that allows more leisure time, rather than finishing their careers and receiving retirement benefits (Heller, 1999).

Many older people with developmental disabilities simply continue to work past the typical retirement age (Sutton, Sterns, & Schwartz-Park, 1993) or stay in their current day activity programs. Often, they like

the structure of their current programs (Mahon & Mactavish, 2000) and worry that changing to a new activity or program would result in the loss of friends and/or income (Janicki, 1992).

Older persons and their families may not be aware that retirement options exist. When planning for retirement does occur, it has usually not included asking individuals with developmental disabilities themselves what their own desires are for changing their daily plans as their health or energy levels change (Sutton et al., 1993). For those who do wish to retire from work, vocational programs, or day activity centers, there have been few retirement options available until recently. Some of the larger developmental disability support providers are starting to provide retirement options, such as supported volunteering or recreational opportunities. There are also attempts to encourage existing senior programs, such as senior centers or senior parks and recreation programs, to be more inclusive of older people with developmental disabilities. Despite the advent of new retirement options, these options are still limited and are altogether unavailable in many areas. Further, the lack of knowledge about these options persists.

Another issue surrounding retirement is the different health trajectories that some people with developmental disabilities may have. Like all people, people with developmental disabilities experience age-related health conditions at different ages. For example, the majority of people with Down syndrome begin to experience health declines at an earlier age than average and may need to consider shifting to retirement at an earlier age, such as in their 50s or even 40s. Other people with developmental disabilities may not experience an earlier onset of age-related health changes. Social workers need to be aware of these different health trajectories, both to allow their clients a chance to experience retirement and to advocate for changing programmatic age requirements that effectively bar some people with developmental disabilities from retiring.

RESIDENTIAL OPTIONS

The types of formal residential options for people with developmental disabilities have expanded dramatically in the past 25 years. For people living in the formal care system, the overall trend is to live outside of large institutions, and the majority of large institutions have been closed across the United States. The U.S. Supreme Court has recently affirmed this trend with its *Olmstead* decision, which guarantees the

rights of individuals with disabilities to live in the community or in the most integrated setting feasible (Olmstead et al. v. L.C. et al., 1999).

Formal living options that have become more common are medium and small group homes and shared homes and apartments with paid staff providing more flexible support. Community-based living arrangements have expanded rapidly in the past several decades. However, the formal system of residential living options for older people with disabilities is currently well beyond capacity. As of 1997, there were more than 80,000 people with developmental disabilities on formal state waiting lists for residential services (Prouty & Lakin, 1998). We can expect the number of individuals on waiting lists to grow dramatically as the number of older people with developmental disabilities increases, with the accompanying need to transfer from their elderly parents' homes.

The most common living arrangement for adults with developmental disabilities is living with their families, rather than in formal or informal arrangements in the community. It has been estimated that about 60% of adults with developmental disabilities live with their families (Braddock, 1999; Fujiura, 1998). For these adults, the types of residential supports available include respite care, personal care assistance, and in-home health care. However, the needs for these services are much greater than their availability, and the waiting lists for these community-based supports are long. Only a small portion of federal and state residential funding is spent on community and family supports for community-based living (Stancliffe & Lakin, 2004).

The growing waiting lists for all types of residential services and supports place stress on aging parent caregivers who are unsure where their adult children will reside when they are no longer able to care for them. It also suggests a need for a coordinated effort to address the lack of community housing options for adults with developmental disabilities.

The concept of "aging in place," which means growing older without having to move as one becomes more functionally limited, is becoming more prominent in the area of developmental disabilities. There is a shift away from expecting people with developmental disabilities to move to an institution or a residential setting, such as a group home, as their first option when they are no longer able to live with their parents. The concept of aging in place becomes more difficult when an older person with a developmental disability suffers an age-related functional disability, such as dementia. For those older people already in

formal care, aging in place requires myriad support services, including early detection, clinical supports to help staff provide appropriate care, program adaptations that fit an individual's changing functional level, specialized programs such as hospice, and environmental adaptations such as ramps, adapting restrooms, or installing alarm systems (Janicki, McCallion, & Dalton, 2002). Despite many advocates' preference for the aging in place model, many group homes do not have the training, finances, or other resources available to offer this option. Alternatives to aging in place for people with dementia include transferring to specialized group homes or to a nursing home (Janicki et al., 2002).

FAMILY CAREGIVER ISSUES

For families, issues surrounding caregiving for adult children with developmental disabilities are some of the greatest concerns associated with aging. As parent-caregivers grow older, they are concerned about caring for their adult children as long as possible and what will happen to their adult children when they die or become unable to provide care. Aging caregivers often find both rewards and stressors in caring for their aging children (Essex, Seltzer, & Krauss, 1999).

Families with both aging parents and an aging adult child with a developmental disability, sometimes called "two-generation elderly families" (Davis & Berkobien, 1994), often have had little or no involvement with the formal disability service network (Smith, Fullmer, & Tobin, 1994). Many don't receive any support services, such as respite care. Some are distrustful of the social service system, especially as the philosophy of the social service system at the time when their children were born was one of customary institutionalization of children. Others simply feel they do not need supportive services (Smith, 1997). Some report a need for support groups, family counseling, or individual counseling, but report that these services are not available (Smith, Majeski, & McClenny, 1996). For some ethnic groups, such as Puerto Ricans, the natural social support system present in their families and communities has taken the place of a formal support system (Magana, 1999). However, the use and availability of respite care and other support services have been increasing, as such services are more and more seen as a support for caregiving rather than only for crisis situations (Freedman, Griffiths, Krauss, & Seltzer, 1999). Further, studies are showing that younger caregivers are more likely to seek sup-

portive services and have higher expectations of the social service system (Hayden & Heller, 1997), which suggests that the next cohort of aging caregivers may make more use of support services.

As parents of adult children with developmental disabilities begin facing their own health concerns, one of the greatest is planning for the transfer of caregiving. Families often have to make the decision of whether to transfer care to another family member, such as a sibling of the adult with a developmental disability, or to a formal residential option. Those who have not been involved in the formal service system are contemplating entering the system for the first time after having been the primary or only caregiver, sometimes for more than 50 years.

Many parents simply do not make plans for their adult children's future care (Heller & Factor, 1991; Kaufman, Adams, & Campbell, 1991). This can be due to a lack of information about their options, as well as the stress and worry related to facing the reality that their children will outlive them. Parents tend to feel fewer worries when planning a transfer to a sibling (Griffiths & Unger, 1994). Social workers have a primary role in supporting families emotionally as they deal with this stressful life stage, as well as helping them learn about and access resources and plan for their adult child's future. Social workers can also be involved in the building of coalitions of aging, developmental disabilities, and other social service agencies that can work together to support the needs of elderly families (Davis & Berkobien, 1994).

LATER-LIFE PLANNING

A key role for social workers supporting older people with developmental disabilities and their families is to assist them in the area of later-life planning. As mentioned, the stresses involved in older-age transition can lead some families to avoid planning for the future. And when planning does occur, people with developmental disabilities themselves are often not included in the planning process or even informed of the changes that will take place in the future (Heller, Miller, Hsieh, & Sterns, 2000).

Person-centered planning is an approach to planning that assists individuals with disabilities to make decisions about how they would like to live their lives, with support from individuals in the community who know them well, such as family members, friends, neighbors, and support staff (Abery & McBride, 1998). This is in contrast to provider-based planning,

in which providers or professionals make plans for individuals based on their professional assessments and service availability, without necessarily asking the individual and his or her family what they envision for their later years. The person-centered planning approach fits well with the social work values of empowerment and self-determination. The social worker's role becomes one of facilitating the process of planning based on an individual's desires and helping the individual to realize his or her vision (Abery & McBride, 1998).

Key areas that are covered in later-life planning include where a person will reside, future work and leisure activities, financial matters, and guardianship concerns. As detailed earlier, residential planning can be one of the most stressful issues for families, as many have never lived away from their parents, and there will at some point be a need for either bringing supports into the home, moving to live with a relative or friend, or entering into formal care. Person-centered planning can help families make the best choice of residence based on the individual's and family's own desires, along with making choices for future retirement and leisure activities.

Individuals and families also have to plan future finances for their adult children, such as determining to what extent an individual can manage his or her own financial matters, planning who might be involved in assisting with this chore, estimating the future costs of different types of support, and assuring that transference of estates do not jeopardize an individual's eligibility for government benefits (Davis & Berkobien, 1994). Social workers can help families understand the wide array of often confusing financial planning options, ranging from informal options to complicated trusts, and help them coordinate the planning process to include financial advisors who are aware of the family's needs. Financial planning is obviously intricately intertwined with residential planning, as the amount of money available to individuals relates directly to the choices they have for living. As Medicaid pays for most publicly funded residential services, directly transferring income on a parent's death to the child or child's proxy may actually limit the adult child's residential options.

The issue of planning for guardianship is also an important consideration in later-life planning. Basically, a guardian has the legal authority to manage the affairs of another person. A family member or state guardianship used to be the norm for people with developmental disabilities; it is now used more specifically to protect individual rights as much as possible.

The decision for guardianship is made by the court, based on an individual's ability to make decisions, not based on diagnosis (Davis & Berkobien, 1994). There are important reasons why an individual may need either a full, partial, or temporary guardian, such as his or her need for help in managing finances or need for medical care.

Planning for guardianship is often discussed in the context of future health care planning. Just as doctors cannot perform medical procedures without informed consent, an individual with a developmental disability who cannot express an understanding of a complicated medical issue cannot demonstrate consent. This necessitates some arrangement of surrogate medical decision making, depending on an individual's ability to understand and make complicated medical choices. Although guardianship protects individuals with developmental disabilities, allowing them to access medical care, for example, it also limits self-determination. Other complicated issues that individuals and parents might want to plan for include advanced directives, such as a living will. Social workers need to help families with these important planning issues.

LOSS AND GRIEF

As is true for all older people, older people with developmental disabilities experience both age-related joys and age-related losses. Some of the losses may be unique or more profound for people with developmental disabilities, but the underlying issues of loss and grief are similar. Social workers need to be aware of these unique losses and help their clients with their grief.

Because so many of these individuals have lived with their parents for so long, the loss of a parent can be extremely traumatic. Not only may they be grieving their parents, but their parents' death may also result in their having to move from the family home that they have been residing in for many years to a formal service system. This change of location and the accompanying change in routines can compound the loss they are already feeling. Further, they may feel a loss of self-worth or self-esteem, as they may have had a valuable role in the family that no longer exists or is disregarded with their parents' death (Ludlow, 1999). People with developmental disabilities may also experience a greater sense of loneliness as they age, as they are often more isolated from the community, whether living in a group home or their parents'

home. If they have not been involved in any later-life planning, they may not understand exactly what is happening to them. Participating in bereavement rituals according to their culture or religion can help people with disabilities cope with their grief (Ludlow, 1999).

Social workers practicing with this population need to be aware of the grief and sense of loss they experience and help them mourn the passing of their family and friends. Involving them in later-life planning may help them anticipate some of the changes they may experience before a major change occurs.

ASSISTIVE TECHNOLOGY AND ENVIRONMENTAL INTERVENTIONS

There is a growing focus on the use of assistive technology and environmental interventions to help older people with developmental disabilities maintain their functioning and independence. Assistive technology includes any products, devices, or equipment that are used to maintain or improve one's functioning. Examples of assistive technology are low-tech devices such as an adapted door handle, a walker, a telephone amplifier, or a grab-bar near the bathtub, and high-tech equipment such as a voice synthesizer or an electronic scooter. Environmental interventions are changes in an individual's environment that help maintain or improve functioning, such as building a fence, painting walls different colors, or adding ramps. Very high-tech environmental interventions are on the horizon, such as "smart homes," which electronically monitor older people's movement in their home, their health status, and even their self-care needs in a perhaps inobtrusive way (Rehabilitation Engineering Research Center on Technology for Successful Aging, 1999).

There is some evidence that the use of assistive technology and environmental interventions do result in better functioning for older people with developmental disabilities (Hammel, Lai, & Heller, 2002). However, there are currently limited resources to pay for such technology and interventions, and little knowledge available about the types and appropriateness of such interventions for older persons with developmental disabilities. Further, social workers need to be sure to keep the issue of protecting privacy and autonomy of the individual in the forefront when using such equipment, especially with some of the new monitoring techniques. There is also a danger that some people will be left behind in benefiting from

these new advances due to a lack of resources, with a resulting digital divide in technological supports for people with disabilities.

RIGHTS AND ADVOCACY

The push for rights for people with developmental disabilities has come from national advocacy groups, such as the ARC and TASH; self-advocacy groups, such as People First; and many individuals and relatives of people with developmental disabilities. The social work profession has not been in the forefront of the disability rights movement (Mackelprang & Salsgiver, 1996), though many social work professionals are now involved in supporting systems-level changes.

Partially as a direct result of such advocacy, the later years of the 20th century brought increased federal and state protections for the rights of people with developmental disabilities. Federal laws, such as the Americans with Disabilities Act of 1990, now protect people with disabilities from discrimination in employment, state and local government, public accommodations, and transportation. State and federal lawsuits have closed down many institutions and required services to be provided in the least restrictive environments.

Of particular importance for older people with developmental disabilities is the worldwide self-advocacy movement, a movement of mostly younger people with developmental disabilities for people with developmental disabilities. Participation in self-advocacy has generally not been encouraged among older adults in this population, though self-advocacy organizations are beginning to look more closely into issues of aging (Levitz, 1999). As individuals' degree of community inclusion and self-determination is linked with their ability to advocate for what they want and need (Herr & Weber, 1999), social workers should encourage older people with developmental disabilities to become or continue to be involved in self-advocacy.

NEW DIRECTIONS FOR SOCIAL WORK PRACTICE

Social workers who embrace the paradigm shift that has occurred in the field of developmental disabilities will find themselves well situated to support older persons with developmental disabilities to live quality

lives. Social workers can assist these clients to have more control of their lives, participate in the community, receive appropriate health care, access appropriate assistive technology, and cope with grief and loss associated with aging. Social workers can assist older people with developmental disabilities and their family members to plan together regarding the future. And social workers can be involved in building collaborations among providers for more effective services and in advocating for civil rights, adequate funding, and a more consumer-directed, community-based service system. Social work researchers can help design and evaluate new models for providing services and supports to older people with developmental disabilities in the 21st century. This will be particularly important, as the next cohort of older people will have grown up with more involvement in the community, and issues such as retirement and community residential options will be more in demand. The values and skills of social workers are ideal for supporting the new paradigm of service provision and supports for older people with developmental disabilities.

This page intentionally left blank

The emotional effects of macular degeneration often seem more troublesome than the physical ones. Anger? Depression? Yes. Several fellow sufferers told me that they had sought help from therapists but found that few, if any were expert at dealing with our problems.

Henry Grunwald, former editor of *Time* (2003, p. 103)

Most of us who lose hearing in adulthood, of whom I am one, do experience diminished hearing as impairment, as disability, as lost competence. Few of us have sign language fluency and, even if we do, most of our family and friends are “culturally hearing” and cannot use a manual language for communication. We too were raised “culturally hearing,” but now are no longer able to use sound to interact freely and comfortably with others. Relationships that once were effortless are no longer easy.

The late Laurel Glass, professor emerita (2003, p. 106)

Groups of people at dinners, meetings, cocktail parties . . . groups turn into faceless blurs. Worse is I can't see who is speaking and my longstanding hearing impairment becomes a greater handicap. Talk about sensory deprivation! I've been dealt a double whammy.

Helen Kandel Hyman, freelance writer (2003, p. 109)

CYNTHIA STUEN

Older Adults With Age-Related Sensory Loss

6

Sensory impairment has a profound impact on older persons, effecting their health, mental health, and quality of life status. Recognition of and attention to age-related sensory loss, particularly vision and hearing, are important in providing social work services to older adults. Knowing the difference between the normal changes in sensory systems and those that are caused by age-related disorders should be basic knowledge for gerontological social workers. It is also important to recognize that for many older adults, sensory losses occur in the context of other comorbid health conditions. Although sensory losses may not be life-threatening in comparison to cancer or heart disease, it may be the condition that has the most impact on the older person's quality of life.

This chapter focuses mainly on the continuum of sensory loss of vision and hearing, although some brief attention will be given to the chemosensory

areas of taste and smell. The focus is on older adults who acquire an age-related sensory loss in later life, not on the population of older persons who are aging with an early-onset sensory loss. Large numbers of older persons experience varying degrees of vision loss and/or hearing loss, which can have a profound impact on their quality of life as well as access to information and health and human services.

I first discuss normal changes and disease-related sensory impairments and their prevalence. An overview of the specialized service systems of vision rehabilitation and aural rehabilitation and the functional and psychosocial consequences of sensory losses are then presented, followed by the implications for social work practice and policy issues. How social work has dealt with people with disabilities concludes the chapter.

DEFINITIONS AND PREVALENCE

Vision

All people experience normal changes in vision, usually beginning in their 40s. The most common normal age-related vision change is presbyopia. The lens of the eye becomes denser, less elastic, and more yellow, making it harder to focus on near-vision tasks such as reading. It is correctable with reading glasses or bifocal, trifocal, or progressive lenses. Another normal age-related change is that one's pupil becomes smaller. As a result, older adults need more light than younger cohorts. There is a slower reaction time in adjusting to changing illumination levels. Generally, older adults have diminished contrast sensitivity and colors appear less vivid, more faded. All of these normal changes generally occur gradually and can either be accommodated to or corrected with regular prescription glasses or contacts.

Vision impairments, on the other hand, typically result from eye disease and are not part of normal age-related vision changes. *The Lighthouse National Survey on Vision Loss: The Experience, Attitudes and Knowledge of Middle-Aged and Older Americans* (The Lighthouse, Inc., 1995), a telephone survey conducted by Louis Harris and Associates, documented that 17% among those aged 65 to 74 and 26% of adults age 75 years and older self-reported a vision impairment.

There is evidence of health disparities by race. The prevalence of age-related vision impairment is higher for African and Hispanic Americans than it is for their white counterparts (Prevent Blindness America,

2002). Glaucoma and diabetic retinopathy are particularly more prevalent for non-White older persons. Given the dramatic projected growth of the minority population of older persons over the next few decades, this disparity needs urgent attention in terms of early identification and treatment. There are no consistent differences by gender, but higher rates of vision impairment are related to lower socioeconomic status (The Lighthouse, Inc., 1995).

The most common age-related eye disorders are macular degeneration, glaucoma, diabetic retinopathy, and cataract. The functional impact of each of these conditions, which can occur independently or in combination, is of concern for social workers interacting with older adults.

Cataract, which is the most prevalent of age-related eye diseases, affects nearly 20.5 million people in the United States age 40 and over. A cataract causes a clouding of the normally clear lens of the eye; this clouding reduces the passage of light to the eye. Things look hazy and blurred, and there is increased sensitivity to glare (Figure 6.1a shows normal vision and Figure 6.1b simulates overall blur). Removal of the cataract is a very successful surgical procedure. However, some older persons are not candidates for surgery; in these cases, a person has very reduced visual function.

Diabetic retinopathy affects more than 5 million adults in the United States. In addition to overall blur, one may have very hazy, distorted, or splotchy vision caused by leaking blood vessels resulting from diabetes (Figure 6.1c). Laser treatment to seal the leaking blood vessels in the eye may arrest the leakage, but wherever the laser seals a blood vessel, scar tissue results, and one is unable to see through the scar tissue. Fluctuation in visual ability, sometimes by the hour, is not uncommon because vision is affected by one's blood sugar level. There is no cure for diabetes, and uncontrolled diabetes can lead to total loss of vision; hence, early and prompt intervention is critical.

Age-related macular degeneration (AMD) affects 6 million people in the United States, with another 13 to 15 million with presymptomatic signs of the disease (AMD Alliance International, 2003). One's central field of view is obliterated so that reading, performing any near-distance task, and recognizing faces is very challenging (Figure 6.1d). There are two forms of the disorder. Dry AMD is the most common form (estimated to be 85% to 90% of cases) and usually progresses slowly. The less common form is wet AMD; it is more threatening to vision because at the early stages, tiny new blood vessels grow under the retina

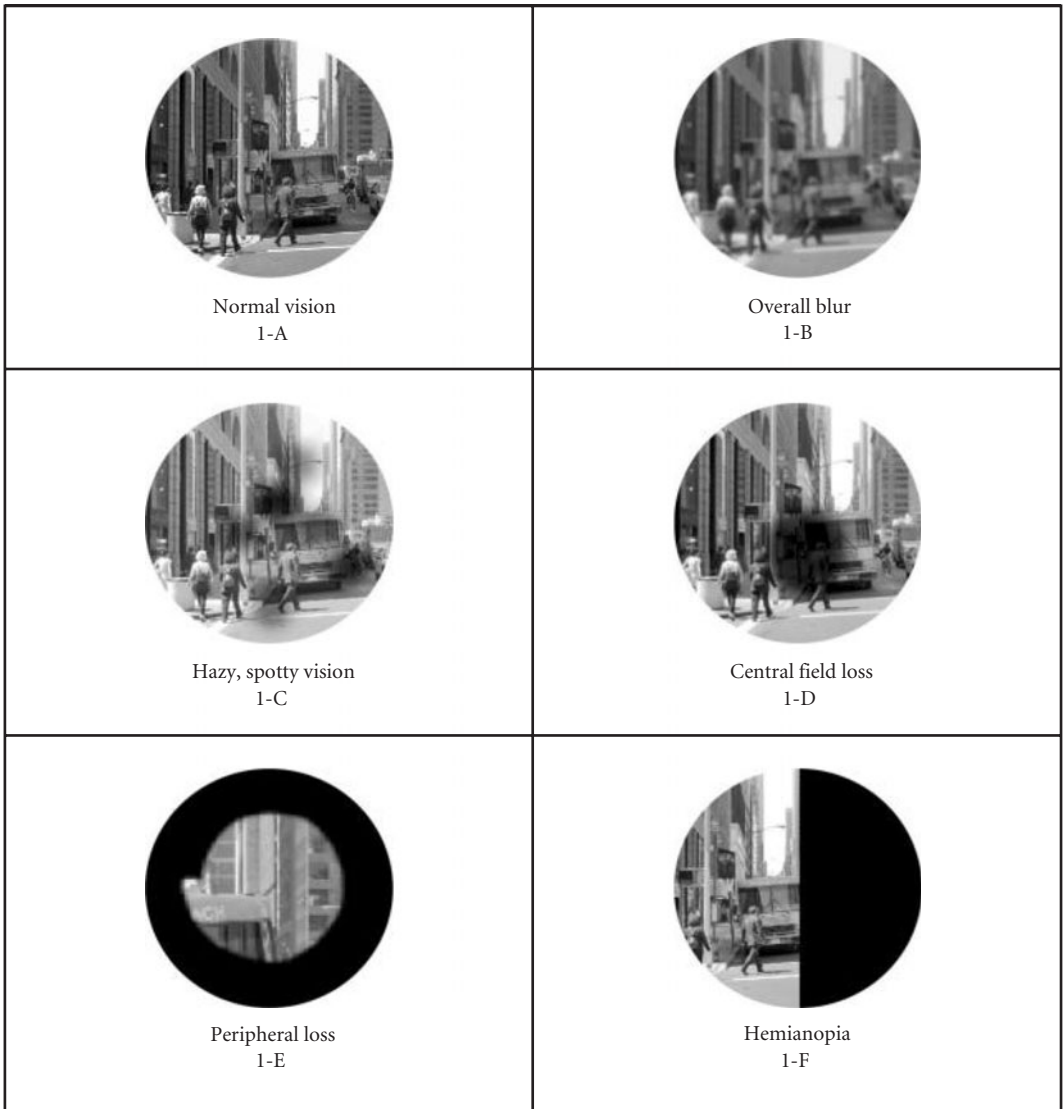

FIGURE 6.1. Composite simulation of age-related eye disorders.

and leak fluid that causes distorted central vision. Two FDA-approved treatments are being used to stabilize the condition, and clinical trials are also under way for other new treatments for the disease. There is no cure for macular degeneration at this time.

Glaucoma has the opposite functional impact of AMD; it takes away the peripheral or side field of vision but leaves the central vision intact. The cause of glaucoma is unknown, but it gradually destroys the cells of the optic nerve that carry information from the eye to the brain. As the nerve cells die, vision is slowly lost at the periphery of one's visual field (Figure 6.1e). Glau-

coma is often referred to as the "silent thief of sight" because the loss happens so gradually that it may take years for a person to realize the loss of peripheral vision.

In most cases, medications, laser treatments, and/or surgery can be used to slow or arrest the loss of vision, but the disease cannot be prevented. Glaucoma affects more than 2.2 million people age 40 and over in the United States and is strongly related to age and race. It is most prevalent among aging adults and among Black and Hispanic Americans. The loss of peripheral vision affects safe mobility in the home and community.

There is one other type of field loss, hemianopia, that gerontological social workers need to understand. This is the loss of half of one's visual field in both eyes; it may be the upper half, lower half, right or left half, and is most common for persons who have experienced a stroke, tumor, or trauma to the head. The most frequent defect is right homonymous hemianopia, which occurs in corresponding halves of the right field of vision (Figure 6.1f). It is often overlooked and not diagnosed among persons who had a stroke. This type of loss affects reading; the person does not realize there is still a half-page or line remaining and wonders why nothing is making sense. Movement and safe mobility are also impacted.

Hearing

Just as there are normal and disease-related changes in vision, the same is true for hearing loss. The auditory system experiences degenerative changes as the individual ages. The organ of Corti houses the sense organ of hearing; it is a structure within the snail-shaped cochlea, and it is most susceptible to age-related hearing changes (Schuknecht, 1993). Age-related atrophy interferes with the reception of high-frequency sounds, which makes it difficult to understand speech even in a quiet environment.

Data from the 1994 National Health Interview Survey (National Center for Health Statistics, 1998) indicate that hearing impairment, defined as deafness in one or both ears, or any other trouble hearing, was reported by 33% of adults age 70 and over, representing approximately 6.7 million persons (Crews & Campbell 2004). It was also noted that only 11.6% of these persons report using a hearing aid.

Hearing loss can be classified as a conductive central auditory processing or sensorineural disorder. A conductive disorder is an impairment in the transmission of sound to the inner ear, which can be caused by a buildup of cerumen (wax) or otosclerosis (a growth). Central auditory processing disorders are problems at the level of the brain, which can be caused by any head trauma or other systemic problem affecting the brain (Strawbridge, Wallhagen, Shema, & Kaplan, 2000).

Older adults are most susceptible to age-related atrophy that diminishes the reception of high-frequency sounds, especially for men; low-frequency sounds are more diminished for women. Both compromise the understanding of speech. This sensorineural loss that accompanies aging is called

presbycusis. The sensory structures within the balance mechanism of the inner ear also undergo degenerative change with age and this contributes in part to the dizziness, instability, and falls so common among older adults (Weinstein, 2003).

Hearing loss can also be caused by a number of other factors. Exposure over long periods to work or recreational noise, genetic factors, trauma, metabolic disease in organs such as the kidney, vascular disease, and infections may cause hearing loss. Another high risk for older persons is ingestion of medications, such as some diuretics, and chemotherapy treatments that have an ototoxic effect, one that is damaging to hearing and balance (Weinstein, 2003).

Dual Sensory Impairment

Having a concurrent hearing impairment and vision impairment, referred to as dual sensory impairment, is quite prevalent and creates a very special challenge for social workers, particularly in the area of communication. Analyses of the Longitudinal Study of Aging Version found that 35% of adults age 70 and older reported some degree of vision impairment, and 42% reported some hearing impairment, with 21% having both a visual and a hearing impairment. African and Hispanic Americans were found to be at greater risk than Whites for both single and dual sensory impairments (Brennan, 2003; Horowitz, Brennan, & Su, 2001). Considered by age cohorts, 13% of those age 70 to 74, 20% of those age 75 to 79, 27% of those age 80 to 84, and 40% of those over age 85 have a dual sensory loss.

Negative outcomes in several domains related to sensory impairment have been documented also. Older persons who have a vision impairment only are more likely to report their health as poor than those with no sensory problems (15.3% vs. 6.7%). Those older persons with dual sensory impairment report higher rates of poor health (18.5% vs. 6.7%; Crews & Campbell, 2004). In this study, older persons with dual sensory impairments were 3 times more likely to have fallen in the past year than people without vision or hearing problems and 2 times more likely to fracture a hip, which often has a cascading set of negative consequences.

For persons with vision impairment and, to a somewhat lesser extent, for those with hearing impairment, the literature also documents greater functional disability, more informal help received in instrumental activities of daily living (IADL) and personal activities of daily living (PADL) tasks, dissatisfaction with social

interactions, and more health care utilization (Brennan, 2003; Brennan, Horowitz, & Su, 2002; Burmedi, Becker, Heyl, Wahl, & Himmelsbach, 2002; Crews & Campbell, 2004). These data are very significant as the population of older persons increases, with the baby boom cohorts nearing retirement age, and the increases in longevity.

Vision and Hearing Loss in the Nursing Home Setting

The rates of vision and hearing impairments are especially high in nursing home populations. Chafee (1967) estimated that 90% of nursing home residents had hearing impairments. A moderate or severe vision impairment among nursing home residents was reported to be over 50% in a study by Horowitz and Balistreri (1994). An earlier study by Horowitz (1994) showed that even in the context of multiple chronic impairments, vision impairment significantly contributed to functional disability among older persons living in an institutional health care environment. A study of nursing home residents found that those with impaired vision and hearing independently predicted lower levels of social engagement and less time spent in leisure activities (Resnick, Fries, & Verbrugge, 1997).

Recognizing vision and hearing impairments in the nursing home setting is very important to ensure that older persons maintain their maximum independence. Because vision and hearing provide critical information for communication and wayfinding, older persons may be mislabeled as confused when in fact they have a vision and/or hearing impairment. Stuen (1994) documented a successful three-part strategy to introduce nursing home personnel to the field of vision rehabilitation. First, facilitywide staff training is an essential strategy to ensure knowledge and sensitivity about vision loss. A second strategy is an environmental assessment and modification to maximize functional independence of residents with normal age-related and abnormal vision loss. The third strategy is the on-site provision of low vision and other vision rehabilitation services. The project resulted in the preparation of a training manual and video to teach and disseminate the strategies.

CHEMOSENSORY IMPAIRMENT

Chemosensation is the term used to describe the sensory systems responsible for taste, smell, and

chemical irritation. Rawson (2003) describes several features that make these systems susceptible to age- and disease-associated changes. Long-term exposure to harsh external environments and exposure to pharmacological agents can induce chemosensory side effects. A reduction in saliva that might be caused by denture use can create a physical barrier to membranes where receptors lie and/or where receptors are exposed to denture adhesives that can have a negative impact on taste. Sometimes, sensory dysfunction is the result of a chronic disease such as diabetes.

Taste sensitivity diminishes with age for some, but not all flavors and odors are affected (Mojet, Christ-Hazelhor, & Heidema, 2001). Older adults often complain that things no longer taste right; however, this is generally due to changes in olfaction (smell). Decreases in smell sensitivity begin sooner for men than women and may be related to the protective role of estrogen for women (Doty, 1984). There is also literature showing that chemosensory deficits may be early indications of neurological disorders, such as Parkinson's disease (Busenbark, Huber, Greer, Pahwa, & Koller, 1992) and Alzheimer's disease (Morgan, Nordin, & Murphy, 1995).

Changes in taste and smell, regardless of the cause, can have consequences for the older person in terms of safety issues, such as not being able to detect an odor when food has spoiled or a gas leak. Of course, the health and social implications of good dietary food selection and the pleasure of eating have tremendous significance for the health and well-being of older adults.

One-third of all older people report dissatisfaction with their sense of taste or smell, and the actual incidence of chemosensory loss among older adults is probably higher (Pelchat & Schaefer, 2000). According to Rawson (2003), the most common complaint among older adults coming to her chemosensory research center is the frustration they experience at not being taken seriously by their health care professionals. She advises that the best approach for health care workers is to make appropriate referrals for medical evaluation and to help older persons develop strategies to compensate for their losses to promote nutritional health and safety in their environment. Some of the strategies involved labeling food stored in the refrigerator with a date to discard and using different spices to enhance the taste areas that are compromised. Supplemental flavorings in food have been shown to improve food intake and the degree of satisfaction among older adults with diminished smell (Mathey, Siebelink, de Graaf, & Van Staveren, 2001).

VISION AND AURAL REHABILITATION

Most of the age-related eye disorders previously described result in partial sight or low vision, although some disorders, if untreated, can lead to total blindness. When there is no treatment, medicine, or surgery to correct vision to the normal range, one is said to have *low vision*. A person needs to be evaluated by a low vision specialist, an ophthalmologist or optometrist with specialized training, who can prescribe appropriate optical and nonoptical aids.

Optical devices include a wide variety of magnifiers, ranging from a small hand-held model to a video magnification system such as a closed-circuit television or portable video magnifier. There are microscopic spectacles and telescopes that can be prescribed, depending on the task to be accomplished and the type of vision loss. Computer hardware and software also provide screen magnification, synthesized speech, and tactile display, and a combination of these can also be useful to persons with vision loss. There are many other assistive devices that can enhance independent daily living for persons with impaired vision, such as voice-output clocks, thermometers, large dial appliances, and specialized telephones.

Members of the vision rehabilitation team include the vision rehabilitation therapist, who helps an individual learn techniques to remain independent at home, at work, and in the community. Techniques range from adapting everyday items, such as a stove or microwave, to labeling medications and adapting a social activity. An orientation and mobility specialist teaches people with vision loss to move safely indoors and outdoors using any residual vision, auditory cues, or other techniques, such as a white cane or dog guide.

Once hearing impairment is recognized and the medical factors explored, usually by an otolaryngologist, to make sure there is no medical or surgical treatment that can restore the hearing to a normal range, an older adult should have an audiological assessment by an audiologist. The goal of the assessment is to identify the areas in which the hearing loss has an impact and to find appropriate hearing technologies and referrals for counseling to help the person overcome the hearing handicap.

Fortunately, hearing aids, which come in many types, are not the only resources available to older persons. Other hearing assistance technologies include hardwired, infrared, and FM systems. A simple hardwired assistive listening device can be very useful for social workers to utilize when interviewing/counseling an older adult with a hearing loss. Theaters

often have infrared assistive listening systems available to patrons upon request.

It is very important that persons with a hearing impairment have an audiologic exam to determine if a hearing aid or other amplification systems will be helpful. The audiologist takes into account the communication needs of the individual, communication partners, and communication environments in which the person functions and makes the best recommendations for aural enhancement. The great majority of older adults with hearing loss could benefit from hearing aids but never acquire them (McCarthy & Sapp, 2000). Some of the reasons cited are cost, cosmetic, and older persons not feeling the need even though those around them may disagree (Montano, 2003).

Counseling by social workers in individual, family, and/or group sessions is an important therapeutic intervention for older adults who experience hearing and/or vision loss. Involvement of the older person's family, friends, and formal and informal caregivers can also be useful to provide information on the nature of the sensory loss and its impact on daily functioning.

Every state in the United States has an office or commission that addresses rehabilitation for people who are visually impaired. There are also not-for-profit vision rehabilitation agencies throughout the country. A Web site that identifies services in local areas is www.visionconnection.org. Until very recently, the vision rehabilitation field itself has not embraced the growing population of older adults who are in need of their services. Historically, the field focused its service delivery on children and vocationally bound adults.

Access to audiologists can be found through the American Speech, Language and Hearing Association at www.asha.org. Gerontological social workers should familiarize themselves with the resources in their locale that serve older adults with vision and/or hearing loss.

SOCIAL WORK AND PSYCHOSOCIAL ADJUSTMENT TO SENSORY LOSS

Empowerment of the individual and the right to self-determination are central values of both social work and independent living; however, social work approaches empowerment from the professional's involvement in the client's or patient's care. Weick, Rapp, Sullivan, and Kisthardt (1989) propose a strengths-based practice approach that is useful for older adults who experience sensory loss. This approach focuses on the strengths and positive ca-

capacities people have, rather than their deficits. It encourages the already recognized positive capacities of individuals so that they will be more likely to continue to build on and develop those capacities as they cope with sensory change. This practice approach holds promise as the social worker seeks to provide services to the very diverse population of persons who are experiencing sensory loss as a disability later in life.

Hearing impairment affects one's ability to communicate with others and can have a serious impact on interpersonal relationships. Research has shown that hearing loss is associated with less satisfaction with life, the loss of independence, isolation, depression, and anxiety (Mehta, 2003; National Academy on an Aging Society, 1999; Smith & Kampfe, 1997). Weinstein (2003) reports that hearing loss in older adults restricts multiple dimensions of quality of life, including functional status and cognitive, emotional, and social function. She states that hearing impairment interferes with face-to-face and long-distance communication, strains family relations, compromises independence, and interferes with therapeutic interventions across all disciplines, including social work.

Similarly, research on the impact that vision impairment has on older persons documents that it may significantly disrupt patterns of behavior and social interaction in a broad range of psychological domains, such as self-concept, self awareness, and social domains of communication, mobility, work, and recreation (Brennan & Cardinali, 2000; Horowitz, 2004).

Depression is a major problem among older adults who experience a functional disability (Blazer, 2003; Bruce, 2001). Horowitz (2003) draws attention to the unique situation of an older person who has functioned a lifetime as fully sighted and hearing and then loses vision and hearing later in life; it can have a profound impact on the older person's well-being. Disability is a key risk factor for the onset of depressive symptoms, and depression in turn creates a risk for both physical illness and functional disability. There is a strong relationship between age-related vision impairment and, to a somewhat lesser extent, hearing impairment and later-life depression. Among community-dwelling elderly, rates of depression range from 8% to 16%, and between 25% and 33% of all visually impaired persons have been found to report clinically significant depressive symptoms (Blazer, 2003). Older adults who experience one or more of the age-related eye disorders are at higher risk for depression and excess disability, especially if not referred for vision rehabilitation (Horowitz, 2003).

Horowitz and Reinhardt (2000) proposed two primary explanations for this particularly strong relationship between sensory impairment and depression. One is that even a moderate vision impairment impacts daily task accomplishment, and, as noted earlier, this increased disability increases the risk of depression. Furthermore, far too few older persons with vision impairment are aware of or receive vision rehabilitation services to learn new ways of accomplishing daily tasks independently. The second explanation posited by Horowitz and Reinhardt involves the subjective experience of a visual disability. Public opinion polls have found that people fear blindness almost more than any other impairment, ranking fourth after AIDS, cancer, and Alzheimer's disease (National Society to Prevent Blindness, 1984). They report that this fear seems to stem primarily from fear of dependency as a concomitant of vision loss and one that threatens the very identity of older people.

Information loss is another major factor associated with both vision and hearing impairments and has been identified as a major trauma for older persons (Herschberger, 1992). Hearing loss makes communication and social interaction more difficult, and the loss of reading and driving abilities become very traumatic for older persons with vision loss. Losing the ability to drive, in particular, is one of the most feared aspects of vision loss (Horowitz & Higgins, 2000).

PRACTICE IMPLICATIONS

Social workers need to educate themselves about the normal age-related vision and hearing changes and how to identify and screen older persons for referral for specialized vision and aural assessment/rehabilitation. The Functional Vision Screening Questionnaire is a 15-item (yes/no) questionnaire; a large-print version is available, or it can be administered in an interview format. It is available for social workers to help determine if a client has probable vision impairment and needs referral for a clinical evaluation by an eye care specialist (Horowitz, 1998). The 10-item Hearing Handicap Inventory can be useful to assess whether the older person has a hearing impairment and needs referral for an audiological assessment (Ventry and Weinstein, 1982). Both instruments are presented in appendixes to this chapter.

As noted, hearing loss can have a profound impact on quality of life for older adults as well as their cognitive, emotional, and social functioning. Hearing loss alters psychosocial behavior, strains family relations,

limits the enjoyment of daily activities, jeopardizes physical well-being, and interferes with communication/understanding across the spectrum of health diagnosis, treatment, and management (Weinstein, 2003). Of course, aural rehabilitation is essential, but a social worker needs to address the hearing impairment at the outset of interactions with the client. The best approach is for the social worker to ask the individual in any initial assessment about difficulties hearing and what causes problems and to determine what can be done to reduce the stress the hearing loss creates.

The environment where the older person is seen can be critical for the social worker dealing with an older adult with hearing impairment. In the office setting, it is important to control the ambient noise and to provide privacy at the front desk when registering private information. Asking the hearing impaired person to repeat back information, such as time of next appointment, is a good strategy to ensure understanding.

As mentioned earlier, one of the simplest and least costly assistive listening devices is a hand-held, battery-operated amplification device. A social worker may keep one of these in the office or a briefcase and find it very useful when an older person is having difficulty hearing.

Family Involvement

Involvement of family in the rehabilitation process has historically been relatively minimal, as the traditional model of rehabilitation focused on the individual. Research has documented the importance of family in providing emotional and instrumental support to older adults with physical and cognitive disabilities; there is also a growing literature to support the importance of the involvement of family and friends in the rehabilitation process to maximize both functional and psychosocial rehabilitation outcomes (McIlvane & Reinhardt, 2001; Reinhardt, Boerner, & Benn, 2003).

A family-focused model is a fundamental shift that takes place whereby family members are involved in the rehabilitation process without diminishing the autonomy of the older person with a sensory impairment. In some cases, helping the older adult deal with his or her relatives is the most important intervention (Stuen, 1999). Social workers should assess the family and friend networks of their clients and determine if they will be potential supporters or detractors of the rehabilitation process. The key is to recognize the family dynamics, the cultural differences, and the dynamics of the larger social network to enable supportive

behaviors that will contribute to maximizing the independent functioning of the older adult and promoting the general well-being of the entire family system.

Sighted spouses or partners of older people with impaired vision may find themselves feeling anger or guilt that are difficult to admit, especially if they feel they have to take on added responsibilities. Support groups for sighted spouses and partners were demonstrated to be very effective in improving their communication with the visually impaired partner and enhancing their functioning in everyday life (Sussman-Skalka, 2003). It is also important for couples to address the balance of giving and receiving in their relationships, to ensure that both feel they are contributing and receiving.

Policy Concerns

Awareness of vision rehabilitation is woefully lacking among the aging network of service providers (Stuen, 1991). Part of this problem may be that this area has been neglected by public policy and ignored by publicly supported programs and by third-party payers (Lidoff, 2003). Lidoff argues that the problem goes beyond the aging and the rehabilitation systems. Sensory impairments are a physical health problem. Medicare reimburses an ophthalmologist or optometrist for diagnosing eye diseases, and otolaryngologists are reimbursed for diagnosing hearing and balance disorders. Audiologists are reimbursed for evaluating hearing loss, and clinical social workers for providing counseling for mental health issues related to the sensory loss.

When an older adult has a stroke, the need for physical, occupational, and/or speech rehabilitation immediately comes to mind; however, this is not the case when someone loses vision. This may be directly attributable to the lack of Medicare funding for vision rehabilitation professionals. The recent Medicare Modernization Act of 2004 carried a provision that calls for a mandated one-year study to look at Medicare reimbursement for vision rehabilitation services provided by certified vision rehabilitation therapists, low vision therapists, and orientation and mobility specialists. This is a very hopeful sign.

SOCIAL WORK WITH PEOPLE WITH DISABILITIES

Blindness and deafness are associated with a lot of myths and stereotypes, and social workers are not exempt from their impact. Judeo-Christian tradition in

the Middle Ages taught that people with disabilities were expressions of God's displeasure, and they were generally ostracized. Literature and drama are also filled with blind people portrayed as evil, as in Robert Louis Stevenson's *Blind Pew* in *Treasure Island*, or as better off dead, as in Kipling's *The Light That Failed*. Blindness has also been portrayed as punishment, as in Shakespeare's *King Lear* with the blinding of Gloucester. In more modern times, blinding and castration are ultimate forms of punishment and humiliation, as depicted in the early 1990s Gulf War.

Equally damaging can be the media accounts of the "super-disabled," such as a blind person ski jumping or a bilateral amputee completing a marathon. The public is filled with admiration for such feats, but behind them lurks the negative stereotype that people with a disability cannot or should not be expected to achieve.

The Americans with Disabilities Act (ADA) was passed in 1990 (P.L. 101-336) as a civil rights landmark case for the 43 million Americans with disabilities. Although social work professes to be a profession with primary responsibility toward people who are subjected to discrimination and oppression, Mackelprang and Salsgiver (1996) claim that it has not embraced the causes of people with disabilities as it has other oppressed groups. As a result, there are few social workers working with people with disabilities and few people with disabilities entering the profession. And the profession has done little to promote disability rights.

The disability movement grew out of the turbulent era of the 1960s but was led by independent living proponents such as Judy Heumann, who advocated for civil rights for people with disabilities. The independent living movement rejects the medical model of treatment approaches and views individuals not as patients or clients but as active and responsible consumers, people in charge of their own lives and care (Berkowitz, 1987). This movement was occurring at a time when there was tremendous growth in the aging network of health and human service delivery. Beginning with the historic passage of Medicare and Medicaid in 1965 and the Older Americans Act, the field of aging came of age quite apart from the disability rights/independent living movement.

The independent living movement and the proliferation of the aging network were occurring simultaneously. Social work philosophy shares much with the independent living movement, but it has had a much greater role in the aging network, especially as the role of case management for the older person emerged. "As social work matured from a person-environment to an ecological systems approach, a major method of practice evolved from casework to

case management" (Mackelprang & Salsgiver, 1996, p. 11). The proliferation of private geriatric care managers and agencies that utilize a case or care management approach is evident in practice settings. As the baby boomers and the middle-aged cohorts of the independent living movement begin to join the ranks of older adulthood, we will likely see a greater shift to a stronger empowerment model. Evidence for this shift is apparent in the *Olmstead* decision of the U.S. Supreme Court on June 22, 1999, that requires states to administer their services, programs, and activities in the most integrated, least restrictive setting appropriate to the needs of qualified individuals with disabilities. This marks a historic trend to end the institutional bias that prevents many from living in their own homes and communities.

"The lack of social work involvement in the independent living movement is disturbing because both have much to offer each other" (Mackelprang & Salsgiver, 1996, p. 12). Both approaches can benefit from each other: Social work can move from case/care management to a more consumer-driven model of practice that is more empowering for the older person, and the independent living movement can recognize that many persons need social work assistance to develop the knowledge and abilities to function more independently.

CONCLUSION

Sensory loss affects a large number of older persons. It is incumbent on social workers to become familiar with normal and age-related disorders and help older people access appropriate interventions and remain socially engaged. The goals are to maximize functional independence, prevent excess or unnecessary disability, and enhance the quality of life for older persons with sensory loss. There is a tremendous need for social workers to be knowledgeable about sensory loss and the interventions available to ameliorate its effect. No area of a social worker's practice is unaffected by sensory impairment in clients.

APPENDIX 6.1

Screening Version of the Hearing Handicap Inventory for the Elderly (HHIE-S)

INSTRUCTIONS: Answer Yes (4 points), Sometimes (2 points), or No (0 points) for each question. If you

are a hearing aid user answer questions according to how you hear with the hearing aid. If the question does not apply merely enter no as your response.

- E-1. Does a hearing problem cause you to feel embarrassed when meeting new people?
- E-2. Does a hearing problem cause you to feel frustrated when talking to members of your family?
- S-1. Do you have difficulty hearing when someone speaks in a whisper?
- E-3. Do you feel handicapped by a hearing problem?
- S-2. Does a hearing problem cause you difficulty when visiting friends, relatives, or neighbors?
- S-3. Does a hearing problem cause you to attend religious services less often than you would like?
- E-4. Does a hearing problem cause you to have arguments with family members?
- S-4. Does a hearing problem cause you difficulty when listening to TV or radio?
- E-5. Do you feel that any difficulty with your hearing limits or hampers your personal or social life?
- S-5. Does a hearing problem cause you difficulty when in a restaurant with relatives or friends?

Abbreviations: S items probe social/situational consequences of hearing loss; E items probe emotional consequences of hearing loss.

Total Score: (Refer if score > 8)

APPENDIX 6.2

Functional Vision Screening Questionnaire (FV)

Purpose

The Functional Vision Screening Questionnaire (FV) is a screening tool to identify functional indicators of vision problems in older adults. The questionnaire is not a clinical or diagnostic assessment and should not be used to replace one. It identifies older people who may be experiencing a vision problem and who would benefit from seeing an optometrist or ophthalmologist.

Administration

The questionnaire may be filled out by the older adult independently or administered by an interviewer. The questionnaire should be read to the subject, if there are concerns about reading ability or literacy.

Be sure to tell the older adult that all questions should be answered in terms of their best vision; that is, how they see when they are wearing their glasses or contact lenses, if they typically use glasses or contact lenses. This does not include the use of any special low vision devices such as magnifiers or telescopes.

There are 15 questions, all of which can be answered by a simple “yes” or “no.” If the subject answers with some qualifier, e.g., “sometimes,” “in bad light,” this should be noted on the questionnaire and scored as a problem.

Scoring

A score of “1” is given for each item where a vision problem is reported and “0” if it is not. Scores are indicated next to the answer for each item. Simply add up the scores. Total scores range from 0 to 15.

1. Do you ever feel that problems with your vision make it difficult for you to do the things you would like to do?
1. Yes 0. No
2. Can you see the large print headlines in the newspaper?
0. Yes 1. No
3. Can you see the regular print in newspapers, magazines or books?
0. Yes 1. No
4. Can you see the numbers and names in a telephone directory?
0. Yes 1. No
5. When you are walking in the street, can you see the “walk” sign and street name signs?
0. Yes 1. No
6. When crossing the street, do cars seem to appear very suddenly?
1. Yes 0. No
7. Does trouble with your vision make it difficult for you to watch TV, play cards, do sewing, or any similar type of activity?
1. Yes 0. No
8. Does trouble with your vision make it difficult for you to see labels on medicine bottles?
1. Yes 0. No

9. Does trouble with your vision make it difficult for you to read prices when you shop?
 1. Yes o. No
10. Does trouble with your vision make it difficult for you to read your own mail?
 1. Yes o. No
11. Does trouble with your vision make it difficult for you to read your own handwriting?
 1. Yes o. No
12. Can you recognize the faces of family or friends when they are across an average size room?
 - o. Yes 1. No
13. Do you have any particular difficulty seeing in dim light?
 1. Yes o. No
14. Do you tend to sit very close to the television?
 1. Yes o. No
15. Has a doctor ever told you that nothing more can be done for your vision?
 1. Yes o. No

Scores are indicated next to the answer for each item. A total score of nine (9) or more indicates the need for a vision examination conducted by an optometrist or ophthalmologist.

Aging and Functional Disability

One of the most significant demographic changes during the 20th century was the increase in average life expectancy. During the period from 1900 to 2000, average life expectancy nearly doubled, from 48 to 73 years for men and 51 to 80 years for women (U.S. Census Bureau, 2004). In 2001, people age 65 can expect to live on average another 18 years—double the length of time most of their parents and grandparents lived from that age (Arias, 2004). Accompanying these gains in life expectancy are declining trends in mortality and a compression of morbidity, or shortened period of time adults live with chronic conditions (Fries, 2003). Overall disability incidence rates among older adults are declining, suggesting that the proportion of older adults experiencing functional impairment as an outcome of having a chronic disease or physical condition is decreasing (Crimmins, 2004; Freedman, Martin, & Schoeni, 2002). Together, these trends have yielded on average a longer and healthier life span for most people.

Despite these improvements, the prevalence of diseases and chronic conditions among the older population is increasing as the duration of time people are able to live with these conditions has increased. Just under 36% of adults age 55 to 64 have a disability. This rate increases to approximately 45% for adults 65 to 75 years. For adults age 70 to 74, 58% experience some kind of disability, and among adults 80 and older this percentage rises to nearly three-quarters (74%) of the population in that age range (U.S. Census Bureau, 2001). Thus, functional impairment remains a common occurrence among older adults, and the absolute number of older adults experiencing functional impairment is expected to increase with the growth of the older adult population (Crimmins, 2004).

For most older adults, being able to do the things they want to do at home and in the community is a significant component of healthy aging (Menec, 2003; Phelan, Anderson, LaCroix, & Larson, 2004). This is true for older adults with and without functional impairments. In this chapter, we highlight individual factors, programs, and policies that contribute to achieving goals of healthy aging for adults experiencing functional impairment. Our primary goal is to present a range of elements that influence opportunities older adults have to meet their individual healthy aging objectives and remain active members of their communities. Our secondary goal is to encourage professional social workers to learn more about these elements by providing brief examples of interventions, including theoretical models, assessment tools,

model programs, and policy initiatives, throughout the chapter.

FUNCTIONAL DISABILITY AND HEALTHY AGING

“Healthy aging” is a somewhat trendy term that generally attempts to counter negative stereotypes portraying old age as a period when physical decline and illness are the most prevalent characteristics in an elder’s life. Although for some individuals, it may be true that their physical health greatly reduces their capacity to participate in home and community life, for the vast majority of people withdrawal from prior activities is related more to lack of appropriate personal and environmental supports. Often, our own personal biases about disability influence our professional assessments of people with disabilities and intervention strategies we may employ to help them meet their healthy aging goals. Thus, before we proceed, it is important to briefly discuss theories and conceptualizations of disability.

Viewing Disability as a Contextual Situation, Not a Personal Health Limitation

Definitions and theories of what disability is and how it occurs differ. The medical model of disability focuses mainly on the person who is experiencing disability, seeking to identify biological and physiological factors contributing to limitations in physical function (Bickenbach, 1993). Social models of disability move beyond a person-centered view to include social and physical environmental factors in the determination of disability (Brandt & Pope, 1997; Lawton & Nahemow, 1973; Nagi, 1965; Pope & Tarlov, 1991; Verbrugge & Jette, 1994; World Health Organization, 2001). Political models of disability examine assumptions and motivations of cultural, social, and physical factors within the disability equation (Hahn, 1994). All of these frameworks influence how persons with disability are categorized and counted, as well as what types of programs and services are designed to meet their needs. Over the past decade, social models of disability have gained wider acceptance in the United States and around the world as necessary for understanding factors that contribute to disability.

The core premise of social models of disability is that disability is a situation, not a characteristic. That

is, individuals have a certain set of (in this case) physical capabilities, and their environments have a specific set of demands or requirements. If an individual’s capabilities and the environment’s demands are not in sync, then it is likely that the person will experience some level of disability. For example, if an older woman needs to reach the second floor of a building that does not have an elevator, and she is unable to climb the stairs, the woman will experience disability. If, however, there is an elevator that the woman can take to the second floor, then there is no disability. In this situation, the woman may have a physical impairment that limits her mobility, but that limitation does not create disability in and of itself. Fundamentally, the issue is this: Can the person do what she needs to do? In some cases, the environment provides supports that help to limit disability. In other cases, assistive technology such as wheelchairs, reaching devices, and even levered door handles serve to eliminate potential disabling situations. Additionally, individuals themselves can modify their physical capabilities through physical and/or occupational therapy and health and wellness practices like maintaining a healthy diet, engaging in regular exercise, and reducing smoking to help limit the amount of disability they experience. Social workers can be of assistance to people with disabilities in both improving environments and facilitating greater physical capacity by helping to identify individual needs and community resources, assess and evaluate individuals and environments, and advocate for any changes required to address unmet needs.

Using this framework, we begin our discussion of healthy aging by looking at a range of factors that influence both the existence and experience of disability for older adults. In this discussion, we recognize two significant populations of older adults with disabilities. The first is the population traditionally considered to constitute older adults with disabilities: those persons who “age into” disability, individuals who experience substantial functional impairment for the first time in later life. The second population comprises those individuals who are “aging with” disability; included in this group are people who first began to experience disability during childhood, youth, or sometime in early or middle adulthood, having diagnostic conditions such as polio, multiple sclerosis, spinal cord injury, cerebral palsy, rheumatoid arthritis, or spina bifida, to name a few. The difference between these populations occurs mainly with regard to when, how, and for how long they have experienced disability and what the impact of disability

has been on their lives. For many adults aging with disability, the experience of disability has shaped their life course by influencing their ability to work, to engage with others in their communities, and to live independently. Access to health care and philosophical orientations of health service models have a corollary role to these activities as well.

Having a long-term functional limitation can have a significant influence on an individual's health and wellness, as well as that of their family. Over their lifetime, persons experiencing disability in early and mid-life generally have higher rates of unemployment (National Organization on Disability & Harris Interactive, 2004), poverty (U.S. Census Bureau, 2001), and health care expenditures (Blanchard & Hosek, 2003; Chan et al., 2002). In addition, they have lower rates of home ownership (O'Hara & Miller, 2001), smaller social networks (Hilari, Wiggins, Roy, Byng, & Smith, 2003; Litwin, 2003; Reinhardt, Boerner, & Benn, 2003), and lower levels of community engagement (National Organization on Disability & Harris Interactive, 2000, 2004). These factors alone are significant. However, when viewed in combination with institutional biases in health care service delivery that have limited home- and community-based care for persons with disabilities, limitations in opportunities of an individual and his or her family members to develop economic and social resources are highlighted further.

Historically, health care services for people with disabilities have been based on a medical model, preferring institutional settings for long-term service provision (e.g., nursing homes) and service delivery by certified health care professionals. Arising from the independent living movement, led by disability rights activists, consumer-directed care options in home health services seek to shift this balance by affording consumers more choice and control over which services they receive, when the services are provided, and by whom. Additionally, in many instances, home care services such as chore work and personal attendant services are "de-medicalized," allowing for non-medical personal to perform these tasks. This shift in perspective on service delivery is part of a growing national trend in health care services that moves away from institutional settings of care toward more home- and community-based settings. In the consumer-directed model, services can become less restrictive and more integrative, allowing persons with disabilities to continue to be active and productive members of their communities.

Many of these trends have the potential to be reversed, and social workers are often in key roles where

they can provide assistance and act as allies to people with disabilities. For example, people with disabilities often face significant barriers to employment due to inaccessible environments, inflexible work schedules, and prejudicial attitudes of both employers and coworkers. The underemployment of people with disabilities combined with the high costs of health care often produce a direct path to poverty for many individuals. Many have smaller social networks and are less engaged in their communities for similar reasons. Social workers engaged in work across these areas (e.g., with low-income populations, in labor relations or employment equity, community development, health care and mental health, and diversity awareness) have the opportunity to become allies to people with disabilities and help promote opportunities for their greater inclusion and advocate for change, whether or not the specific focus of their work is with people with disabilities.

For adults aging with disability, many challenges they encounter at older ages are familiar, as they have occurred previously during their lifetime. Other challenges, such as the development of secondary health conditions and health care needs related to aging, are less familiar and constitute new experiences. However, for older adults for whom disability is recent and previously not experienced, disability represents a new, and often unknown, experience. We attempt to recognize these variations in our discussions when possible. The net effect of functional impairment and disability in old age is generally the same: reduced opportunities to achieve healthy aging objectives and participate fully as community members when appropriate supports, accommodations, and/or accessible environments are not available. We now turn to some specific factors that influence healthy aging and community participation and provide examples of potential interventions.

FACTORS INFLUENCING HEALTHY AGING AND COMMUNITY PARTICIPATION

Health and Wellness

Health and wellness is defined by persons with disabilities as including a range of factors, such as health behaviors, social contribution, and access to health care (Putnam et al., 2003). Levels of health and wellness among adults aging with and aging into disability are significantly lower than their nondisabled same-age counterparts when measured by prevalence

of depression (Kemp, 1999), self-rated health status (Patrick, Kinne, Engelberg, & Pearlman, 2000), engagement in physical activity (DiPietro, 2001), and participation in community activities (National Organization on Disability & Harris Interactive, 2000, 2004). Health and wellness are sometimes believed to be unachievable goals for adults aging with and aging into disability. This is primarily the case when disability is viewed as a medical condition indicative of illness or loss of function. However, new models (Hughes, Nosek, Howland, Groff, & Mullen, 2003; Reynolds & Silverstein, 2003; R. Seeman & Chen, 2002) are being developed that point to the significance of diet, exercise, and social engagement in maintaining health and wellness for persons experiencing functional limitations. Additionally, new research is producing encouraging evidence that engagement in health and wellness behaviors such as regular exercise (King, 2001), diet and nutrition programs (Amarantos, Martinez, & Dwyer, 2001), reduction in smoking and alcohol consumption (Burke et al., 2001), and productive engagement such as volunteering (Musick, Herzog, & House, 1999) may reduce the impact of a variety of chronic diseases and health conditions.

Across the country, health and wellness as an issue for older adults has become more visible and helped to facilitate specific evaluation measures of and programs for health and wellness for older adults. At the individual level, measurement instruments of physical activity among older adults, such as the Community Health Activities Questionnaire (CHAMPS; A. Stewart et al., 2001), the Physical Activity Scale for the Elderly (PASE; Dinger, Oman, Taylor, Vesley, & Able, 2004), and the Yale Physical Activity Survey (YPAS; Harada, Chiu, King, & Stewart, 2001) have all been shown to be robust. Model program interventions within communities include the Escalante Health Partnership and the OASIS program. The Escalante Health Partnership is a community-based health and wellness program in Arizona that develops individual wellness plans for older adults through local senior centers. The program's offerings include prevention screenings, nurse consultations, educational courses, and medical referrals. Initial postprogram evaluations of clients indicate higher levels of health and wellness compared to national averages (Nunez, Armbruster, Phillips & Gale, 2003). Focused more broadly on wellness, OASIS, a national nonprofit educational organization, provides physical activity programs, educational courses, and volunteer activities for adults 50 and older; the program has had positive effects on

older adults' perceived levels of well-being (Morrow-Howell, Kinnevy, & Mann, 1999). The OASIS Friends Program in St. Louis, Missouri, provides opportunities for persons aging with developmental disabilities to partner with OASIS members and receive mentorship and support across OASIS courses and programs.

At each of these levels of intervention, it is important for professionals to engage older adults in determining and evaluating their own health and wellness needs. All of the interventions described are consumer-focused, allowing for individuals' behaviors and preferences to be addressed and appropriate personal and environmental modifications to be made.

Social Support

The use of social supports both formal (programs and services) and informal (family and friends) is a common strategy to mediate the potential consequences of functional impairment and disability. There are many definitions of social support. From a therapeutic perspective, social support for individuals with disabilities is often defined by determining whether they are cared for, loved, and able to count on others should the need arise (McCull & Friedland, 1993; McCull & Skinner, 1995). Social support can include practical support, informational support, and emotional support (McCull, Lei, & Skinner, 1995). Practical support is generally considered tangible, physical support. Assistance with transfers between seating or laying positions, preparation of meals, and driving to a doctor's appointment are examples of practical support. This support can be informal (provided by a family member or loved one) or formal (provided by a paid caregiver or personal care attendant). Informational support is generally considered to be advice or guidance. Social workers often serve in this role, offering assistance across a range of activities, from case management to referrals. Peers (individuals with the same or similar disability) often provide this type of information also. Emotional support is generally the provision of a sense of belonging or esteem. Although professionals such as social workers and occupational therapists may provide this type of support, it is generally the role of family members and peer groups to provide everyday opportunities to be a member of a group or to provide moral support during difficult times.

Although practical problems can be solved by providing any of these types of support to older adults, the outcome results are often negative when practical support has been offered as the only solution (McCull

& Rosenthal, 1994; Weinberger, Tierney, Booher, & Hiner, 1990). Informational support has been perceived as helpful when provided by professionals (Kondo, Mann, Tomita, & Ottenbacher, 1997), and emotional support has consistently been shown to demonstrate positive outcomes (Holicky & Charlifue, 1999), pointing out the importance of interventions that allow caregivers the opportunity to provide more emotional support and less instrumental (practical) assistance. In some cases, the care of family members with disabilities in the home has contributed to increased caregiver stress or burden (Banks, 2003; Schulz & Beach, 1999; Tolson, Swan, & Knussen, 2002), so that the intervention plan may also include social support provided directly to the caregiver through peer support programs (Goldstein et al., 2004; Peacock & Forbes, 2003).

There is both anecdotal and empirical evidence that social support interventions can improve the overall well-being of older adults experiencing disability as well as their family members who may provide them support. Social workers are often engaged in the development and implementation of social support programs, including peer support and training for families and caregivers. Peer support programs are frequently cited as being important contributors to successful rehabilitation and aftercare treatment models for chronic conditions ranging from heart disease (Winder, Hiltunen, Sethares, & Butzlaff, 2004) to stroke (Fink & Schwartz, 2000) and spinal cord injury (Sable, Craig, & Lee, 2000). In addition, such programs have been found to have both short- and long-term positive effects in areas such as coping (Stewart, M. et al., 2001), life satisfaction (Sherman, DeVinney, & Sperling, 2004), and maintaining functional ability (Avlund, Rikke, Holstein, & Due, 2003). Being providers of social support has also been shown to have positive effects on the well-being of older adults with functional impairments (Boerner & Reinhardt, 2003; Brown, Nesse, Vinokur, & Smith, 2003). For family members, peer support programs for family members, including those sponsored through local nonprofit organizations such as the Alzheimer's Association and the National Multiple Sclerosis Society, have been significant in bringing education, information, and support to families.

Social and Productive Engagement

There is a growing body of evidence suggesting that active social engagement may provide significant

health benefits for older adults with functional limitations. Broadly defined, social engagement includes interacting with friends and family, participation in community organizations and events, and engaging in leisure activities. Productive engagement can be thought of broadly as meaningfully contributing to community life in a socially and/or economically valued way (Hinterlong, Morrow-Howell, & Sherraden, 2001). Positive outcomes related to greater social activity engagement include increased quality and length of life for older adults (Avlund, Rikke, Holstein, & Due, 2003; T. Seeman, Luginolo, Albert & Berkman, 2001) and enhanced well-being among older adults serving as volunteers (Morrow-Howell, Hinterlong, Rozario, & Tang, 2003). However, older adults with functional impairments may encounter various personal, social, and physical barriers that reduce their levels of participation.

For adults aging with and aging into disability, personal barriers to social engagement and productive contribution may include mental or physical health issues related to living with disability, such as chronic depression, pain, fatigue, or ill health (Strain, Grabusic, Searle & Dunn, 2002; G. Williamson & Shaffer, 2000). In addition, individuals may lack social support that encourages continuous engagement (Duke, Leventhal, Brownlee, & Leventhal, 2002; Eyley et al., 1999). Common social and physical barriers include lack of accessible environments and accommodations in social settings. Such issues as accessible parking, appropriate walking surfaces, and the provision of seating may influence whether or not a person with functional limitation attempts to participate in an activity. Regarding productive engagement, flexible work schedules, ergonomic workspaces, easily accessed buildings, and sensitive colleagues all have the potential to impact engagement.

Strategies to assess interest in social activities include the Activity Card Sort (Baum & Edwards, 2001; Katz, Karpin, Lak, Furman, & Hartman-Maeir, 2003), an assessment tool evaluating individual participation in activities both at home and in the community. Activity Cards have pictures of adults performing a host of tasks that clients sort into piles according to the frequency with which they engage in them. Scores are derived by dividing the total of current activities engaged in by the total of activities previously engaged in. This provides a guide to understanding how activity levels have changed and provides possible activities to target for increased participation. At the community level, tools are being developed to evaluate the receptivity of communities in an attempt to quantify how open an

entire community is to persons with functional impairments and make specific recommendations on how opportunities for access and participation by persons with disabilities can be improved (Bricout, Stark, Gray, & Hollingsworth, 2004).

Housing

“Aging in place” is a term describing aging adults living in familiar home environments. It is in the home that individuals perform some of their most important activities of daily living (ADLs) and instrumental activities of daily living (IADLs), such as bathing, dressing, and preparing meals, leisure activities such as hobbies, and productive pursuits such as managing a household. The home is also the context of many activities related to valued roles, such as preparing and sharing holiday meals and caring for children. As the setting of these important activities, home is frequently one of the most cherished environments in people’s lives. Home has been described as a reflection of individual values and has been associated with personal identity (Smith, 1994). Although there is significant growth in senior communities, including independent apartment complexes for older adults, continuing care communities, and assisted living facilities, most older adults say that they prefer to live out their later years in their own home (AARP, 2003).

The goal of maintaining a home is often threatened by the high number of environmental barriers present in the homes of individuals who experience functional limitations. Mismatches between the home environment and the physical capacity of community-dwelling older adults is estimated to be as high as 80% (Gill, Williams, Robison, & Tinetti, 1999). Common barriers in the home include items located out of reach, stairs, controls that are difficult to manage, and safety issues such as slippery floors (Mann, Hurren, Tomita, & Bengali, 1994; Stark, 2004). Estimates of the presence of barriers in the homes of older adults range from approximately 4 per household (Mann et al., 1994; Stark, 2004), when individual homeowners rate their current accessibility barriers, to an extreme of 75 per household during professional audits to identify safety, home maintenance, and accessibility problems (Steinfeld & Shea, 1993).

Given that most older adults prefer to age in place, many intervention strategies target modifying home environments to make them more accessible or accommodating. Through individual assessments, occupational therapists and other trained professionals

are able to evaluate homes and determine appropriate changes to make. Widening doorways, installing shower grab bars, and changing door handles are frequent suggestions. Changes such as these have shown environmental modification to be an important intervention strategy to help manage chronic health care conditions, maintain or improve functioning, increase independence, ensure safety, reduce the need to relocate to institutional facilities, and even reduce the costs of personal care services (Connell & Sanford, 2001; Gitlin, Levine, & Geiger, 1993; Gitlin, Mann, Tomit, & Marcus, 2001).

Another important way to change the environment is by providing specialized products or assistive technology (AT). Such products include adaptive hardware and modifications to environmental controls. AT is defined as any product or system that is used to improve the functional capacity of persons who have disabilities (U.S. Congress, 1988). This technology is designed to make best use of an individual’s abilities in order to overcome environmental barriers that may prevent the person from achieving maximal occupational performance (Seelman, 1993). There are numerous types of assistive devices and systems, including seating and mobility devices that can influence community access, computer access systems, augmentative communication devices, adapted driving devices, and environmental control units, as well as adaptive equipment that make it possible to accomplish tasks such as dressing. When providing AT, the costs must be considered, as much AT available today is still costly and may not be funded by a health insurance program. Additionally, the possibility of disuse or abandonment of AT by individuals for various reasons, such as complexity of use or embarrassment related to using something different, may occur (Gitlin, Corcoran, & Leinmiller-Eckhardt, 1995). However, despite these barriers, our knowledge of people’s use of AT to help maintain independence is growing, as is our recognition of the significant role it plays in moderating the disability experience.

Removing environmental barriers and increasing use of AT have been shown to significantly improve occupational performance and satisfaction with performance of everyday activities (Stark, 2004). Many evaluation tools are available to determine home modification and AT needs, including the Gerontological Environmental Modifications assessment (Bakker, n.d.) and the Americans with Disabilities Act accessibility guidelines (U.S. Department of Justice, 1994). Commonly, occupational therapists or other health science professionals conduct individualized evalua-

tions to determine the particular needs of older adults and their homes. Home modification services are often provided through area agencies on aging. At the national level, programs working to further these initiatives include the National Resource Center on Supportive Housing and Home Modification at the University of Southern California and AARP's Livable Communities initiative (Pollack, 1999). Social workers working with older adults with functional limitations are in key positions to help initiate home assessments and advocate for home modification and AT resources as part of any care management and healthy aging plan.

Transportation

Older adults who are unable to drive often rely on family members, friends, public transportation, and Paratransit programs to get to community destinations. Although there appear to be multiple transportation options, community surveys indicate that unmet need for transportation services is high (Coughlin, 2001). Many older adults with functional limitations experience difficulty using public bus or metro systems given the duration of waiting, limitations in seating, and distance to transportation stops (Straight, 1997). In particular, low-cost services available to transport adults with functional impairments to social engagements, community activities, and during evening hours are extremely limited in most communities. Transportation is often the crucial difference between participating in community activities and becoming isolated and home-bound (Glasgow, 2000). Given the importance of engagement in activities on life satisfaction, health, and depression (Everard, Lach, Fisher & Baum, 2000), transportation becomes a critical link to health and wellness.

Despite extensive reviews regarding the problems of and potential solutions for unmet transportation needs, there is a significant shortage of research to inform policy and program development. Much available evidence suggests that the majority of older adults prefer driving themselves or using a car to reach their destination (Straight, 2001). Losing one's driver's license is a significant life event (Sandeen, 1997), as automobiles are a means of facilitating community participation for older adults. Transportation solutions range from helping older adults prioritize transportation needs (Cvitkovich & Wister, 2001) to creating supplemental transportation services that fill the gaps between private and public transportation (Freund, 2003; Kerschner, 2003).

Discrimination: Physical, Social, and Cultural Barriers

Adults of all ages with disabilities are subject to prejudice and discrimination. Experiences with prejudice and discrimination among persons aging with disability may be different from experiences among persons aging into disability; primarily, the duration of bias may be longer, and it may affect or have affected aspects of their lives differently, for example limiting opportunities in employment, selection of housing, and ability to engage in community activities. In some cases, it may be difficult to distinguish bias against disability from ageism, as ageist beliefs tend to incorporate prejudice against physical and mental impairments commonly found among older adults (Wilkinson & Ferraro, 2002). In addition, many older adults themselves do not distinguish between disability and age, subscribing to a medical model that traditionally views disability as representing a decline of physical function related to old age (J. Williamson & Fried, 1996). There is also a cultural history of older adults with disabilities and younger adults with disabilities having negative perceptions of each other, older adults not wanting to be labeled as disabled and younger adults not wanting to be thought of as having the same characteristics as the elderly (Campbell, 1997; Torres-Gil & Putnam, 1999).

Despite these differences in experience and perception, adults aging with and aging into disability face many of the same physical, social, and cultural barriers, including inaccessible environments, pervasive stereotypes and discriminatory actions, and general lack of education about and respect for physiological difference. Interventions to reduce discrimination include educational training for professionals (Alford, Lawler, Talamantes, & Espino, 2002; Madan, Aliabadi-Wahle, & Beech, 2001), age-related diversity awareness trainings for the broader public (Braithwaite, 2002; Ragan & Bowen 2001), and increasing opportunities for community participation and community integration for persons aging with and aging into disability.

Broader Program and Policy Issues

There is a web of social welfare policies that broadly supports healthy aging and community participation for older adults with functional impairments. Although distinct in their origins and scope, taken together they form a foundation for developing, im-

plementing, and evaluating programs and services for adults aging with and aging into disability. Key policies in this web include the Older Americans Act, Medicare, Medicaid, the Rehabilitation Act, and the Americans with Disabilities Act.

Historically, there have been different service networks and programs for adults based on age and/or life stage. For persons experiencing disability at younger ages, certain types of rehabilitation services, including employment training, counseling, and personal attendant assistance, were provided in conjunction with Centers for Independent Living, established through the Rehabilitation Act of 1973. Although there is no upper age limit for these services, they have traditionally been targeted to working-age persons, typically 64 and younger. Adults age 60 and older are eligible for a wide variety of programs and services provided through the Older Americans Act, such as transportation assistance, low-cost meals or meal delivery, health and wellness screenings, and assistance with some home health care needs and home repairs. Although there is some overlap in age eligibility for these programs and services, traditionally there has been little crossover, due in part to the limited number of adults aging with disability who lived long enough to enter old age, a lack of awareness about program offerings, and the capacity of traditional aging and/or disability service networks to meet the needs of the respective nontraditional consumers.

Over the past few years, the lines separating aging and disability service networks are beginning to fade somewhat as program innovations in Medicaid emphasizing home- and community-based care have grown in significance. Following the U.S. Supreme Court's ruling in the 1999 *Olmstead* case (*Olmstead v. LC*, 1999), President Bush issued two executive orders in 2001, *Olmstead* and the Freedom Initiative. Both have furthered initiatives to ensure that persons experiencing disability remain integrated in their communities. Of particular significance is the elevation of consumer control and direction as a program feature in home- and community-based services. We believe these steps help to move forward broader goals of healthy aging by providing greater opportunities for older adults with functional limitations to participate in home and community life.

THE ROLE OF THE SOCIAL WORKER

When working with older adults experiencing disability, one of our challenges as professionals is to under-

stand the range of factors that influence healthy aging and determine what types of interventions are needed for persons who are not reaching their own healthy aging goals. Social workers bring much knowledge and skill to this endeavor. However, the wide array of issues that factor into fostering healthy aging and community participation often requires partnering with professionals such as occupational therapists, psychologists, physicians, recreational counselors, public administrators, and policymakers to further interventions at the individual, community, and policy levels. In this area, we have many research and practice gaps. As noted earlier, there are often substantial differences in how disability is viewed and understood based on which field of knowledge scholars and professionals are trained in. Only recently have we begun to view people with disabilities and older adults as having similar interests and needs. Much of the research on interventions and strategies to improve quality of life has not been conducted across populations, but either for older adults or for persons with disability alone. As policies change and demographics shift, developing partnerships and building bridges across service agencies and organizations will become increasingly important for understanding the needs of older adults aging with and aging into disability and the programs that are available to help meet these needs. To do so effectively, scholars and practitioners need to work together to identify both successful models of collaboration and areas where further research is required. There is a substantial role for social workers to play in fostering cross-population and cross-network connections, and we strongly encourage those working with older adults experiencing disability to do so.

HIV-Infected and HIV-Affected Older Adults

8

This chapter presents an overview of social work practice implications that can arise when the experience of HIV¹ and aging intersect. It is important to consider HIV and aging together for two reasons. First, medical and/or social service practitioners still frequently fail to identify and serve HIV-infected midlife and older adults; thus, HIV-infected persons over the age of 50 often remain hidden and their needs unaddressed. Second, the caregivers of HIV-infected younger adults or children with HIV are often midlife and older persons, who may be grieving, unprepared, unsupported, hidden, and frail. While there is no certainty regarding the number of HIV-positive adults being cared for by older adults, it has been estimated that half of the persons with AIDS are being cared for by older relatives (Allers, 1990; Joslin, 1995).

HIV-related advocacy, service provision, and policy analysis are highly compatible with social work because the profession is focused on forming productive partnerships with disenfranchised, oppressed, and marginalized individuals, couples, families, and groups (Shernoff, 1990). However, examining and addressing the intersection of HIV and aging has not been a strength of social work. HIV service systems have tended to underserve midlife and older persons, and social service workers in the HIV field need to know more about and attend to aging-related issues. At the same time, local service systems for older Americans have rarely sought out older persons with HIV, and gerontological social workers sometimes seem to be uncomfortable or unknowledgeable about HIV disease (Emlet, 1996, 1997; Emlet & Poindexter, 2004).

However, after initially neglecting this population, both HIV and aging researchers and advocates are more recently attending to the special needs of HIV-infected and HIV-affected midlife and older persons (Zablotsky & Kennedy, 2004). The task at hand is to distribute this knowledge and awareness to social work practitioners in both micro and macro practice, no matter their setting or specialty. (For a discussion of service delivery specific to these populations, see Emlet and Poindexter, this volume).

MIDLIFE AND OLDER PERSONS WITH HIV

When HIV was first identified, it was typically considered a young person's disease. However, from the beginning of the pandemic, the Centers for Disease Control (CDC, 1998) were documenting that 10% to 12% of the persons with AIDS were over age 50.² By 1998, there was a greater increase in the incidence of

AIDS in adults over 50 than among young adults. By 2001, 11% of all persons in the United States diagnosed with AIDS were over age 50 (CDC, 2002). Mack and Ory (2003) recently reported that 18.9% of persons living with AIDS were 50 years of age or older. As is the case in all age groups, females, Blacks, and Latinos are overrepresented in midlife and older persons with HIV (CDC, 2003). As people are now living longer with HIV due to more effective and accessible medical and pharmaceutical treatments, the numbers of older people with HIV are increasing. At the end of 2001, 1.4% of all reported cases of AIDS were in persons 65 and older (CDC, 2003). At the end of 2002, nearly 2% of all persons living with AIDS in the United States were 65 years and older (CDC, 2003). Advances in treatments have improved longevity for persons with HIV, thus increasing the likelihood that persons diagnosed in late life will live into older age. These individuals, like older adults in the general population, will face a myriad of issues, including concurrent medical conditions and chronic illnesses, decreasing social networks, and increased risk of needing care.

Persons who are living with HIV disease tend to face some of the same emotional and interpersonal concerns, regardless of their demographic characteristics (Poindexter, 2000). Older persons face exactly the same issues as younger persons, with the added strain of physical, familial, and existential concerns that arrive with middle and older age (Lavick, 1994). Older people who have HIV tend to be isolated and afraid to disclose their diagnosis to family members and friends and may be even more reluctant than are younger persons to seek social services and mental health support (Emler, 1997). Older HIV-positive persons are more likely to live alone than their younger counterparts (Crystal & Sambamoorthi, 1998; Emler & Farkas, 2002); therefore, it is important to recognize that decreased social support can be a complicating and serious issue.

MIDLIFE AND OLDER HIV-AFFECTED CAREGIVERS

It is common for older family members to serve as caregivers for their adult children and/or their grandchildren living with HIV (Joslin, Mevi-Triano, & Berman, 1997). When children (whether HIV-negative or -positive) are orphaned by HIV, their care often falls to grandparents or great-grandparents (Levine, 1993). Older adults with HIV are frequently cared for by friends, partners, or parents who are also old. Older gay men are especially likely to serve as caregivers to friends or partners with symptomatic HIV (Gross-

man, 1995). The lived experience of HIV-affected midlife and older caregivers has been inadequately explored by researchers (Brabant, 1994) and by service providers and advocates in both the aging and the HIV fields (Linsk, 1994); social service practitioners should better understand and address the needs of this population (Mellins & Ehrhardt, 1994).

Midlife and older caregivers are often providing HIV care as they are struggling with difficult family dynamics, grieving deaths or illnesses, becoming socially isolated, lacking information about HIV, fearing the effects of HIV stigma, managing their own physical or emotional difficulties, and feeling unequipped to be involved in caregiving or child rearing at this stage of their lives. Often out of necessity, they tend to neglect their own health and become more vulnerable to burnout or illness. Older people who lose their adult children to HIV are robbed of the informal caregivers on whom they would have been able to count when they are ill or dying (Emler, 1996; MacLean & Clapp, 2001; Poindexter, 2001).

■ For example, Bea, a divorced African American woman in her mid-50s, was looking forward to some time to herself after her children had grown. She then learned that an adult son, Kevin, from whom she had been estranged for several years, had tested positive for HIV while he was serving prison time for drug possession. The mother of his children had died from AIDS. Bea is now taking care of Kevin, who lives with her, and helping to raise his 3 children, the youngest of whom has HIV. She feels burdened at times by having to start over with childrearing, but she would never consider turning them away. She has told none of her friends or fellow churchgoers that Kevin has HIV because she wants to protect her family from stigma and judgment. Because she is not talking with anyone honestly about the extent of her caregiving responsibilities or the fact that she is worried that Kevin will die, sometimes she feels very isolated and sad. She does not know much about the trajectory of HIV disease, which leads her to wonder about how sick Kevin might get and what she might be facing. She is so busy managing the household, attending to Kevin's medical needs, and getting everyone to appointments, that she has not seen her own doctor in 2 years. She worries sometimes about how little she sleeps and eats, but keeps pushing on through the days, thinking, "What choice do I have?" ■

SPECIFIC CONCERNS AND RESPONSES

It is almost impossible to generalize about the experiences, feelings, and concerns of HIV-infected and HIV-affected midlife and older persons, because both aging and HIV cause different reactions in each human body, individual personality, and family unit. However, there are certain emotional and social realities that are common for many persons given the nature of HIV. In this section, we discuss several of these commonalities and suggest basic social work considerations. The issues are living with a chronic and dangerous disease; dealing with increased crises, grief, and stress; managing HIV stigma and disclosure; making decisions about safer behavior; and deriving spiritual meaning from their struggles.

Disease Management

AIDS is a collection of cancers, opportunistic infections, and symptoms related to a suppressed immune system. AIDS is so variable that there is no normal illness trajectory. Not only is HIV disease frightening and unpredictable, but the medication protocols are quite complex and often lead to debilitating side effects. Persons with HIV must work hard to adhere to complicated regimens, monitor and medicate side effects, and manage health and stress through nutrition, exercise, and complementary therapies. Older persons living with HIV tend more than younger people to report other ongoing medical difficulties and limitations in physical functioning (Nokes et al., 2000). An older person with HIV as well as other aging-related chronic illnesses may have to juggle many complex medication protocols that may result in confusion about which cognitive or physical symptoms are caused by which conditions (Linsk, 1997). As a 51-year-old woman living with HIV recently asked, "Is it HIV or A-G-E? That's my question all the time" (Cafazzo, 2004, D4).

Midlife and older caregivers are often heavily involved in the monitoring and maintenance of the infected person's health status. Often, these caregivers are struggling with reading labels, managing schedules, learning about drug and food interactions, watching for side effects, and supporting infected persons in taking medications that may make them feel sick. If a caregiver is taking care of more than one person with HIV, such as a daughter and grandchildren, the management of HIV, infections, medication, and side effects becomes a full-time job.

HIV-positive persons tend to be able to adhere to their complex medication protocols better when they have professional support to do so, such as good case management or social workers and involved medical professionals. (Powell-Cope et al., 1998). Social workers should be familiar with the importance of medical and pharmaceutical adherence and should work in partnership with older persons with HIV and older caregivers to maximize housing stability, respectful medical care, culturally competent services, and accepting social support (Ka'opua, 2001; Linsk & Bonk, 2000).

Crisis, Grief, and Heightened Stress

Because HIV disease has a wildly uncertain trajectory, it can lead to a physical and emotional roller coaster, a life filled with episodes of crisis (Poindexter, 1997). Even in a stable life, HIV can wreak havoc. For those who are in a marginal financial position, are underinsured, have immigrant status, abuse substances, and/or have mental health concerns, HIV can be overwhelming. People who receive an HIV diagnosis usually enter into a world characterized by fear, regret, panic, sadness, anxiety, isolation, existential despair, hopelessness, and helplessness. It is inescapable that difficult decisions lie ahead, that illnesses, disability, and dying are likely (Dworkin & Pincu, 1993; Forstein, 1994; Jue, 1994). Existing data suggest that mental health issues may be a prominent problem for older adults living with HIV. Heckman and colleagues (2002) found in a study of 83 older HIV-infected adults that 25% suffered from moderate or severe depression as determined by the Beck Depression Inventory Scores. Emler (2005) reported that 36% of study respondents had CES-D scores above the clinical cut-off for depression.

Midlife and older caregivers can experience much stress as they work to balance complex medical, financial, emotional, physical, and logistical needs. Their own emotional, financial, and physical stability can be at risk (Leblanc, London, & Aneshensel, 1997; Wardlaw, 1994). Many older persons are overburdened with multiple care responsibilities. Caregivers also experience sorrow as they witness the struggles and deterioration of the person with HIV. They feel the loss of their old relationship with the sick person and the HIV-positive person's functioning, health, dreams, and future (Jankowski, Videka-Sherman, & Laquidara-Dickinson, 1996). In addition, many HIV-affected families have experienced or are anticipating

multiple deaths, which increases grief (Wardlaw, 1994).

Social workers should be observant for serial and serious HIV-related crises in the lives of those they serve and respond with immediacy, creativity, sensitivity, and flexibility when someone is especially troubled. In a crisis, HIV-affected or infected elders may not be best served by having to wait for an appointment or being limited to a formal visit in an office. The social worker may need to adjust hours, settings, or timeframes to respond to someone in a crisis, such as visiting someone in a hospital during the evening. In addition, depression and anxiety may be problems for elders who are HIV-infected or HIV-affected, so social workers may work with medical and mental health professionals on comprehensive assessments, differential diagnoses, and appropriate social and pharmaceutical interventions to support the person. Sadness is not the same as depression; social workers should incorporate that differentiation into their assessments and interventions, offering bereavement counseling and support groups if appropriate rather than immediately assuming pathology and referring to psychiatrists.

Concern With Stigma

HIV is probably the most intensely stigmatized physical condition (Crawford, 1996). Although HIV stigma has decreased in the United States over the course of the pandemic, it is still an impediment to disclosure and requests for support or services (Herek & Capitanio, 1993; Powell-Cope & Brown, 1992). HIV stigma can hold persons with HIV and their loved ones hostage behind a wall of silence and social isolation, hiding their experiences, needs, emotions, and health status (Crandall & Coleman, 1992; Laryea & Gien, 1993). Feelings of isolation and depression may result from the fact that social networks tend to shrink for HIV-infected (Shippy & Karpiak, 2005) and HIV-affected midlife and older adults (Poindexter & Linsk, 1999) because of stigma and fear of disclosure. Older caregivers may feel associative stigma acutely; a disclosure of HIV infection may trigger a disclosure of sexual activity, sexual orientation, or drug use, which can cause feelings of judgment or shame (McKinlay, Skinner, Riley, & Zablotzky, 1993).

HIV stigma may be the cause of persons not seeking, delaying, or refusing social services and information. Midlife and older persons who are living with HIV and/or caring for someone with HIV are highly

sensitized to the threat of ostracism, judgment, and censure and will carefully manage disclosure of diagnosis and help seeking as a result (Poindexter, 2002; Poindexter & Linsk, 1999; Solomon, 1996). Emlert (2003) found in a sample of 88 individuals with HIV/AIDS that 51% of the older adults in the sample stated they felt ashamed of their illness sometimes or often, and 46% felt people were uncomfortable being with them. Thus, they may seek services, information, and medical care outside of their home neighborhood or town out of this concern for protecting privacy.

A social worker cannot work with HIV-infected or HIV-affected midlife and older persons without being constantly aware of the context of virulent stigma. When an older person discloses that he or she is dealing with HIV, that person is honoring and trusting you. A practitioner may need to repeatedly assure the person of confidentiality measures, normalize concerns about information management, and help with problem solving about disclosure decisions.

Need for Safe Behavior Assessment and Education

Because of deeply ingrained ageist attitudes and misinformation, social service and health care providers are often blind to the possibility that an older person is at risk for or has HIV or even wants information about transmission and safety. Stereotypes about older persons include that they do not inject drugs, have sex with opposite- or same-gender partners, or employ sex workers. Gott (2001) found that 80% of persons over age 50 surveyed at a genital-urinary clinic in the UK were at possible risk of contracting HIV, and 25% reported that they desired more information on HIV and sexually transmitted diseases than they had been offered.

While conducting assessments and throughout the case management or counseling relationship, social workers should strive to forge a climate conducive to discussing health concerns, including HIV status and risk. The practitioner should periodically ask if the service recipient has any concerns about safe sex or drug behavior, and be prepared with answers to questions. Older persons who are taking care of children or grandchildren with HIV may be uninformed about how the retrovirus is and is not transmitted, and social workers should be prepared to teach them. If professionals treat condom use and syringe cleaning as taboo subjects, where can service consumers turn for this life-saving information?

Concern for Relationships and Communication

Knowing that you or a loved one has HIV throws you into a complex, frightening communication arena. An HIV-infected or HIV-affected older person will likely have to decide when and to whom to disclose the diagnosis, decide whether and from whom to ask for help, learn to be appropriately assertive with health care providers and case managers, negotiate with loved ones around caregiving boundaries, and learn about HIV transmission and safety.

Social workers can help older persons practice approaching others about painful topics and being assertive with physicians, caregivers, and sexual partners, perhaps using various forms of rehearsal or coaching. Older persons may need assistance with decision making about HIV disclosure as well; in this case, social workers can review family history and behavior regarding difficult disclosures to facilitate realistic problem solving and putting safeguards and supports into place.

Spiritual Concerns

HIV brings myriad challenges, but the literature is also very clear that HIV-infected and HIV-affected caregivers frequently take the opportunity to forge better relationships, increased spirituality and meaning, and personal growth in the wake of their crises (Ayres, 2000; Jankowski et al., 1996; Wardlaw, 1994). Social workers in the HIV field have consistently marveled at the level of resilience, fortitude, and strength they find in HIV-infected and HIV-affected persons. Although HIV-infected and -affected older persons are at times quite vulnerable and fragile, practitioners are often surprised by their energy, optimism, hope, ability to laugh and love, and adaptation. Social workers should do everything possible to support these positive outlooks, not labeling the fortitude and optimism as denial or resistance.

In contrast, older persons often report that because of HIV stigma and judgment about infection routes, they feel unable to turn to formal religious organizations for comfort regarding their HIV challenges and losses (Poindexter, Linsk, & Warner, 1999). Social workers may need to help older persons find more accepting faith communities or clergy when their clients desire spiritual community or pastoral counseling.

GENERAL PRACTICE IMPLICATIONS

In addition to the social work responses to the concerns discussed above, the following general practice considerations may help in designing services for HIV-infected and HIV-affected midlife and older persons.

Offering Specific Outreach and Services

Ageism interacts with HIV stigma to render HIV-infected and HIV-affected midlife and older persons invisible and neglected. Older people can feel out of place in AIDS service organizations, which they perceive to be geared to younger people, and in the aging network, which has historically been unwelcoming to persons with HIV. Although specialized AIDS service organizations are vital, it is also important that HIV be mainstreamed into every social service agency so that older persons with HIV concerns are not marginalized. No matter the organization in which or level at which they work, social workers can help improve access to information, services, benefits, and social networks for older persons with HIV concerns.

Practitioners in the aging network, hospitals and clinics, and AIDS service organizations should strive to identify older persons with HIV concerns so that they can be steered to HIV education, relevant support groups, benefits advocacy, legal services, individual and group counseling, and case management. AIDS service organizations should not just wait for older persons to arrive at their doorsteps, but rather should develop and advertise programs with this population in mind, train workers in aging concerns, strive to make agencies more welcoming to older persons, and form interagency partnerships with aging network organizations. Likewise, gerontological social workers should ask older people, in a way that is nonjudgmental and normalizing, if they have any HIV-related concerns they wish to discuss, make sure that staff are adequately trained regarding HIV, and reach out to AIDS service organizations to make sure that case management programs are intersecting successfully for this population.

Inviting Individual Participation

In addition to formulating systemic ways in which to serve older persons with HIV concerns, social workers in individual practice must gently open the door

so that older persons can discuss their sexual and drug histories, HIV status, and caregiving realities. It helps to ask people about their knowledge and experience with HIV as a matter of course, just as you would approach any other health concern. Gerontological social workers can begin by identifying those service applicants and recipients who have HIV concerns. Practitioners in the aging network can offer educational programs about HIV and the number of older persons infected and affected, and offer support groups geared specifically to midlife and older men and women with HIV or to grandparents caring for AIDS orphans. HIV practitioners can ask HIV-positive persons about their networks and thus identify midlife and older persons' caregivers who may need information and support.

Assessment

A social worker who is working with an HIV-affected or HIV-infected midlife or older person should first acknowledge the intense struggle inherent in the situation and create a safe and confidential working contract. It is then necessary to conduct a mutual, comprehensive, culturally competent, and HIV-knowledgeable assessment, including both assets and needs. Assessments should include HIV as well as aging concerns. Emler, Gusz, and Dumont (2002) have suggested eight domains that should be included in the assessment process: physical functioning, cognitive issues, social support, sexual and drug health, spirituality, immune function, disclosure, and caregiver well-being. Additional discussion of each domain is provided in Table 8.1.

Services

Depending on the HIV-positive older person's perceptions of his or her needs, the social worker can offer information on HIV transmission, safety, pathogenesis, treatment, and adherence; care management, crisis intervention, and referrals; supportive individual, dyadic, family, or group counseling; legal services; concrete services and logistical help; and benefits advocacy. HIV-affected midlife and older caregivers may require competent child care, respite services, home health and hospice, homemaker or chore services, transportation, individual or group supportive counseling, education about HIV transmission and safety, and financial assistance. Support-

ive counseling for HIV-infected or HIV-affected midlife and older persons can be for an individual, couple, family, or group and can take place in person or over the telephone. Nokes, Chew, and Altman (2003) report on time-limited psychoeducational support groups for HIV-infected persons over age 50 that occurred weekly over the telephone through conference calling. They found that it worked well for persons who were not too hearing-impaired or cognitively impaired to participate fully found the support group helpful. A similar model would work well for older HIV-affected caregivers who cannot leave children or ill adults at home.

■ It might be useful to return to the earlier example of Bea and Kevin to illustrate how social work might help. A social worker in Kevin's medical clinic asked him to get his mother an appointment. Over a series of meetings, both at the clinic and at Bea's home, the social worker talked to her about HIV transmission, trajectory, and medications and left written material for her; referred the HIV-positive grandchild to a special day care for children living with HIV; referred Bea and Kevin to a legal clinic to discuss permanency planning and guardianship for the grandchildren in the event of his death; arranged for weekly help with housecleaning; helped her complete an application for food stamps; and arranged for her to join a support group of other older HIV-affected caregivers. ■

SUMMARY

When working with HIV-infected and HIV-affected midlife and older persons, social workers will likely need to be creative and flexible. For example, regardless of the organization's norms, it might be necessary to incorporate home visits for all stages of helping: assessment, arranging for services, ongoing case management, benefits advocacy, legal and estate planning, and supportive counseling. Although a good social worker treats everyone with respect and honors all individuals' experience, dignity, privacy, and right to choose, this may be doubly important when in a helping relationship with an older person with HIV. HIV-positive persons, as well as older persons, often do not fare well in the vast machinery of human service and health care provision. Social workers must monitor

TABLE 8.1. Assessment Domains for Specific and Combined Populations

<i>Domain</i>	<i>Older Adults</i>	<i>Persons Living With HIV/AIDS</i>	<i>Older Persons With HIV/AIDS</i>
Physical Functioning	✓	✓	Comorbidity may result in decline in functioning from various sources. Functioning may decline more rapidly and more sporadically with HIV disease than with chronic diseases typically associated with aging.
Cognitive/Affective	✓	✓	Cognitive decline in older adults may be due to a variety of factors, including dementias normally associated with aging in addition to HIV dementia. Initial symptoms of HIV-related cognitive decline may not be found using traditional mental status exams often used with older adults.
Social Support	✓	✓	Depending on their history, older adults with HIV/AIDS may have limited contact with biological family. Additionally, social supports common to younger persons with HIV, such as parents and even siblings, may be unavailable to older adults due to death or frailty of family members.
Sexual and Drug Health	✓	✓	Taking sexual and drug histories with older adults requires an understanding of cohort terminology and may require altering language typically used with younger clients. Ageist attitudes among professionals about sexuality and drug use must be recognized and avoided.
Spirituality	✓	✓	Older adults may need assistance with disclosing diagnosis to clergy or may need to locate spiritual resources that are HIV-sensitive. Individuals may have broken past ties with religious organizations that engaged in blaming behaviors.
Immune Function		✓	Senescence of the immune system (aging process) may serve to accelerate the decline of CD4 t-cells that are diminished through HIV. Older adults will need to be educated about the importance of CD4 and viral load and may need to be assisted with regular and ongoing testing.
Disclosure		✓	Determine to whom clients have disclosed their HIV status. This should include various family members, friends, health care providers, clergy, as well as individuals from the client’s job (if working).
Caregiver Well-being	✓	✓	Caregivers of individuals with HIV may suffer from many of the same physical, emotional, financial, and social burdens as other caregivers. In addition, associative stigma may exist, depending on the disclosure of the care receiver’s HIV status.

their own attitudes and behaviors for ageism and HIV stigma, along with other prejudgments, so that the helping relationship does not become yet another place where people suffer from maltreatment and misunderstanding.

NOTES

1. The human immunodeficiency virus (HIV) is an infectious retrovirus leading to an incurable life-threatening condition known as HIV disease or AIDS (Ac-

quired Immune Deficiency Syndrome). Persons living with HIV are also called “HIV-positive” or “HIV-infected”; those who are significant to them are called “HIV-affected.” HIV diminishes and then destroys the human immune system so that the infected person is more susceptible to cancers and bacterial, viral, parasitic, fungal, and other opportunistic infections. Despite effective and promising pharmaceutical developments, HIV remains highly life-threatening, and to date there is no vaccine or cure.

2. When CDC began monitoring reported incidence and prevalence of AIDS in 1982, age was reported by the

following categories: under 25, 25 to 44, 44 to 49, and over 49. For that reason, "aging" in the HIV field was initially defined as over 50. CDC now includes HIV and AIDS reporting by these age groups: 45 to 54, 55 to 64, and 65-plus (CDC, 2003, p. 14).

**Social Work Practice With Older Adults
With Mental Health Problems**

This page intentionally left blank

OVERVIEW

The chapters in this section cover a range of neurological and mental disorders having cognitive, affective, and behavioral components that present challenges for those suffering from the disorder as well as their providers and caregivers. Some of these disorders are biological in origin, others are rooted in psychosocial causes. Yet all share a degree of diagnostic uncertainty and unpredictable trajectories dependent on a number of factors beyond the efficacy of biomedical treatment. It is here that social work practice can make an important difference.

Diagnostic confusion refers to the need to rule out alternative conditions when symptoms are variable and overlapping—a situation exacerbated by stereotypical assumptions that older adults should be expected to be depressed, fatigued, or confused. On the other hand, conditions older people are not expected to manifest, such as substance abuse, may go unaddressed. Thus, depression may be considered a normal reaction to aging, and alcoholism might be overlooked entirely.

Although reversing the course of degeneration is usually not possible for progressive neurological diseases, careful assessment and intervention can reduce disability and significantly enhance quality of life. Emotional problems—depression, anxiety, substance abuse, and suicidality—may be comorbid with physical illness (or coexist in some combination).

Taken together, these disorders usually involve pharmacological treatment; recent advances in medications for Parkinson's disease and multiple sclerosis along with new generations of psychotropic drugs have brought significant advances in symptom reduction and improved functioning. Though often necessary, medication for these conditions is never sufficient. Even pharmacologic management has a psychosocial context that must be taken into consideration to be effective.

Gladys González-Ramos describes growing public concern around Parkinson's disease and multiple sclerosis, two neurological diseases that bring uncertain but almost inevitable decline and disability to afflicted patients. The age of onset is earlier for persons with multiple sclerosis and fewer live to old age, whereas Parkinson's disease is associated with the aging process. Both cause significant motor problems and neurological impairment resulting in reduced mobility and an increased risk of psychological comorbidity for patients and their burdened caregivers.

Practitioners with dementia patients confront cognitive rather than motor deficits. In the chapter by Ronald W. Toseland and Michael Parker, dementia is described as an insidious disease whose course is marked by subtle, then more pronounced impairments in memory, executive functioning, and speech. As caregivers' responsibilities increase, practitioners assist in linking dementia patients and their families to support services (including home care and caregiver respite).

As noted by Zvi D. Gellis in his contribution to this section, depression and anxiety are widely prevalent in aging populations as in younger groups. Typically overlooked by primary care physicians, who are focused more on physical than psychological states, depression and anxiety take a toll on older adults, who are themselves less likely to recognize it as a problem in need of formal treatment. This phenomenon, in which younger generations are more likely to seek specialty mental health services, means that the gap between mental health needs and service use is greatest for older adults. The aging baby boom generation may reduce this gap, as this cohort matured during the post-World War II era of expanded attention to mental health and less stigma associated with seeing a therapist or counselor.

The enormous demographic impact of aging baby boomers can be seen in the increased prevalence of the relatively invisible problem of substance abuse among elders. Tazuko Shibusawa's chapter on this topic is a thorough portrayal of how alcohol abuse and misuse of prescription and over-the-counter medications constitute a growing problem often neglected by providers insensitive to their presence and ill-prepared to assess or treat them. Though far less common, illicit drug abuse among elders is not unknown and poses a serious threat in terms of exposure to HIV. Poor oversight of multiple drug prescriptions with lack of attention to side effects and drug interactions as well as stereotypic assumptions that older adults are less likely to abuse alcohol increase the likelihood that substance abuse will be overlooked as a problem among elders.

Margaret E. Adamek and Greta M. Yoder-Slater address what is perhaps the most urgent need a social work practitioner can face with an aging adult: suicidality. Although the causes of elder suicide are as poorly understood as in younger populations, patterns differ in terms of fewer warning signs in older adults as well as lower likelihood of completion in younger adults. Notwithstanding the faulty assumption that aging brings inevitable health declines and a

sense of futility, it is true that social isolation, easy access to firearms, and poor mental status place elders at risk. Promising interventions such as cognitive-behavioral treatment are available to provide help.

Taken together, these chapters provide comprehensive coverage of the scope of each problem as well as practice-relevant guidelines. Common themes include the following:

- **Comorbidity:** The possible co-occurrence of poor mental health, chronic physical illness, and one or more forms of substance abuse should underlie assessments and treatment plans.
- **Greater attention to these disorders among older adults of non-European descent:** Persons of African American, Hispanic, and Asian backgrounds—to name only a few broad categories—are too often overlooked in research and practice among geriatric populations.
- **The multidisciplinary nature of practice:** Best practices employ a team approach that includes medicine (psychiatry, neurology, and primary care), nursing, and social work. The role of clergy and attention to spirituality are additional components.
- **Importance of balancing medication regimens with psychosocial support for patients and caregivers:** Caring for older adults with neurological and/or mental health problems can too easily be confined to medications without adequate attention to psychosocial context.
- **The unique and complementary role of social work:** Social workers are ideally prepared to address physical and mental health problems among elders and the needs of their caregivers. Working alongside health providers, they fill important roles in linking clients to formal support systems and counseling patients and families.

GLADYS GONZÁLEZ-RAMOS

Older Adults With Neurological Problems Without Significant Dementia

This chapter covers two of the most prevalent neurological disorders, Parkinson's disease (PD) and multiple sclerosis (MS). Although both diseases typically can be quite debilitating and impact a person's entire life, social workers have been largely absent from involvement in the care of persons and families living with these diseases. In fact, because so few social workers have specialized in the understanding of PD and MS, social work-based best practices with these populations are virtually nonexistent. This absence of attention starts in social work education, where most curricula do not cover material about these disease entities, despite their prevalence and the fact that persons living with PD and MS have high rates of comorbid mental health problems and need multiple social work services. As the number of older persons in the United States continues to grow, the prevalence of these diseases (particularly PD) is likely to continue to rise.

This chapter aims to provide readers with a beginning understanding of both PD and MS as they impact individuals and families so that informed care and referrals can be provided. Social workers have an opportunity to make a true contribution to practice with and research about persons and caregivers affected by neurological disorders such as PD and MS.

PARKINSON'S DISEASE

It was Dr. James Parkinson in 1817 who first described this disease in "An Essay on the Shaking Palsy." In recent years, celebrities such as Michael J. Fox, Muhammad Ali, and Janet Reno have publicly acknowledged their diagnosis of this disease. *Parkinsonism* is a clinical entity with multiple pathologic processes and various causes. It is divided into four categories:

- *Primary or idiopathic Parkinson's* (PD), which accounts for 80% of the cases of Parkinsonism.
- *Secondary parkinsonism*, which is associated with infectious agents, drugs, toxins, vascular disease, brain trauma, and tumor. Drugs that can produce secondary parkinsonism includes neuroleptics such as Thorazine, Haldol, Prolixin, Zyprexa, and Risperdal (Parkinson's Disease Foundation, 2004).
- *Parkinson's-plus syndromes* (such as progressive supranuclear palsy, dementia with Lewy body, multiple system atrophy). This group of disorders progresses rapidly and is often not as responsive to the usual antiparkinsonian medications.

- *Hereditary degenerative diseases*, which include inherited degenerative disorders such as Huntington's disease and Wilson's disease. (Waters, 1999)

Parkinson's disease (PD), the most well-known and prevalent among the group of disorders known as parkinsonism, is a chronic, progressive, neurological movement disorder thought to affect approximately 1 million persons in the United States (Waters, 1999). The exact number of persons with PD (PWP) is not known, as many are undiagnosed or misdiagnosed. PD is the second most prevalent neurodegenerative disorder, following Alzheimer's disease. Typically, the first and most prominent symptom noticed is one of impaired movement, but PD can also present with symptoms of depression and may be misdiagnosed by a clinician unfamiliar with this phenomenon. Although the disease is nonfatal, its progression brings increasing functional limitations and disability. Medications for treatment of PD provide symptomatic relief but can have debilitating side effects, with persons coming to rely heavily on their caregivers.

Because primary or idiopathic Parkinson's disease is the most prevalent in parkinsonism, this chapter focuses on this form of the disease.

Etiology

Although there is extensive research on PD, there is still no clear understanding of its etiology; at present, it is thought to be multifactorial. Environmental and genetic factors appear to play a role in the development of the disease, but their exact role is still unclear. It is known that about 15% to 25% of PD patients have a relative with Parkinson's. Although the majority of PD cases are not inherited, research has found that in a small number of families, several genes have been shown to cause the disease (Parkinson's Disease Foundation, 2004).

The pathological features include:

- Loss of cells in the substantia nigra, a section in the midbrain residing in a motor control area located above the brain stem. These cells are responsible for manufacturing the chemical dopamine, a neurotransmitter that helps to regulate movement. The result is a significant depletion of dopamine in this part of the brain, which leads to the cardinal motor symptoms found in PD (tremor, slowness of movement, rigidity, and postural instability).

- The presence of Lewy bodies (pink-staining spheres found in nerve cells), thought to be a marker for PD. Lewy bodies can only be found at autopsy.

Epidemiology and the Challenge of Getting Accurate Numbers

Typically, PD begins between the ages of 40 and 70; the average age of onset is 60 years. It is not unusual to have PD for several years before the actual diagnosis is made, as symptoms may be attributed to other health problems or thought to be signs of normal aging. Diagnosis is also complicated by the scarcity of specialty PD services, such as movement disorder neurologists, who can best diagnose PD. Household prevalence surveys have found that 35% to 42% of cases in the general population remain undiagnosed (Hagestuen, 2002). About 5% to 10% have young-onset Parkinson's, a diagnosis given to those under the age of 40. Parkinson's before the age of 20, called juvenile PD, is extremely rare and thought to have a stronger genetic link than other forms of the disease.

PD is more common in men, with a male:female ratio of 3:2 (Waters, 1999). Although previously thought to be most prevalent among non-Hispanic Whites, researchers are finding the same if not higher incidence of PD within Hispanic and other ethnically diverse populations (Chaudhuri, Hu, & Brooks, 2000; Nicoletti, Sofia, & Bartoloni, 2003).

Diagnosing Parkinson's Disease

PD is diagnosed by a physician's clinical exam; there are no definitive diagnostic tests, though a person may be sent for neurological imaging evaluations to rule out other possible diseases. PD begins on one side of the body and progresses to involve the other side as well. The symptoms may not be of equal severity on both sides. Symptom severity can fluctuate within and across individuals; this high rate of unpredictability causes much stress and anxiety.

Typically, a physician makes the diagnosis of Parkinson's if the person has two or more of these four cardinal signs:

- *Resting tremor*: where the limb, usually an arm or leg, shakes at rest, but the tremor might also be in the jaw or the face. This is the most easily recognized symptom, initially seen in about 75% of

PWP. This symptom typically starts unilaterally and distally (arm or leg) and may progress to the opposite side and involve the chin and tongue. The tremor usually disappears during sleep, is temporarily suppressed with voluntary movement, and is accentuated by anxiety or stress. Although in the long run it may be the least disabling symptom, it is often the most embarrassing for patients, with many trying to hide the tremor if they can.

- *Rigidity*: stiffness; the involuntary increase in muscle tone that results in resistance to passive movement of muscles. This symptom contributes to the characteristic stooped posture, forward-flexed head, flexed knees, and elbows seen in PWP.
- *Bradykinesia*: slowness of movement. This is a central feature of PD, which impacts most daily activities such as writing, eating, and dressing. It also has secondary effects such as decreased eye-blink, facial masking, slowed chewing and swallowing, and drooling. A slowed shuffling gait with decreased arm swing is common in the early stage.
- *Postural instability*: usually the last of the cardinal signs to appear. Impairment of postural reflexes accompanied by gait disorder is a major contributing factor in the progression from being ambulatory to being wheelchair-bound. The loss of postural reflexes and associated inability to make rapid postural corrections to compensate for any imbalance leads to falls and loss of independent gait. (Hagestuen, 2002)

Other symptoms of PD are listed in Table 9.1. PWP may come to experience any or all of these. Many of these functions will become significantly impaired as the disease progresses.

Parkinson's Disease and Comorbidity With Mental Disorders

Depression is the most frequently reported psychiatric comorbidity in PD, yet it is usually underdiagnosed and/or undertreated. Depending on the study criteria and patient population, depression has been reported in between 4% and 75% of PWP. The National Institute of Mental Health (NIMH, 2002) places the prevalence at about 50%. Depression may predate the diagnosis of PD and, in certain cases, may be the first symptom and may be a biological risk factor for those later diagnosed with PD (Leentjens, Van den Akker, Metsemakers, Lousberg, & Verhey, 2003).

Certain symptoms of depression in PWP are the same as in dysthymia or major depression (using *Diagnostic and Statistical Manual of Mental Disorders IV-TR* criteria); however, sadness, apathy, and anxiety are more prevalent than self-blame, suicidal tendencies, or feelings of guilt (NIMH, 2002). There are no standardized assessment tools to evaluate depressive symptoms in the context of PD; many studies use the Beck or Hamilton scales to assess depression, though they all have limitations. These scales may overdiagnose depression, as they include features such as motor slowing, fatigue, and trouble concentrating (symptoms that are present in PD).

Although the causes of depression in PD are not known, current theories link it to specific neurochemical changes and/or the psychological responses of having PD. Some researchers have observed that depression is associated with advancing severity, recent deterioration, and falls. It also seems to be more influenced by the person's perception of disability rather than actual disability. The PWP's own perception of disease is important to consider in treatment (Schrag, Jahanshahi, & Quinn, 2001). Psychotropic medications used currently are typically the selective serotonin reuptake inhibitors (SSRIs), though there are few studies showing the effectiveness of these drugs with this population. There are also potentially dangerous interactions of the SSRIs with antiparkinsonian medications, with some patients reporting an exacerbation of PD symptoms. Research on nonmedical treatments of depression in PWP is lacking.

Adding to the development or worsening of depression is the fact that many PWP tend to isolate themselves from their social networks because of the loss and/or unpredictability of their motor movements and other complicating symptoms. In addition to unpredictability of movement are communication difficulties; in many PWP, speech becomes slurred or the volume becomes too low to be heard. Such symptoms make it very difficult for many to continue to interact socially. This isolation can contribute to depression (Cote, 1999).

Table 9.2 lists other neuropsychological problems in this population.

Treatment of Parkinson's Disease

The National Parkinson Foundation, Inc. (NPF), with over 40 Centers of Excellence across the United States and internationally, along with other Parkinson organizations strongly recommends the use of inter-

TABLE 9.1. Other Symptoms of Parkinson's

-
- *Speech changes*—low voice volume; monotone; slurred speech; hoarse or breathy quality
 - *Swallowing problems* (dysphasia)—may occur in up to 40% of PWP, usually in advanced stages; can lead to development of aspiration pneumonia
 - *Cognitive changes*—problems with memory and executive functions
 - *Visual changes*—loss of contrast sensitivity and/or poor or blurred vision
 - *Handwriting changes* (micrographia)—handwriting becomes small or illegible
 - *Seborrhea*—excessive oiliness and scaling of skin
 - *Sialorrhea*—drooling, from loss of autonomic swallow reflex
 - *Decreased olfactory function*—loss of sense of smell
 - *Autonomic disturbances*—orthostatic hypotension (drop in blood pressure upon standing); causes dizziness, lightheadedness, fatigue
 - *Bladder, bowel, and/or sexual dysfunction*
 - *Neuropsychiatric symptoms* (see table 9.2)
-

disciplinary teams for the assessment and treatment of PD. There is growing recognition in the field that, given the complexity of this disease and its impact on the person and family, an integrated team consisting of movement disorder neurologists, nurses, physical therapists, occupational therapists, speech-language pathologists, and social workers is essential for good care. Best practices for the nonmedical treatment of PD have not yet been developed in the United States, although teams have been used in Australia and Israel for years, and the use of teams and their effectiveness is currently under investigation in the United States (Hagestuen, 2002).

The medications most often used to treat PD either replenish or enhance dopamine levels in the brain, with carbidopa/levodopa (Sinemet) being the cornerstone of pharmacologic treatment, taken by approximately 70% to 80% percent of PWP. Because

medications do not stop the progression of the disease, most patients require more medication and a combination of medications as time passes. As Sinemet becomes less effective, several side effects become common, including dyskinesias (abnormal, involuntary, writhing movements), motor fluctuations, and neuropsychological complications, described earlier. Dyskinesias and sudden “freezing” can be severe; after 5 years of therapy, 50% of patients develop these problems.

Motor fluctuations caused as a side effect of PD medications are very different from the symptoms of PD, even though they are also motor problems. As Sinemet becomes less effective, it causes an “on-off” effect, so that in the “off” state, persons experience a sudden drop in mobility; that is, they freeze and are unable to move for moments of time. If they are in an “on” state, they might move well or have excessive

TABLE 9.2. Facts About Other Neuropsychiatric Problems in Persons With Parkinson's

-
- Dementia occurs in more than 20% of PWP, more frequently in persons older than 65 and rare in those with young-onset PD. It is associated with poorer prognosis. Early dementia is indicative of other dementias such as Alzheimer's and dementia with Lewy body (Hagestuen, 2002).
 - Anxiety is common in PWP and can range from mild discomfort to panic attacks. It may be part of the disease or due to the medication wearing off (Hagestuen, 2002; see section on treatment).
 - Sleep disorders, quite common in progressing PD, may be related to or independent of the depression and/or anxiety states. For many, this becomes one of the most difficult symptoms.
 - Psychosis is most likely to occur if the person is older, has dementia, has a prior psychiatric history, or has been on anti-parkinson medication for some time. Psychosis, including hallucinations, delusions, and paranoia, can be drug-induced by PD medications. Visual hallucinations are typically nonthreatening and more common than auditory hallucinations. Psychotic symptoms often can be treated by changing the medication regimen (Waters, 1999).

Reports are emerging from the field about compulsive behaviors that include excessive fixation and inappropriate sexual behavior and compulsive gambling and shopping. These behaviors are often exacerbated by medications or surgery for PD (Hagestuen, 2002).

movements, such as dyskinesias, where the PWP will be involuntarily writhing. This on-off effect is progressive and can cause much anxiety to the PWP and caregivers because of its unpredictability. In this situation, it is impossible to know how the person with PD will be functioning on any given day or time in the day; no two days are the same. The off times increase and become more pronounced as the disease progresses (Hagestuen, 2002; Parkinson's Disease Foundation, 2004).

Dopamine agonists such as Mirapex, Requip, Comtan, and Stalevo are also used as a way to stimulate dopamine receptors or to boost and prolong the effect of levodopa. Other classes of medications also exist, but all have side effects, which can become quite disabling and need to be closely monitored by a movement disorder neurologist. Most of these medications are not in generic form and can be very costly. In addition, surgical treatments, particularly deep brain stimulation (DBS), have recently become a viable and effective treatment for those persons who are carefully evaluated by specialists and found to be suitable candidates for surgical intervention. DBS can be very helpful to those with advanced PD as it can help to manage some symptoms or side effects such as disabling dyskinesias (Parkinson's Disease Foundation, 2004). Surgery is neither a cure for PD, nor does it always work well, and it can have serious side effects. Thus, it is important that patients and caregivers be well informed about the pros and cons of this treatment and the risks involved.

There is growing recognition of how traditionally underserved populations are affected by PD. There are various programs that are now specifically reaching out to diverse communities, particularly via the NPF network. One such NPF program is the Community Partners for Parkinson Care (see NPF's Web site, www.parkinson.org). The program is now in six regions of the United States and is expected to expand.

Specific Caregiver Considerations in Parkinson's Disease

Research is consistently finding that caregivers of PWP experience high levels of stress, and spousal caregivers are more severely depressed than adult children or other caregivers (Aarsland, Larsen, Karlsen, Lim, & Tandberg, 1999). Depression and cognitive impairment frequently contribute more to caregiver distress than motor problems; caregivers experience strain even when PWP have minimal motor problems

(Carter, Lyons, Stewart, & Archibald, 2002). These high levels of strain have been found even when comparing caregivers of PWP to other caregivers of persons with dementia but without PD (Parrish & Giunta, 2003). Speer (1993) found that the strongest predictor of later adjustment in the disease was based on the PWP's and caregiver's own earlier adjustment to the disease. There is often a lack of recognition as to the importance of family caregivers and their needs in caring for someone with PD. Research points to the importance of understanding the strain and burden experienced by caregivers from early on and being responsive to their needs (Hodgson, Garcia, & Tyndall, 2004). In 2003, a quality of life measure was validated for caregivers of PWP, making it possible to more accurately study caregiver strain (Calne et al., 2003).

MULTIPLE SCLEROSIS

Multiple sclerosis (MS) is a chronic, frequently progressive, neuroimmunologic disease of the central nervous system (brain, optic nerve, and spinal cord). Although it can start at any age, the onset of MS typically occurs in early to mid-adulthood, from ages 20 to 50. Three-quarters of persons with MS living in the United States are diagnosed by age 40 (Rumrill, 1996). The disease usually has been thought of as one affecting younger persons, but it is also associated with near-normal life expectancies (Hennessey & Rumrill, 2001). Thus, older persons diagnosed with MS and their caregivers often need and seek social work services.

MS was first described in detail by the physician Jean-Martin Charcot in 1868. Although extensive research continues, no cure has been found, though in recent years, great strides have been made in the treatment and management of MS. A particular characteristic is that the course of the disease is very unpredictable from person to person and within the diagnosed individual. This unpredictability, which can affect everything from getting the correct diagnosis to managing a life fraught with uncertainty, can make for high levels of stress and anxiety in persons with MS and their caregivers (Holland 2002; Minden & Frankel, 2002).

Epidemiology

MS is more common in women than in men by a ratio of about 2:1, with differences most noted in younger

ages. The National Multiple Sclerosis Society (NMSS; Holland, 2002) reports that prevalence is inversely related to the person's proximity to the equator. In the United States, the estimated prevalence is 100–150/100,000 above the 37th parallel. Below this latitude, the rate is 57–78/100,000. This phenomenon is not well understood. It is estimated that perhaps there are 350,000 to 400,000 people in the United States diagnosed with MS. The latest estimates from NMSS are that approximately 90% of individuals diagnosed are non-Hispanic Whites. Non-White Hispanics, Blacks, and other races are thought to account for the remaining 10%. Whether these are accurate numbers, or whether the traditionally underserved populations have been undercounted because of lack of access to specialty diagnostic and treatment services, is unknown.

Etiology

MS is an autoimmune disease in which the body's own defense system attacks myelin, the fatty substance that surrounds and protects the nerve fibers of the brain, optic nerves, and spinal cord. The damaged myelin forms scar tissue (called lesions), and sometimes the nerve fiber is damaged. When either the myelin or the nerve fiber is damaged, nerve impulses, which coordinate all mental and physiological processes, are distorted and/or interrupted. This slowed or blocked conduction of information can disrupt every physical, sensory, mental, and emotional activity. The exact causes of MS are unknown, but current thinking is that it is due to a combination of immunologic, viral, and genetic factors. It is hypothesized that MS develops when a person has a genetic predisposition in combination with an environmental agent (including viruses) that trigger autoimmune responses (Hennessey & Rumrill, 2001).

Diagnosis, Symptoms, and Course of Multiple Sclerosis

There is no one definitive medical test for MS; the diagnosis is primarily based on clinical criteria established some years ago. In recent years, extensive use of magnetic resonance imaging (MRI) has helped to clarify the diagnosis. Most persons with MS show specific changes (white spots in the myelin) in the brain, which can be detected by an MRI. Tests of the spinal fluid can also show changes consistent with MS.

However, misdiagnosis does occur, especially by those who are not specialists in this area. The diagnostic process may take a long time as a neurologist will not make a diagnosis until there has been more than one episode of neurological impairment and more than one symptom. Because persons may have very mild symptoms or the symptoms may come and go, there can be long periods of uncertainty before a final diagnosis of MS can be made (Minden & Frankel, 2002; Schapiro, 2001).

A particular characteristic of MS is the presence of symptoms that affect several sensory or motor functions in the central nervous system (CNS; see Table 9.3). Symptoms may fluctuate or steadily progress in severity. MS can be marked by long periods of stability, even for those who progress to having a severe disability. However, even 20 years after diagnosis, two-thirds of persons are ambulatory, though many will require a cane or some other assistive walking device (Schapiro & Schneider, 2002).

There are several factors that can make MS symptoms worse. Aside from fatigue, body temperature is also an important issue. If body temperature rises for whatever reason (e.g., due to a hot day or because of fever), MS symptoms will often worsen (Schapiro, 2001). For more specific information about this aspect of the disease, see www.nationalmssociety.org/Sourcebook-Heat.asp.

Multiple Sclerosis and Comorbidity With Mental Disorders

Approximately 50% of persons with MS are reported to experience at least one episode of major depression during the course of illness. It is unknown whether this is due to neurological changes in the brain or to a psychological response to living with a chronic illness. Risk for suicide is significantly higher than in the general population (Minden, Frumin & Erb, 2003).

Other mood disturbances have been reported. The second most prevalent psychiatric disorder found in persons with MS is anxiety and can exacerbate physical symptoms and bring on other secondary problems such as insomnia (McReynolds & Koch, 2001). Persons with MS also evidence higher rates of bipolar affective disorder than the general population; the cause is unknown. The incidence is estimated to be up to 13% (Hennessey & Rumrill, 2001). "Pathological laughing and weeping" with no provocation and mood incongruence can also be experienced by individuals with MS (Minden et al., 2003).

TABLE 9.3. Symptoms of Multiple Sclerosis

-
- *Fatigue* is reported by 75% to 95% of persons with MS. Fatigue is not a single, easily identifiable symptom, as it varies greatly and is experienced in very different ways by persons with MS. Fatigue can be felt as persistent and general tiredness, a “worn out” feeling, or as overwhelming exhaustion that comes suddenly and without warning. It can be a primary symptom due to depression or a side effect of medication. Fatigue is recognized as a significant cause of unemployment among persons with MS (NMSS, 2003a).
 - *Motor problems* are often the first symptom and can include gait problems caused by muscle weakness, loss of balance, and severe numbness of the feet. Spasticity, a condition caused by abnormal increase in muscle tone, means muscles are resistant when stretched; this impacts motor function. Tremors manifest in the extremities and can range from small, barely noticeable tremors to those that are quite obvious.
 - *Pain and other sensory symptoms*, such as numbness, tingling, and burning sensations, are very common. Pain can either be a primary symptom due to the loss of myelin, or it can be secondary symptom as a result of poor posture or balance problems for ambulating individuals or improper fit or use of a wheelchair.
 - *Bladder and bowel dysfunction* can include urgency, frequency, constipation, or complete incontinence. These are very common problems early on and increase with disease progression.
 - *Visual changes* usually manifest as blurred or double vision from inflammation of the optic nerve. For most, it is temporary; for others, it can lead to functional blindness. For many, optic neuritis is a first symptom of MS.
 - *Diminished sexual function* and sexual dysfunction can include problems such as impotence, vaginal dryness, and decreased feelings in the genitals.

Cognitive loss may be experienced by approximately 50% of persons with MS and is considered a common symptom of all stages and disease types. Cognitive loss includes slowed information processing, impaired attention and concentration, impaired recent memory, and reduced executive functioning (Hennessey & Rumrill, 2001; Schiffer, 2002).

Clinical Course of Multiple Sclerosis

The clinical course of MS varies, but usually falls under one of the following four categories:

- *Relapsing-remitting MS*: Persons in this category experience clearly defined relapses, or episodes of acute worsening of neurological function, followed by periods of remission.
- *Secondary progressive MS*: Persons in this category experience relapsing-remitting course at the onset, followed by progression, minor remissions, and plateaus.
- *Progressive-relapsing MS*: Persons in this category experience progressive illness from the onset, with clear, acute relapses that may or may not resolve with full recovery. In this pattern, periods between relapse are characterized by continuing disease progression.
- *Primary progressive MS*: Persons in this category experience a nearly continuous worsening of the disease that is not typically interrupted by distinct relapses. Some do have occasional plateaus and temporary minor improvements.

Most persons start with a relapsing-remitting course and go on to develop a progressive course.

Treatment of Multiple Sclerosis

Due to the unpredictable and changing course of the illness, treatment needs to be individualized. Because this disease potentially affects every aspect of the person’s life, a holistic approach is recommended. Symptom management is crucial and can make for better quality of life. The NMSS and many MS specialists recommend the use of an interdisciplinary team approach for the treatment of the person with MS as well as for the family affected by this disease. This includes not only rehabilitation specialists, but social workers and others who can attend to the mental and cognitive changes as well as the many other changes experienced by people living with MS. The use of support services, formal and informal, is essential in the management of MS.

There is no one medical treatment that has been found to work for everyone, prevent new lesions from forming, or stop the progression of existing CNS lesions. There is no medical procedure to change or eliminate existing lesions. There are various medications that can slow or moderate relapses, but none cures the disease. Avonex, Betaseron, Copaxone, and Rebif are self-injectable drugs for long-term use that have been shown to reduce the frequency of exacerbations and to reduce new or active lesions on MRI. The NMSS

(2003b) Medical Advisory Board's published opinion is that all four self-injectable drugs may reduce future disability for many who have MS. To learn more about these medications, refer to www.nationalmssociety.org/Brochures-Comparing.asp.

In addition, costly intravenous treatments are sometimes used, such as Novantrone, indicated for rapidly worsening relapsing-remitting MS or progressive-relapsing or secondary MS. It can only be given for a limited period of time to avoid possible side effects (NMSS, 2003b). Rehabilitation therapies (physical therapy, occupational therapy and speech-language pathology) are very helpful in maintaining functionality and are seen as part of the comprehensive care model. Exercise and learning different ways to manage and compensate for loss of function are essential aspects of living with MS.

Management of stress, which can precipitate and/or exacerbate symptoms, is an important part of living well with MS. Suggestions have been made about the positive use of meditation, Tai Chi, and relaxation exercises (McReynolds & Koch, 2001). Because a rise in the core body temperature can make symptoms worse, managing this situation is essential. Typically, regular cooling will be needed, which can be accomplished by drinking cold beverages and/or being in air-conditioned places (Schapiro, 2001). The NMSS has numerous booklets with recommendations for how to best manage the various symptoms. This information can be downloaded from their Web site (www.nationalmssociety.org).

The Family Experience and Caregiver Concerns

When someone develops MS, the lives of family members tend to be affected as well; who is affected and how will vary. Because most people with MS are diagnosed between 20 and 50 years of age, there may be life cycle issues to consider, such as pregnancy, parenting young children, and employment. Parents of young people with MS, who may be facing their own aging, will have specific caregiver issues and may feel strain in their role. The NMSS has a wealth of excellent re-

sources for professionals and persons affected by the disease that can be downloaded from their Web site or ordered in hard copy (see appendix to this chapter).

Specific to MS, much like Parkinson's, is the unpredictability of the disease. This has been shown to add to the stress families feel. In addition, many of the symptoms of MS are invisible, such as the fatigue, visual problems, and pain, and family members may not recognize the symptoms or may misinterpret them, often adding to stress in the couple or family relationship (Crawford, 2001). Changes in role functioning are not uncommon, particularly with disease progression. This can disrupt the romantic-sexual bond, which is worsened if the couple has not learned how to cope together with the stressors and unpredictability of MS. Support groups have been helpful to couples and families in learning to understand MS and manage how best to live with the disease.

SUMMARY

The following are key points for social workers working with populations affected by PD or MS:

- Current trends in best practice recommendations call for care delivery in an interdisciplinary team. Social workers have been largely absent in such teams.
- The caregiver has specific stressors that need attention. Problem-solving approaches seem to be helpful with this population.
- Persons with MS and PD and their caregivers tend to experience a series of ongoing losses that need to be assessed.
- Depression and anxiety are common, yet are underdiagnosed and undertreated in populations with MS and PD. Support measures and clinical services might be helpful.
- It is likely that persons from diverse populations have been undercounted; outreach to the traditionally underserved is important as a way to serve whole communities. Most care reaches only the middle-class, educated population able to access existing services.

APPENDIX 9.1**Resources for Parkinson's Disease and Multiple Sclerosis****Parkinson's Disease**

National Associations

National Parkinson Foundation (NPF)

1501 NW 9th Avenue

Miami, FL 33136

800-327-4545; Web site: www.parkinson.org

NPF has over 40 Centers of Excellence in the United States and internationally and chapters with support groups throughout the United States. NPF offers education, support, outreach, and information and funds research to find the cause and cure for PD. The user-friendly Web site is full of information. They have numerous publications in English and Spanish which can be ordered, free of charge, with many available on the Web. NPF also offers Allied Team Training for Parkinson (ATTP), a specialty PD training program for allied health professionals, including social workers.

American Parkinson Disease Association (APDA)

1250 Hyland Boulevard Suite 4B

Staten Island, NY 10305

800-223-2732; Web site: www.apdaparkinson.org

APDA offers information and referral centers, chapters, and support groups throughout the United States. They have numerous publications in English and other languages, which can be downloaded or requested free of charge.

Parkinson's Advocacy Network (PAN)

1000 Vermont Avenue, NW, Suite 900

Washington DC 20005

800-850-4726; Web site: www.parkinsonsaction.org

PAN, the leading advocacy organization, educates the community about pressing issues regarding PD to advocate for increased funding to find the cause and cure.

National Institute for Mental Health (NIMH)

Office of Communications and Public Liaison

Information Resources and Inquiries Branch

6001 Executive Blvd., Room 8184, MSC 9663

Bethesda, MD 20892-9663

301-443-4513; Web site: www.nimh.nih.gov

NIMH Depression Publications 800-421-4211

Worldwide Education and Awareness for Movement Disorders (WE MOVE)

204 West 84th Street

New York, NY 10024

800-437-MOV2; Web site: www.wemove.org

This Web-based resource offers information for both the lay population and professionals about many movement disorders, including Parkinson's. The Web site is constantly updated and monitored by physicians.

Melvin Weinstein Parkinson's Foundation

1340-1272 North Great Neck Road, #193

Virginia Beach, VA 23454

757-313-9729; Web site: www.mwvf.org

This foundation helps PWP who are financially challenged by helping to purchase equipment and supplies necessary to maintain a safe and healthy environment.

Books and Magazines

There are a growing number of paperback books readily available in popular bookstores about Parkinson's. A recent publication with an extensive resource list is *What Your Doctor May Not Tell You about Parkinson's Disease: A Holistic Program for Optimal Wellness* by Jill Marjama Lyons, MD, and Mary Shomon (New York: Time Warner Books, 2001).

A free magazine for PWD and families, which can also be helpful to professionals, is *Parkinson's Disease Living Well*, which can be obtained from:

c/o Clinicians Group

1515 Broad Street

Bloomfield, NJ 07003

973-954-9306

Multiple Sclerosis

National Multiple Sclerosis Society (NMSS)

733 Third Avenue

New York, NY 10017

800-344-4867; Web site: www.nationalmssociety.org

The NMSS provides education, emotional support, and a variety of programs and services for people with MS, their families, and the public. They have an extensive list of publications (many in Spanish) on a wide variety of topics, which can be downloaded from their Web site. They provide professional consulta-

tion via their Professional Resource Center at 800-MS-TREAT or HealthProf_info@nmss.org. They also offer a variety of continuing education programs.

Multiple Sclerosis Association of America
706 Haddonfield Road
Cherry Hill, NJ 08002
800-532-7667; Web site: www.msaa.com

United Spinal Association
75-20 Astoria Blvd.
Jackson Heights, NY 11370-1177
800-807-0192; Web site: www.unitedspinal.org
United Spinal assists all persons with spinal cord injury or disease. They publish a quarterly newsletter and have programs to assist members to improve home accessibility.

Books

There are a variety of books for persons with MS available at local bookstores. Two to consider are the following: *Meeting the Challenge of Progressive Multiple Sclerosis* by P. K. Coyle and J. Halper (New York: Demos Medical, 2001) and *Health Insurance Resource Manual: Options for People with a Chronic Illness or Disability* by D. E. Northrop and S. Cooper (New York: Demos Medical, 2003).

Older Adults Suffering From Significant Dementia

10

Dementia is very difficult to cope with because it affects both mental and physical functioning progressively, until death. Dementing illnesses have been called “the most feared and devastating disorder of later life” (Zarit & Zarit, 1998, p. 32). The purpose of this chapter is to provide an overview of the social work role in the care of persons with dementia. The social work role is to provide services and support to persons with dementia to help them cope with the disease. These services also extend to family members and to those who care for persons with dementia.

BACKGROUND

Dementia comes from the Latin term *de mens* or “out of mind.” It is used to describe a group of symptoms, a syndrome, characterized by multiple cognitive deficits of sufficient severity to interfere with daily activities and social relationships (American Psychiatric Association, 2000). Typically, the symptoms are insidious at onset, gradually progressing until death as an increasing number of brain cells become impaired. Although progressive, the course of dementia symptoms is variable depending on underlying disease processes.

Because dementia affects many areas of functioning, social workers’ assessments and interventions must be broad, focusing on the whole person. Thus, assessment and intervention should include the emotional, physical, psychological, social, and spiritual aspects of the functioning of persons with dementia and their caregivers. Also, because of the progressive nature of the disease, advance planning is essential. Good social work intervention focuses both on current functioning and planning for the future.

Dementia in the elderly can be grouped into four broad categories by etiology and approximate incidence: (1) primary degenerative dementia (in 50% to 60% of dementia cases, e.g., Alzheimer’s disease, Pick’s disease); (2) multi-infarct dementias (stroke-related, 10% to 20%); (3) partially reversible dementias (20% to 30%, e.g., vascular diseases, infections, metabolic disorders); and (4) other neurological disorders (5% to 10%, Huntington’s and Parkinson’s diseases; Kane, Ouslander, & Abrass, 2004). Alzheimer’s disease is by far the most common cause of dementia, with vascular-related diseases a distant second. Dementia can be caused by a variety of other diseases and conditions, including HIV/AIDS, alcoholism, traumatic brain injury (i.e., head trauma), Creutzfeldt-Jakob’s disease, Down syndrome, and dementia due to other general

medical conditions and etiologies (American Psychiatric Association, 2000; Gauthier, 2003; Kane et al., 2004; Weiner, 1991; Zarit & Zarit, 1998).

The prevalence of dementia increases rapidly with advancing age. For example, it has been estimated that at age 65, only about .06% of males and .8% of females have dementia, whereas by age 85, the rates rise to 21% for males and 25% for females. By age 95, 36% of males and 41% of females are affected with some form of dementia (American Psychiatric Association, 2000). Because of the aging of the population in the United States and other nations, the prevalence of dementia is expected to increase dramatically in the next several decades (e.g., Katzman, 2001). Therefore, social workers can be expected to encounter an increasing number of persons with dementia and their caregivers in future years.

Dementia causes profound changes in a person's functional abilities. The essential feature of dementia is memory impairment, but at least one of the following cognitive disturbances must also be present: (1) aphasia (vague or empty speech), (2) apraxia (impaired ability to execute motor functioning), (3) agnosia (failure to recognize or identify objects), and (4) disturbance in executive function (ability to think abstractly and to plan, initiate, sequence, monitor, and stop complex behavior; American Psychiatric Association, 2000).

As dementia progresses, memory, judgment, language, and abilities to engage in activities of daily living become increasingly impaired, and behavioral disturbances can arise. Psychiatric symptoms may also occur and cause personality changes, depression, anxiety, delusions, or hallucinations. Gerontological social workers need to be able to recognize and treat these symptoms. They also need to help persons with dementia and their caregivers to cope with the limitations and impairments that arise with continuing declines in physical and mental functioning.

ASSESSMENT

The first step in working with older persons with dementia and their caregivers is to conduct a thorough assessment of the situation. If a diagnosis of dementia has not already been established, the social worker's role is to help people with dementia and their caregivers get an accurate diagnosis. Dementia is diagnosed by ruling out other physical illnesses that may be causing the symptoms and by history taking, which establishes progressive memory loss. Because it affects

many aspects of functioning, a good assessment of dementia is conducted most thoroughly by a multidisciplinary team (Mulligan, Linden, & Juillerat, 2003).

For example, social workers should encourage older persons with suspected dementia and their caregivers to get a comprehensive geriatric assessment that includes a social and medical history, a physical exam, appropriate laboratory work, a mental status exam, environmental assessment, and assessment of functional status (ADLs, IADLs; see Table 10.1; Kane et al., 2004; Toseland, Derico, & Owen, 1984). Such an assessment is necessary to rule out other illnesses and to track the trajectory of the illness and the effects of care. Therefore, it is important to have referral sources of physicians who specialize in dementia (Toseland et al., 1984). This includes geriatric-trained doctors who can lead a team of professionals in conducting and coordinating a comprehensive assessment (Fuller et al., 2003; Kane et al., 2004). Memory clinics and Alzheimer's disease assistance centers, now available in some communities, often employ multidisciplinary, geriatric teams that include the disciplines of medicine, nursing, and social work. If a dementia specialist or geriatric-trained internist or family practitioner is not available, the social worker may need to recommend to the family the involvement of other professionals (neurologists, psychiatrists, nurses, nutritionists, physical and occupational therapists) in the assessment process.

While making an assessment, social workers should consider using one of the instruments available to assess the level of cognitive impairment experienced by the person, such as the Mini Mental Status Exam (Folstein, Folstein, & McHugh, 1975). Social workers may also want to use other instruments, such as the Global Deterioration Scale, to determine the stage of disease progression (Reisberg, Ferris, & deLeon, 1982), or the Life Space Assessment (Parker, Baker, & Allman, 2002) to assess early changes in functional status and to monitor changes in mobility over time.

The assessment of dementia should include determining the current stage of the disease. Many resources are available to identify what stage of dementia a person is currently experiencing. For example, a CD-ROM is available that can be used by both professionals and laypersons to identify the stage of the disease and to address concerns arising during each stage (Health Care Interactive, 2001). There is still some controversy about whether to disclose the diagnosis of dementia to the person with the disease, and some have argued that the best approach is to ask the person at the outset whether he or she would like to know the result of the diagnosis-

tic process (Downs, 1999). Although we respect the person's right not to know, in the overwhelming majority of situations, our clinical experience suggests that people want to know the diagnosis. Disclosing the diagnosis is also important because it affirms the person's

right to know and because early diagnosis can lead to earlier and better treatment.

Part of the role of the social worker in the early stage of work with persons with dementia and their caregivers is to provide support as they go through the process of accepting the diagnosis and understanding its implications. Social workers provide information to help persons with dementia and their caregivers gradually understand the consequences of the diagnosis to functional abilities. According to Kaplan (1996), caregivers of dementia patients go through the following states of adjustment: (1) denial and making excuses for the person's behavior; (2) overinvolvement and overcompensation for the person's losses; (3) anger over the loss, frustration about the inability to halt the disease progression, and embarrassment caused by the person's behavior; (4) guilt about the inability to accommodate and fully meet the person's behavior and care needs; and (5) grieving and acceptance.

During the assessment process it is important to identify the primary caregiver. For persons with early-stage dementia, Kuhn (1999) suggests that at least one person who is close to the person with dementia should be helped to step into a leadership role. This person takes overall responsibility for ensuring the well-being of the person with dementia, while not undermining the remaining abilities of the person, and encouraging the active involvement of others interested in the person's well-being. However, because caregiving frequently involves a primary caregiver and secondary caregivers, an important role for social work is to help families define roles, to cooperate in care planning and decision making, and to negotiate and resolve conflicts as they occur.

Once a diagnosis of dementia has been confirmed, the social worker can proceed with the assessment process. A comprehensive assessment of persons with dementia should consider the physical, emotional, psychological, social, practical, and spiritual aspects of their functioning and that of their caregivers.

PHYSICAL FUNCTIONING AND DEMENTIA

Dementia has a profound impact on functional abilities, language and speech, motor ability, judgment and reasoning, and many other areas of functioning. Functional status measures can be used to measure basic activities of daily living skills such as bathing and toileting and also higher-level instrumental activities of daily living skills such as managing money and driving. In early stages of dementia, social workers' role

is often to help the person with dementia and caregivers to make adaptations in their environment to help them compensate for memory loss. In the middle stages of dementia, functional assessments can aid social workers in helping caregivers to learn communication strategies that compensate for impairments in language and speech. Later in the disease process, social workers' role is often focused on assessing informal support services and providing information about formal community supports such as day care and home care. At a minimum, this information can help to reassure caregivers that help is available and that they are able to have some respite from caregiving if needed. Social workers may also help caregivers to obtain needed home care, adult day care, or nursing home services.

PSYCHOLOGICAL AND EMOTIONAL IMPACT OF DEMENTIA

Emotional lability and emotional problems are common among both persons with dementia and their caregivers. Caregivers often struggle emotionally as they reflect on the continual cognitive decline. They face profound changes in their loved one. Social workers can help caregivers in many ways, including providing support and reassurance, developing long-term care plans that address medical care (e.g., locating a geriatrician), addressing legal issues (e.g., completion of a durable power of attorney), understanding family dynamics (coordination of a family meeting to determine who does what), and addressing work and financial issues, spiritual concerns, grief and loss counseling, emotional support, and assistance with practical issues such as obtaining needed health and social services (Parker et al., 2004). Because people cope in many different ways with emotional challenges, a careful assessment of the emotional concerns of persons with dementia and their caregivers can help to guide intervention efforts. Some persons with dementia and their caregivers may, for example, benefit from early-stage dementia support groups (Yale, 1995). Others may benefit from individual or family counseling to alleviate emotional problems.

Psychological impairments can occur in all stages of the disease. In early stages, depression is a common problem, and anxiety may also be present. In later stages of the disease, psychotic symptoms such as hallucinations and delusions may occur, and agitation is common. Pharmacologic treatment may help, but the

use of psychotropic medications is complicated by the underlying disease processes, and some medications, such as the benzodiazepines, may make the dementia worse. Therefore, it is essential for social workers to work closely with psychiatrists who are familiar with the treatment of persons with dementia.

We have observed that behavioral symptoms are often the result of inappropriate environmental stimulation or poor pain management. Therefore, it is important to conduct a careful assessment of the environment and the physical comfort of the person with dementia before assuming that behavioral symptoms are due to psychiatric problems. Because of the adverse effects that psychotropic medications can have on persons with dementia, it is always preferable to use nonpharmacological approaches if these are effective. (For additional information, see Callaway, 1998; Galasko, 1996; Kennedy, 2000; Zarit & Zarit, 1998.)

THE SOCIAL IMPACT OF DEMENTIA

Socially, the person with dementia often becomes isolated. Dementia causes problems in word finding, in sentence structure, and in ability to communicate. As dementia progresses, it becomes increasingly difficult to understand what the person is trying to communicate. Even close family caregivers may become frustrated, and some become angry and short-tempered. Because of these problems, caregivers often feel ashamed to take the person out in public or to have visitors. When visitors do come, they may find it difficult to interact with the person with dementia.

Caregivers also often become socially isolated as they increasingly have to be available around the clock to make sure that the person with dementia is safe. Therefore, it is important for social workers to encourage caregivers to take care of themselves. It is also important to make use of informal and formal services as part of the care plan. Social workers can teach caregivers communication skills and activities that can be used to continue engagement as skills deteriorate and dementia progresses. Some of these skills and activities are briefly described later in this chapter.

PRACTICAL ASPECTS OF CARE

Another important social work assessment and intervention role is to help with the practical aspects of care planning and management. Social workers assess

the capacity of persons with dementia and their caregivers to get practical needs met. As a result of this type of assessment, social workers, for example, frequently become involved in helping the person with dementia and family caregivers to understand the role of Medicaid and Medicare and other health and social service programs, such as home heating assistance and food stamps. This assistance may include helping them with questions about eligibility and with required application procedures. It also may include helping to coordinate or manage services once they are obtained.

Social workers frequently become involved in planning for future care needs. For example, social workers may help persons with mild dementia and their caregivers to develop health care proxies and advance directives regarding medical care wishes if they become incapacitated. They may also encourage caregivers and persons with dementia who are still capable to develop or update wills, powers of attorney, and other legal documents, to review financial arrangements, and to plan for the assistance and support that will be needed during later stages of the disease.

THE ROLE OF RELIGION AND SPIRITUALITY

Many families confronted with the effects of dementia find strength in their spiritual beliefs and the support they receive from their communities of faith (Myers, Roff, Klemmack, & Parker, 2004; Parker et al., 2004; Roff & Parker, 2003). Religious beliefs are particularly strong in North America among elderly women and members of some minority groups (Koenig, McCullough, & Larson, 2001; McInnis-Dittrich, 2002; Roff, Klemmack, Parker, Baker, & Allman, 2005; Tobin 1999).

The early stage of a dementing illness is a good time to help persons express what type of religious or spiritual support, if any, they would like as their symptoms progress. For some individuals, this may include continued or renewed contact with clerics or with formal religious organizations such as churches or synagogues. For others, it may mean help in coming to terms with the illness and its course, the meaning of their lives and making peace with family, friends, and those with whom they may have had conflictual relationships. Social workers can help older persons with mild dementia to incorporate spirituality and religion in life review, reminiscence, and legacy work that helps to make sense of and give

meaning to life (Roff & Parker, 2003). It can also mean helping persons with dementia to articulate and record preferences for medical care and funeral arrangements at the end of their life that reflect their religious and spiritual values.

ATTENDING TO THE NEEDS OF CAREGIVERS

Although we have already mentioned the importance of including the primary caregiver in the assessment process, a comprehensive biopsychosocial and environmental assessment should always consider the needs of all family members and other concerned persons who are involved with the person with dementia. In some families, for example, a diagnosis of dementia can rekindle or exacerbate long-standing family conflicts. In others, it can bring family members closer together. One or more family meetings are often helpful to assess the strengths and weaknesses of the family system in planning for the future, in problem solving, and in resolving conflicts and differences of opinion about care options and roles (Toseland, Smith, & McCallion, 1995).

Cummings (1996) points out that it is essential for social workers to recognize that understanding, accepting, and coming to terms with the dementing illnesses of a family member may be a long and slow process and that this process varies significantly by individual family member. Family caregivers are faced not only with the prospect of providing care over the long term, but also with the emotional challenge of coming to grips with the gradual loss of their loved one and changing expectations about the relationship they will have with the person as disease processes progress (Cummings, 1996). Social workers have an important role to play in helping individual family members and the entire family system to cope with these emotional adjustments and to work together to plan for and manage the care of the person with dementia as symptoms progress.

INTERVENTION ROLES

Social workers can be called on to play a variety of roles when working with persons with dementia. These roles can include consultant, coordinator, care manager, and interdisciplinary care team member (Toseland, Smith, & McCallion, 2001; Toseland, Smith, & Zinoman, 2004). In consulting roles, social

workers utilize the competencies, expertise, and skills of persons with dementia and their family care systems to the maximum extent possible. They rely heavily on the input of persons with dementia and their caregivers during both assessment and care planning. Social workers assume that caregivers and persons with dementia will take primary responsibility for the day-to-day implementation and monitoring of the care plan.

After an intensive period of consultation during which the assessment is conducted and a care plan is made, social workers in the consulting role reduce contact, occasionally checking that the care plan is being implemented properly and responding to problems or issues as they arise. Frequently occurring problems often include emotional lability, agitation, and behavioral disturbances such as aggressiveness and apathy. They may also include adjustments in living status (such as when a person with dementia moves in with a caregiver or moves to supportive housing or a nursing home), resistance to some forms of care such as bathing, or safety issues arising from the declining judgment and reasoning of the person with dementia. The consultant role is often used by private social work care managers and agency-based social workers in outpatient memory clinics, housing projects, family service agencies, and senior centers in the early stages of dementing illnesses and when strong family supports are available.

In the care coordinator role, social workers take greater responsibility for implementing the care plan they have developed with family members and persons with dementia. Social workers help to link persons with dementia and their informal caregivers to needed community resources and services and help to ensure that these services are received in a timely and consistent fashion by resolving any ongoing care plan implementation issues. In the care coordinator role, social workers are frequently called on to help with applications for medical, social service, and housing assistance and may serve as an advocate to help obtain them. As care coordinators, they may also provide education about the disease and limited individual, family, or group counseling. The social worker plays a broker role linking the person with dementia and family members to more extensive counseling services if needed.

Once services are in place, the care coordinator's role is to ensure that services continue to meet ongoing needs and that they are responsive to changing circumstances as the dementia progresses. The care coordinator role is frequently used by social workers

who are called on to work with persons with moderate dementia. Care coordination is also frequently needed in situations where informal caregivers can't assume these responsibilities or where they are unable or unwilling to provide day-to-day monitoring of care plans.

The care management role is assumed by social workers when their comprehensive assessments reveal that persons with dementia are severely impaired or when informal caregivers are unavailable or unwilling to provide the type of around-the-clock monitoring of the situation and the extensive day-to-day care that is often needed. In this role, social workers involve informal caregivers in the care planning and implementation process. In general, however, care managers help caregivers by putting services in place that remove some or all of the responsibility for day-to-day care of persons with dementia.

Kaplan (1996) points out that there are several different forms of care management. Medical care management was originally developed by health maintenance organizations and insurance companies to contain medical costs. Typically, medical care management emphasizes the provision of quality care at the lowest possible cost, coordination of care between providers and informal caregivers, and the utilization of benefit coverage to provide preventive services, health care maintenance services, and the management of chronic diseases. Social care management services typically help persons with dementia and their caregivers obtain needed social services such as Meals on Wheels and day care. Social care management may also include limited or extensive medical care management. Kaplan also mentions that there are mental health care management services that provide supportive care or rehabilitation and private geriatric care management provided to persons with dementia and their family members on a fee-for-service basis. These latter services are particularly useful for long-distance caregivers who have sufficient resources to pay for these services but who are not in a position to relocate to provide the necessary ongoing monitoring and day-to-day assistance that may be needed by the person with dementia.

Typically, in the care management role the social worker (1) completes a comprehensive assessment of the situation, (2) develops a care plan, (3) implements the plan by coordinating health and social service delivery from different providers and by providing services directly to both the caregiver and informal caregivers, (4) maintains regular and frequent contact with the person with dementia and informal care-

givers to ensure that appropriate care is delivered in a timely fashion and that adjustments to changing circumstances are made on an ongoing basis, and (5) advocates to close gaps and fill in needs that are not being fully met by the care plan. Overall, the focus of care management is to keep the person living at home for as long as possible in a safe and comfortable setting. When needs become too great, the care manager's role includes helping to place the person with dementia in a more sheltered environment such as assisted living or a special care unit in a nursing home that may better meet his or her needs.

Social workers' roles may include being members of interdisciplinary teams in outpatient and inpatient organizations designed to help persons with dementia. These include outpatient programs such as memory clinics designed to provide multidisciplinary assessment and care plans (often a geriatrician, nurse, and social worker team) to help caregivers maintain persons with dementia in community settings (see, e.g., Freed, Elder, Lauderdale, & Carter, 1999). These may also include social workers in home care agencies, adult day care centers, and other community agencies designed to support caregivers and persons with dementia. Social workers play vital roles in sheltered housing programs and nursing homes where they work with other team members to provide high-quality care to persons with advanced dementia. In their role as interdisciplinary team members, social workers frequently serve as care coordinators but may also take on consultation or care management roles.

INTERVENTION STRATEGIES

There are a wide variety of intervention strategies that can be used to help persons with dementia and their caregivers cope with the disease. These can be classified into strategies focused on prevention, remediation, and support. Although an extensive discussion of each of these types of intervention strategies is beyond the scope of this chapter, brief overviews are presented with references to more comprehensive resources for further reading.

The label "prevention" is not meant to imply that there are intervention strategies that can prevent or reverse the course of dementing illnesses. At this time, there are no such strategies. There are, however, intervention strategies that can slow the course of dementia and mitigate some of its harmful side effects.

There are now several drugs on the market that are helpful in slowing the course of the dementia in some

persons. For an overview of pharmacological treatment from a social work perspective, see Callaway (1998), but for up-to-date information about the latest medications to reach the market, a review of the results of recent clinical drug trials is necessary. Some reviews of the recent literature are written in language easily understood by practicing social workers and include medications not only to treat cognitive loss but also to treat depression, agitation, delusions, and hallucinations (e.g., Kawas, 2003). The social work role in pharmacology management is to help persons with dementia and their caregivers to obtain appointments with geriatricians, neurologists, and psychiatrists who can help them determine whether they are good candidates for medications useful in the treatment of symptoms of dementia. In general, it is thought that pharmacological agents to treat cognitive loss are most effective if they are administered in early dementia. Therefore, social workers can play an important role in urging persons with dementia and their caregivers to have medication reviews as early as possible. Social workers can also play an important role by helping persons with dementia to consistently take medications as prescribed.

Another type of preventive intervention consists of cognitive stimulation programs. Early attempts at cognitive stimulation include reality orientation, reminiscence, and remotivation therapy. The efficacy of these approaches for persons with dementia is limited (the evidence is discussed in several reviews; e.g., Beck, 1998; Kasl-Godley & Gatz, 2000; Miller & Morris, 1993; Spector, Davies, Woods & Orrell, 2000; Spector, Orrell, Davies, & Woods, 1998a, 1998b, & 2001; Van der Linden, Juillerat, & Adam, 2003; Zarit & Zarit, 1998). More recent cognitive stimulation and training programs that have focused on cognitive deficits in episodic memory, language, and numerical skills have also been attempted (for a review, see Van der Linden et al., 2003).

Although social workers sometimes become involved in cognitive training programs, most of their involvement has been limited to cognitive stimulation programs, such as reality orientation and reminiscence programs, and to efforts designed to structure the environment of persons with dementia by providing external cognitive aides to enhance memory. These interventions include suggesting specific places to store keys and other items used daily, medication organizers, the use of labels and color coding, and similar memory aides.

Apathy and lack of engagement are major problems for persons with dementia, particularly during

middle and late stages of the disease, problems that can be vexing to family caregivers. Programs to maintain communication and to stimulate interaction have been developed (e.g., Toseland & McCallion, 1998). Table 10.2 presents some general strategies for maintaining communication. Other strategies for maintaining communication with persons with dementia at early, moderate, and severe stages of the disease can be found in Toseland and McCallion.

Memory albums and memory charts can be used to stimulate reminiscence and life review and to engage persons with dementia whose language abilities may be quite limited. Memory albums are small photo albums with pictures of important people, places, and events from the distant past that are particularly meaningful to the person with dementia. Simple words describing each picture are placed underneath the picture or on the opposite page of the photo album. Memory charts are larger boards that contain photographs and simple words in different panels that can be placed where a person with dementia spends a considerable amount of time. Memory albums and memory charts are particularly effective for engaging persons with moderate and severe dementia (for more information, see Toseland & McCallion, 1998).

Remedial intervention strategies include those that are focused on emotional and psychological problems and personality changes that are frequently

observed in early- and middle-stage dementia as well as agitation and behavior problems that are commonly encountered in moderate to severe stages of dementia. Emotional and psychological problems such as depression, anxiety, delusions, and hallucinations (more common in later-stage dementia) can be treated effectively with psychotropic medications, but support and reassurance also play an important role.

A useful theoretical framework to reduce emotional and psychological problems is the Progressively Lowered Stress Threshold (PLST) model originally developed by Hall and Buckwalter (1987). Adapted from stress adaptation and coping models, the PLST model identifies clinical triggers such as fatigue, change in routine, inappropriate stimulation, and internal and external demands that exceed the capacities of the person with dementia. According to PLST, these triggers can lead to a sudden decline in functional ability. The PLST model recommends establishing daily routines, making environmental modifications, minimizing fatigue, managing inappropriate stimuli, minimizing affective responses, decreasing excessive demands, limiting physical triggers, and improving communication and behavior management strategies (Buckwalter et al., 1999; Gerdner, Hall, & Buckwalter, 1996; Hall & Laloudakis, 1999; Toseland & McCallion, 1998).

Most remedial approaches to agitation and behavior problems rely on some form of behavioral

TABLE 10.2. General Communication Guidelines

-
1. Begin all communications by first ensuring that you are relaxed and are conveying that you are relaxed.

One technique to get rid of stress has been called deep breathing. This is a method of breathing for relaxation. This technique should not take more than approximately two minutes.

 - Concentrate on one spot in your stomach.
 - Concentrate on the flow of your breath as you inhale.
 - Concentrate on the flow of your breath as you exhale.
 - Focus on your breathing as you repeat this procedure several times slowly.
 - Visualize your breath going in through your nose, into the center of your body, and out again.
 2. Reduce background noise and other distractions and stimuli.
 3. Ensure that there is adequate lighting for the person with dementia or move to a brighter location.
 4. If the person with dementia usually wears glasses or a hearing aid, try to have the person with dementia use them. However, do not argue if the person with dementia does not want to wear them.
 5. Speak in a slow, calm, respectful manner and keep the pitch of your voice low.
 6. Avoid speaking to the person with dementia as if he or she is a child.
 7. Even when the person with dementia has severe language problems, never assume that he or she does not understand you. Always assume that he or she will understand at least some of the information you are attempting to convey.
 8. Do not talk about the person with dementia with others as if the person with dementia is not there.
 9. Sit at the same eye level as the person with dementia to show that your attention is focused on him or her.
-

analysis, with caregivers becoming behavior detectives identifying when problems occur and the antecedents and consequences of behavior. The idea is to find out precisely when behaviors occur and to try to determine the underlying needs that are not being met. Caregivers can be encouraged to identify antecedents that may stimulate the behavior and consequences that maintain the behavior. Based on these data, the environment can often be modified so that the comfort of the person with dementia is restored. Simple strategies such as making the room cooler or warmer, engaging the person in an activity, reducing noise or other stimulation, and reassurance and attention to positive behaviors often help reduce behavior problems.

Some agitated behaviors and behavior problems may be the result of poor pain management. Therefore, a careful review of physical causes (e.g., arthritis pain) for such behavior problems should be undertaken before behavioral intervention programs are initiated. A number of helpful books give directions for how to handle a variety of specific behavior problems, including but not limited to apathy, combativeness, food refusal, insomnia, resistance to care, and wandering (e.g., Hoffman & Platt; 1991; Mahoney, Volicer, & Hurley, 2000; Rau, 1993). There are also many excellent articles and book chapters that address apathy as well as behavioral and sleep problems (e.g., Cohen-Mansfield, 2000; Engelman, Altus, & Mathews, 1999; McCurry, Logsdon, Vitiello, & Teri, 1998). Recently, a CD has been created to help social workers and allied professionals to address problem behaviors and promote positive behaviors (McCallion, Lacey, & Toseland, 2003).

In our haste to address agitation and behavior problems and to prevent further declines in memory and communication, support strategies are sometimes neglected. Social workers, however, have a vital role to play in supporting persons with dementia and caregivers through the inevitable decline to death that is the ultimate result of dementia. In the early stages of dementia, support may take the form of affirming the coping abilities of persons with dementia and their caregivers. In later stages, reassurance and gentle touch can be used, and strategies to continue verbal and nonverbal engagement can be implemented by continuing to engage and stimulate whatever aspects of long-term memories and language abilities remain intact. Supportive interventions also include keeping caregivers and persons with dementia educated about the stages of the disorder new developments in care, helping caregivers and persons with

dementia to obtain needed services and resources, and helping them plan for the future. For family members and other caregivers, supportive interventions may include family care planning and problem-solving meetings, supportive counseling and reassurance, and assistance with community and institutional options for care as dementia advances.

CONCLUSIONS

Because it affects many different aspects of emotional, physical, mental, social, and spiritual functioning, dementia is a very challenging disease to cope with both for the person afflicted and for family caregivers. Social workers are called on to play a vital role in supporting and assisting persons with dementia and their family caregivers in many different community and institutional settings. During assessment and intervention, it is essential for social workers to take a broad view of the whole person, considering the impact of dementia on the biopsychosocial and environmental functioning of the person with dementia and their informal caregivers. The social work profession is ideally suited for this role, working alone and in conjunction with other disciplines to help persons with dementia and their family caregivers cope with the devastating impact of this disease.

Older Adults With Mental and Emotional Problems

The changing demographics of American society have received a great deal of attention in recent years. As the population ages, the overall number of elderly persons with mental disorders, particularly anxiety and mood disorders, will increase. Older adults with mental health problems are likely to have relatively longer life spans in the future due to expected advances in treatments and healthier aging lifestyles. Mental health problems will demand more attention from providers to minimize their effects on disability, the use of health care services, and the quality of life for older adults and caregivers. This chapter presents the current state of knowledge on mental disorders of late life, focusing on prevalence, consequences, and effective evidence-based treatments.

Common mental disorders in late life include anxiety disorders and mood disorders such as depression. The development of schizophrenia in late life is less common, but a significant number of persons diagnosed with these disorders as young adults do age (Jeste & Nasrallah, 2003). Suicide among the elderly, particularly among men, is an epidemic in our society. Older men (80+) take their own lives 4 to 6 times the rate of women (Scocco & DeLeo, 2002). Depression, isolation, loneliness, lack of social supports, and declining physical disabilities are some of the probable factors.

Older adults are seriously underserved by mental health service systems across all care settings. Current estimates of the incidence of mental illness among older persons range from 15% to 25% (Gallo & Lebowitz, 1999), yet only 2.5% receive assistance from traditional mental health services and another 2% receive help for mental health problems from their primary care physician (Schulberg, Pilkonos, & Houck, 1998). Research suggests that the rate of emotional disorders among the baby boomers exceeds the rate among the current cohort of older persons (Koenig, George, & Schneider, 1994). The large anticipated growth in the number of older persons makes the provision of mental health services to older adults increasingly important. Combining this growth with an increased rate of emotional disorders magnifies the problem.

The provision of mental health care to older adults with severe mental disorders poses a unique set of challenges to service providers. Barriers to the provision of care exist at both the individual and system levels. Many older adults are reluctant to seek mental health services due to stigma, denial of problems, access barriers, language barriers, or a lack of culturally appropriate programs. Sometimes older adults do not

receive appropriate care when they do seek help due to fragmented mental health services, or gaps in services. Moreover, there is a critical shortage of professional staff trained in the geriatric mental health field.

LATE-LIFE DEPRESSION

Depression is the most well-researched psychological problem of later life. Evidence is clear that late-life depression is one of the most common mental disorders to present in primary care settings (Lyness, King, Cox, Yoediono, & Caine, 1999; Reynolds & Kupfer, 1999). According to the Surgeon General's Mental Health Report, depression in older adults leads to physical, mental, and social dysfunction (U.S. Department of Health and Human Services [DHHS], 1999). Nearly 5 million of the 31 million Americans over 65 suffer from clinically significant depressive syndromes. The prevalence of major depression increases as one moves from community settings (1% to 3%) to primary care (5% to 9%), to institutional settings such as nursing homes (12% to 30%; Hendrie et al., 1995; Unützer et al., 1997; Unützer, Katon, Sullivan, & Miranda, 1999). Rates of depression among medically ill elderly range from 10% to 43% (Peterson, Williams-Russo, & Charlson, 1996; Steffens et al., 2000; Williams-Russo, Sharrock, & Mattis, 1995).

Primary care and home care services are essential to maintaining elders with disability in the community and reducing their hospitalization and nursing home use. Compared with the general elderly population, home care recipients are older, more socially isolated, more likely to be women, and more likely to have high rates of physical illness and disability and depression (Banerjee, 1993). The Cornell Institute of Geriatric Psychiatry at Weill Medical College estimated a prevalence of current *Diagnostic and Statistical Manual of Mental Disorders IV (DSM-IV)* major depression at 13.7% in a probability sample (N=539) of older (age ≥ 65) new patients from a home care agency (Bruce et al., 2002). These researchers found that depression was highly prevalent, characterized by symptoms and various conditions (functional disability, cognitive impairment, and comorbid vascular disease) associated with poor outcomes (Alexopoulos et al., 1996). Other researchers have estimated a prevalence of depressive symptoms at 27.5% in a probability sample (N=618) of older (age ≥ 65) community-dwelling persons (Gellis et al., 2004). However, few elderly receive appropriate treatment of depression. For instance, in two stud-

ies, only 21% (E, L. Brown, McAvay, Raue, Moses, & Bruce, 2003) and 16% (Banerjee, Shamash, Macdonald, & Mann, 1996) received treatment.

The older person, treating physician, and health care organizational factors interact to impede the detection and treatment of depression, particularly among older clients (Klinkman, 1997; Meyers, 1996; Schulberg, Magruder, & deGruy, 1996). From a biopsychosocial framework, the complexity of depression is reflected by variability in onset, presentation, and course, as well as functional disability, negative life events, and medical comorbidity. The heterogeneity of depression coupled with physical and cognitive impairment, social vulnerabilities, and various medical conditions prevalent in health care make it more difficult for accurate assessment, diagnosis, and treatment in the elderly population. Older patients are less likely to voluntarily report affective symptoms of depression (Lyness et al., 1995). They are more likely to ascribe symptoms of depression to a physical illness (Knauper & Wittchen, 1994). Depressed older adults of various ethnic backgrounds are less likely to use specialty care and more likely to use the general health care system (S. L. Brown et al., 1995; Unützer et al., 1997).

Comorbidity of Depression and Suicide in Older Adults

The consequences of depression in later life are potentially serious. Depressive disorders can be persistent (Unützer et al., 1997, 1999), intermittent, and/or recurrent (Little et al., 1998) and result in significant physical and psychological comorbidity and functional impairment (Katon, Lin, Von Korff, & Bush, 1994) that negatively influences the course of depression (Sherbourne & Wells, 1997).

Depression with physical illness increases levels of functional disability (Alexopoulos et al., 1996), use of health services (Beekman, Deeg, Braam, Smit, & Van Tilburg, 1997; Saravay, Pollack, Steinberg, Weinsched, & Habert, 1996), and health care costs (Callahan, Kesterson, & Tierney, 1997; Simon, Von Korff, & Barlow, 1995), particularly among older adults (Unützer et al., 1997). It also delays or inhibits physical recovery (Covinsky, Fortinsky, Palmer, Kresevic, & Landefeld, 1997; Katz, 1996).

Late-onset, unipolar depression is characteristic of suicides in later life (Bruce et al., 2004; Conwell et al., 1996; Henriksson et al., 1995). Older suicide victims often have had late-onset undetected or untreated de-

pressions, although typically they have had contact with their primary care provider prior to their death (Conwell, 1994; Van Casteren, Van der Veken, Tafforeau, & Van Oyen, 1993), presumably reflecting high rates of comorbid illness (Conwell, Rotenberg, & Caine, 1990) and/or fears of dependency or pain (Duberstein, 1995). Taken altogether, these findings support the importance of treatment of depression in late life. For further discussion of suicide in older adults, see the chapter by Adamek and Yoder-Slater in this section.

Evidence-Based Psychosocial Treatments

Psychosocial interventions have been demonstrated to be effective among the elderly, particularly those who reject medication or who are coping with low social support or stressful situations (Lebowitz et al., 1997). Evidence-based approaches, including structured cognitive-behavioral, interpersonal, and problem-solving treatments (PST), are effective alternatives or adjuncts to medication treatment (DeRubeis, Gelfand, Tang, & Simons, 1999; Gath & Mynors-Wallis, 1997; Hegel, Barrett, Cornell, & Oxman, 2002; Jacobson & Hollon, 1996; Schulberg, Katon, Simon, & Rush, 1998). There is evidence that psychosocial interventions alone are effective with older populations, including members of ethnic minority groups (Coulehan, Schulberg, Block, Madonia, & Rodriguez, 1997; Mossey, Ying, Bernal, Perez-Stable, 1996; Munoz, Knott, Higgins, & Talerico, 1995). Cognitive therapies, including PST, are particularly promising (McCusker, Cole, Keller, Bellavance, & Berard, 1998; Nezu, 2004; Robinson et al., 1995) among older men and women of diverse ethnic backgrounds (Gil, Wilson, Edens, & Webster, 1996). Patient attitudes and preference for type of treatment has been shown to affect acceptance of and adherence to the prescribed treatment for depression (Schulberg et al., 1996), and the majority of primary care patients prefer counseling over medication (Brody, Khaliq, & Thompson, 1997; Landreville, Landry, Baillargeon, Guerette, & Matteau, 2001).

Brief psychosocial interventions by nonmedical mental health practitioners are effective for medically ill populations (Mynors-Wallis, Gath, Davies, Gray, & Barbour, 1997). Adjunct written educational materials for patients and family members have been shown to improve medication adherence and clinical outcomes (Robinson et al., 1997). P. A. Arean and colleagues (1993) found robust effects in treating elderly

depression using 12 sessions of PST. Some studies have found that 6 sessions of PST are as effective as pharmacotherapy among ambulatory primary care patients with minor and major depression (Hegel et al., 2002; Mynors-Wallis, Gath, Lloyd-Thomas, & Tomlinson, 1995), are modestly effective with older adults with minor depression, and lead to greater improvement in self-reported social adjustment (Mynors-Wallis, Gath, Lloyd-Thomas, & Tomlinson, 1995). PST can also be used by therapists of different theoretical orientations (P. A. Arean et al., 1993; Mynors-Wallis et al., 1997).

Pharmacologic Interventions

During the past two decades, there have been over 30 randomized placebo-controlled clinical trials as well as many comparative trials (das Gupta, 1998; Salzman, Wong, & Wright, 2002) documenting the efficacy and safety of antidepressant medications (tricyclics and selective serotonin reuptake inhibitors [SSRIs]) for older adults with depression. There has been one trial in relatively old medically ill patients randomizing nortriptyline and placebo (Katz, Parmelee, Beaston-Wimmer, & Smith, 1994). This trial generally showed efficacy of nortriptyline but with side effects including orthostatic hypotension. Nortriptyline is effective with older adults (Reynolds, Frank, & Perel, 1995), but it may have intolerable side effects for some. One large efficacy study of fluoxetine showed efficacy but a relatively low response rate (Tollefson, Rampey, Beasley, & Gregory, 1994). Another study demonstrated that fluoxetine was equivalently effective to nortriptyline but with fewer cardiovascular side effects among a sample of late middle-aged and older adults with co-existing cardiovascular disease (Roose et al., 1997). Because the SSRIs appear to be as effective as the older tricyclic antidepressants, their use in treatment in late-life depression may result in improved outcomes due to their lower side effect profile (Schneider, 1996).

Minor Depression

Recently, attention has been given to subthreshold or subsyndromal mental disorders. As a subthreshold disorder, minor depression is viewed as a set of symptoms that does not meet full criteria for a specific depressive disorder, yet the symptoms are associated

with clinically significant impairment (Pincus, Davis, & McQueen, 1999). Minor depression is generally defined as the presence of at least two but fewer than five depressive symptoms, including depressed mood or anhedonia during the same 2-week period with no history of major depressive episode or dysthymia but with clinically significant impairment (American Psychiatric Association, 1994). Rates of minor depression range from 10% to 30% in older community-dwelling adults (Hybels, Blazer, & Pieper, 2001) and 5.2% to 8.5% in older primary care patients (Lyness et al., 1999). Minor depression has been found to be associated with an increased risk for mortality in older men and has a relatively high prevalence in some ethnic groups (Penninx, 1999). As many as 15% of older Latinos, 12% of older Asian Americans, and 10% of older African Americans meet criteria for minor depression (A. Arean & Alvañez, 2001). Cognitive-behavioral, interpersonal and problem-solving practice models appear to be promising treatments for older adults with minor depression.

Importance of Depression Screening

Much effort has been expended trying to improve the psychiatric skills of primary care physicians but with only modest effects (Lin et al., 1997; Rihmer, Rutz, & Pihlgren, 1995). Integration of specialty mental health care within primary care and system of care enhancements are found to be more effective (Meyers, 1996). Flaherty and colleagues (1998) found that a collaborative management home care intervention for depression resulted in lower hospitalization rates (23.5%) compared to a historical control group (40.6%). A randomized controlled trial with blind follow-up 6 months after recruitment found that psychogeriatric team home care versus usual primary care improved depressive outcomes for 58% versus 25% of people 65 and over (Banerjee, et al., 1996).

Leading researchers cite the need for future studies to address critical questions about feasibility, generalizability, and cost of treatment for depression in home health and primary care systems (Bruce et al., 2002; Katon et al., 1997; Schulberg et al., 1996); use of brief intervention models by nonphysicians (Brown & Schulberg, 1995); the management of detected patients (Coyne, Schwenk, & Fechner-Bates, 1995); and ways to improve access to care among low-income populations (Miranda et al., 2003). See chapter by Adamek and Yoder-Slater (this volume) for information on depression assessment scales.

ANXIETY DISORDERS IN LATER LIFE

Anxiety is defined as a subjective state of internal discomfort reflecting autonomic nervous system arousal. Anxiety becomes constructed as an emotional problem in the following situations:

- It is experienced with great frequency and intensity.
- It interferes with psychosocial functioning.
- The response is out of proportion to the stimulus.

Psychological and physical symptoms may include reduced concentration, impaired attention, impaired memory, anxious thoughts, fears, cardiac palpitations, respiratory problems, and motor, muscular, and gastric problems. *DSM-IV-TR* anxiety disorders include general anxiety disorder, panic disorder, phobias, posttraumatic stress disorder, and obsessive-compulsive disorder.

Research suggests that clinically significant anxiety symptoms affect as many as 20% of older adults living in the community. The prevalence of anxiety disorders among older adults is a serious public health issue in the United States, yet they remain underdiagnosed and undertreated. Older adults with anxiety disorders are less likely than older adults with depression or any other mental disorder to receive treatment from a mental health specialist.

Anxiety disorders are often associated with common age-related medical and chronic conditions such as asthma, thyroid disease, coronary artery disease, dementia, and sensory loss. Unfortunately, anxiety in later life has been identified as a risk factor for greater disability among older adults in general and has also been associated with less successful recruitment into and outcomes of geriatric rehabilitation services. Researchers and practitioners are beginning to recognize that aging and anxiety are not mutually exclusive: Anxiety is as common in the old as in the young, although how and when it appears is distinctly different in older adults.

Recognizing Anxiety in Older Adults

Recognizing an anxiety disorder in an older person poses several challenges. Aging brings with it a higher prevalence of certain medical conditions, realistic concern about physical problems, and higher use of prescription medications. As a result, separating a medical condition from physical symptoms of an

anxiety disorder is more complicated in the older adult. Diagnosing anxiety in individuals with dementia can be difficult, too: Agitation typical of dementia may be difficult to separate from anxiety; impaired memory may be interpreted as a sign of anxiety or dementia, and fears may be excessive or realistic depending on the person's situation.

Prevalence of Anxiety Disorders in Later Life

Anxiety disorders appear to be the most common class of psychiatric disorder among older people, more prevalent than depression or severe cognitive impairment (Beekman et al., 1998). Prevalence rates range from 0.7% to 18.6% for all anxiety disorders of individuals at least 65 years and older, with phobias and generalized anxiety disorder (GAD) most common (Flint, 1994). Other researchers summarized the prevalence of various anxiety disorders in older community-based epidemiological samples as follows: phobias, including agoraphobia and social phobia, 0.7% to 12.0%; GAD, 1.1% to 7.1%; obsessive-compulsive disorder, 0.1% to 1.5%; and panic disorder, 0.0% to 0.3% (Krasucki, Howard, & Mann, 1998).

The prevalence of clinically significant anxiety, including symptoms that do not meet criteria for a specific disorder (subthreshold anxiety syndrome), may be as high as 20% among older adults (Beekman et al., 1998). This includes anxiety symptoms associated with common medical conditions such as asthma, thyroid disease, coronary artery disease, and dementia, as well as adjustment disorders following significant late-life stressors such as bereavement or caregiving. There is also controversy over whether the prevalence of anxiety has been accurately determined in older adults, because *DSM-IV* criteria may not apply as well, and the clinical presentation of anxiety in late life may be more likely to include depressive symptoms (Fuentes & Cox, 1997).

Consequences of Anxiety in Later Life

Anxiety symptoms and disorders are associated with increased disability, lower levels of well-being, and inappropriate use of medical services among older adults (De Beurs et al., 1999). Primary care patients with untreated anxiety report functioning and well-being scores within ranges characteristic of patients

with chronic physical diseases (Fifer et al., 1994). Comorbid medical conditions such as hypoglycemia, hypertension, and coronary heart disease can be worsened through chronic stress and anxiety (Hersen & Van Hasselt, 1992). Compared with men reporting no symptoms of anxiety, men in the Normative Aging Study reporting two or more anxiety symptoms had elevated risk of fatal coronary heart disease (Kawachi, Sparrow, Vokonas, & Weiss, 1994). Higher levels of anxiety have been associated with greater use of pain-relieving medications and more postoperative disability days for surgical patients (Taenzer, Melzack, & Jeans, 1986). Anxiety was also related to pain in a sample of nursing home residents (Casten, Parmelee, Kleban, Lawton, & Katz, 1995).

Pharmacological Treatment for Anxiety Disorders

Anxiolytic medications, including the benzodiazepines, are the most common treatment for late-life anxiety (Kennedy, 2000). Epidemiological data suggest that benzodiazepine use among the elderly is approximately 14%, higher than the rates for younger adults (Swartz et al., 1991). Benzodiazepines and tricyclic antidepressants have been associated with increased risk of hip fracture (Ray, Griffin, Schaffner, Baugh, & Melton, 1987). Benzodiazepines can impair memory and other cognitive functions and can also cause tolerance and withdrawal, interactions with other drugs, and toxicity (Krasucki, Howard, & Mann, 1999).

Other medications, such as SSRIs, are often used to treat anxiety in later life because they have a lower side effect profile. However, SSRIs have not completely replaced benzodiazepines as a treatment for anxiety in older people. Benzodiazepine use among older adults decreased somewhat over a 10-year period in one recent investigation, although approximately 10% of those over the age of 65 were still taking benzodiazepines in 1996 (Blazer, Hybels, Simonsick, & Hanlon, 2000).

Psychosocial Interventions for Anxiety Disorders in Later Life

Relatively few studies have explored the treatment of anxiety in older adults (Krasucki et al., 1999; Stanley & Beck, 2000). Most have used community or senior center volunteers. For example, DeBerry and col-

leagues (DeBerry, 1982; DeBerry, Davis, & Reinhard, 1989) found significant effects on subjective anxiety for relaxation and relaxation with meditation over cognitive restructuring and pseudo-relaxation conditions. These gains were maintained at 1-year follow-up. Scogin and his colleagues (Scogin, Rickard, Keith, Wilson, & McElreath, 1992) compared the efficacy of four sessions of individual progressive relaxation (involving tensing and releasing muscle groups) or imaginal relaxation (no tensing required) to a wait-list control condition among a group of older adult volunteers who reported subjective tension or anxiety. Both active conditions significantly reduced state, but not trait, anxiety and miscellaneous psychological symptomatology relative to the control condition; neither active condition was superior to the other.

Barrowclough and colleagues (2001) reported on a randomized trial of individual, home-delivered cognitive-behavioral treatment (CBT) versus supportive counseling. Most of the sample (51%) had panic disorder, whereas 2% had social phobia, 19% had GAD, and 28% had anxiety disorder not otherwise specified. The CBT for GAD consisted of 8 to 12 one-hour sessions over a 16-week period and included the following components: psychoeducation, challenging dysfunctional cognitions and maladaptive behaviors, addressing metabeliefs about the worry process (Wells, 1997), and relapse prevention. Results provided evidence for the superiority of CBT on self-ratings of anxiety and depression, with better performance for CBT on most measures across a 12-month follow-up period.

PSYCHOTIC DISORDERS IN LATER LIFE

Psychotic disorders such as schizophrenia are among the most costly medical disorders (Cuffel, Alford, Fischer, & Owen, 1996). The high cost of care in nursing homes, state hospitals, and general hospitals contributes to the greater economic burden associated with late-life psychotic disorders. Schizophrenia is generally thought of as an illness of young adulthood, yet it can both extend into and first appear in later life. Diagnostic criteria for schizophrenia are the same across the life span, and *DSM-IV* places no restrictions on age of onset for a diagnosis to be made. Symptoms include hallucinations, delusions, disorganized speech, disorganized or catatonic behavior ("positive" symptoms), as well as affective flattening and avolition ("negative" symptoms).

Prevalence of Psychotic Disorders in Late Life

Although it is estimated that 80% of older adults diagnosed with schizophrenia developed the disorders as young adults (early onset), about 20% developed schizophrenia in middle-age (late onset; Howard, Rabins, Seeman, & Jeste, 2000). Most older adults with schizophrenia (85%) are living in the community (Cohen et al., 2000). One-year prevalence of schizophrenia among those 65 years or older is estimated at around 0.6%, about half the 1-year prevalence of the 1.3% that is estimated for the population age 18 to 54 (Howard, Rabins, Seeman, & Jeste, 2000).

Studies have compared patients with late-onset (age at onset 45 years or older) schizophrenia and similarly aged patients with earlier onset of schizophrenia (Jeste et al., 1997); both were very similar in terms of genetic risk, clinical presentation, treatment response, and course. Patients with late-onset schizophrenia were more likely to be women in whom paranoia was a predominant feature of the illness. Patients with late-onset schizophrenia had less impairment in specific neurocognitive areas of learning and abstraction/cognitive flexibility and required lower doses of neuroleptic medications for management of their psychotic symptoms. These disparities between patients with early- and late-onset illness suggest that there might be neurobiological differences mediating the onset of symptoms (Jeste et al., 1997).

Treatment of Schizophrenia in Later Life

The primary treatment of schizophrenia in later life consists of long-term use of antipsychotic medications (neuroleptics) such as haloperidol, proven effective in managing the positive symptoms (such as delusions and hallucinations) of many older patients, but these medications have a high risk of potentially disabling and persistent side effects (Jeste, Dunn, & Lindamer, 2004). Studies with mostly younger schizophrenia patients suggest that the newer, atypical antipsychotics, such as clozapine, risperidone, olanzapine, and quetiapine, may be effective in treating those patients previously unresponsive to traditional neuroleptics. They also are associated with a lower risk of side effects (Jeste & Dolder, 2003). Two barriers to the widespread use of atypical antipsychotic medications in older adults are the lack of large-scale studies to demonstrate the effectiveness and safety of these medications in older patients with multiple

medical conditions, and the higher cost of these medications relative to traditional neuroleptics (Thomas & Lewis, 1998).

SUMMARY

Mental health problems such as depression and anxiety disorders are associated with increased disability, lower levels of well-being, and increased use of medical services among older adults. Geriatric social work practitioners require specialized skill sets in assessing and managing mental disorders of late life. In examining the scientific evidence supporting routine screening for depression, for example, practitioners would be advised to review the following criteria: (1) The incidence is sufficiently high in the older adult population; (2) mental health problems have a significant impact on the older person's life; (3) effective treatments are available; (4) valid and cost-effective screening tests are available; and (5) adverse effects of screening should be acceptable to patients and clinicians. The goal of screening is early identification and thus prevention through early intervention to reduce costs and improve the quality for life for older adults. The implications of not detecting the possibility of mental disorders in the elderly are serious.

Alcohol and drug abuse and misuse among older adults are one of the fastest growing public health problems in the United States (U.S. Department of Health and Human Services [DHHS], 1999). The problems, however, remain underdiagnosed and undertreated and have been referred to as an invisible epidemic (Center for Substance Abuse Treatment [CSAT], 1998). With the aging of the baby boomers, a cohort with more liberal attitudes toward substance use than previous cohorts, the problem is expected to increase in the coming years (DHHS, 1999). As with the younger population, the three types of substance abuse among older adults are alcohol abuse, medication abuse and misuse, and illicit drug use.

ALCOHOL ABUSE

Although alcohol abuse declines with age, it is estimated that 4% to 20% of community-dwelling older adults abuse alcohol (Adams, Garry, Rhyne, Hunt, & Goodwin, 1990). According to some reports, 20% of the residents in retirement communities have two or more drinks per day (Gurnack, 1997). The National Institute of Alcohol Abuse and Addictions recommends that older adults consume no more than one drink per day because of age-related physical changes (Dufour, Archer, & Gordis, 1992).

In health care settings, 6% to 11% of older adults exhibit symptoms of alcoholism (Ondus, Hujer, Mann, & Mion, 1999). The rates for alcohol abuse among older adults in psychiatric settings and emergency rooms are 20% and 14%, respectively (CSAT, 1998). In acute care settings, just as many older adults are admitted for alcohol-related problems as for heart attacks (Adams, Yuan, & Barboriak, 1993).

As with younger populations, alcohol abuse and dependence are more common among older men than women. Approximately 4 times the number of older men than women abuse alcohol (CSAT, 1998). Although alcoholism rates are higher for Whites among younger men and women, the rates among older adults are higher among African American men and women and Latino men. Latinas, on the other hand, have much lower rates than Whites or African American women (Helzer, Burnam, & McEvoy, 1991).

Older adults who abuse alcohol can be categorized into early- and late-onset groups (Benshoff, Harra-wood, & Koch, 2003). It is estimated that two-thirds of older adults are early-onset drinkers who developed alcohol problems while young (Rigler, 2000). These adults suffer from various physical and psy-

TAZUKO SHIBUSAWA

Older Adults With Substance/Alcohol Abuse Problems

12

chological consequences of long-term alcohol abuse, such as impaired cardiovascular, digestive, neurological, and skeletal functioning (Atkinson, Tolson, & Turner, 1990). Late-onset drinking is often precipitated by life events such as retirement, death of a spouse or partner, loss of status, and chronic health problems as well as loneliness and depression (Atkinson et al., 1990; Rigler, 2000). The prognosis for later-onset drinkers is better than that for early-onset drinkers because they have not suffered from the physical and psychological consequences of long-term abuse (Benshoff et al., 2003).

MISUSE OF PRESCRIPTION AND OVER-THE-COUNTER MEDICATION

Older adults consume large amounts of prescription drugs and over-the-counter (OTC) medications. They are estimated to spend \$15 billion annually on prescription drugs, which is 4 times the amount spent by younger populations (DHHS, 1999). An average older patient takes 5.3 prescription medicines per day (Gurnack, Atkinson, & Osgood, 2002). OTCs that are commonly used by older adults include pain relievers, sleeping aids, cold remedies, antacids, laxatives, and vitamins (CSAT, 1998).

When discussing prescription and OTC medication abuse, it is important to distinguish between the terms *misuse* and *abuse*. Misuse refers to the inappropriate use of medications and includes underuse, overuse, and erratic use (DHHS, 1999). Misuse can be caused by difficulties with reading and following prescription labels, keeping track of medications, and taking inappropriate dosages. Vision and hearing loss can increase the misuse of prescription and OTC medication among older adults. Misuse can also be caused by inappropriate prescribing by physicians. Abuse, on the other hand, refers to the use of medication in a way that is nontherapeutic and not for its intended purposes (Ondus et al., 1999). A typical form of abuse occurs when older adults use prescription or OTC medications as a form of self-medication.

Psychoactive drugs tend to be more misused than other medications. Older adults use 2 to 3 times more psychoactive drugs than do younger groups (Sheahan et al., 1995). Benzodiazepines, which are prescribed for conditions such as insomnia, anxiety, and chronic pain, are prescribed widely among older adults. Studies report that 17% to 23% of drugs prescribed to older adults in North America are benzodiazepines (D'Archangelo, 1993). Older women are more likely

than men to receive psychoactive drugs, and drug dependence is more common among older women than men (Adams et al., 1990).

ILLCIT DRUG ABUSE AND DEPENDENCE

Older adults use fewer illicit drugs such as marijuana, cocaine, and heroin than younger populations. Recent studies, however, cast doubt on the "maturing-out theory," which contends that people age out of illicit drug use or die prematurely from abuse (Levy, 1998). According to the 2000 National Household Survey on Drug Abuse (NHSDA), 568,000 adults age 55 or older (1% of all older adults in the United States) reported using illicit drugs in 2000 (SAMHSA, 2001). Methadone treatment and needle exchange have added to the longevity of heroin and injection drug users. In addition, there are a number of older adults who start to use crack cocaine for the first time after age 50 (Johnson & Sterk, 2003).

A major concern related to this phenomenon is HIV transmission because sexual risk behavior is a critical exposure category for HIV infection among older injection drug users (Kwiatkowski & Booth, 2003). As mentioned earlier, baby boomers as a cohort are more accepting of illicit drug use (DHHS, 1999) which could result in an increase in illicit drug use and HIV exposure.

EFFECTS OF ALCOHOL AND SUBSTANCE ABUSE ON OLDER ADULTS

Older adults have a decreased tolerance for alcohol and drugs. Their bodies do not absorb food and drugs as well as they did in their younger years. Because of reduced body mass and body water, slowed metabolism, and decreased absorption rate in the gastrointestinal system, alcohol and drugs remain in the body for longer periods of time and at higher rates of concentration (Benshoff et al., 2003). Alcohol, prescription drugs, and illicit drugs have stronger effects on older than younger adults, especially when they are used in combination.

Long-term alcohol use can result in malnutrition, osteoporosis, decreased red blood cell production, increased cancer risk, myopathy, hypertension, hepatitis, pancreatitis, stroke, dementia, and esophagitis/gastritis (Gurnack, 1997). Depression is often comorbid with alcohol and substance abuse; mood and anxiety disorders can be exacerbated by alcohol or drug use. Pre-

scription or OTC medication misuse or combining drugs with alcohol can lead to decreased functional capacity and cognition, including impairment of memory and attention, excessive sedation, delirium, and greater risk for falling (Benshoff et al., 2003). Psychoactive medication when taken with alcohol can have serious consequences. For example, benzodiazepines when mixed with alcohol can result in decreased alertness, impaired judgment, respiratory failure, and falls and accidents (CSAT, 1998).

IDENTIFICATION OF ALCOHOL AND SUBSTANCE ABUSE

Although alcohol abuse by older adults is less prevalent than in younger populations, it is more difficult to detect, particularly because the workplace is where alcohol and drug problems are frequently detected. In particular, older adults who are White, female, or of upper-middle-class background are less likely to be identified by health care providers because they do not fit the stereotype of someone who has an alcohol or drug problem (CSAT, 1998). Other risk factors for alcohol and substance abuse are listed in Table 12.1.

Questions about alcohol and substance use are rarely included in routine intake sessions in health care and social service settings. Symptoms of alcohol and substance abuse often present as age-related problems such as insomnia, gastrointestinal problems, sexual dysfunction, forgetfulness, dementia, and depression, further deterring service providers from exploring the possibilities of alcohol and substance abuse (Ondus et al., 1999; see Table 12.2). The trend toward shorter medical visits and the shortage of providers with training in geriatric medicine also serve as barriers to the detection of alcohol and substance problems (CSAT, 1998).

Patient-related deterrents to identifying alcohol and drug problems in older adults include a lack of awareness or denial on the part of the elder. In addition, older adults in general are reluctant to seek non-medical help such as counseling and mental health care because of stigma and shame. This reluctance de-

ters older adults with substance abuse problems from accepting referrals for treatment even when made by the provider.

Perhaps not surprisingly, caregivers and health care professionals often shy away from confronting the older adult or referring him or her for treatment. Some believe that older adults should not be forced to give up a life-long habit that is one of the few pleasures left for them to enjoy. They believe that forcing abstinence would be cruel. Another reason for inaction is a mistaken assumption that alcohol and substance abuse treatment is not effective for older adults. Research, however, indicates that older adults have better outcomes for treatment than younger adults (Curtis, Geller, Stokes, Levine, & Moore, 1989).

Screening Instruments

Screening instruments that have been utilized with older adults include the CAGE, the Michigan Alcohol Screening Test–Geriatric Version (MAST-G), and the Alcohol Use Disorders Identification Test (AUDIT; CSAT, 1998). The CAGE (Ewing, 1984) is used commonly in assessment and evaluations and has been used by physicians examining older patients (Fleming, 2001). However, the questions need to be modified when inquiring about prescription of OTC medicine misuse and abuse (CSAT, 1998; see Table 12.3).

The MAST-G includes items that address issues related to aging such as increased drinking following death and losses (Blow et al., 1992). AUDIT is a 10-item survey that measures negative alcohol-related consequences and descriptions of total alcohol consumption. According to research, MAST-G is more sensitive than AUDIT for identifying alcoholism in older adults (Menninger, 2002).

It is important to note that these screening instruments are limited in that they rely on client self-report. Screening questions need to be integrated into health assessments or other forms of assessments in a confidential setting. The questions should be asked in a nonjudgmental manner and as part of a health assessment to lessen the sense of stigma for older adults.

TABLE 12.1. Risk Factors for Alcohol and Substance Abuse Among Older Adults

Depression/anxiety	Homebound	Retirement
Loss and bereavement	Chronic pain	Loss of employment
Social isolation	Loss of physical mobility	New caregiving role
Living alone	Loss of spouse or partner	

TABLE 12.2. Signs of Possible Alcohol and Substance Abuse in Older Adults

Dementia	Depression/anxiety	Mood swings, irritability
Dulling of senses	Recent memory loss	Disorientation
Swelling	Inflammation of joints	Slowed thought process
Indigestion	Malnutrition	Heart disease
Changes in sleep patterns	Changes in eating habits	Lack of energy
Loss of short-term memory	General loss of interest	Social isolation
Unexplained accidents and falls	Self-neglect	Tremors

AGE-SPECIFIC TREATMENT FOR ALCOHOL AND SUBSTANCE ABUSE

Intervention and treatment for alcohol and substance abuse depends on the severity of the problem and includes educational sessions, outpatient care, residential care, and psychiatric hospitalization (DHHS, 1999). It is important that all levels of intervention are tailored to meet the physical, psychological, and social needs of older adults (Schonfeld & Dupree, 1995; Zimberg, 1996). Programs serving older adults should include the following:

1. Identify and address stressors that are related to the aging process, such as loss and bereavement.
2. Assess and understand alcohol and substance abuse problems in the context of the life stage of the older adult.
3. Focus on enhancing (or rebuilding) the client’s social support network.
4. Assist clients in restoring a sense of self-worth by helping them to develop or maintain activities of interest.
5. Refer clients to services that are age-sensitive and age-appropriate, such as Alcoholics Anonymous for seniors.
6. Attend to aspects of the older adult’s life such as nutrition, activities of daily living, and physical functioning.

7. Link clients with medical and social services such as housing, transportation, and senior programs.
8. Maintain a flexible treatment program that meets the changing physical, psychological, and social needs of the clients.

Practitioners and researchers note that alcohol and substance abuse treatment for older adults needs to be more supportive and less confrontational than interventions for younger populations (Schonfeld & Dupree, 1995). Because older adults are reluctant to receive help, especially important are developing a trusting relationship and a nonjudgmental attitude on the part of the service provider.

Barriers to treatment must also be addressed before referring older adults for services. Facilities where programs such as Alcoholics Anonymous (AA) meetings are offered must be able to accommodate functional disabilities such as ambulation problems. Transportation to programs must be secured and special accommodations need to be made for older adults with vision and hearing losses. Service providers must also attend to financial resources so that older adults can pay for treatment. Medicare requires a 50% copayment for the treatment of substance abuse problems (CSAT, 1998). This can be a challenge for service providers in finding affordable treatment for older adults.

TABLE 12.3. CAGE Questions

- (a) Have you ever tried to cut down on your drinking?
- (b) Do you become annoyed when others ask you about your drinking?
- (c) Do you ever feel guilty about your drinking?
- (d) Have you ever used alcohol in the morning, taking an “eye-opener”?

Service providers conduct a more thorough assessment of alcohol abuse if a client answers yes to any of the above questions.

Note. One drink equals 12 ounces of beer, 1.5 ounces of distilled spirits, or 5 ounces of wine.

INTERVENTIONS AND TREATMENT

Educational and Psychological Interventions

Single-session *educational interventions* have been effective for older adults who are not aware that they are consuming too much alcohol or misusing medications (CSAT, 1998). Some practitioners use the CAGE screening questions, then educate older adults about alcohol consumption while reviewing the results of the screening. Interventions for older adults who misuse prescription or OTC medications include medication checklists and home visits by care providers to remove unwanted pills from the home (CSAT, 1998).

Psychological intervention strategies include unstructured and structured counseling to motivate older adults to change their behaviors to reduce alcohol and substance use. Although traditional treatment emphasizes total abstinence, a harm-reduction approach, which focuses on clients' readiness to change, has been increasingly utilized in the field of substance abuse treatment. Research indicates that counseling that employs motivational interviewing, which helps clients develop a desire to change, has been effective for older adults (Fleming, 2001). Another therapy modality that has been found to be effective for this population is cognitive-behavioral therapy (CBT; Barrowclough et al., 2001; Schonfeld & Dupree, 1995). CBT has also been effective in working with older adults with chronic pain, depression, and anxiety.

CBT can be conducted in individual as well as group sessions. Group interventions that have been effective working with older adults with alcohol problems include psychoeducation and self-help groups such as AA. Couples and family interventions are also useful in resolving conflicts between the older adult and his/her spouse or partner and between the older adult and other family caregivers (CSAT, 1998).

Detoxification and Psychopharmacological Interventions

Withdrawal from alcohol can be a life-threatening medical emergency for older adults with significant physical dependency on alcohol. Compared to younger adults, withdrawal can take longer, and hospitalization is recommended for the detoxification of older adults because of potential medical complications (CSAT, 1998).

The use of medications to inhibit alcohol use among older adults has not been adequately studied (DHHS, 1999). Disulfiram (Antabuse), a medication that is used to deter patients from alcohol consumption, causes toxic reactions when a patient consumes even a small amount of alcohol. It can have side effects for older adults such as confusion and memory impairment. One medication that has been proven effective in reducing cravings for alcohol when used in conjunction with counseling is naltrexone (ReVia), and it has been reported to be safe for older adults (Oslin, Liberto, O'Brien, Krois, & Norbeck, 1997; DHHS, 1999).

Spirituality is receiving increasing attention as playing an important role in recovery from alcohol and substance abuse (CSAT, 1998). However, studies of programs that employ spirituality in assisting this population with alcohol and substance abuse problems are absent from the literature. Seeking help from clergy and being involved in spiritual communities, however, has been found to have positive outcomes among older adults (CSAT, 1998).

CONCLUSION

Alcohol and substance abuse problems in older adults are less likely to be recognized by health care providers than in younger populations because the symptoms are often mistaken for problems associated with aging such as dementia and depression. The high prevalence of older adults who receive prescription medication also exacerbates the risk of medication misuse and abuse. Furthermore, lack of awareness of this problem among family members and denial on the part of elders often deters them from receiving appropriate treatment.

Although it is difficult to identify and treat older adults with substance abuse problems, research indicates that once elders are in treatment they have better outcomes than younger adults. Evidenced-based treatments such as CBT, when tailored to the specific needs of older adults, have been proven effective in treating alcohol and drug abuse in this population. With demographic changes resulting in an increase in the number of older adults at risk for alcohol and substance abuse, it is important for social workers to be able to identify the symptoms and signs of abuse and provide age-appropriate treatment.

THE NATURE AND SCOPE OF ELDER SUICIDE

Adults age 65 and over have the highest suicide rate of any age group in the United States. In 2001 5,393 persons age 65 and older took their own lives—an average of 16 per day (Centers for Disease Control and Prevention [CDC], 2004a). That translates into approximately one older adult suicide in the United States every 90 minutes (Center for Elderly Suicide Prevention & Grief Counseling, 2004). Although they are 1 out of 8 (12.8%) individuals in the population, older adults accounted for nearly 1 in 5 (19%) suicides (American Association of Suicidology, 2003). Older adults' rate of suicide, 16.8 per 100,000 in 1997, was significantly higher than the rate for young adults (age 15 to 24), which mirrored the national rate of 11.4 per 100,000 (Murphy, 2000). Not surprisingly, the surgeon general's *Call to Action to Prevent Suicide* (U.S. Public Health Service, 1999) identified older adults as a priority group for research and intervention.

It is likely that official rates of elder suicide are undercounted. Clark (1992) estimates that 5% of suicides in the United States go unreported in mortality data. The stigma attached to suicide and the potential loss of insurance benefits are two factors that likely contribute to this phenomenon. In addition, deaths resulting from self-neglect or “intentional life-threatening behaviors (ILTB)” (Osgood, Brandt, & Lipman, 1991) are not typically labeled a suicide. Farberow (1980) used the term “subintentional suicide” to describe a collection of covert behaviors such as refusing to eat, drink, or take required medications, and other forms of self-neglect. This class of behaviors is also called “intentional self-destructive behaviors” and was the focus of Osgood's research in long-term care (LTC) facilities (Osgood, 1992; Osgood, Brandt, & Lipman, 1989, 1991). Estimates from probability-based national samples of LTC facilities have found overt rates of suicide of 15.8 deaths per 100,000 and deaths due to ILTB as high as 94.9 per 100,000 (Osgood et al., 1991). A study in New York found the overt rate of suicide in LTC was 19.7 per 100,000 (Abrams, Young, Holt, & Alexopoulos, 1988).

Despite documentation that thousands of older adults in the United States kill themselves each year, suicide remains a “relatively silent epidemic” (Dahl, 2004). As helping professionals we must be informed about the extent and nature of elder suicide.

Suicide among older adults is a complex phenomenon, with many risk factors and seemingly few protective factors. A variety of risk factors, including age,

Older Adults at Risk for Suicide

13

gender, race, physical and mental health, multiple losses (e.g., retirement, widowhood, functional ability), and access to lethal means, have been associated with increased suicide risk in late life. Older men have a suicide rate about 5.5 times that of older women (CDC, 2004a). In fact, males 75 and older have the highest rates of suicide in nearly all industrialized countries (Conwell et al., 2002; Pearson, Conwell, Lindsay, Takahashi, & Caine, 1997; World Health Organization [WHO], 2003). Although ethnic minority elders have often faced significant structural obstacles such as racism, oppression, and overt and covert discrimination throughout their lives, they are unlikely to commit suicide. African American older women have the lowest rates of suicide among their age cohort (CDC, 2002). In contrast, White men over 85 are at the greatest risk of suicide, with rates nearly 6 times the national rate (National Center for Health Statistics [NCHS], 2000).

Epidemiological studies have revealed several important differences between older and younger suicides. Duberstein and colleagues (1999) found that increased age was associated with significantly less suicidal ideation; older adults often do not give warnings about suicide and seldom seek mental health treatment. Not only are older adults less likely to seek treatment, but physicians are less likely to offer treatment for depression to older patients (Uncapher, 2000). There are also age differences with regard to substance abuse and suicide. Garlow (2002) found that older adults were the least likely group to have alcohol or inhalants in their body at autopsy following suicide. Adults over 65 have a much lower attempt-to-completion rate (4:1) than younger people, whose rate is estimated to be between 8:1 and 200:1 (McIntosh, Santos, Hubbard, & Overholser, 1994; Szanto et al., 2002). It is likely that these rate differentials reflect the fact that older adults frequently have more health problems, are more likely to live alone, tend to avoid interventions, are less likely to communicate suicidal ideation, take precautions to avoid discovery, and are less likely to be detected immediately after an attempt (Duberstein et al., 1999; Szanto et al., 2002). In addition, older adults are more likely than younger persons to use a firearm to end their lives (NCHS, 2000).

Physical illness is more prevalent with advancing age and has been widely identified as an issue in suicide completions among older adults (McIntosh et al., 1994). Nevertheless, it is estimated that only 2% to 4% of terminally ill older adults kill themselves (Szanto et al., 2002). The risk of suicide is significantly increased among older adults with certain illnesses. Using a

population-based controlled study, Juurlink, Herrmann, Szalai, Kopp, and Redelmeier (2004) found an increased suicide risk for older adults with depression, bipolar disorder, severe pain, and several other chronic illnesses, including seizure disorder, congestive heart failure, and chronic lung disease. Furthermore, treatment for multiple illnesses was strongly associated with an increased suicide risk. Chronic physical illness has been associated with higher risk of completed suicide when accompanied by depression (Szanto et al., 2002). Researchers suggest it is actually the comorbid depression or mental illness that increases suicide risk (Harris & Barraclough, 1994).

Many older adults, as many as 20%, experience mental health problems that are not associated with normal aging (U.S. Department of Health and Human Services [DHHS], 1999). Depression has been well-established through several recent meta-analyses as a risk factor for suicide (Bartels et al., 2002; Kleespies & Dettmer, 2000; Oei & Free, 1995; Szanto et al., 2002). Among older adults, depression is associated with suicide in approximately 90% of cases (DHHS, 1999). Many instrument development studies have documented the correlation between depression and suicidal ideation or suicide risk (Beck, Kovacs, & Weissman, 1979; Brown, n.d.; Szanto et al., 2002). Although there is a strong link between depression and suicide, not all depressed people kill themselves. Clinically, it is important to distinguish between those at high risk of suicide and those who are depressed.

The cumulative effect of multiple losses in late life—of roles, functional ability, relationships, and resources—has been associated with depression and suicidality. For example, studies have demonstrated higher rates of suicide among divorced and widowed elders (McIntosh et al., 1994; Stillion & McDowell, 1996). The greatest challenges and needs are among the oldest-old (ages 85+), who more often have significant health restrictions and require assistance with activities of daily living (ADL) and instrumental activities of daily living (IADL; McInnis-Dittrich, 2002; Quadagno, 1999). Although there are many exceptions to the frail-elder stereotype, many in this age group have significant needs that make them vulnerable to depression.

Perhaps the least understood risk factor for elder suicide is access to lethal means. Numerous studies link access to lethal means, primarily firearms, to higher rates of suicide (Conwell et al., 2002; Cutright & Fernquist, 2000; Kellerman et al., 1992; Killias, van Kesteren, & Rindlisbacher, 2001; Miller, Arazel, & Hemenway, 2002; Romero & Wintemute, 2002; Shenassa, Catlin, & Buka, 2003; Wiebe, 2003). Inter-

national comparisons point to increased suicide death when a gun is available. For example, the UK has a low percentage of households with guns (4%) and a relatively low suicide rate (.03 per 100,000). By comparison, in Canada, 26% of households have a gun and the suicide rate is 3.35. In the United States, 41% of households have guns and the suicide rate is 7.23—nearly twice the rate of the UK and Canada combined (Cukier, 1998).

Firearms are the most common method of suicide for both men and women (see Table 13.1), including older adults. Between 1980 and 1992, firearm-related suicides increased from 60% to 69% among older adults (Adamek & Kaplan, 1996), and this upward trend has persisted. The firearm suicide rate for older women has increased 10% since 1979, replacing poisoning as the most commonly chosen method of suicide among older women (Adamek & Kaplan, 1996). Firearm-related suicides accounted for 70% of all suicides among older adults from 1990 through 1996: 77.3% of suicides among men and 34.4% among women (CDC, 2002). Whereas the rate of firearm suicide among youth has been decreasing (CDC, 2004b), it has increased over time for older adults (see Table 13.2). In 2000, 73% of older adults who killed themselves used a firearm (CDC, 2002).

Access to a firearm may be the aggravating factor differentiating attempts from completions among older adults when other high-risk factors are present, such as isolation, retirement stress, and depression. Using the psychological autopsy method, Conwell and colleagues (2002) examined the suicide deaths of 86 victims age 50 and older. They matched the victims with 86 community-dwelling residents on age, sex, race, and county of residence and found that, even after controlling for psychiatric illness, the presence of a handgun was associated with increased risk for

suicide. Clearly, social workers need to be aware of the risk factors for suicide among older adults: age, race, gender, physical and mental health, cumulative loss, and access to lethal means. We need a better understanding of how multiple risk factors interact to increase the suicide risk among this population.

EVIDENCE-BASED PRACTICES WITH SUICIDAL ELDER

Psychological risk factors found to be associated with elder suicide include chemical imbalances, learned helplessness, personality disorders, unmet needs, irrational thoughts, and attachment problems (McIntosh et al., 1994; Stillion & McDowell, 1996). It is beyond the scope of this chapter to discuss the theoretical context of elder suicide; instead, we offer several useful sources for more information. McIntosh et al. give a thorough summary of original sources examining various psychological approaches to understanding suicide: psychoanalytic (Achté, 1988; Adler, 1968; Kastenbaum & Aisenberg, 1972), behavioral (Beck, 1995; Jerger, 1979; Seligman, 1975), personal construct theory (Hughes & Neimeyer, 1990; Kelly, 1955; Neimeyer, 1983), and the cubic model of suicide (Schneidman, 1985). The common thread in the various psychological theories of suicide is a focus on the individual psyche and sense of agency.

When practicing with high-risk clients, clinicians must take time to conduct frequent, comprehensive suicide risk assessments to learn if the individual is experiencing suicidal ideation. Several treatment approaches have been empirically tested for intervention with suicidal elders, including cognitive-behavioral therapy (CBT), interpersonal therapy, psychopharmacology, and crisis intervention services.

TABLE 13.1. Cause of Death Among 1998 Suicide Victims (All)

<i>Method of Suicide</i>	<i>Male (percentage)</i>	<i>Female (percentage)</i>	<i>Total Number</i>
Firearm	61.6	38.4	17,424
Drugs, medicaments, and biologicals	6.4	26.1	3,138
Hanging, strangulation, or suffocation	19.2	16.8	5,726
Gases and vapors	5.4	6.7	1,726
Solid or liquid poisons	0.6	1.0	208
All other (fire, falling, cutting, drowning, and unspecified)	6.9	11.0	2,353
Total number of suicides in 1998	24,538	6,037	30,575

Cognitive Therapy/ Cognitive-Behavioral Therapy

There are several variations of cognitive and cognitive-behavioral therapies, but all share the basic idea that thinking and behavior are learned and can be unlearned as well. Several prominent experts have written about CBT and the ways that thinking affects behavioral outcomes (Adler, 1963; Beck, 1995; Ellis, 1962). For example, when a person is depressed, thoughts like “I am worthless” come to mind. In reality, the person has worth, so the thinking is considered irrational and the person can work on replacing those negative thoughts with positive, more realistic ones like “I make mistakes sometimes.” This process takes training and often requires exercises outside of the therapy setting to “cognitively restructure” the client’s thinking process. McInnis-Dittrich (2002) provides a good overview of CBT as it is practiced with older adults. Bartels and colleagues (2002) summarized meta-analyses of psychosocial treatments for geriatric depression and reported significant evidence for using cognitive and cognitive-behavioral therapy with suicidal and depressed elders.

Interpersonal Therapy

Interpersonal therapy, or solution-focused therapy, is the process of identifying problems that cause interpersonal or personal distress. McIntosh and colleagues (1994) emphasize that interpersonal therapy emphasizes role transitions and conflict, social skills training, and complicated grief. This type of therapy is expected to be time-limited and focused on tangible, specific problems. Both individual and group

psychosocial interventions have been shown to be effective with depressed older adults (e.g., Husaini et al, 2004; Schwartz, 2004).

Psychopharmacology

Psychopharmacology is the use of psychotropic medications to alter mood. It is the most common intervention for depression in late life (Blazer, 2003). Clinical trials have demonstrated the effectiveness of selective serotonin reuptake inhibitors (SSRIs) for reducing suicidal ideation and behavior (Hawton et al., 1998). Bartels et al. (2002) summarized the extensive research on antidepressant medication and recommend the use of SSRIs (e.g., Prozac, Zoloft, Paxil, Celexa). These medications have highly effective treatment benefits and far fewer side effects than the older monoamine oxidase inhibitors and tricyclics (Bartels et al., 2002). These authors also note that despite the evidence supporting the use of antidepressants, organizational obstacles and poor service coordination often interfere with compliance and management of medications. It is interesting to note that none of the 26 studies reviewed by Bartels et al. mentioned strategies to reduce firearms or at least screen for them in the assessment or intervention process.

Combination Therapies

Although a combined psychosocial-pharmacologic approach for treating geriatric depression has been recommended for some time (National Institutes of Health Consensus Panel, 1992), too often psycho-

tropic medication is the only intervention for depressed elders (Adamek, 2003). A comprehensive review of geriatric suicide and parasuicide literature by Szanto and colleagues (2002) confirmed the recommendation for combination therapies, specifically CBT with an SSRI protocol. These researchers are involved with a multisite collaborative research study funded by several National Institute of Mental Health grants, the Prevention of Suicide in the Primary Care Elderly Collaborative Trial (PROSPECT; Brown, Bruce, & Pearson, 2001; Luoma, Martin, & Pearson, 2002; Mulsant et al., 2001; Raue et al., 2001). The aim of the study is to evaluate the effectiveness of a multidisciplinary primary care intervention in preventing and reducing suicidal ideation and behavior, associated hopelessness, and depressive symptoms in a population-based sample of older adults. Preliminary results suggest that the intervention has been effective in reducing the number of suicides among older primary care patients (Mulsant et al., 2001). The PROSPECT studies provide strong support for routine screening for depression among older adults and for the use of combination, multidisciplinary approaches to preventing suicide. Callahan (2001) notes that the systems of care for late-life depression have not caught up with the latest research. He also suggests that older patients have a responsibility to be motivated and informed about their own treatment for depression.

Crisis Intervention Services

Although many studies assess suicidal ideation or a specific treatment regimen for particular diagnoses, few studies guide clinicians about evidence-based practice with acutely suicidal elders. Kleepsies and Dettmer (2000) conducted a meta-analysis of studies addressing strategies for managing acutely suicidal patients of all ages. They stress the importance of viewing risk factors within a framework of comprehensive suicide assessment. At the point of acute suicidal emergency, it is important to thoroughly assess for comorbid features. A high-risk profile includes depression with comorbid alcohol abuse, insomnia, decreased concentration, anxiety, obsessive-compulsive features, and previous history of suicide attempts. Despite the thoroughness of their review, Kleepsies and Dettmer (2000) do not discuss or explain the differences between older and younger adults in managing acute suicidal emergencies. At the time this chapter was written, no meta-analyses of interven-

tions for older adults in suicidal crisis or best practice guidelines for work with acutely suicidal elders had been published (Yoder, 2004).

BEST PRACTICE MODEL

Given the lack of evidence-based practices for acute suicidal emergencies with older adults, we recommend the following model as a *promising practice* for reducing older adult suicidal behavior. The CBT model of intervention with older adults has demonstrated effectiveness with depressed and suicidal elders (Bartels et al., 2002; Hawton et al., 1998; Wampold, Minami, Baskin, & Tierney, 2002). The premise of this therapeutic strategy is to identify *cognitive distortions* and formulate more realistic alternative thoughts, which then lead to changes in behavior. Because CBT is not recommended for those with cognitive disabilities or dementia, helping professionals may need to assess for cognitive deficiencies. This type of therapy is not recommended for people with mental illness of the psychotic or organic type, such as Alzheimer's disease.

Phase I: Orientation, Preparing, and Beginning

The clinician-client relationship is the most important part of the therapeutic endeavor. When meeting an older adult client for the first time, it is important to make good eye contact, unless that is not considered respectful by the client's culture. (Alemán, Fitzpatrick, Tran, & Gonzales, 2000 provide a useful review of cultural issues in working with ethnic elders.) If the older adult has been referred because of suicidal ideation or behavior, it is particularly important to maintain a calm, empathic presence during the interview. Brown et al. (2001) recommend being attentive and present for the person while interviewing. Although this seems simply basic advice, it is sometimes true that this initial level of empathy and intervention is successful in reducing the suicidal ideation. Many older adults are aging in place, which often means they do not have many contacts outside their home. Clients should be given time to talk and not have to rush through an assessment with a prescribed explicit agenda. It is necessary to use an assessment instrument, but it is damaging to the therapeutic relationship when a client feels like "just another case." Multidisciplinary, combination therapy is recom-

mended for reducing suicidal behavior among older adults, and a thorough medical and mental health assessment is essential for developing a treatment plan with older adults at risk of suicide.

During the assessment phase, clinicians should use valid, reliable instruments designed for older adults. There are many well-developed instruments for assessing suicide risk and the often-associated diagnosis of depression (see Appendix 13.1). The Beck Depression Inventory (BDI), Center for Epidemiological Studies Depression Scale (CES-D), and Geriatric Depression Scale (GDS) are the most widely used and offer highly valid and reliable results in assessing depression. One particularly useful instrument, the Geriatric Depression Scale (Brink et al., 1982), is available in a long (30-item) or short (15-item) form and in several languages. A recent modification of the GDS is geared toward a residential population (Sutcliffe et al., 2000). An online version provides an automatically scored format, allowing older adults to screen themselves as an assignment for therapy, to assess their own progress, and to determine outcomes at the completion of therapy (Yesavage, 2003).

After forming an alliance, there are several good ways of addressing suicidal ideation and plans for suicidal behavior. Szanto et al. (2002) recommend asking the older adult the following questions:

- Have you been feeling so sad lately that you were thinking about death or dying?
- Have you had thoughts that life is not worth living?
- Have you been thinking about harming yourself?

Given that 73% of older adults who committed suicide in 2000 used a gun, we want to emphasize the importance of asking specific questions about firearms, for example, “Do you have any guns at home?” If the client answers affirmatively, then it is crucial to follow up with the question, “Have you thought about using the gun to end your life?” or “Do you have plans to use the gun to end your life?” These questions may seem blunt, but it is important to ask clients about plans and means to end their life.

Sherman et al. (2001) demonstrated the efficacy of a multidisciplinary Firearms Risk Management (FRM) program with suicidal adults (N=46). In addition to tracking gun availability using a firearms flow sheet, the social worker took several steps to neutralize the risk of the patient’s using a firearm to commit suicide upon discharge. These steps included contacting the patient’s family and case manager as well as

law-enforcement officials. The social worker provided gun-risk education and worked with families to remove the gun from the home. The multidisciplinary team provided ongoing consultation and evaluation. Neutralization of the risk of firearm use was stable for 89% of the sample at 24 months. In other words, only 5 of 46 patients threatened the use of a gun or had access to a firearm following the intervention. Though not yet tested with older adults, this model offers a promising direction for the reduction of firearm suicide in late life.

Phase II: Contracting

No-harm contracts, as they are sometimes called, were initially designed to manage and document suicide risk (Miller, 1999). The American Psychiatric Association (APA; 2003, p. 41) states:

Since the utility of the suicide prevention contract is based on subjective belief rather than objective evidence, it is over-valued as a clinical or risk management technique. Furthermore, the suicide prevention contract is not a legal document and cannot be used as exculpatory evidence in the event of litigation.

Thus, these contracts should not be used as the only accountability measure with suicidal older adults, but they are one way to demonstrate that the issues of safety and emergency contact procedures have been discussed and documented. Such contracts for safety have no demonstrated effectiveness and are *contraindicated* with clients who are new, in active psychosis, under the influence of substances, or agitated (APA, 2003). With older adults, this might include persons with dementia or who are heavily medicated.

Although suicide prevention contracts have limited effectiveness, they can be helpful as a means of communicating who, what, and how to contact professional help in a suicide crisis (APA, 2003). Miller, Jacobs, and Gutheil (1998) outline a model of suicide prevention treatment that uses informed consent to outline risks and benefits of treatment with clients in order to assess the client’s willingness to form a therapeutic alliance with the clinician. When the suicide prevention contract is used alone, as an agreement that the client will not harm himself or herself, the real issue is the strength of the therapeutic alliance. If a client is unwilling to sign the contract, he or she is really putting the clinician on notice that the therapist

tic alliance is in jeopardy and the suicide risk needs to be reassessed (APA, 2003). When practicing with high-risk clients, clinicians must conduct frequent, comprehensive suicide risk assessments and thoroughly document such procedures.

In the CBT model, establishing a plan (or contract) for therapeutic work with the client is as important as frequent, comprehensive risk assessments. A therapeutic contract—not to be confused with a no-harm, suicide prevention contract or a contract for safety—is an agreement between therapist and client on the scope, goals, and procedures for therapeutic change. Clients are expected to work at least 30 minutes each week on the assigned homework regarding their thinking patterns. Clients can be given assignments on a schedule or as they fit into the session.

Phase III: Working and Evaluation

Several useful tools are available for working long term with older clients who are at risk of suicide. Burns's *Feeling Good Handbook* (1999) and *Ten Days to Self-Esteem* (1993) are client-directed workbooks that come with evaluation instruments and tracking sheets to record data each week about the client's mood, thoughts, progress, and homework. Another useful resource is the *Therapist's Tool Kit* (Burns, 2003), which includes tools for keeping the client on track and for demonstrating effectiveness in the evaluation. One such example is a cost-benefit analysis. The client lists one particularly troubling thought and the outcomes that could come from this way of thinking. After listing pros and cons for these behavioral outcomes, the client then reevaluates the practical value of these thinking patterns. This analysis has demonstrated effectiveness with reducing problem behaviors and thoughts that lead to depression (Burns & Nolen-Hoeksema, 1991; Burns & Spangler, 2000).

Phase IV: Ending and Follow-up

The conclusion phase of treatment needs to include a summary of the goals and outcomes achieved with the client. This is helpful for both the client and the therapist in reviewing the progress made and lessons learned and for reaching agreement that the treatment process is coming to an end. The client must be given time to talk about the termination process and the feelings associated with ending the therapeutic relationship.

Clients often are reminded of other losses and transitions in life when the treatment process ends. It is crucial to assess for depressive symptoms and suicidal ideation again at termination. Follow-up procedures should include checking on the client's progress at 3-, 6-, and 9-month intervals. The clinician should carefully record and analyze the evaluation data to determine the overall effectiveness of the CBT course of treatment. The clinician should review with the client the emergency contacts for safety in case suicidal thoughts arise in the future.

Clearly, clinical social workers need to develop specific skills for work with depressed and suicidal older adults. Given the scope of elder suicide, it is also critical to work for prevention on a broader scale.

POLICY AND PREVENTION

Federal funding for mental health programs for older adults has been relatively meager. Funding through the Community Mental Health Services block grant has not required states to address the unique mental health needs of older adults separately from the general adult population, as they are required to do for children (Volkert, 2003). In 2002, Substance Abuse and Mental Health Administration (SAMHSA) received \$5 million to increase evidence-based mental health services for older adults through a program called Mental Health Outreach and Treatment to the Elderly. Despite this promising start, the program was eliminated. The Older Adult Consumer Mental Health Alliance is leading the effort to raise public awareness and restore this funding (Volkert, 2004). Social workers can partner with such consumer groups to advocate for increased funding for mental health services for older adults.

Prevention programs specifically focused on elder suicide are few and far between, but there are some promising initiatives. At the national level, the National Strategy for Suicide Prevention (SAMHSA, 2004) provides a framework for action aimed at reducing and preventing suicide among all groups. According to the crafters of the National Strategy:

A public health approach to suicide prevention represents a rational and organized way to marshal prevention efforts and ensure that they are effective. . . . The *National Strategy* requires a variety of organizations and individuals to become involved in suicide prevention and emphasizes coordination of resources and culturally appro-

priate services at all levels of government . . . and with the private sector. The NSSP represents the first attempt in the United States to prevent suicide through such a coordinated approach. . . . The *Goals and Objectives for Action* articulates a set of 11 goals and 68 objectives, and provides a blueprint for action.

A related national resource, the Suicide Prevention Resource Center (SPRC, 2004), helps states and communities increase their capacity to develop, implement, and evaluate suicide prevention efforts. The SPRC “supports suicide prevention with the best of science, skills and practice. The Center provides prevention support, training, and informational materials to strengthen suicide prevention networks and advance the National Strategy for Suicide Prevention.” Although some states have suicide prevention plans in place (existing state-level suicide prevention plans can be accessed at the SPRC site) few statewide plans specifically target older adults.

In California, HHS Prevention 2010 block grants were awarded by the EMS Authority to local EMS agencies to support the Toolkit for Elderly Suicide Prevention project (Injury Prevention Network, 2002). The San Diego County EMS Agency distributed the funds to the 32 statewide local EMS agencies to assist providers in recognizing and intervening with potentially suicidal older adults. In San Francisco, the Center for Elderly Suicide Prevention and Grief Counseling (Institute on Aging, 2004) targets older adults suffering from life-threatening depression. Recognizing the importance of older adults being connected to the community, the Center offers a 24-hour Friendship Line, outreach calls, supportive home visits, grief support, and workshops on suicide intervention for volunteers and the community. In South Carolina, a collaborative effort involving the Institute of Psychiatry, State Office on Aging, Area Agency on Aging, South Carolina Center for the Study of Suicide, and the Charleston County Redevelopment Authority is offering a life review intervention to older adults with minor depression as a suicide prevention measure (National Center for Injury Prevention and Control, 2004). Dr. Barbara Haight, the study’s principal investigator, explains:

Since older people attach a stigma to mental illness and suicide, many do not seek help even if they suspect a problem. Accordingly, an intervention must be perceived as acceptable to older people in order to be effective. The life review is

an intervention that is empirically based and conceptually grounded. . . . Because the life review is a seemingly natural storytelling process with no stigma attached, it engages older people with minor depression who often, otherwise, refuse mental health services.

A description of the intervention can be found at: <http://www.cdc.gov/ncipc/dvp/suianno.htm>. Risk of suicidal ideation was assessed at 8 weeks, 1 year, and 2 years following the life review intervention and compared to older adults receiving no life review intervention. The forthcoming findings are expected to show reduced suicide risk among program participants.

It seems counterintuitive that the group with the highest rate of suicide, older adults, and the means by which most who commit suicide take their lives, firearms, are persistently neglected in practice and policy-relevant research. Firearm access is a policy issue that social workers can help address. “Evidence from many countries and cultures shows that limiting access to lethal means of self-harm may be an effective strategy to prevent self-destructive behaviors” (National Mental Health Information Center, 2003, p. 3).

Although there are many programs aimed at preventing youth suicide, few programs are geared toward preventing suicide among the group with the highest rates (Jenkins & Kovess, 2002; McIntosh et al., 1994). Given the strong connection between depression and suicide among older adults, social workers interested in suicide prevention must advocate for better assessment and treatment of depression among older adults. Social workers can play a role in assessing for depression and educating older adults, their family members, and other health and mental health providers about the connections among physical illness, depression, and suicide among older adults (Csikai & Manetta, 2002).

CONCLUSION

The high rates of elder suicide should alarm every helping professional encountering older adults. The problem of elder suicide will likely be magnified with the demographic trends of the post-World War II generation steadily moving toward retirement and older adulthood (CDC, 2002). According to Pearson, Caine, Lindsay, Conwell, and Clark (1999, p. 203), “Suicide in later life represents a significant public

health challenge that will rapidly grow during the early decades of the 21st century.” One estimate projected a twofold increase in the number of elderly suicides by 2030 (Haas & Hendin, 1983).

The impending demographic shift underscores the urgent need for effective measures to reduce late-life suicide. The prevention of suicide among older adults has been identified as “a major opportunity and priority for research in geriatric depression” (Reynolds & Kupfer, 1999, p. 1170).

Even though firearms are the most likely and lethal method, there are significant gaps in the practice, policy, and epidemiologic research on this topic. Clinicians who work with older adults need to have more evidence about the relationship between guns and suicide. Practitioners need to know how, when, and in what way to ask about firearms with their older patients, especially when the elder is depressed or suicidal. Although the data suggest that suicide risk increases with access to lethal means, we need a clearer understanding of the connections between gun policy, firearm access, and elder suicide (Yoder, 2003).

Although research on elder suicide is relatively sparse, published work on protective factors that operate against suicide among older adults is rarer still. Good health, no or limited disability, a strong social support network, and spiritual beliefs are obvious protective factors for adults of all ages. The low rate of suicide among members of older ethnic minority groups, despite the many burdens brought on by structural inequalities, suggests the presence of a racial or cultural protective factor, perhaps related to social support and spirituality. Given the strong connection between depression and suicide in late life, much more research is needed to understand the dynamics of late-life depression and the protective factors that stave off depression among some older adults, even in the presence of chronic illness.

APPENDIX 13.1

Beck Depression Inventory*

Beck, A., Ward, C., Mendelson, M., Mock, J., & Erbarugh, J. (1961). An inventory for measuring depression. *Archives of General Psychiatry*, 4, 561–571.

Brief Symptom Inventory

Scocco, P., & Leo, D. (2002). One year prevalence of death thoughts, suicide ideation, and behaviors in an

elderly population. *International Journal of Geriatric Psychiatry*, 17, 842–846.

Geriatric Depression Scale

Special Populations

This page intentionally left blank

OVERVIEW

The heterogeneity of the aging population is well recognized. This section of the handbook is intended to provide an understanding of the characteristics, needs, and practice issues of particular at-risk subpopulations of older persons. Specifically, the section focuses on the following issues: (1) an overview of the extent of poverty among at-risk subgroups of elderly persons; (2) the role of work among older adults; (3) characteristics and service needs of the oldest old; (4) the nature and extent of elder immigration and refugee status; (5) an overview of mistreatment of the elderly; and (6) the characteristics of older prisoners in state and federal prisons.

Chapter 14, by David E. Biegel and Sylvia Leibbrandt, demonstrates that although overall rates of poverty are lower for elderly than for nonelderly adults, there are large differences in the rates of poverty among subgroups of elderly persons. In particular, older elderly persons, elders living alone, and elders from minority racial and ethnic groups have higher rates of poverty than other elders. A framework for examining service delivery barriers on system, community, agency staff, and individual and family levels is presented. Recommendations are made for addressing identified barriers and strengthening practice and service delivery among women, racial and ethnic minorities, and rural elderly persons.

Chapter 15, by Sheila H. Akabas and Lauren B. Gates, discusses the nature of work, the types of different work statuses of the elderly, policies designed to protect older workers, factors affecting labor force participation by older adults, and implications for social work practice with working older adults. Today many older adults are working beyond the traditional retirement age, with almost one fifth of persons 65 and older still in the labor force. Factors identified by Akabas and Gates that can serve to keep older adults in the labor force include increasing recognition that aging doesn't inevitably lead to a decline in abilities or the obsolescence of skills, increased number of elderly and reduced numbers of younger people available for work, inadequate accumulation of wealth, economic insecurity, and an increase in numbers of women in the labor force who often come to their career peaks later than men. The authors discuss roles for social workers on micro, mezzo, and macro levels in assisting older adults to address their relationship to the labor force.

Chapter 16, by Ruth E. Dunkle and Hae-Sook Jeon, discusses the fastest-growing group of older adults, the

oldest old, those elderly individuals who are 85 years old and older. This group is projected to compose 2% of the population in 2010, growing to 5% of the population by 2050. The authors provide a description of the demographic and socioeconomic characteristics of the oldest-old population, as well as their mental and physical health needs and need for social support. They note that the oldest old have more combined health and mental health problems, with fewer financial and social resources to address these problems, than do other older adults. Implications for mental health service delivery and caregiving are presented.

Chapter 17, by Ailee Moon and Siyon Rhee, discusses social work practice with immigrant and refugee elders. As Moon and Rhee point out, the elderly immigrant population in the United States is becoming increasingly diverse based on racial and ethnic background, reasons for immigration, age at time of immigration, length of residence in the United States, and English proficiency. The well-being and process of adjustment of immigrant elders is affected by their immigration histories, cultural norms and values, and socioeconomic backgrounds. The authors discuss the role of family and caregiving with immigrant elders, emphasizing both the importance of traditional family values and the impact on family issues of living in a different culture. The authors also discuss mental health issues and psychological distress, service utilization and barriers to service use, and implications for social work practice with immigrant and refugee elders. They stress the need for social workers to be culturally competent and to recognize both intragroup and intergroup differences within this population.

Chapter 18, by Susan Tomita, focuses on social work practice with elders who have been mistreated or neglected, a problem area that has been recognized only within the past two decades. A variety of types of elder mistreatment are discussed, including physical abuse, sexual abuse, psychological abuse, financial abuse, identity theft, undue influence, and neglect and self-neglect. Whether an act is considered abusive or neglectful is defined based on intentionality, severity, intensity, frequency, and consequences. Tomita reviews theories of causation of elder mistreatment, as well as the characteristics of perpetrators and victims. A major emphasis of the chapter is the presentation of specific assessment and counseling strategies for social workers to use in working with elders when maltreatment is suspected.

Chapter 19, by Ron Aday, addresses the issue of older adults who are in state and federal prisons. The

number of such individuals has been steadily rising during the past decade. There are now 10,000 individuals in state and federal prisons ages 50 years and older (8.6% of all prisoners), the age that correctional officials usually consider to be an older adult. Given the overcrowding in these institutions and the increasing number of prisoners with mental illness, Aday points out the significant need for social and health services for older adults in state and federal prisons. He discusses the heterogeneity of the population of older

prisoners, as well as their extensive mental health, medical, and social needs. Although about half of the states now provide geriatric facilities and programming for elderly inmates, these programs have limitations, such as restricting prisoner contact with outside communities, inadequate monitoring of inmate needs, and insufficient funding. Aday presents a variety of suggestions for social work services with this population, including educational and social programming and use of therapeutic groups.

Despite the advent of a variety of federal-level income support and social service programs that have had positive effects in reducing the extent of poverty among older adults, poverty among the elderly is still a significant problem. Given the heterogeneity of the elderly population, poverty is of particular concern among elderly women, elders who are 75 years and older, elders of color, and elderly persons living in rural communities. This chapter reviews the extent of poverty among the elderly and discusses the characteristics and needs of vulnerable older populations. Of significant concern to social workers is the underutilization of health, mental health, and social services by older people, especially by those at-risk populations most in need. A framework for conceptualizing service delivery barriers is presented, and the literature concerning the nature and extent of these barriers is reviewed. Practice and service delivery recommendations to address the identified barriers are then presented and discussed.

EXTENT OF POVERTY AMONG THE ELDERLY IN THE UNITED STATES

Poverty rates among adults ages 65 years old and over have been steadily falling since 1965, from about 30% of the overall elderly population below the poverty line to 10.2% of elderly persons below the poverty line in 2003 (U.S. Census Bureau, 2004a). This significant drop in poverty rates among the elderly is principally due to the increases in Social Security benefits and the advent of federal Medicare and other safety net programs (Bok, 1996; Hungerford, Rasette, Iams, & Koenig, 2001–2002). In fact, as Ozawa and Lum (1996) indicate, social insurance benefits (Social Security and unemployment insurance) and welfare payments (all means-tested cash payments and food stamps) for the elderly raised their median income status from 1% to 70% of poverty-line income. The rate of poverty among elderly persons in the United States is now lower than the poverty rates of both children under 18 years of age and nonelderly adults (U.S. Census Bureau, 2004a). It should be noted, however, that poverty rates for the elderly in the United States, especially for elderly men and elderly women who live alone, are considerably higher than for elderly citizens of European industrialized nations (Smeeding & Sandstrom, 2004).

The declining rates of overall elderly poverty in the United States have been interpreted by some to indicate that we no longer have to be concerned with elders in poverty and that, rather, our attention and

resources should be spent primarily on other population groups with higher rates of poverty. However, examining only a cross-sectional view of overall poverty among elderly persons can be misleading for several reasons. First, the elderly population is very heterogeneous, with resultant higher poverty rates among vulnerable elderly subpopulations. Second, there is a failure to consider the “near poor,” those individuals whose incomes are below 150% of the poverty line and who therefore still have significant income needs (Bogdon, Katsura, & Mikelsons, 2001; Villa, Wallace, & Markides, 1997). As will be seen, rates of elders who are “near poor” are considerably higher than the rates of near-poor nonelderly adults. Third, a cross-sectional analysis of elderly poverty does not provide any information about elders’ cumulative chances of being poor during their elder years, the duration of their poverty, or their chances of escaping from poverty and thus does not provide an accurate picture of the degree to which elderly individuals experience poverty during their later years.

Heterogeneity of Poverty Rates Among the Elderly

As can be seen in Table 14.1, which is based on census data from 2003, there are large differences in the rates of poverty among subgroups of elderly persons. Thus

older elderly persons, women, elders living alone, and racial and ethnic elders have higher rates of poverty than other elders (U.S. Census Bureau, 2004b). For example, the poverty rate for elderly individuals who live alone is almost double the poverty rate for elders overall, whereas the poverty rate for Black elderly and elders of Hispanic origin is over twice as high as the poverty rate for White elders. In addition, the poverty rates for elderly Blacks, Asians, and individuals of Hispanic origin are all higher than the corresponding poverty rates for nonelderly adults in these racial and ethnic groups (U.S. Census Bureau, 2004b).

There are also differences in rates of poverty within elderly racial and ethnic groups, presented in Table 14.1. Thus in each group the poverty rates for women are higher than those for men and for older as compared with younger elderly individuals. The rates of poverty for elderly persons living alone are at least twice as high among Black, Asian, and elders of Hispanic origin as compared with White elders. The poverty rate for females living alone is higher than that of males for the three racial/ethnic groups for which data are available.

“Near Poor” Elders

The “near poor”—those with incomes less than 150% of the poverty rate—often have incomes too high to

qualify for public assistance, but yet too low to cover their housing, food, transportation, and health care needs. In addition, researchers have noted a shrinking of the elderly middle class, with a resultant drop of income among the bottom fifth of elderly households (Bogdon et al., 2001; Villa et al., 1997).

As can be seen in Table 14.1, overall more elders are living in “near poverty” than under the poverty level. Overall, one quarter of all elders live near the poverty line, a higher figure than that of nonelderly adults who live in near poverty. Table 14.1 also shows the same patterns for near poverty as for poverty, reported earlier, with higher near-poverty rates among elders who are 75 years and older, among female elders, among racial and ethnic elders, among elders living alone, and among combinations of these variables. The highest subgroups of elderly persons in near poverty are women living alone who are Black or of Asian or Hispanic origin; over two thirds of these individuals are living in near poverty (U.S. Census Bureau, 2004).

Long-Term Poverty Among the Elderly

Rank and Hirschl (1999) examined poverty among the elderly from 1968 to 1992 using data from the Panel Study of Income Dynamics in order to estimate the probabilities of poverty across the entire elderly life span. Major findings of this study showed the following: 4 out of 10 elders between the ages of 60 to 90 experienced at least 1 year living below the poverty line, with almost one half of elders having at least 1 year in which their income fell 125% below the poverty line. The likelihood of experiencing poverty was considerably higher for elderly individuals who were Black, who had lower educational levels, and who were not married. The combination of these variables produced extremely high rates of poverty. The study also pointed out that almost 9 out of 10 unmarried Black females with low levels of education fell below the poverty line at some period of time during the 60- to 85-year age period.

Several other studies using the same data source examined exits from poverty of elderly at-risk populations. Focusing on the period from 1981 to 1992, Wu (2003) found that older persons were less likely than younger persons to exit from poverty regardless of their length of time in poverty. Additionally, findings showed that almost one third of older persons remained in poverty for 10 years or more, as compared with only 1 of 10 for those under 65 years of age. Jensen and McLaughlin (1997) found that elderly persons in nonmetropolitan communities had a lower exit rate out of poverty than elderly persons living in metropolitan communities.

Future Rates of Poverty Among the Elderly

It is difficult to predict future rates of poverty for elderly individuals given the multiple variables that affect poverty levels. Nonetheless, Wentworth and Pattison (2001–2002) estimate that if benefit rules for Social Security and Supplemental Security Income (SSI) are not changed and if real earnings and other income of the elderly increase at 1% per year (the intermediate assumption cited in the *2000 Report of the Social Security Board of Trustees*), poverty among the elderly would decrease to an overall rate of about 7.2% in 2020 and to 4.1% in 2047. However, as the authors point out, future poverty rates of the elderly could be affected by changes in SSI levels, earnings and pensions, longevity, and marital patterns. One can add other variables to the equation that could affect future poverty rates of the elderly, including the fact that the population of vulnerable elderly with higher poverty rates—for example, older elders and elders of color—is anticipated to grow at a faster rate than the elderly population as a whole in the future (Administration on Aging, 2003; Gonyea, 1995; Sotomayor, 1997), as well as concern about rising health care expenditures of the elderly (Johnson & Penner, 2004; Manchester, 1997). Thus there are pessimistic as well as optimistic future projections about the rates of elderly poverty. Given the difficulty of predicting economic trends even over the short term, predictions made far into the future are often inaccurate and should therefore be examined with some caution.

AT-RISK ELDERLY POPULATIONS

Women

The poverty rate data presented in the previous section have demonstrated the higher poverty rates of el-

derly women as compared with elderly men; older women from racial and ethnic minority groups are at greatest risk for poverty and near poverty. A number of variables that influence the risk for women becoming poor have been identified in the literature, including divorce, widowhood, increased longevity, intermittent work histories, lower likelihood of receiving pension income, and lower wages (Anzick & Weaver, 2001; Kingson & Williamson, 2001; Rupp, Strand, & Davies, 2003).

Marital status in particular has a significant impact on the income of elderly women (Ozawa, 1997; Sevak, Weir, & Willis, 2004). Although there has been a large drop in the impact of widowhood on women's poverty, from 37% of new widows falling below the poverty line in the 1970s to 12–15% by the 1990s, widowhood nevertheless remains a significant risk factor for older women's transition into poverty (Sevak et al., 2004). Ozawa (1997) examined the income status of elderly women 10 years after retirement. She found that older women who were already widowed at retirement had only 59% of the income status of elderly women who were married throughout this 10-year period. Meanwhile, elderly women who became widowed after retirement had 68% of the income status of elderly women who were married throughout the 10-year postretirement period. Sevak et al. (2004) point out that given the strong relationship between mortality and wealth, Social Security policy needs to consider the particular situation of widows. Women widowed after their children have grown but before their retirement preparations have been completed are usually not eligible for Temporary Assistance for Needy Families (TANF), Supplemental Security Income (SSI), or Social Security and are therefore particularly vulnerable to poverty.

Racial and Ethnic Minorities

The higher levels of poverty among elders of color is of increasing concern given the fact that the non-White elderly population is growing at a faster rate than is the White elderly population. It is projected that one quarter of the elderly population will be non-White by the year 2025. This number will increase to a third within a decade of that (American Association of Retired Persons [AARP], 1993). Given the significantly higher rates of poverty among adults ages 45 to 54 years, the growing percentage of minority elderly in the future will mean growing numbers of elderly individuals without adequate financial as-

sets (Binstock, 1999). Higher rates of poverty among racial and ethnic elderly individuals are also associated with greater deficits in education, lower self-reported health status, greater physical impairment, less access to health care, underutilization of health care services, and inadequate housing (Binstock, 1999; Greene, 2000; Harris, 1998; Reed, Hargraves, & Cassil, 2003; Tran & Williams, 1998). However, as Torres-Gil and Moga (2001) point out, racial and ethnic minority elder populations have developed considerable strengths and resiliencies from their physical and social survival in the face of poverty and, oftentimes, racial and ethnic discrimination.

Rural Elderly

Rates of poverty among elderly persons living in nonmetropolitan areas are higher than those of elderly persons living in metropolitan communities. Using data from the 1990 Census, McLaughlin and Jensen (1993) reported that 15.4% of nonmetropolitan elders lived in poverty as compared with 10.0% of all metropolitan elders and 13.8% of central city elders. These differences were not explained by differences in the population by gender, age, race, education, marital status, or living arrangements (McLaughlin & Jensen, 1993). In addition, nonmetropolitan elders are more likely to be near poor (less than 150% of the poverty line) than metropolitan elders, with over one third of nonmetropolitan elders being near poor as compared with about one quarter of metropolitan elders (McLaughlin & Jensen, 1993). Finally, it has been reported that nonmetropolitan elderly individuals are more likely to become poor than metropolitan elders, even after controlling for other confounding variables such as race, education, marital status, and widowhood (McLaughlin & Jensen, 1995). Higher poverty rates among the elderly in nonmetropolitan areas are felt to be due to certain aspects of the rural economic and social structure that have negative effects on economic security. Elders in rural communities have lower lifetime earnings, fewer Social Security benefits, less pension coverage, and less likelihood of enrollment in the SSI program (Glasgow & Brown, 1998; McLaughlin & Jensen, 1993). Given the higher levels of elder poverty in rural areas, there would be an anticipated greater need for services. Yet a number of researchers point out that few services are available and used in rural communities due to lack of governmental resources, lower population densities, shortages of trained professionals, and high

levels of self-reliance in the rural elderly (Krout, 1998). There is also concern that the out-migration of younger populations from rural communities weakens the informal social networks of elderly persons (Glasgow, 1993).

SERVICE DELIVERY BARRIERS

A variety of barriers to the use of health, mental health, and social services by at-risk older people have been identified in the literature (Baker & Pallett-Hehn, 1995; Biegel, Farkas, & Song, 1997; Biegel, Petchers, Synder, & Beisgen, 1989; Jervis, Jackson, & Manson, 2002; Minear & Crose, 1996; Tran, Dhooper, & McInnis-Dittrich, 1997; Yeatts, Crow, & Folts, 1992). These barriers are often the greatest for subgroups of the most vulnerable elders in poverty that we have described earlier. Biegel and colleagues (Biegel & Farkas, 1989; Biegel, Johnsen, & Shafran, 1997) have categorized service delivery barriers on four different levels—system, community, agency staff, and individual and family (see Table 14.2). This framework highlights the places at which barriers occur in order to guide the development of interventions at the proper locations to address these barriers and thus improve practice and service delivery to elders in need. In addressing barriers to service delivery to older people, we believe that it is important to focus on all four levels.

Though the four levels of barriers are relevant and appropriate for any type of service, the specific barriers identified in Table 14.2 will vary to some degree depending on the type of service. In addition, some barriers pertain to a greater degree or in particular to vulnerable elderly subpopulations. For example, a barrier such as lack of services is a greater problem in rural than in urban communities, whereas past experiences with racial/ethnic discrimination and lack of culturally competent service providers pertain particularly to minority older populations.

Systems-level barriers refer to deficits at the service agency and at the agency network level that are affected by political, economic, and social forces that shape the development of agency services and funding for such services. The principal system-level barriers to elderly individuals' use of services that have been identified in the research literature include: lack of accessibility of services (cost, location, transportation); fragmentation of services as reflected by lack of linkages with other service systems and providers, both formal and informal; lack of supports provided

TABLE 14.2. Service Delivery Barriers for Elders in Poverty

System Level (Agency and agency network deficits)

- Lack of linkages with informal networks
- Lack of linkages with other service systems and providers
- Financial/cost of services
- Lack of services/lack of specialized services
- Inappropriately designed services
- Location of services/transportation issues

Staff Level (Knowledge, skills, attitudes, and behaviors of staff)

- Lack of non-English-speaking staff members
- Lack of cultural competency of agency staff members/insensitive service providers
- Lack of knowledge of problems/needs of elders in poverty
- Lack of training to address specific problems of the elderly
- Staff is not reflective of the racial and ethnic diversity of the population to be served
- Ageism

Community Level (Attitudes toward service use by lay helpers and organizations/relationships between lay helpers and professional services)

- Discouragement of formal help seeking
- Lack of knowledge of agency services
- Lack of relationships with service providers
- Unwillingness to recognize/define “problems” of elders in poverty

Individual/Family Level (Personal and family attitudes and behaviors toward service use)

- Language barriers/lack of proficiency in English
- Past/present experiences with racism, racial/ethnic or age discrimination
- Past negative experiences with service use/distrust of service providers
- Negative attitudes toward seeking help—stigma, fear, embarrassment, shame, confidentiality concerns
- Discouragement of service use by family members
- Belief that treatment/services will not be effective
- Preference for use of family care and other informal networks
- Lack of knowledge of services
- Accessibility issues—concern about transportation, location of services, cost of services
- Concern about acceptance by agency staff
- Unaware of need for services/denial of problems

to informal caregivers; lack of services or specialized services; and inappropriately designed services (Baker, 1994; Baker & Pallett-Hehn, 1995; Burggraf, 2000; Damron-Rodriguez, 1998; Ford & Hatchett, 2001; Greene, 2000; Jervis et al., 2002; Knight & Kaskie, 1995; Noelker & Bass, 1988; Rittner & Kirk, 1995; Yeatts et al., 1992). Given the importance of informal support networks in minority communities (Jackson & Wolford, 1992; Urdaneta, Saldana, & Winkler, 1995), the lack of supports provided to informal caregivers and the purported lack of linkages between professionals and informal caregivers is of particular concern.

Staff-level barriers are the levels of knowledge, skills, attitudes, and behaviors of agency staff. Staff-level barriers that have been identified in the literature include: lack of knowledge of specific problems and needs of subgroups of older people; lack of staff members who are specifically trained to handle the problems associated with these needs; negative attitudes by professionals about aging and/or particular problems of the elderly (e.g., mental health problems); lack of staff members who speak languages other than English; lack of culturally competent staff; and insufficient number of staff members that reflect the racial and ethnic makeup of the communities of elders they

serve (Applewhite, 1998; Baker, 1994; Biegel et al., 1989; Browne & Broderick, 1994; Burggraf, 2000; Damron-Rodriguez, 1998; Jones, 1999; Yeatts et al., 1992). Lack of professional commitment and the tendency to treat minority elders without regard to differences of individuals within minority groups are two issues which present particular difficulties for the delivery of services to African American, Asian, and Hispanic elders. The failure of professionals to fully understand the unique life experiences of particular older minority individuals can be an important service barrier.

Community-level barriers refer to negative attitudes and behaviors toward professional service use by informal helpers and community-based organizations (neighborhood associations, self-help groups, ethnic and fraternal organizations, etc.; Biegel, Johnsen, & Shafran, 1997). Community-level barriers to service use by the elderly that have been identified in the literature include: unwillingness to recognize or define “problems” of elders in poverty; lack of knowledge of agency services by informal helpers; lack of relationships between informal and agency service providers; and discouragement of formal help-seeking by informal helpers.

Individual-level barriers refer to personal and family attitudes and behaviors toward service use. Individual and family-level barriers that have been identified in the research literature include: negative attitudes toward service use (stigma, fear, distrust, or lack of confidence in service providers, preference for self-reliance, confidentiality issues); denial of problems; accessibility issues (language barriers, transportation, concern about cost); lack of knowledge of services; negative experiences with previous attempts at professional help seeking; and preference for use of family care and other informal networks (Baker, 1994; Burggraf, 2000; Dancy & Ralston, 2002; Gordon, 1995; Jervis et al., 2002; Knight & Kaskie, 1995; Miller & Stull, 1999; Minear & Crose, 1996; Richardson, 1992; Yeatts et al., 1992). A number of the aforementioned barriers are especially relevant for African American, Asian, and Hispanic elders. There is considerable evidence of negative experiences by minority individuals with a variety of service delivery systems. These problems can be expected to influence elders’ use of community services. For health services in particular, given the evidence that ethnicity plays an important role in the conceptualization of illness (Hall & Tucker, 1985; Urdaneta et al., 1995), how ethnic elders define illness and their knowledge of service delivery systems can also affect service utilization.

PRACTICE AND SERVICE DELIVERY RECOMMENDATIONS

In order to fully address and remedy the widespread health and psychosocial ramifications of economic hardship of at-risk elders in poverty, a multidimensional approach targeting all four barrier levels—system, staff, community, and individual/family—is required. Recommendations are, therefore, directed toward these levels as they pertain to the needs of poor elderly women, racial and ethnic minorities, and rural residents.

One of the greatest barriers to service delivery, affecting all at-risk elderly, is the lack of knowledge about the problems and needs of poor elders, both at the system and staff levels. This barrier is significant, as it contributes to the development and delivery of services that do not adequately meet the needs of this population. A second barrier at the staff level involves the provision of services by professionals who lack the specialized knowledge and skills needed to attend to older adults in poverty. In general, competent practice with these at-risk elders requires a specialized knowledge of gerontological social work and of the resources (both formal and informal) that are available to support older women, racial and ethnic minorities, and rural clients. Equally important is a thorough understanding of the experience of being poor in older adulthood, including a familiarity with the risk factors and implications of poverty, an awareness of the barriers these older adults face, and the cumulative effects of lifelong discrimination (e.g., racial, gender, and now age discrimination).

Elderly Women

As we have seen, one subgroup that is especially vulnerable to the risks of poverty is elderly women. The prevalence of poverty among elderly women, as compared with men, is significantly greater. Those who are particularly vulnerable to these effects are divorced, widowed, or single women over the age of 70 and living alone. Minority and rural women are the most vulnerable. Although a large majority of those in poverty rely on Social Security to survive, women and widows generally receive the fewest benefits because of their low-wage histories and major interruptions in their employment histories. At the staff level, social workers should be aware of the unique issues facing older women, including their financial constraints, and understand that, although many would prefer to

continue working to support themselves, greater numbers of them are leaving the workforce prematurely due to health problems (Perkins, 1992). In addition to health and financial barriers, elderly women are subject to gender discrimination and social isolation. With this awareness, the social worker's primary role should be to assess the older woman's financial and health status, the social supports she has in place, and her ability to afford health care. If gender discrimination figured prominently in her life, she may have little faith in "the system" and be reluctant to accept services.

Recommendations at the individual level might involve resource counseling and provision to support women who are socially isolated (e.g., widows and childless older women) through enrollment at a senior center, a support group for widows, a volunteer homemaker program, or some other social or religious organization that appeals to the client. Social work advocacy may be necessary to ensure that the client is not assuming any excess costs for enrollment or transportation. Following psychosocial and supportive counseling, the older woman might be more willing to reach out to family, friends, and neighbors to bolster her support system. Interventions at the individual level might also include referral to a health promotion program, financial counseling, or application to a more affordable housing facility. At the community level, social workers can disseminate information at churches, community centers, and social organizations about resources available to support socially isolated older adults, widows, or those who are frail. At the systems level, staff can learn about other services in the community and develop linkages by visiting other agencies, sharing the ways in which the two can work together to serve at-risk elders, and by becoming involved in a social worker exchange (in which two social workers exchange roles and spend a week at the other agency to become familiarized with staff, the agency's programs and services, and its clientele). Given the growing number of elderly women in poverty, creative interventions directed at all barrier levels will be necessary to ameliorate the living conditions of older women, especially those who are also ethnic minorities.

Racial and Ethnic Minority Elders

When the older woman's ethnicity differs from that of the provider, the helping process becomes even more complex. Intervention with ethnic minorities,

regardless of their economic status, requires a specific set of skills and competencies in order to respond in a manner that is culturally sensitive, relevant, and empowering.

The National Association of Social Workers [NASW] Code of Ethics (1996) outlines key social work values and principles for working with ethnic minorities. Informed practice, for example, is characterized by a respect for the *inherent dignity and worth of the person* and a *cultural competence* that reflects an understanding of *social diversity*. A major barrier to service delivery with ethnic minorities, therefore, is the social worker's unwillingness or inability to respect differences in other individuals. Tripp-Reimer (1999) advocates three elements necessary for cultural competence: (1) awareness-oriented strategies, to use the process of self-examination to identify prejudice; (2) knowledge-oriented strategies, to promote learning about the elder's culture; and (3) skill-oriented strategies, to develop the skill sets of those working with ethnic minorities. A central feature of culturally sensitive social work is the provider's capacity for self-insight for the purpose of identifying early on any bias that might interfere with client assessment and treatment. Equally important is an acknowledgment of one's own values and conceptualization of health, illness, help seeking, treatment, and quality of life vis-à-vis the client's, because various ethnic groups use different paradigms to interpret these conditions (Sotomayor, 1997). Self-analysis is not complete without a fuller understanding of the older adult in his or her cultural context. For example, a determination of the elder's social boundaries, degree of acculturation and assimilation, approaches to problem solving, and perception of his or her life situation and presenting problem is necessary in order to provide culturally sensitive interventions. Language, both spoken and unspoken, is one aspect of the professional exchange that requires preliminary consideration given that fundamental concepts and terms used throughout the helping process may not exist in the primary language of the client or that the terms may simply have a different meaning. Therefore, careful preparation, ongoing assessment, and active listening are necessary to avoid conduct that may be perceived as offensive to the elder or, at the very least, irrelevant to the problem at hand (Applewhite, 1998).

Although it is important to acquire knowledge about the ethnic group in question, it is perhaps more important to understand that there is always within-group diversity. For example, a provider may believe

that African Americans tend to use home remedies to treat illness. But without checking this preconception with the client, the social worker is apt to make inappropriate assumptions about the senior's attitude toward treatment. Therefore, a comprehensive evaluation of the older adult's values and attitudes is necessary, including the elder's self-perceptions regarding his or her affiliation to the racial/ethnic group.

These cultural competencies are essential when interacting with any minority client. One subgroup that is growing in numbers and is at high risk for poverty and its repercussions is that of grandparent caregivers. Although grandparents represent a wide variety of racial and ethnic groups, African American women account for the highest proportion of grandparents raising grandchildren. These elders living in poverty have unique challenges that require effective resourcing and support services. Social workers should be aware of the high prevalence of health problems in this special population, including physical impairment and depression, both of which could become exacerbated in the role of caregiving. Therefore, access to respite services to provide relief from caregiving or, at the very least, from the more strenuous tasks of child care should be facilitated. In addition, providing home health care to offer emotional and instrumental support, education, and information regarding effective coping strategies and alternative resources is recommended. Important too is the knowledge that grandparents with the most health problems and caregivers whose grandchildren have physical or behavioral problems tend not to seek help (Burnette, 1999; Fuller-Thomson & Minkler, 2000), yet these are the seniors at greatest risk.

To be truly effective, the social worker should be informed about the reasons that increasing numbers of African American grandparents are taking over the responsibility of raising their grandchildren. Research indicates that this move is often a result of parental substance abuse, incarceration of the mother, or HIV/AIDS. Given the stigma associated with each of these issues, it is not surprising that grandparent caregivers become socially isolated and fail to utilize the supports and services to which they are entitled (Fuller-Thomson & Minkler, 2000). Social workers should be involved in outreach efforts to connect with these individuals who, for whatever reasons, do not take advantage of available services.

Failed attempts at outreach might be the result of two barriers in particular: (1) the provider, whose ethnic identity does not match the client's, and (2) the service offered, which does not cater to members

of the client's ethnic group. Recommendations at the staff level involve hiring a diverse group of staff members representing a variety of ethnic backgrounds, using multilingual staff members as resources to provide translation and interpretation when necessary, providing in-service staff training and education to nonminority agency consumers regarding minority groups and cultural sensitivity, incorporating activities and meals that also appeal to minority consumers, and including ethnic minority representatives on the advisory board of the agency (Yeatts et al., 1992). A community-level recommendation would involve providing services to ethnic minority elders in a location that is culturally sensitive and familiar to these seniors, such as a church or ethnic organization.

Jones (1999) developed two strategic approaches to addressing the barriers faced by older African Americans in poverty: administrative strategies and direct service strategies. The most relevant recommendations follow:

Administrative Strategies

- Community-based care must be viewed and administered via a social rather than a medical model. It should be organized under the county levels of government.
- Practitioners and researchers must educate health service staff, elected officials, and the community about the health status of the Black elderly population.
- Adequate financial resources must be provided for primary and preventive services.
- Valid and reliable health status needs assessments must be conducted. These can range from something as simple as focus groups to more sophisticated research designs.
- Legislation that may impact health status and minority elderly should be monitored by all.
- Structured coordination must be provided in order to reduce the fragmentation that currently exists within various health-promotion and disease-prevention services.

Direct Service Strategies

- Community partnership arrangements must be developed to meet the total community health needs of the Black older population (Jones, 1999, pp. 230–231).

Rural Elders

Whereas outreach with ethnic minority seniors presents enormous service delivery challenges, social work in rural regions presents a unique set of challenges in delivering services, especially to at-risk groups, including the oldest old, racial and ethnic minority elders, and older women. Older adults living in nonmetropolitan settings have fewer community resources, especially specialized services; therefore, they experience greater deprivation than do urban elderly (Coward, Duncan & Netzer, 1993; Glasgow, 1993; Krout, 1994). An awareness of the minimal services for older adults, the inadequate transportation available, and the social isolation of rural elders lends appreciation for the struggle of seniors and providers and an understanding of the creativity necessary to ameliorate conditions.

Krout (1998) identified some creative initiatives implemented by some rural Area Agencies on Aging (AAA). He cautioned, however, that consideration is needed when developing such initiatives so that recommendations are realistic yet without rural stereotypes, respectful of the local values and social systems in place, and mindful of the diversity that exists within and between rural regions. Interventions should incorporate the community's preference for services, using flexibility and multimethod approaches, and should build on the strengths and resources already present in these rural areas. The goal is to maximize these resources through efficient service coordination and coalition building, utilizing existing relationships with local leaders and the private sector to offer services that promote personal autonomy and dignity (Krout, 1998). Of particular relevance to these points is that a majority of care in rural communities is provided by family members and that these providers need to be supported, too (Stoller & Lee, 1994).

Given the preceding considerations, recommendations are directed at all barrier levels to overcome obstacles to access and utilization of services (including transportation issues), reluctance on the part of the older adult to access community resources, availability of specialized services and professionals, and the lack of variety in services that are offered. One recommendation in particular addresses a variety of obstacles, including the social isolation elders experience as rural residents. This initiative, implemented by several AAAs, establishes a network of satellite senior centers to provide outreach to socially isolated older persons. For those seniors who are reluctant to access formal services, this familiar site offers health promotion, in-

formation, screening, and referral, while providing them with social stimulation and nutrition. Employing another familiar location—local parishes—public health nurses are able to provide health screening and education to frail seniors. One AAA leveraged its relationship with area hospitals and nursing homes to increase the availability and array of home health services that could be offered to at-risk elders. Exploiting the linkages between rural AAAs enabled the development of housing coalitions, thereby increasing the housing resources for older adults (Krout, 1989).

Access to these services can be facilitated through the development of a transportation system, which for one AAA involved the use of local and federal funds and community volunteers to provide an alternative to the transportation resources already in place. The issue of access pervades any discussion of services for rural seniors. Aside from transportation resources, a common approach to improving access to services is through the use of mobile health services, which offer screening, treatment, and referral (Bell, 1975). Another option to providing essential services involves a recommendation at the systems level and concerns the use of urban resources to meet rural needs. For example, a psychogeriatric social worker based in an urban center might be assigned to a county in which there are three rural communities. Providing assessment and treatment services to all these rural and urban communities means that elderly clients do not miss out on specialized care. Seniors who accept these services can then receive clinical intervention from other multidisciplinary members of the psychogeriatric team, such as the geriatric nurse, occupational therapist, and geriatric psychiatrist. Although access is important, equally important is the utilization of these services, which can be facilitated in rural areas by employing consumers to act as peer educators and mediators between formal and informal systems. This resource is especially relevant when designing interventions for ethnic minority elders.

In summary, despite reductions in overall poverty rates for the past four decades, very old individuals, women, racial and ethnic minorities, and rural elderly residents are at significantly greater risk for poverty, with the population of at-risk poor elderly individuals increasing at a faster rate than that of the elderly population as a whole. In addition, we have noted the significant barriers to the use of health, mental health, and social services by older adults and have presented strategies for social workers to help address these barriers on system, staff, community, and individual and family levels.

THE MEANING OF WORK

What would you like to be when you grow up? What do you do? What did you do before you retired? These are probably the most frequently asked questions in our daily dialogues, and, not surprisingly, they all have to do with work. That is probably because work is the most universal phenomenon in society. We tend to define ourselves by the work we do. Our fantasies are about accomplishments at work and our sorrows are about the pain at work. When we are young, we prepare for work. When we are in our middle years we depend on it, hoping it will bring fulfillment economically, socially, and psychologically. When we are older we reminisce about work. Our social policy is directed at getting people to work. Where and how families live and grow is determined by work. How we live in old age has very much to do with our experiences when we were at work.

Work is so ingrained in the American spirit that it is almost seen as unpatriotic not to be employed. People may have more money than they can ever expect to spend in their or their children's lifetimes, yet they are often the most dedicated and committed workers. Lucky lottery winners, when asked their future plans now that they are millionaires, frequently indicate that they will buy a home, give to family members or charity, but they will continue to spend their daily hours at work. We are a nation that prioritizes work as others do religion or respect for the family (Akabas, 1995). As Akabas and Kurzman (2005) note, "Being in the world of work means that one is swimming with the prevailing current and therefore is likely to be part of the mainstream of America rather than on the margin."

We may ask why work is so significant in American society. Work offers us social status, helps structure our daily life, secures our financial rewards, gives us a sense of self-efficacy and accomplishment, and assures us of a context for social interactions (Akabas, 1995). For older adults, work may have particular meaning as an opportunity to transfer knowledge, skill, and experience to younger generations (Mor-Barak, 1995). Countless observers have commented on the importance of work. Jahoda (1988, p. 17) observes, "Whether one likes or hates one's job, it structures time for the day, the week, the years; it broadens the social horizon beyond family and friends, it enforces participation in collective purposes, it defines one's social status; it demands reality-oriented activities." "It's the economy, stupid!" (widely interpreted as the universal desire for jobs) was the winning

Older Adults and Work in the 21st Century

15

motto of the first Clinton campaign. Camus observed, “Without work all life goes rotten.” Freud identified the two hallmarks of adult functioning as the ability to love and to work—but he and the rest of the mental health professions have concentrated on love (Freud, 1930).

A distinct lack of attention has been paid to work not only by Freud but also by social work in general. Yet entering work, remaining at work, and leaving work are some of the main passages of life for most of us, including those who seek social work services. Being able to find meaningful, rewarding work is one of the greatest challenges facing individuals and society today, and older adults are not exempt from this challenge. Although some welcome the end of work demands and retire at the earliest possible moment, many people work long after retirement age (for example, the 2000 U.S. Census reported a labor force participation rate for persons 65 and older at 17.5%), and still others crave work after retirement (Fullerton & Toossi, 2001).

Policy makers in the world of work respond in varied ways to employment of older adults. Some encourage their participation because they value the older adults’ experience, knowledge, and flexible availability, among other reasons, recognizing their significant contribution to the bottom line. Others discriminate against aging workers, believing them to be too expensive, unable to learn, or likely to become ill, among other myths (Moen, 1990). Many workplaces provide incentives for older workers to leave employment. Whatever the situation, the role of work in aging seems worthy of our attention for its importance to well-being throughout life and because the individual who is thinking about leaving work is usually facing a complex and often difficult transition point in the life cycle.

This chapter identifies who older working adults are by legislative definition, workplace policy, and life experience. We examine their contact with work in relation to the various statuses they may occupy, including transitional retirement, total retirement, and continuing employment, and how this varies with individual characteristics and other factors affecting withdrawal from the labor force due to age. We then suggest what social workers can do to help older workers achieve the connection to a work role that they may desire or to satisfy a successful termination of that role if that is their choice. We contend that it is not possible to serve the needs of older adults without understanding their work histories, what has influenced the status they now hold with regard to work, what their preferences are in relation to work,

and how to help them achieve their desired state, as well as how the workplace culture and social policy act as an influential context for individual experience. There are clear indications that the issue of work warrants attention from social service personnel.

AGING AND WORK: A DEFINITION

One means of establishing a definition of aging is to base it on the way society behaves around age with relation to work. In a subsistence economy, everyone works except very young children and the infirm. In such an economy, not being able to work defines “aging,” and falling into the category of “aging” can even be a death sentence from starvation—witness the Inuit culture that abandoned the aged to remain on the ice floe (McDonald, 2002). It is only as societies become more affluent that some members, among them the older adults, have an option to be financially supported by virtue of prior accumulation of wealth or by generous contribution of their family or the community. Thus retirement is a recent option historically. For many, retirement itself defines “aging” in relation to work.

Legislative Definition

Extensive studies have confirmed that, starting at age 40, individuals in the labor market encounter stigma attached to their aging. Bendick, Brown, and Wall (1999) found that when two candidates of exactly equal competence who are different in age, one being 32 and one 57, present themselves for hire, the younger will be preferred 42% of the time, and both candidates, regardless of age, will be equally treated only 58% of the time. Many others confirm that age discrimination in hiring continues to exist (Shen & Kleiner, 2001). Other data indicate that unemployed long-tenured workers (those employed 3 or more years at the time of displacement) ages 55 and over take longer to find jobs than their younger colleagues and tend to be reemployed in jobs that provide lower earnings than their lost jobs (U.S. Department of Labor, 2004; Brewington & Nassar-McMillan, 2000). The Age Discrimination in Employment Act of 1967 (ADEA), therefore, acknowledged that being over 40 places one in jeopardy of discrimination in the workplace when seeking employment. By designating age 40 as the limit of its protection, the Act defines the beginning of “aging” with regard to workplace partic-

ipation. The congressional statement of findings and intent attached to the ADEA states:

- (a) The Congress hereby finds and declares that—
- 1) in the face of rising productivity and affluence, older workers find themselves disadvantaged in their efforts to retain employment, and especially to regain employment when displaced from jobs;
 - 2) the setting of arbitrary age limits regardless of potential for job performance has become a common practice, and certain otherwise desirable practices may work to the disadvantage of older persons;
 - 3) the incidence of unemployment, especially long-term unemployment with resultant deterioration of skill, morale, and employer acceptability is, relative to the younger ages, high among older workers; their numbers are great and growing; and their employment problems grave;
 - 4) the existence in industries affecting commerce, of arbitrary discrimination in employment because of age, burdens commerce and the free flow of good in commerce
- (b) It is therefore the purpose of this chapter to promote employment of older persons based on their ability rather than age; to prohibit arbitrary age discrimination in employment; to help employers and workers find ways of meeting problems arising from the impact of age on employment.

Although the Act originally protected those ages 40–65, the protection coverage was raised to 70 in 1978, and a 1986 amendment prohibited mandatory retirement (Neumark, 2003). It applies to all employers of 20 or more workers, government agencies, and labor organizations. ADEA is administered (since 1979) by the U.S. Equal Employment Opportunity Commission, which is charged with enforcement of all affirmative action legislation.

Another influential piece of legislation is the Social Security Act of 1935. As a social invention, retirement is mostly confined to Western, highly advanced economies (Clark, York, & Anker, 1999). Legislation offering insured formal retirement, by which income continues beyond working years, started in the Bismarck era in Germany toward the end of the 19th century. The age of retirement was set at 65 largely because almost no one was expected to live that long, thereby keeping down the cost of this social benefit.

In the United States, the Social Security Act used the same cutoff age for eligibility for fully funded retirement. Recent amendments have moved the age of withdrawal from work with total pension, so that by 2027 it will be 67, but reduced payments remain available starting at age 62. Mandatory retirement has been eliminated, as has payment penalty for earned income after 65. Further, life expectancy has increased appreciably, and large numbers of persons live long years after reaching 65 (Hogan & Kerstein, 1999). Although life expectancy differs by gender, marital status, race, and income level, the average life expectancy for all Americans who reach age 65 was 17.6 more years in 1966, and this number was expected to increase by 0.05 annually for the following 75 years (Weller, 2000). The Social Security Act, therefore, though it is the single most influential force for defining age at work, has inherent contradictions as policy, both encouraging and discouraging a specific definition for exit from the labor force.

Workplace Policy

Although there are gender, race, ethnic, and many other categories of difference that correlate with labor force participation rates, at least until 1985 participation rates declined noticeably for all groups after the age of 55, encouraged by private pension plans (Hayward, Friedman, & Chen, 1996). Retirement in pension plans varies, from eligibility at any age with 20 years of service—the plan used by the armed forces and police and fire departments—to provisions of the Social Security Act that allow reduced-benefit retirement at 62, to private plans in which a combination of years of service and age allow the application of a floating retirement opportunity depending on circumstances. A 2003 survey by the Society of Human Resource Managers found that human resource professionals differ widely in defining the age of older workers, ranging from age 40 to age 70 (Lockwood, 2003). Thus we can conclude that the definition of age in relation to work is a condition based on personal circumstances and the particular policy applied by a specific work organization and that it may start at age 40, with upper boundaries limited only by individual mortality.

Individual Experience

Who are the aging workers? Thinking about those over 40, they are the baby boomers, their parents, and

perhaps a few of their grandparents, that is, anyone born before 1964 who is still available and looking for work or is employed. In numbers they include more than 38 million individuals. They entered the workplace during the Great Depression, during World War II, or during the feminist movement. They include persons who started life believing that men were the breadwinners and the world of work was the domain of men to those who have been introduced to work at a time when the labor force is almost equally distributed between women and men. The aging include the first cohort of women who have had a significant labor force attachment, as well as those who have gone through the civil rights movement that made it a matter of public policy to provide equal opportunity in employment for racial and ethnic minorities, among other disadvantaged groups. They have experienced a period of non-European immigration, resulting in the most diverse labor force ever.

Aging workers also have lived through an evolution in the economy that has involved significant change in the industrial mix. This has resulted in a steady decline in manufacturing—the stronghold of male employment—to an economy dominated by service industries. This shift has tended to displace men and has pushed them out of the workplace as they saw their jobs disappear. It has pulled women into the workplace as such traditional female occupations as retail sales, clerical work, health care, and government employment have expanded and proven less vulnerable to global competition and its accompanying recession layoffs (Cotter, Hermsen, & Vanneman, 2002). The aging have lived through a period during which longevity has increased so significantly that the old model of school, work, and death has been replaced by a life course that includes more than a decade of leisure following formal retirement (Encel, 2000). Notably, each cohort of workers has a different experience, which leads to the many unique characteristics among this population in relation to the world of work.

OLDER ADULTS AND THEIR CONNECTION TO WORK

Favreault, Ratcliffe, and Toder (1999, p. 484) suggest that the forces that influence an older adult's decision concerning work are one's ability, economic resources, psychological condition and family situation: "The importance of each of these factors varies both across and within different birth cohorts."

Ability

Ability implies that one is physically able to do the job and has the skill required for job performance. Today, jobs are less physically demanding, and people reach older years in better health than ever before. Life expectancy has increased appreciably, and large numbers of persons live many years after reaching 65. There is scientific validation that aging *may* cause a decline in abilities (Johnson, 2003) and evidence that, in the absence of training, skills *may* become obsolete (Schwartz & Kleiner, 1999). But Schwartz and Kleiner (1999) report finding great variations in the aging process such that "optimal agers" do as well as or better on aptitude tests than those in their prime of life. Other experts note that older workers tend to have more positive work attitudes and have valued traits such as loyalty, motivation, and a solid work ethic. As well, older workers are viewed as being willing to work different schedules, they have the ability to serve as mentors, and they bring invaluable experience to the workplace (Lockwood, 2003). It is largely the obsolescence of skills, therefore, which is the primary limiting factor in the ability of older workers to continue on the job. Skill obsolescence is compounded by negative attitudes of employers who believe that investing in training is not cost effective because older workers will not stay long enough to provide the employer with a sufficient return on investment (Encel, 2000). Researchers find that training can overcome lack of skill and that intellectual decline is far from universal. On balance, it is probable that aside from those who experience a severe decline in health, few are driven from the workplace by inability to perform.

Economic Resources

As workers reach the age and financial circumstances at which retirement is a serious option, the literature suggests that economic resources play a major role in the decision-making process concerning the relation of the older adult to work. Today's aging workers include the first generation of Americans that was covered by the Social Security Act of 1935 from the onset of their employment and that hence enjoys the individual right to the social invention of public financial support in retirement. This social policy has encouraged, through financial incentive, the exit of older workers, and older workers have responded in kind with sharp withdrawal at age 62, when reduced Social

Security payments become available, and another spike at age 65, when full payment is available (Moen, 1990; Ruhm, 1995). For example, the labor force participation rate for men at age 63 dropped from 80% in 1950 to less than 50% by the end of the century, showing precipitous decline starting when men became eligible for Social Security benefits at age 62 in 1961 (Woodbury, 1999). Similar patterns are observable for women, but because of the overall increase of women in the labor force during this period, they are less pronounced. Employers, too, have solicited the exit of workers, providing incentives in the form of pensions and liberal financial buyouts, often by age 55. Affluence has also increased so that many find themselves able to leave work at much earlier ages if they wish. This has caused a massive exit from the labor force by men, who previously worked until death or serious disablement. Thus retirement has taken over for many, and the average age of retirement seems to have grown younger and younger (Hardy, 2002).

Yet recent economic and other trends have also had a reverse influence. The increasing number of the elderly and the reduced numbers of young people available for work has fostered some reduction in the pressure for early retirement. This reflects both the desire to reduce the economic burden of early retirement and increased longevity and the concern about inadequate labor force replacement coming from the “baby bust” generation (Hirschman, 2001). As baby boomers reach the older years, furthermore, they are not expected to be as affluent as their parents. This is the result of the law of supply and demand. Their numbers have been so numerous that their earnings have tended to be lower than their parents’ because of the competition of their excessive supply. The decline of stock market values has also influenced their savings situation. The longevity they face may be welcome, but it might be longer than the lasting power of their accumulated wealth or the impact of inflation on pension plans that do not include cost of living adjustment provisions (Herz, 1995). Fixed incomes are savaged by the passage of time. The rising cost of health care and medication, less and less likely to be covered by previous employers, constitutes an undefined but frightening future burden. For women, all these limitations on the level of earnings are magnified by the fact that they drop out of employment for periods to provide free and “invisible” labor in caring for children and elderly family members and friends (Cotter et al., 2002); also, fewer women can look forward to pensions from employers than men of the same age. Aged women are often victims of poverty as

a result of these circumstances (U.S. Census Bureau, 1996). In short, potentially inadequate accumulation of wealth and economic uncertainty is a prevailing force in the lives of many aging baby boomers, causing them to consider remaining in the labor force for a longer period of time than originally planned (Fullerton & Toossi, 2001).

This trend is not entirely unwelcome, because other realities are reinforcing an interest in having older adults continue their labor force participation. As the baby boomers move toward retirement, there is an expected shortage of replacement workers (Hirschman, 2001; Herz, 1995). Given that women’s labor force participation rates are almost equal to those of men, the largest single pool of additional labor is the older work force (Doeringer, Sum, & Terkla, 2002). There is also a growing concern about paying the retirement bill for the nonemployed elderly as their numbers expand (Hardy, 2002). Finally, the numbers of older adults in the population will grow at accelerated rates over the next decades. Whereas the number of workers 45 or younger is expected to grow slowly or actually to decline between 2002 and 2012, those 55 to 64 years of age will increase by 51%, and those over 65 are projected to increase by 43% as the baby boomers shift to older age groups (“Labor Force,” 2003–2004). There is concern about who will care for them, given smaller families and higher labor force participation rates expected for their children, those in the “baby bust” generation (otherwise known as Generation X). Older adults themselves are viewed as a potential supply of paid caregivers (Rix, 2001).

Psychological Condition

The issue of economic uncertainty is not just an economic circumstance but is reflected in an individual’s psychological condition as well. A primary consideration is one’s feeling of physical well-being and perception of one’s ability to meet the demands of formal employment. The issue of health has a complex relationship to continued employment. It is obvious that some work (think about the job of sanitation truck operators, for example) is too physically demanding to continue into later years. For those who are getting older, the view that one’s personal health is at risk is the most likely influence in driving individuals from the labor force. But because most people gain health care insurance through work, even those who see work as a risk to their health are torn about leaving

work and losing their health benefit (Blau & Gilleskie, 1997). Sorting this out differs depending on how this issue plays for a particular individual.

Gender becomes another determinant of one's reaction to continued employment. Research has identified that women as a specific group are increasingly interested in paid employment for later periods in their lives as compared with men. Because many women change their work roles to comply with the demands of the household (Zimmerman, Mitchell, Wister, & Gutman, 2000), they come to their career peaks at later ages than men, and they value work at that point in their lives because they are experiencing success. Thus women, instead of being tied to spouses' decisions, have become actors in their own right (Coile, 2003) and often maintain an impressive level of attachment to employment beyond their personal age of eligibility for retirement, even if their spouses decide to retire (Choi, 2000). Having to retire before one is emotionally ready can lead to depression and lack of personal satisfaction (Zimmerman et al., 2000).

Alternatively, the perception that older workers have of attitudes toward them influences their actions. When faced with unemployment, many withdraw from the labor force, believing that employers will not be interested in them as workers (Taylor & Walker, 1998). There is evidence to support the accuracy of older workers' perceptions. Findings show that some employers believe that older workers are fearful of new technology, slower to learn, less educated, and unwilling to change the way they do things (Doeringer et al., 2002; Shen & Kleiner, 2001) and that they are more costly and may resent taking orders from younger people or that younger workers may feel uncomfortable supervising them (Brewington & Nassar-McMillan, 2000). These beliefs are at odds with the experience of older workers, who find work to be mentally energizing and seek to maintain some active work roles, confirming researchers' findings that the quality of life is enhanced by continuing labor force involvement (Ruchlin & Morris, 1991; McMahan & Phillips, 2000; Francese, 2004).

Family Situations

Throughout their lives, family situations often determine the actions of individuals. American society offers limited child care or elder care resources, leaving these responsibilities to families, and particularly women (Akabas & Kurzman, 2005; Akabas & Gates,

in press). Those who care for more than one person, for a seriously ill person, or for a male spouse are most likely to withdraw from work permanently to fulfill these family needs (Dentinger & Clarkberg, 2002). This may differ by ethnic group as well as gender, with African American women more likely than others to respond to family crisis by withdrawal from work (Bullock, Crawford, & Tennstedt, 2003). Marital relationships also may influence personal behavior. Individuals in situations characterized by serious tensions are less likely to opt for joint retirement than those in more supportive relationships. Unquestionably, the decision of older adults to work or not is a complex one with many interrelated conditions that influence the process of disengagement from work (Blau, 1994).

OPTIONS AVAILABLE FOR OLDER WORKERS

Total retirement is not the only possible response. Although many forces are moving toward early retirement, a countertrend is in the making—people are living longer and longer. Instead of death at the heels of retirement, a life expectancy of 20 years of leisure emerges, an unwelcome and long time for some. If retirement is defined as a situation in which an individual draws a pension for severance from a particular job, abrupt retirement is on the decline. The most recent evidence reflects a pattern of alternative work arrangements (Ruhm, 1995). Researchers have noted retirement as a process rather than a single event. People engage in what is variously known as “bridge employment,” “phased retirement,” “revolving retirement,” or “transitional retirement.” All refer to a process by which individuals reduce their work schedules or responsibilities. They leave their career jobs to take on less demanding responsibilities with their customary employer; or they “reverse retire” by terminating employment with a particular employer and then gaining new employment on either a full- or part-time basis with a new employer; or they achieve self-employment; or they delay retirement altogether (Blau, 1994; Hirschman, 2001; Kim & Feldman, 2000; Ruhm, 1995; Quinn, 1999; Quinn & Kozy, 1996). It appears that only 13.2% of adults over 65 are employed or seeking employment (Administration on Aging, 2003), but observers view this figure as misleading. Because of the just described activity of these workers, moving in and out of the labor force and replacing each other, the percentage at any one time does not reflect the reality. Research confirms that the actual

numbers are greater (Herz, 1995). Furthermore, these trends appear to be long term. Surveys of younger workers indicate that 80% expect to work after the age of 65 (Quinn, 1999).

Notably, patterns differ by age, race, ethnicity, gender, education, and type of work represented by career job (Ruhm, 1995; Quinn & Kozy, 1996). It is beyond the scope of this chapter to do anything more than indicate these differences, but, in general, total disengagement at an earlier age without subsequent work experience is characteristic of less educated, minority males who have done physical labor and find themselves in poor health. Some, particularly the white, older age group with economic security, utilize volunteer positions to fulfill their desire to achieve continuity and adjustment to retirement (Kim & Feldman, 2000). In their conclusion, Quinn and Kozy (1996, p. 373) sum up the situation:

The retirement patterns of older Americans are far from simple. Although the majority do leave their career jobs and the labor market simultaneously, a significant minority use bridge jobs to retire more gradually. Second careers are a common phenomenon. As the nation ages and changes in federal policy, including Social Security, reduce the work disincentives facing older Americans, these rich and varied retirement routes are likely to become all the more prevalent and important.

THE PROFESSIONAL ROLE

Clearly, there is much to do on micro, mezzo, and macro levels for social workers interested in assisting older adults in their relationship to the labor market. Professionals who work with those who are aging need to know about the world of work, policies and practices in that world, the rights, benefits, and opportunities available, and the expectations that employers are likely to hold concerning those wishing to continue employment or presenting themselves for hire. To be uninformed or misinformed in this area is to rob clients of the help they need with regard to their work options.

Older adults need assistance in reviewing their present status and potential opportunities, in making decisions concerning choices, and in adjusting to the transitions involved in their choices. On the individual or micro level, the issue of work should enter into

any assessment and counseling relationship so that individuals can receive help in sorting out the varied circumstances they face, causing work or retirement decisions to be made in a planned manner rather than by default. A social work professional needs to take a work history and to listen with the third ear concerning what is or was rewarding about the work experience, what are or were the difficulties with that experience, and how the person feels, now, about work, its demands, and its rewards. This will provide information on the meaning of work to the client. Is the individual employed at a physically or mentally overdemanding or unpleasant job from which retirement would come as a relief? Is the individual interested in continuing, reassuming, or being released from a work role? Does he or she have skills that will be valued in today's workplace, or is the person interested in training or pursuing educational opportunities to meet such demands? What are the motivations leading to work engagement or its termination? Are financial considerations significant? Is satisfaction in contributing to a work setting dominant? Is the individual pulled by a need for companionship and an activity around which to organize his or her time? Alternatively, is there a long desired activity that can be undertaken only at the end of a formal work connection or a volunteer opportunity the individual wishes to pursue? These questions will help identify what relationship to work is right for the particular individual and will offer guidance concerning what issues need attention if the person wishes to prepare for work.

Such an exploration will allow individuals to assess their ability (including health), economic resources, psychological needs, and family situations and the influence of each with regard to a work decision and may provide clues as to how to help the candidate for work communicate successfully at job interviews. Preretirement counseling and attention to financial management education can enrich these discussions. When offered significantly before an individual reaches the point of decision, they can be extremely helpful. Providing these services calls on the social worker's developmental understanding, and educational and therapeutic skills (Steun & Worden, 1993). Additionally, older workers need to be exposed to the skills of negotiation so that they are empowered to take an active role in determining their own work conditions and status. Social workers also can help guide the preparation of résumés and the identification of possible job openings. These interventions can be performed by a professional in pri-

vate practice, by one offering services in a family or other community counseling agency, or directly through an Employee Assistance Program (EAP) or its union counterpart, a Membership Assistance Program (hereafter subsumed under the heading EAP) at a worksite (Kurzman, 1992; Kurzman, 1993; Akabas & Kurzman, 2005). Notably, EAPs are usually staffed by social workers who know the culture and personnel of a particular workplace. EAP staffers can and do advise on the best approaches for older adults seeking to maintain or gain access to jobs in an organization, including negotiating the accommodations necessary to make the employment successful from everyone's point of view. Because they often are interconnected with such workplace units as human resource services, social workers with EAP status can influence recruitment, hiring, and retention policy decisions within organizations. Although many EAP personnel are reluctant to extend their turf to encompass organizational policy, others view such activities as the natural outcome of a systems approach to service delivery and participate actively in preretirement counseling and other aspects of planning for older working adults (Akabas & Kurzman, 2005; Kurzman & Akabas, 1993). As the workforce ages, social workers in EAPs may find increasing pressure from both individuals and organizations to take an active role in planning with older workers for their future labor force participation.

But it is not only EAP social workers who can influence organizational behavior. On the mezzo level, social workers should be prepared to develop organizational programs, in work settings and in community agencies, that will meet the needs of those older adults who are seeking new careers, developing entrepreneurial initiatives, maintaining existing work roles in organizations, searching for training opportunities, looking for fulfilling volunteer activities, or needing help adjusting to their new status, including overcoming social isolation. Individual interactions can serve as the basis for a needs assessment to identify the kind of program development that is indicated. Workplaces and unions can establish retirees' clubs which provide social support in a familiar setting to those who have given long years of service to the organization. Such programs are usually run by occupational social workers who either are employed by the sponsoring organization or are employed by a service provider that is workplace focused and may have a contract with the retirees' former employer or union. These programs can be duplicated in community settings. Organized to help people through the

transition from work to retirement or to explore alternative work options, such efforts require a different focus than is placed on the more typical older adult recreation groups offered by community social service providers. They need to be concerned with the coordination of services with the workplace itself.

Programs that would help older adults deal with employment and retirement issues need to build bridges to workplaces, bridges that develop trust among the parties on which job development can be based. The time is exceedingly propitious for such initiatives. The expected shortage of workers as baby boomers reach retirement age will make employers more desirous of maintaining older workers or recruiting from among the older adult pool than they have been in the recent past (Porter, 2004). Social workers can use this trend to establish ties with work organizations and educate them to the potential contribution of older workers independent of the interests or job placement needs of any particular client. The goal of such endeavors would be to build an employer network that is ready, willing, and able to provide employment to interested older adults, that is, to put the structure in place that can be responsive when the need arises. It is then possible to use such connections to follow the client/worker into the workplace and help create interrelationships that are supportive of successful employment through interventions such as psychoeducation with the work group (Gates, Akabas, & Oran-Sabia, 1998).

The advocacy such activities require has even more relevance on the macro level. Social workers need to be aware of current legislation and more general social policy dilemmas and use advocacy to encourage policy changes that would respond to the issues of social concern posed by the graying of the American labor force. Attention to the enforcement of the ADEA is another outlet for social work advocacy. Laws are only as effective as the strength of the effort invested in enforcement. There is need to overcome the present circumstances, identified by Neumark (2003, p. 315), who concluded that despite the ADEA there is "ample evidence consistent with hiring discrimination against older workers."

For the social worker who would take on these new but important responsibilities, there are many sources of help. The *O-Net Occupational Dictionary*, easily accessible on the Internet, provides information on different occupations in the United States economy and the demand for each. Local and state departments of labor tend to have information and knowledgeable staff ready to provide advice on labor

market issues. The American Association of Retired Persons (AARP), the AFL-CIO, and many other organizations offer Web-based information that can be quite helpful. Research findings on related issues are increasingly available.

Certainly our society should not renege on the promise of basic economic security for older adults provided in the Social Security Act of 1938. Neither should society pressure, by stereotyping and stigmatizing, older adults who seek to maintain work past an age for labor force exit set when life expectancy was several decades shorter and when the physical demands of work were much greater. Social workers have an important role in helping to sort out this changing horizon and can offer significant services to aging adults and to our society by so doing.

As the demographic landscape of the world changes, people are curious about those who live well beyond their life expectancy; those people we call the oldest old. Their chronological age has been a fascination to researchers and practitioners. In this chapter, we report findings in the main areas of function and well-being, sociodemographic factors, mental health, social support, and health. Where possible, findings regarding the very old (85+) are compared and contrasted with those on the young old (65–75 years of age) and the old old (75–85 years of age). Racial and ethnic variations are addressed, as well as caregiving and service delivery issues and culturally competent care for the very old.

SOCIODEMOGRAPHICS

The increase in life expectancy and the decline in fertility have contributed to the aging society in developed countries. With the aging of the baby boomers, American society has grown old rapidly, resulting in a dramatic increase in the demographic projections for the oldest old. There will be 71 million people ages 65 years and over by 2030, representing 20% of the population in 2030 (U.S. Census Bureau, 2003). The oldest old, the fastest-growing age group, will constitute 2% of the population in 2010, and it is projected to be 5% of the population by 2050 (U.S. Census Bureau, 2003). Figure 16.1 graphically displays the population distribution by age over a 100-year period (1880–2080). It is clear that the coming decades bring many more people into the very old age groups and fewer into the younger age periods.

Race

As shown in Table 16.1, there were 4.6 million people age 85 and over in the United States, representing 1.6% of total population, in 2002 (U.S. Census Bureau, 2003). Among the oldest old, the majority of people were non-Hispanic Whites, compared with Blacks, those of Hispanic origin, and Asians (U.S. Census Bureau, 2003). Even though this racial composition reflected much less diversity than that of the U.S. population as a whole in 2002 (U.S. Census Bureau, 2003), the racial diversity among the oldest old is projected to increase somewhat during coming decades (U.S. Census Bureau, 2003).

Gender

Gender disparity becomes more remarkable with advancing age. As shown in Table 16.2, 70% of women

and 30% of men are among the population age 85 and over, whereas there were 45% elderly women and 55% elderly men among the young old (U.S. Census Bureau, 2003). The extreme gender gap in advanced age poses more challenges for elderly women than for men. For instance, elderly women are more likely to be widowed, economically disadvantaged, physically frail, and institutionalized than their male counterparts (Taeuber & Rosenwaike, 1993).

Marital Status

The pattern of marital status is changing with advancing age. In addition to age, gender imbalance among the oldest old influences the shift in the pattern of marital status compared with other older age groups. As shown in Table 16.3, whereas 9% of women and 45% of men among the oldest old are married and living with their spouses, 72% and 35% are widowed, respectively. The oldest old men are five times as likely as women to be married (Kreider & Simmons, 2003).

Living Arrangements

Although most of the oldest old live in the community, people in this age group constitute the largest proportion of nursing home residents. In 1999, 47% of the nursing home residents were among the oldest old, compared with 32% for elders ages 75–84 and 12% for those ages 65–74 (Bernstein et al., 2003). Overall, though, the proportion of elders living in nursing homes is declining, and this is true for the oldest old as well. Eighteen percent of the oldest old lived in nursing homes in 2000, down from 25% in 1990 (Hetzl & Smith, 2001).

Socioeconomic Status

With advancing age, the poverty rate among older adults is increasing, indicating that the oldest old are more likely to be poor. In 1992, the poverty rate among community-dwelling elders ages 65 to 74 was 10.7%, which was not significantly different from other adult age groups, such as people ages 55 to 59 or those ages

60 to 64. The poverty rate was 15.3% for elders ages 75 to 84 and 19.8% for the oldest old (Hobbs, 1996).

Educational attainment, one of the crucial determinants for socioeconomic status, was found to be lower among the oldest old than the young old. In 2002, 61% of oldest old men and 57% of oldest old women had had at least a high school education, whereas 73% of men and 74% of women 65–74 years of age had completed high school (Smith, 2003).

Mortality

Life expectancy increased significantly during the 20th century. According to *National Vital Statistics Reports* (Arias, 2004), from 1900 to 2001, overall life expectancy at birth increased from 49 years to 77. Specifically, for Whites, life expectancy increased from 49.6 in 1900 to 77.7 in 2001; for Blacks, life expectancy at birth was 72.2 in 2001, an increase more

than double that of 33.8 in 1900. Life expectancy for the oldest old increased as well. At age 85, the average number of years remaining in life was less than 4 years in 1900, but it increased to 6.5 in 2001 (Arias, 2004). In part, lower mortality is the reason that people are living longer (Preston, Himes, & Eggers, 1989). This is a particularly interesting issue among the oldest old of color. Recent examination of racial mortality highlights that racial crossover in mortality rates is one of the newly emerging issues among the oldest old. It has been a general notion that White Americans outlive African Americans, given that African Americans are more disadvantaged and face more discrimination than White Americans (Rogers, 1992). Empirical research reports mortality rates crossing over at age 80 years or so. Specifically, mortality rates for those younger than age 80 were higher for African Americans than for Whites but lower for African Americans than for Whites after age 80 (Corti et al., 1999; Manton & Stallard, 1981; Markides & Machalek,

1984). One explanation of the racial crossover effect is explained by “survival of the fittest” (Manton & Stallard, 1981). Specifically, because African Americans have experienced more disadvantages and unfavorable health conditions, it is likely that more vulnerable people died earlier (Preston, Elo, Rosenwaike, & Hill, 1996). On the other hand, some researchers indicate that crossover may be the result of misreporting of age on the death certificate (Crispell, 1996). Preston and colleagues (1996) showed that the reported age on the death certificate was lower than that in Social Security records, especially for African Americans. After adjusting for age at death, mortality rates in African Americans substantially increased above age 85, and racial crossover disappeared.

MENTAL HEALTH

Depression is one of the most common mental health problems among older populations. Five million older Americans age 65 and over suffer from serious and persistent symptoms of depression, and 1 million out of 5 million suffer from major depression (American Psychological Association, 1993). Among older populations, the oldest old are at high risk for mental disorders due to multiple functional disabilities, medical illness, and increasing vulnerabilities to various stressors with age, resulting from declining health and dwindling social relationships (Borson, Bartels, Colenda, Gottlieb, & Meyers, 2001). The oldest old reported higher levels of depressive symptoms than the young old dwelling in the community (Blazer, 2000; Blazer, Burchett, Service, & George, 1991; Stallones, Marx, & Garrity, 1990). In a longitudinal study of the oldest old, the participants reported increasing depressive symptoms over a 9-year period (Dunkle, Roberts, & Haug, 2001).

Although literature supports the notion that the oldest old present higher levels of depressive symptoms, the prevalence of clinically diagnosable depression among this population is not clear. Available literature, however, suggests that the amount of clinically diagnosable depression among the oldest old may be lower than that among younger populations. For example, in Haynie and colleagues’ (Haynie, Berg, Johansson, Gatz, & Zarit, 2001) longitudinal study with Swedish twins over age 80, most participants had a depressive symptom level that was below the clinical cutoff for the Center for Epidemiologic Studies Depression Scale (CES-D), suggesting low rates of clinical depression among the oldest old.

Given that the oldest old survive longer than many of their age cohort, the low prevalence rate of depression among the oldest old may be explained by their physical and mental advantages, as well as their coping capacities (Kiljunen et al., 1997).

Suicide is strongly associated with depression among older adults (Katz, 1998). Recent research suggests that the oldest old are at higher risk of suicide (e.g., Erlangsen, Bille-Brahe, & Jeune, 2003; Turvey et al., 2002). The rate of suicide is the highest among people age 65 and over and continues to increase for those over age 80 (Turvey et al., 2002). Erlangsen and colleagues (2003) examined suicide trends among the young old, ages 65 to 79, and the oldest old in Denmark who committed suicide for the period 1972–1998. They found that the suicide level among the oldest old remained very high, whereas that of the young old declined. Their study also showed that the oldest old employed determined suicide methods, such as hanging or jumping, compared with the young old, indicating that suicide intention is stronger with advancing age. Similarly, Barnow and Linden (1997) found that 15% of the very old from the Berlin Aging Study (BASE) presented symptoms of tiredness of life, 5% had a wish to die, and 0.5–1% showed suicidal behavior. Age was significantly associated with suicidal ideation; 1.2% of those ages 70 to 80 reported having plans to commit suicide or wished to be dead, whereas 7.6% of the oldest old, ages 90 and over, had plans for suicide. Cook, Pearson, Thompson, Black, and Rabins (2002) examined suicidal ideation in a sample of 835 Black elderly residing in six urban public housing developments. They found that passive suicidal ideation was associated with depressive and anxiety symptoms, whereas social support and religiosity were protective factors of suicide ideation.

Worry is another significant factor influencing mental health. Examining worry in the sample of the very old, ages 85 and over, living in the community over a 9-year period, Dunkle et al. (2001) found that worry was low at the initial interview but significantly increased over the 9 years of the study. The oldest old reported that their greatest worries were associated with health and dependence in daily activities. Consistent with other studies including predominantly young old participants (Skarborn & Nicki, 1996), for the oldest old, worry was strongly associated with depressive symptoms and poor mental health (Dunkle et al., 2001; Robert, Dunkle, & Haug, 1994).

Dementia, in particular Alzheimer’s disease, affects predominantly the oldest old and increases even

in advanced ages. This is another major mental health issue among the elderly. A recent study reports a prevalence of dementia of 13% among elders ages 77 to 84 that increased to 48% in those age 95 and over (Strauss, Viitanen, Ronchi, Winblad, & Fratiglioni, 1999). In 2000, the number of people age 85 and over with Alzheimer's disease was 1.8 million, making up 40% of the 4.5 million people with Alzheimer's disease (Hebert, Scherr, Bienias, Bennett, & Evans, 2003). This number of the oldest old with Alzheimer's disease will increase to 8 million in 2050 (Hebert et al., 2003). In addition to the prevalence rate, the oldest old reported an 8.4% annual incidence of Alzheimer's disease. The incidence rate was 0.6% for the young old, ages 65 to 69, 1.0% for elders ages 70 to 74, 2.0% for elders ages 75 to 79, and 3.3% for elders ages 80 to 84 (Hebert et al., 1995).

HEALTH

The often-heard discussion of an increasing life span incurs thoughts of a longer and healthier life, but an increasing life span often comes at a price of increasing health problems. Evidence indicates that in the face of declining mortality, there is worsening health among those who survive (Olshansky, Rudberg, Carnes, Casse, & Brody, 1991). Health is no longer regarded as an absence of disease because of the increasing number of diagnosable diseases in old age, especially among the very old (Steinhagen-Thiessen & Borchelt, 1999). After age 45, issues of disability and declining functional ability become a concern for many. With advancing age, these concerns escalate, with an increasing prevalence of activities of daily living (ADL) limitations (Guralnik & Simonsick, 1993). The greatest limitations are among those over the age of 85 (Parker, Thorslund, Lundberg, & Kareholt, 1996). During this age period, elders become more dependent, with greater reliance on social and health resources (Schneider & Guralnik, 1990; Thorslund, Norstrom, & Weinberg, 1991). About 88% of the very old have at least five diagnosable physical illnesses. Thirty percent are diagnosed as having at least five moderate to severe illnesses, and 21% have five illnesses that are treated with medications (Steinhagen-Thiessen & Borchelt, 1993). With the belief that health is no longer defined as "disease free" for the elderly, Steinhagen-Thiessen and Borchelt coined the term *rather healthy*, now being used to identify a reference category of healthy old people with the recognition that most very old people have some health problems. As Steinhagen-Thiessen and Borchelt (1993) note, this

term describes "those having less than five somatic diagnoses, less than five prescription drugs, no diagnosis of dementia or depression, no severe loss of vision or hearing, who are mobile, continent, and not restricted in ADL" (p. 634).

Although diagnosis, medication issues, and other factors are very important in describing the health of the elderly, the most essential component of geriatric practice is the functional aspects of physical health (Steinhagen-Thiessen & Borchelt, 1993). Functional capacity includes the ability to do instrumental activities of daily living. It also includes sensory and sensorimotor capacity. The instruments used to evaluate these have recently been extended to include measurements of social activity and psychological state (Applegate, Blass, & Williams, 1990; Reuben & Siu, 1990), as well as mobility (Guralnik, Branch, Cummings, & Curb, 1989; Tinetti, 1986). The measures of ADL among very old adults produce heterogeneous results (Zarit, Johansson, & Malmberg, 1995). In addition, an inconsistent pattern of decline emerges from longitudinal studies of the oldest old (Dunkle et al., 2001; Femia, Zarit, & Johansson, 1997), indicating significant variability in function among the very old.

Even with the identification of functional problems among the very old and their increase with advancing age, disability is not always the result. Recent figures from the U.S. Census (McNeil, 2001) indicate that 34.9% of people over age 80 need personal assistance (57.6% indicating they have severe disability). Severe disabilities are greater for women than men overall (61.4% vs. 51.1%), with the gender difference holding for all racial groups and for all degrees of severity. Overall, the oldest old are not viewed as in a state of eventual decline but rather a state influenced by social, psychological, and physical factors (Femia et al., 1997).

Disability is usually defined using self-reported functional ability and includes the older person's ability to interact with his or her environment (Schoenfeld, Malmrose, Blazer, Gold, & Seeman, 1994). Taking this idea of environment into consideration, Verbrugge and Jette (1994) make the distinction of intrinsic versus actual disability. They describe *intrinsic disability* as the physiological hardship or medical problem that someone faces in attempting to accomplish a task. *Actual disability* is the case in which the physical demands placed on an individual are difficult or impossible to meet (Johnson, 2000). Having help in walking with the use of a cane or walker does not erase the intrinsic disability, but it does allow the individual to get around, thus diminishing the actual

disability faced. Disability is conceived as a gap between personal and environmental factors. Therefore, the nature of disability involves the measure of both physical and psychological abilities.

Little research exists that identifies the factors associated with narrowing the gap between actual and intrinsic disability. Identification of these factors could promote independence and delay disability (Femia et al., 1997), thereby improving the quality of life of the elder, as well as decreasing the cost of treatment in the health care system (Johnson, 2000).

Identifying risk factors that accelerate the need for care, as well as determining the effectiveness of intervention strategies, would help in the development of prevention strategies. Some work has been designed to understand what socioeconomic and demographic factors are related to the use of an assistive device. Zimmer and Chappell (1994) found that age predicted the use of assistive devices. Verbrugge, Rennert, and Madans (1997) found that people over age 75 were more likely to accept assistance in managing a lower-extremity problem than were those under age 75. Hartke, Prohaska, and Furmer (1998) note that Whites were more likely than African Americans to use any assistive device. Gender plays a role. Older women were more likely than men to use personal assistance devices only, and men are more likely to use equipment such as motorized scooters than women (Verbrugge et al., 1997). Johnson (2000) explored the influence of living environments of elders (metro vs. nonmetro) on the use of assistive devices and personal helpers. No differences in intrinsic disability were found between people residing in the two types of environments, but the nonmetro elders were less likely to overcome the hardship of walking across the room due to having fewer architectural accommodations in their residences than those living in metropolitan areas. Overall, as long as the elders lived in the community and not in a sheltered environment such as an assisted-living facility or nursing home, they were more likely to be stable in functional ability (Femia et al., 1997).

In addition, psychological resources such as mastery and subjective evaluation of health also influence functional ability. Psychosocial resources influence need for help among older people (Mor et al., 1989). In numerous studies, subjective health is associated with stability in ADL functioning, at least in the short run (Femia et al., 1997). Others (Heckhausen & Krueger, 1993) suggest that subjective health is the result of social comparison, in which one's health is viewed in relationship to another person's. Mastery is

also a predictor of short-term changes in ADL (Femia et al., 1997), with lower mastery predicting more ADL problems. Although mastery diminishes over time (Mirowsky, 1995), the variability in mastery seems to increase with age (Rodin, 1989). Others have also found the importance of mastery in later life, suggesting that mastery can affect level of activity (Roberts, Anthony, Matejczyk, & Moore, 1994; Schoenfeld et al., 1994). All in all, research on the oldest old is expanding the evidence of an existing relationship between physical and psychological functioning.

Physical morbidity and disability often lead to decline in social and psychological functioning (Borchelt, Gilbert, Horgas, & Geiselmann, 1999). Functional problems can produce depression or even dementia (Katona, 1995) and lower subjective well-being (Smith, Fleeson, Geiselmann, Settersten, & Kunzmann, 1999). For example, Borchelt et al. (1999) suggest that immobility is a risk factor for depression. Vision and sensory limitations create problems for the older person in interacting with the environment, a strong detriment to limiting disability (Verbrugge & Jette, 1994). Conversely, poor social and psychological functioning can lead to poorer physical health through self-neglect, poor diet, and so forth (Maier, Watkins, & Fleshner, 1994; Marmot et al., 1991). Age alone does not explain the relationship between health and psychosocial factors.

Evidence of this relationship has important implications for intervention in this very old group of elders. Mastery, in particular, represents a sense of control over events confronted in life. Practitioners could help very old people by acknowledging the relationship between health and mental health and the importance of a sense of effectiveness in promoting better functioning over time. Femia et al. (1997) suggest that increasing physical frailty in very late life may be offset by these psychological resources that function as protective factors and that compensate for decline in health with increasing age.

SOCIAL SUPPORT

Extensive research on the importance of social support among the elderly has filled behavioral and social science journals over the past two decades (Antonucci, Sherman, & Vandewater, 1997; Biegel, 1984; Minkler, 1985; Wan, 1982).

Competing perspectives describe social support across the life span. The continuity perspective articulates the relative stability of social support (Palmore,

1981), whereas the social problems approach describes the constriction of social support with advancing age due to retirement, relocation, and death of friends and family (Hess, 1972; Morgan, Schuster, & Butler, 1991). Research, primarily involving the younger old, supports the continuity perspective, showing that these elders are embedded in kin and family contexts (Bengtson & Schutze, 1992; Troll, 1986). Among the very old, social isolation is more likely to exist than among the younger old (Knipscheer, 1986), more in line with the notion of constriction of support.

Age differences exist regarding who belongs to social networks. With personal social networks of elders, the young old name significantly more people in their social networks than the very old do (this was primarily among friends and acquaintances and not among intimates; Smith & Baltes, 1999). Field and Minkler (1988) examined social contacts among young old and very old people, as well. Although they found that involvement within the family and friendship patterns did not change over time for the young old or the very old, the picture was different when other facets of social support were examined. Their very old participants had less frequent contact with some children, were less likely to have a spouse in their social network, and had lessened involvement in church and social club activities. In part, these changes in social contacts resulted from death of family and friends and geographic dispersion among family members. Another longitudinal study (Dunkle et al., 2001) found similar results. Although many women were without spousal support, they had confidants, family, and friends who were available to provide support. One study (Dunkle et al., 2001) provides a longitudinal view of support among the very old over time. Their participants who completed all waves of the study most frequently identified a child as someone who could provide occasional assistance if needed (25%). This increased to 42% eighteen months later. Most had living children at the beginning of the study (78.3%), but this number declined to 21.7% after 9 years. With increasing age, elders relied less on family and more on neighbors and friends; this may be due to the health conditions of their children, as well as their children living farther away. Siblings were not identified as being able to provide even occasional help. In all likelihood, they were very old as well and in need of support themselves. Evidence suggests that the network size shrinks over time. At wave 1, about 95% of the sample knew someone to visit. Nine years later, 83% said they knew someone to visit. About 68% of the respondents in this study said

that they were lonely (Dunkle et al., 2001). This is significantly different from the 10% identified as lonely in the Georgia Centenarian Study (note that participants were all over 100 years of age; Martin, Poon, Kim, & Johnson, 1996). Even though worry seemed to be an issue among the very old, it does not necessarily jeopardize the well-being of these elders. Research supports the idea that well-being is associated with the feeling that there is at least one person on whom you can rely for emotional support (Thomae, 1994).

Unfortunately, most authors do not consider the influence of the health of the elder on social support. It seems clear that the relationship of the elder's health to social support is significant (Kaplan & Haan, 1989; Ory, Abeles, & Lipman, 1992); that is, as old people age, their health is likely to change in significant ways and thus influence the need for social support. The greater likelihood of change in social support among the very old suggests an ebb and flow that may be very dynamic for these elders.

Older people are more likely to need social support related to health care needs in particular. Roberts and colleagues (1994) found that men and women dwelling in the community mobilized social support differently when facing stressful circumstances. Women with better mobility had more tangible support and greater emotional support than men with similar mobility.

CULTURALLY COMPETENT CARE

Although little has been written about culturally competent care among the oldest old, nonetheless it is important to begin to think about its relevance for elders in this age group. They are more likely to be frail and in need of health and social services. Social service practitioners are increasingly aware of the need for culturally competent health care. There continue to be health disparities between racial/ethnic groups that need to be addressed (Lillie-Blanton, Parsons, Gayle, & Dievler, 1996; Williams, Lavizzo-Mourey, & Warren, 1994). One area is within the caregiving network. Research conducted on caregiver networks and race shows that the effect of race on expanding the caregiver network beyond the marital dyad is unclear. Feld, Dunkle, and Schroepfer (2004) found that Black couples were more likely than White ones to have instrumental activities of daily living (IADL) caregiver networks including helpers outside the dyad. On the other hand, Stoller and Cutler's (1992) results did not show racial differences in sole reliance on the spouse

for either IADL or ADL caregiving. Unfortunately, race and gender were not considered simultaneously.

Community service is another area that has been examined. Work conducted with various minority groups sheds light on variations in service utilization by race as well. In work conducted by Miller and Stull (1999), they determined that African American elders were more likely to distrust the staff of community services than were Whites. As suggested by these authors, factors contributing to this distrust are probably lodged in heterogeneity of attitudes toward care. Service-providing individuals, as well as service contexts, influence service use and should be taken into account when designing services (Miller & Stull, 1999). One service context, the care system of Kaiser Permanente Health System, has designed diversity training programs that include handbooks for health care with specific minority populations (Gilbert, 1998).

Service providers need to master three elements of cultural competence: awareness-oriented strategies, knowledge-oriented strategies, and skill-oriented strategies. With awareness-oriented strategies, the practitioner engages in self-examination of personal biases and prejudices. Knowledge-oriented strategies aid the practitioner in learning about the culture of his or her clients; and with skill-oriented strategies, the practitioners learn behaviors that are culturally responsive. With the growing recognition that the elderly are better served with team-based care (Wadsworth & Fallcreek, 1999), individual practitioners are being organized into culturally competent care teams with educational programs designed for interdisciplinary teams of health care professionals who understand the elements of cultural competence (Wadsworth & Fallcreek, 1999). The oldest old are a heterogeneous group of people. More will be people of color; more will embrace their own cultures. Practitioners need to learn about these cultures and health beliefs if they hope to care successfully for these very old people.

IMPLICATIONS FOR SERVICE DELIVERY AND FUTURE RESEARCH

In many ways, those who are very old are not very different in their needs from other older people. What does make them different is their heterogeneity of needs. The very old experience more health and certain mental health problems simultaneously, and as a group they have fewer health, financial, and social resources to deal with the problems they face. Researchers have only begun to examine service needs of

the very old and the resources that they bring to their health and mental health needs.

Mental Health Service Delivery

With increasing numbers of older adults with mental health problems, demand for mental health services is expected to increase. Interestingly, the utilization rate of mental health service among older adults is found to be lower than among younger adults with certain mental health problems. In part, this may be due to the lack of specialized mental health services for older adults (Koenig, George, & Schneider, 1994). Jin et al. (2003) found that community-dwelling elders with schizophrenia used fewer public mental health services, except case management, than young adults and middle-aged people. In addition to age, mental health problems such as depression seem to deter elders from seeking help. Whereas elders utilized fewer mental health services compared with other age groups, older adults with depression were more likely to use health care services. For example, Luber et al. (2001) examined the association between primary care provider's diagnosis of depression and health care utilization in the sample of elderly patients seen in a primary care practice. They found that older people diagnosed as depressed utilized more outpatient visits, underwent more laboratory tests, and had more consultations with medical, surgical, and other specialists than nondepressed counterparts.

Identifying resources that aid the very old in dealing with their mental health and health needs is important. Mastery is one resource that has been suggested as particularly helpful for the oldest old. Elders who feel some control over the events in their lives may be able to function at a higher level than those with a lower sense of mastery. Another resource is found in social support. Who provides social support to the very old is not clearly understood. It seems that their support networks shrink, and yet they report adequate help (Dunkle et al., 2001). Identifying the members of the support network and bolstering those people with formal support could aid in the development of a network that has enough depth to function not just in a crisis but over a prolonged period of time if needed.

Even though it is difficult to know the reason for age variations in mental health service utilization rates, it is important to identify barriers that may contribute to lower usage among elders in order to understand mental health service delivery issues among the oldest old. Older adults are less likely to seek help

than younger adults, as they are more vulnerable to the stigmatization of mental illness and have more negative attitudes toward seeking help (Hastings, 1993; U.S. Department of Health and Human Services, 1999). Older adults tend to seek help from primary care physicians or clergy than from mental health specialists (Husaini, Moore, & Cain, 1994; Tiemens, Ormel, & Simon, 1996; Unutzer et al., 1997). The characteristic of late-life depression that is frequently comorbid with chronic illness seems to influence help-seeking patterns among elders. Given that the oldest old are at greater risk of frailty and comorbidity (Blazer, 2000), they may think depressive symptoms are a normal part of growing older and thus may consult with primary care physicians or religious persons. In spite of inconsistent findings in depression and age, depression among the very old is associated with comorbid physical conditions or chronic illness (Blazer, 2000), resulting in greater need for paid care, as well as informal care. Because older adults are more likely to have financial limitations, especially when they reach advanced ages, it might be difficult for the very old to obtain appropriate care. In particular, when the oldest old with depressive symptoms fail to get care, emotional distress, as well as physical dysfunction, might be exacerbated, causing higher dependence on others and increase in societal costs. Given that the prevalence of driving among the oldest old rapidly declines compared with that of the young old, causing the very old to be more transportation dependent (Foley, Heimovitz, Guralnik, & Brock, 2002), transportation may be a bigger issue in lower utilization of mental health services among older adults (Lasoki, 1986).

Caregiving Issues

The significant increase in the prevalence and incidence of dementia among the oldest old has imposed a great burden on informal caregivers, as well as on the public health care system. Dementia caregiving is more complicated and burdensome than nondementia caregiving, as dementia affects cognitive, behavioral, and affective functioning (e.g., Ory, Hoffman, Yee, Tennstedt, & Schulz, 1999). Dementia caregivers spend more time providing care and report more stressful situations related to work, family, and health than do nondementia caregivers (Ory et al., 1999). In addition, caregivers with higher stress levels are more likely to place elders with dementia in nursing homes (McFall & Miller, 1992; Montgomery & Kosloski, 1994).

Related to the issue of need for assistance is a focus on the availability of caregivers, those who can provide support. In large part, caregivers are children or age peers, with spouses making up the greatest percentage of caregivers (Rivlin & Wiener, 1989). This is particularly true with female caregivers (Feld, Dunkle, & Schroepfer, 2004). This situation has implications for caregiving. Recently published work on caregiving in marital dyads provides insight into who is involved in the caregiving network of older couples (not among the oldest old). Wives are especially likely to provide all the functional care their frail husbands receive, and husbands are more likely to share their caregiving with others. IADL and ADL caregiver networks were more likely to include helpers other than the spouse when the help recipient was the wife than when the husband was the help recipient. This gender difference has been found in a study of both IADL and ADL networks (Feld, Dunkle, & Schroepfer, 2004, under review; Stoller & Cutler, 1992).

When the care recipient is very old, the spouse and children are also likely to be old. Because of this, the caregivers often face similar problems to those of the older care recipient. Among these very old people, this may mean that the social support network shrinks due to death and illness of the caregivers themselves. With evidence of increasing health problems among the very old, coupled with the likelihood that social support systems shrink with age (Bould, Sanborn, & Reif, 1989; Soldo & Manton, 1985), research is needed that examines the relationship of health and social support among very old people.

CONCLUSION

The heterogeneity in health and functional ability among those who are very old is a critical feature that practitioners should remember. Inconsistent patterns of decline (Dunkle et al., 2001) suggest that a comprehensive evaluation of very old patients is in order to determine the strengths and weaknesses of each individual. In part, this evaluation consists of awareness-oriented strategies that require the practitioner to examine his or her own feelings and beliefs about aging. In addition, the practitioner should be educated in the intervention strategies that have been successfully used with older people and consider what adaptation may be helpful to meet the needs of the oldest old. Lastly, executing the intervention in a fashion that has been found to be helpful to older people is a necessity. Identifying risk factors that accelerate

the need for care, as well as the effectiveness of intervention strategies, would help in the development of prevention strategies.

A growing body of literature exists regarding the oldest old. Unfortunately, little is known about successful intervention strategies to meet the health and mental health needs of these very old people. By learning who these very old people are, where they live, who they care about, and what health issues they face, practitioners can begin to develop relevant services to meet the health and care needs of the very old.

IMMIGRATION HISTORY AND PATTERNS

As a nation of immigrants, the United States has admitted more than 68 million immigrants, including refugees and asylum seekers, between 1820 and 2002 (U.S. Department of Homeland Security, 2003). Whereas immigrants in the late 19th century and early 20th century were mostly from European countries, the past five decades have seen rising numbers of immigrants from the Americas and Asia (U.S. Department of Homeland Security, 2003). Beginning with the Displaced Persons Act of 1948, more than 600,000 people came from Eastern Europe and what were then “Iron Curtain” countries, and the Immigration and Naturalization Act of 1965 opened the door to several million Asians. Following the fall of South Vietnam in 1975, more than 1.1 million Vietnamese, Hmong, Laotians, and Cambodians came to the United States as refugees between 1975 and 2002 (Niedzwiecki & Duong, 2004).

Of 9.1 million new immigrants from more than 200 countries between 1991 and 2000, almost one half (49%) were from the Americas, 31% from Asia, 15% from Europe, and 4% from Africa. The percentage of older adults age 65 years or older fell from 5.6% of all immigrants in the 1980s to 3.2% in the 1990s (U.S. Census Bureau, 2001). In 2002, however, 7.6% were 60 years or older, and 14.4% were 50 years or older. The vast majority of the 60 and older age group arrived in the United States under the category of “immediate relatives of U.S. citizens.” Over 60% of immigrants live in six states: California, New York, Florida, Texas, New Jersey, and Illinois. In 2000, the median length of residence in the United States was 14.4 years.

The continued increase in the immigrant population, which has grown at a rate faster than that of the U.S. population, especially during the 1990s, has led to an increase in the proportion of the foreign born, from 6.2% (14.1 million) in 1980 to 10.4% (29 million) of the U.S. population in 2000 (U.S. Census Bureau, 2001). In 2000, Mexico, as the country of origin, accounted for over one fourth (7.8 million) of all foreign born in 2000, followed by China (1.4 million), the Philippines (1.2 million), India (1 million), Cuba (1 million), Vietnam (0.9 million), El Salvador (0.8 million), Korea (0.7 million), the Dominican Republic (0.7 million), Canada (0.7 million), and Germany (0.7 million). These numbers represent underestimates to the extent that foreign-born or illegal immigrants did not participate in the census.

Immigrant and Refugee Elders

17

GROWING DIVERSITY AND ITS IMPLICATIONS

The continued influx of older adult immigrants and refugees from more than 200 countries, together with the aging younger immigrants of past decades, has meant that the elderly immigrant and refugee population in the United States has become increasingly diverse. This diversity includes not only racial and ethnic background but also reasons for immigration (e.g., family reunification, economic opportunities, fleeing from war, fear of persecution, or political turmoil in the country of origin), age at the time of immigration, length of residence in the United States, and English proficiency. Besides historical and demographic diversity, one finds expanding diversity in cultural norms and values governing the family, its role as caregiver for the elderly, living arrangements, family relations, interpersonal behavior, health beliefs, the role of religion and spirituality, and attitudes toward health and social services.

The immigration history, cultural norms and values, and socioeconomic background of immigrants have significant effects on their well-being and on the process of adjustment in the new environment. These factors may vary not only among immigrant elderly groups from different regions or countries but also within the same ethnic group. For example, ethnic Chinese elders from the People's Republic of China, Hong Kong, Singapore, and Taiwan may have different values and ideologies, different educational and economic backgrounds, different levels of acculturation and English proficiency, and different service needs. Muslim war refugee elders who recently came from Kosovo and Bosnia may experience different levels and types of war-related trauma than Afghan elders who came in the 1970s, when they were in their 40s, fleeing the war with Russia. On the other hand, the importance of religious and spiritual coping and healing may be similar among predominantly Christian Korean, Buddhist Cambodian and Laotian, and Muslim Indonesian immigrant elderly people.

For many immigrant elders who escaped from persecution and poverty in their homeland, the United States is the land of relief and improved economic opportunities. For many of those who immigrated to join children who had already been living in the United States, arrival in America brings tremendous happiness. Some elders, however, may conclude that the losses involved in immigration to the United States outweigh perceived advantages of the move to the new country (Gelfand, 2003). Indeed, it is difficult

to generalize the life experiences and issues of increasingly heterogeneous immigrant and refugee elderly populations, not only because they all have different backgrounds, but also because their experiences and expectations change in the process of adjustment and settlement in the United States.

Although immigration may have a varied impact on individuals, most elderly immigrants and refugees, especially during the early period of adjustment to their new environment, experience stresses associated with migratory grief, attachment to their home country, language, social isolation, unfamiliarity with health and social services, limited social support and mobility, increased dependency on children and their families, lowered status within the family and the society, and barriers to participating in mainstream social and political activities (Casado & Leung, 2001; Gelfand, 2003; Moon, Lubben, & Villa, 1998; Strumpf, Glicksman, Goldberg-Glen, Fox, & Logue, 2001; Wong, 2001). For example, a study of caregiver and elder experiences of Cambodian, Vietnamese, Soviet Jewish, and Ukrainian refugee elders in Philadelphia (Strumpf et al., 2001) found that, with few exceptions, the major impact of immigration on refugee elders was loneliness and isolation. As a result of increased vulnerability and lowered status in the family, some immigrant and refugee elders have become subject to various types of mistreatment by family members (Moon, 2000; Tataara, 1999).

FAMILY AND CAREGIVING

From a general perspective, the family, in all cultures, is the main source of support, and many of the issues and challenges faced by the elderly and their families may be more similar than different among different cultures and ethnic groups. However, the specific problems and needs of older people, and the perceptions of issues and approaches to problem solving, can vary substantially depending on the cultural norms, available economic and social resources, and special circumstances in which the family and the elderly person are situated.

Immigrant/refugee families from developing countries have often been characterized by a strong family tradition of parental authority, rigid sex roles and male dominance, mutual support, strong parent-child bond, and filial piety. For example, a study of caregiver and elder experiences of Cambodian, Vietnamese, Soviet Jewish, and Ukrainian refugees in Philadelphia found that in Asian populations, family harmony,

negation of personal needs, and self-control were emphasized. For Cambodian caregivers, the “rightness” of parental care was understood as proper repayment of debts owed to elders and a way to show gratitude. Obligation, love, and respect were common themes as well among the Soviet Jewish and Ukrainian caregivers; and for the Ukrainian cohort, commitment to the Baptist faith was highly emphasized, and the focus on spiritual life appeared to mute the losses associated with relocation (Strumpf et al., 2001). In some cultures, an elderly woman who lives with her child’s family, cares for her grandchildren, and helps with house chores typifies happy aging, as opposed to elder exploitation; whereas placing an elderly parent in an institutional facility, such as a nursing home, is considered an abandonment of filial responsibility.

Families have played a critical role in caring for and assisting with daily needs of their elderly members in most immigrant/refugee populations. As reflected in *familismo*, which can be defined as a “strong feeling of reciprocity and solidarity among family members,” immigrant Latino families mobilize a large network of relatives and friends in order to provide needed care and support for their elderly relatives (Gelfand, 2003). Family is an even more important source of care for the elderly in rural areas, where supportive services in general and culturally and linguistically tailored services in particular may be less available than in urban areas. In a study of Vietnamese immigrant elders in Texas, the family was almost the exclusive source of help with language issues, loneliness, and internal family problems (Die & Seelbach, 1988). A study of South Asian caregivers composed of Hindus, Muslims, Sikhs, and Christians concluded that belief in filial piety norms among caregivers plays a significant role in lowering perceived levels of caregiver burden (Gupta & Pillai, 2002).

In examining living arrangement patterns, Wilmoth, DeJong, and Himes (1997) found that even after controlling for the differences in demographic characteristics, economic resources, functional limitations, and acculturation, elderly immigrants were significantly more likely to live in a household with extended family and nonfamily than were nonimmigrants. Another study further demonstrated that elderly immigrants from developing countries, as compared with those from developed countries, were significantly more likely to live with their children and/or others (Kritz, Gurak, & Chen, 2000). This study also indicated that reduced socioeconomic resources, lack of integration (measured by English-language skills), shorter durations of U.S. residence,

noncitizenship status, and demand for the elderly relative’s assistance with domestic work significantly influenced the likelihood of immigrant elders’ living with children and/or others. Thus practitioners must not automatically regard a multigenerational living arrangement as a sign of a strong family ties or practice of filial responsibility for care of the elderly client.

Similarly, living alone or with a spouse only may not necessarily mean isolation or a lack of family support. For example, in some locales, the majority of Asian immigrant elderly appear to live alone. This in part reflects suburbanization of younger Asian American families and the desire of the elderly parents to live near the center of their ethnic community, such as Chinatown, Koreatown, Little Saigon, and Little Tokyo (Cheung, 1989; Yoo & Sung, 1997). By living close to the ethnic community, they can socialize with people in their ethnic language and take advantage of various health, social, recreational, and other services offered by ethnic-specific agencies.

Thus the location of the residence, in terms of geographic proximity to their ethnic community, appears to be an important factor in influencing the ability to live independently and the quality of life among immigrant elders, although perceived good relationships and frequent contacts with their children still remain important for their life satisfaction (Moon, 1996). This also suggests that those who live alone in locations where there are few people like themselves or where access to health and social services for the elderly is severely limited due to language and cultural barriers are at higher risk for developing health and psychological problems associated with isolation and loneliness.

Although the centrality of the family and the norm of family care for the elderly prevail in many immigrant families, there has been a gradual shift in values and attitudes regarding traditional family structure, relations, and care arrangements for the elderly. Typically, younger immigrant women tend to experience these changes sooner and faster than their older relatives. This implies that to the extent to which American norms and values differ from those of the country of origin, elderly immigrants may face cultural conflicts and related problems with their children who have been assimilated or acculturated into the American culture.

For example, an elderly immigrant from a culture of extended, hierarchical family structure that emphasizes interdependence and collective well-being of the family may find it difficult to accept or adjust, initially at least, to the American norm of nuclear family

arrangement and the values of independent living and individualism, as well as the principle of democracy in defining the status and relationships among family members. Tension, conflict, and distress can result from the differences between the elderly immigrant/refugee and the children in their expectations about where and how they should live, what and how much the children should do for the parents, and what the parents should do for the children in return.

Studies suggest that dissatisfaction and isolation of the elderly in immigrant families stem from the elderly's high expectations for family socialization and from constraints on kin interaction, limited mobility, inability to speak English, and heavy domestic responsibilities in their children's household (Balgopal, 1999; Jones, Zhang, Jaceldo-Siegl, & Meleis, 2002; Treas & Mazumdar, 2002). Overall, fear of dependence on children or others and uncertainty about whether children will care for them as they grow older and whether they would be placed in a nursing home are perhaps the most common concerns across the immigrant elderly population (Balgopal, 1999; Kropf, Nackerud, & Gorokhovski, 1999). Practitioners, however, must not underestimate the ability of immigrant elders to cope with and adapt to the new environment.

Issues and challenges faced by family caregivers of elderly immigrants may vary depending on the intensity of care needed, available economic and other resources, and quality of the relationship with the elder, as well as culturally expected roles of family caregivers. After moving to the United States, most elders, especially those from non-English-speaking countries, become dependent on their children and grandchildren for help with even the tasks of daily living, such as making doctor's appointments and going places. After some adjustment period, however, some elders find other sources of help and become independent in performing a variety of tasks.

Although this situation undermines elders' authority and their traditional status in the family and may cause distress and worry for the elderly, their family caregivers are also challenged to adjust not only their thinking back and forth between the traditional and Western values in the process of caregiving but also their ability to perform caregiver roles, as they have other competing demands for their time and resources (Chenoweth & Burdick, 2001; Jones et al., 2002). Prolonged dependence of the elderly can lead to the caregiver's feeling of overburden and frustration, causing intergenerational conflicts in families. This is especially true for women in immigrant/refugee families who are already overburdened

by dual or triple roles they perform in and outside the family: the traditional role as homemaker and a new role as participant in the labor force.

Performing filial responsibilities is especially challenging to those children who have their own adjustment problems and other family issues, such as unemployment, conflicts with their children, crowded housing, and pressure to succeed in the new homeland. Caring for immigrant/refugee elders may require a greater intensity of care than in the previous homeland, but family caregivers may be less able to provide adequate care due to decreased economic resources, limited knowledge of services, few appropriate coping resources, and little experience in resolving cultural conflicts with their elderly parents (Kropf et al., 1999). Studies have also shown that caregivers' ambivalence about the use of formal services, misperceptions about the legal and other eligibility requirements of government programs, and strong view of formal services as the last resort, as well as the elder's belief that children would provide full support and care, present additional barriers to use of social services among some immigrant/refugee elderly and their families (Chicago Department on Aging and Disability, 1988; Chenoweth & Burdick, 2001; Jones et al., 2002; Kropf et al., 1999; Strumpf et al., 2001).

Increased burden on family caregivers and limited coping resources, combined with lower social pressure to practice filial piety and declining status of the elderly, could result in neglect and abuse of elders in immigrant/refugee families. In fact, there is a growing concern that elder abuse and neglect in immigrant/refugee populations may be equal to or even more serious than in U.S.-born populations and that incidents in immigrant/refugee populations may be more likely to be kept hidden or secret within the family (Tatara, 1999). In two similar studies, 34% of Korean and 33% of Mexican immigrant elders reported awareness of at least one incident of elder abuse in their respective community (Chang & Moon, 1997; Sanchez, 1999).

MENTAL HEALTH PROBLEMS AND PSYCHOLOGICAL DISTRESS

Stressful life events have a significant impact on physical morbidity and mental health problems, and depression, both major and minor, has been reported to be the most prevalent affective disorder found in the elderly population in the United States (Blazer & Koenig, 1996; Hendrie et al., 1995). Given the inher-

ently stressful nature of the immigration experience and the concomitant stressors associated with living as an immigrant/refugee, these problems have been more pronounced in elderly immigrant/refugee populations (Black, Markides, & Miller, 1998; Brener, 1991; Casado & Leung, 2001; Ghaffarian, 1998; Min, Moon, & Lubben, 2005; Mui, 1996, 2001; Ngo, Tran, Gibbons, & Oliver, 2001). For example, one study found a high prevalence of depression among elderly Chinese immigrants and identified migratory grief as the most significant contributing factor (Casado & Leung, 2001). A similar significant relationship between psychological distress and migratory grief was found among Mexican, Haitian, and Hispanic immigrants (Brener, 1991; Prudent, 1988; Lakatos, 1992).

In another study (Black et al., 1998), 26% of the immigrant Mexican elderly showed high levels of depression. As found in other ethnic minority groups, gender (female), lack of health coverage, financial difficulty, and presence of chronic health conditions and disabilities were major predictors of depressive symptoms. Brener (1991) found low acculturation levels associated with high depression and high perceived losses among most of the Mexican immigrants. In a study of Iranian immigrants, a significant relationship was found between age and acculturation: The older Iranians had lower levels of cultural shift and cultural incorporation and higher levels of cultural resistance than the younger Iranians (Ghaffarian, 1998). These findings suggest that older immigrants may experience more difficulties in learning and adjusting to the new environment than younger immigrants, as reflected in low acculturation levels, thereby experiencing more mental and psychological difficulties than younger immigrants. Among older Soviet immigrants, unsatisfactory living arrangements, such as the stress of multiple generational households, could lead to the feeling of depression (Kropf et al., 1999), whereas lack of contact with children was a significant factor contributing to low morale and high depression among older Korean immigrants living alone or with spouse only (Lee, Crittenden, & Yu, 1996; Moon, 1996).

Depression is also one of the most significant risk factors associated with suicide in late life (Carney, Rich, Burke, & Fowler, 1994; U.S. Surgeon General, 1999). In addition, immigration, particularly during old age, and being female seem to be associated with high risk of suicide (Barron, 2000; Yu, 1986). For example, Yu (1986) found that the suicide rate for elderly Chinese immigrants was almost three times higher than the rate for U.S.-born Chinese elderly in 1980. The high prevalence of depression and suicide

among elderly Asian immigrant women may be attributed to a variety of adjustment difficulties and stressful life events, poverty, and low socioeconomic status (Bagley, 1993; Gelfand & Yee, 1991).

Refugees from war-torn countries are a high-risk population for mental health problems because of their extensive exposure to numerous premigration traumatic events and stressors, such as torture, extensive detention, starvation, battlefield experiences, massacre, separation and loss of significant others, and hardships during the flight and/or in the refugee camps (Abueg & Chun, 1996; Morioka-Douglas, Sacks, & Yeo, 2004; Ngo et al., 2001; Olness, 1998). The effect of traumatic life experiences among refugees is often a lifelong process that is likely to continue from the country of origin to the country of exile (Olness, 1998).

Studies also show that immigrants and refugees are more susceptible to a broad range of symptoms associated with culture-bound folk illnesses (Molina, Zambrana, & Aguirre-Molina, 1994; Pang, 1990). For example, Hwa-Byung (HB), literally anger syndrome, is a widely perceived folk illness among elderly immigrant Korean women who endured feelings of victimization within their oppressive patriarchal family structure and experienced suppressed anger for an extensive period of time in life. Many of those experiencing HB report a variety of somatic, as well as psychological, symptoms, such as headache, sensations of heat, oppressed sensations in the chest, presence of epigastric mass, diminished concentration, and anxiety (Lin et al., 1992; Park, Kim, Schwartz-Barcott, & Kim, 2002).

In fact, physical complaints or somatizations of psychological or emotional problems are relatively common among many immigrant and refugee elderly groups. According to Hong, Lee, and Lorenzo (1995), typical somatic symptoms commonly reported by immigrant Chinese clients, especially elderly Chinese, include difficulty falling asleep, loss of appetite, headaches, feeling weak, shortness of breath, and pain all over their bodies. Pang (2000) also found a significant relationship between somatization and symptom expression among elderly Korean immigrants: Those who met the criteria for depression on the Brief Symptom Inventory (BSI) had the highest mean score on the BSI somatization dimension.

As a result of their tendency to experience the body and mind as a unitary system and to communicate psychosocial distress arising from old age, immigration, cultural adjustment difficulties, and other stressful life events through somatic symptoms and complaints, these elderly are more likely to seek med-

ical care for physical symptomatology than to seek mental health services (Brodsky, 1988; Trevino & Rendon, 1994). Among the Afghan immigrant elders, for example, the most frequently reported “health” complaint was mental health problems, particularly depression and physical symptoms related to stress from refugee trauma and loss, occupational and economic problems, cultural conflict, and social isolation (Lipson, Omidian, & Paul, 1995; Morioka-Douglas et al., 2004). Similarly, in the Russian culture, mental health and psychosocial problems are defined in somatic terms (Kropf et al., 1999), and it is a cultural norm among elderly immigrants from the former Soviet Union to use medical rather than psychiatric or social services for loneliness and depression (Aroian, Khatutsky, Tran, & Balsam, 2001).

In many of the cultures from which immigrant and refugee elders come, mental illness is a stigmatized condition, and cultural explanations of mental health problems often do not coincide with Western interpretations (Die & Seelbach, 1988; Gelfand, 2003). The non-Western traditional causes of mental or even physical illness may be strongly rooted in traditional spiritual and religious beliefs, such as punishment for sins committed in one’s previous life among some Buddhist elders from Asian countries or failure to adhere to the principles of Islam and the will of God and possession by evil spirits among Muslim elders. Many elders from Asian cultures tend to view mental health problems as one’s emotional weakness and failure to control one’s own emotions and thereby internalize the problems.

It is generally found that acculturation—often measured by the length of residency in the United States and ability to speak English—economic well-being, and social support can reduce the negative impact of premigration traumatic experiences and postmigration adjustment difficulties on the psychological well-being among immigrant and refugee elders. For example, in a recent study of 261 adult Vietnamese Americans, premigration traumatic experiences had a stronger effect on depression among those with lower levels of acculturation than among those who were highly acculturated (Ngo et al., 2001). Research generally shows that family and social support or coping resources as potential mediators for stressful life events can help prevent the development of psychological pathologies, such as depression, anxiety, and posttraumatic stress disorder (PTSD), not only among the U.S.-born elderly population but also among the immigrant and refugee elderly (Husaini et al., 1990; Mui, 1996, 2001; Ngo et al., 2001).

HEALTH AND SOCIAL SERVICE UTILIZATION

Research shows that immigrant and refugee elders, especially among those recently arrived from non-English-speaking and less developed countries, tend to underutilize community-based health and social services, whereas a higher proportion of them receive government income support and have access to health care services through Medicare and/or Medicaid. For example, a study of foreign-born Hispanic elderly (707 Cubans, 369 Mexicans, and 295 Hispanics from other countries) found that Hispanic immigrants had a generally low use of both community-based health and social services (Tran, Dhooper, & McInnis-Dittrich, 1997). Age, activity of daily living (ADL) limitations, and living alone were common factors associated with use of health services in these groups, whereas living alone and being in poverty were common factors for social service use. The study also revealed that psychological factor variables had no significant relationship with the utilization of either health or social services among these Hispanic immigrant groups.

Choi (2001) also found that far fewer Asian Americans and Hispanics took advantage of elderly nutrition programs, especially home-delivered meal programs, than did African Americans and attributed the lower participation rates to different food habits and preferences, as well as the lack of English-language proficiency among many recent immigrant elders. Lai (2001) reported that although most of the elderly Chinese immigrants visited senior centers, they substantially underutilized support services; predictors of supportive services use were living arrangements (living alone), satisfaction with services, and fewer mental health symptoms. Korean immigrant elderly were found to have very low levels of awareness and utilization of most of the 15 community-based long-term-care health and social services used in the study (Moon et al., 1998). It was evident, however, that they did use the services that were known to them.

Many immigrant and refugee elderly seek both Western medical services and indigenous health care services, predominantly herbal and acupuncture treatment, in their ethnic communities. Chung and Lin (1994), in their study of almost 3,000 Southeast Asian refugee adults (ages 18–68) in California, found that traditional health care methods still continued to be important, whereas all five groups showed a significant increase in the usage of Western medicine after they migrated to the United States: The percent-

ages of each group seeking Western medicine in the United States were 88% for Cambodians, 86% for Laotians, 76% for Vietnamese, 69% for Chinese Vietnamese, and 56% for Hmong. The study also reported that younger and more educated respondents and those with a high level of English proficiency were more likely to utilize Western medicine. In fact, studies have generally found that culture and levels of acculturation are related to health and mental health service utilization among immigrants and refugees, specifically suggesting a direct effect of acculturation on increased levels of service utilization (Calderon-Rosado, Morrill, Chang, & Tennstedt, 2002; Chesney, Chavira, Hall, & Gary, 1982).

Many immigrants and refugees, especially those from non-Western and less developed countries, do not seek help for their mental health problems. Recent immigrant Asians and Hispanics, regardless of age differences, are particularly more reluctant to utilize mental health services than Anglo Americans are (Trevino & Rendon, 1994; Wells, Golding, Hough, Burnam, & Karno, 1989). An analysis of national survey data indicates that the proportion of Asian Americans and Pacific Islanders utilizing mental health services at all types of public and private facilities was a third of the proportion for European Americans (Matsuoka, Breaus, & Ryujin, 1997). They may not seek help with mental health problems for several reasons in addition to the barriers to access mentioned earlier. Some of the major reasons include unfamiliarity with formal mental health services or the concept of professional psychosocial counseling, as these things often did not exist in their home countries; skepticism about the treatability of mental illness; institutional barriers such as lack of understanding regarding the nature of their problems among biomedically trained psychiatrists or other mental health professionals, especially when the service providers are not from the same culture or class (Trevino & Rendon, 1994); and fear of shame and stigma attached to mental illness.

Furthermore, in many of the cultures from which immigrants and refugee elderly come, religious and spiritual beliefs seem to influence their views of illness, methods of coping, and utilization of formal services (Die & Seelbach, 1988; Gelfand, 2003; Paulino, 1998). Those from Asian cultures prefer not to talk to anyone, including family members, about their emotional or mental health problems. Among them, it is still more common practice to seek advice and help from religious and spiritual leaders for their family problems and emotional support. This situation sug-

gests that effective strategies to increase service use among immigrant and refugee elderly groups whose religion and spirituality have strong influences on them should include working with their religious and spiritual leaders as brokers to link the elderly to potentially beneficial services.

Service utilization among immigrant and refugee elders, regardless of the type of services and agency offering them, requires that services are available, accessible, and acceptable to them (Cox & Ephross, 1998). Although this general principle is also applicable to the U.S.-born elderly population, immigrant and refugee elderly groups face numerous challenges and barriers to service use, including lack of information about available services; language, transportation and financial barriers; negative attitudes toward formal services; culturally and religiously unacceptable perceptions of services; and culture-specific definitions of illness and healing that contrast with Western concepts and biomedical perspectives (Fetzpatrick & Freed, 2000; Marshall, Koenig, Grifhorst, & Ewijk, 1998; Moon et al., 1998; Tsai & Lopez, 1997; Weech-Maldonado et al., 2003).

The most fundamental barrier is the lack of knowledge about available services. Available but unknown services are meaningless and practically nonexistent to the intended population. In this regard, some research findings raise a serious concern. In a study on caregiver and elder experiences of Cambodian, Vietnamese, Soviet Jewish, and Ukrainian refugees, most elders and their caregivers across all groups reported that services for the elderly did not exist or were unknown to them (Strumpf et al., 2001). Across all groups, caregivers identified home health care, transportation, and social opportunities as the most urgent needs for their elders. Tsai and Lopez (1997) found the lack of knowledge of services, English skills, and transportation to be important barriers to Chinese immigrant elders' utilization of formal services. These and other similar findings on the lack of knowledge and understanding of health and social services reported by other immigrant and refugee groups suggest an urgent need for effective dissemination of information about available services to them (Fetzpatrick & Freed, 2000; Moon et al., 1998; Strumpf et al., 2001).

Even when immigrant and refugee elders are eligible for health care services through Medicare and/or Medicaid and are provided with access to other services, those with limited English skills still face barriers. Some services may not be culturally responsive or acceptable. For example, some ethnic immigrant el-

ders who have strong preferences for their ethnic foods may not use day activity centers and residential facilities that serve typical American-style meals. Although ethnic-specific service facilities may more easily accommodate those who prefer ethnic food, multiethnic agencies or those in areas where ethnic food is not readily available face a challenge.

Similarly, health and social service providers' lack of knowledge about cultural norms of interpersonal behavior and patterns of relationship formation that are different from the American norms can result in dissatisfaction with the services and consequent underutilization of services by the immigrant and refugee elderly (Cox & Ephross, 1988). Cultural differences can create misunderstanding and tension between service providers and their elderly clients. For example, a handshake as a polite greeting gesture may be considered rude by most Asian cultures, especially if the service provider is much younger than the elderly individual and the two are meeting for the first time. Also, it is often a culturally desirable pattern to start a meeting with remarks about topics unrelated to the purpose of the meeting, such as weather, upcoming holidays, and even asking about personal and family well-being rather than "getting down to business" as quickly as possible. The latter can be viewed by some elderly clients as being uncaring and cold, creating a barrier to establishing rapport and trust with the client. In many cultures, respect, authority, and wisdom are closely tied to one's age: calling an elderly client by his or her first name is disrespectful, and an elder receiving services from a young professional may doubt the professional's expertise. Elderly men from the Muslim culture are particularly reluctant to be treated by female health and social service providers. Also, asking questions related to sexual behavior is a taboo in most cultures. Therefore, practitioners must be aware and sensitive to potentially different cultural norms and beliefs of their clients, although they must be cautioned not to overgeneralize or stereotype, as clients may be at different levels of acculturation or may be bicultural in both American and their own ethnic culture.

IMPLICATIONS FOR SOCIAL WORK PRACTICE

Consideration of the characteristics, major issues, and service needs of immigrant and refugee elders and their families suggests the following social work practice implications within an evidence-based generalist perspective:

1. Understand that there are intergroup and intra-group differences among immigrant and refugee elderly in their religious and spiritual beliefs and practice, in their attitudes toward health and social services, in the appropriateness of involving family caregivers in service planning, in cultural norms for effective interpersonal behavior and relationship formation processes, and in other cultural preferences, such as food and type of program activities, as they influence help-seeking decisions in general and utilization of formal services in particular.
2. Become familiar with and sensitive to the cultural norms of living arrangements and family caregiving practices while acknowledging the potential variability in the actual roles the elderly client's family is willing and able to perform in meeting the needs of the client.
3. Carefully consider whether and how involving family members in discussions regarding service needs and planning would help or hinder service delivery; family endorsement is essential for some elders, yet for others it is inappropriate to involve adult children and caregivers in an open discussion.
4. Become knowledgeable about legal and other eligibility requirements of financial, medical, and other benefit programs that are applicable to different immigrants and refugees. Even when the elderly client and the family seem to be aware of their entitlements, social workers should identify and address their reluctance to use services or their confusion with procedures, which can limit the client's utilization of the supposedly helpful benefits/services.
5. Address the need for concrete services, such as transportation, and for resources for learning English, for performing basic tasks of daily living, and for accessing the community health and social service systems. Provide opportunities for socialization, job skill development, and employment. All of these services and opportunities can contribute to lower dependence on the family and less isolation and loneliness while increasing self-esteem and life satisfaction of the elderly client.
6. Develop intergenerational programs to address cultural conflict between the elderly and their caregivers, to increase mutual understanding across generations, to reduce generation gaps and isolation, and to thereby restore respect and commitment to care for the elderly.

7. Considering the importance of interdependence rather than self-reliance among immediate and extended family members in ethnic minority cultures, mental health service programs targeting the immigrant/refugee elderly should employ treatment strategies designed to facilitate support from family members (Blair, 2000).
8. For optimal treatment effects, identify and respect the indigenous beliefs about the cause and healing practices of physical and mental health problems as an essential part of a holistic treatment plan while addressing the gap between traditional and Western methods of treatment. Mental health practitioners should consider and validate indigenous approaches, including comfort by spiritual leaders and the use of folk medicines, in addition to mainstream treatment methods such as cognitive-behavioral therapy and family intervention.
9. For an effective approach to relationship formation with an elderly client, practitioners must be aware that many immigrant and refugee elders, especially Asians and Latinos, respond better to a congenial, personal manner rather than to an impersonal, businesslike one (Lum, 2000; Molina et al., 1994). Because most immigrant and refugee elders are not familiar or comfortable with the existing service system, it is especially important for the practitioner to show a personal interest and empathy with the client's problems and to be warm, friendly, and reassuring.
10. Practitioners serving relatively recently arrived refugee groups must consider their premigration trauma as the immediate focus of assessment and treatment. The worker should be aware that those refugee clients who experienced the loss of immediate family might have a higher risk for developing both PTSD and major depression than those who were able to live with immediate family in refugee camps.
11. Practitioners must assess whether somatic complaints are indicators of some type of mental health problem or a real physical ailment in order to address the client's problems and service needs accurately and effectively. It is important to consider the cultural perspective that physical complaints, rather than psychological symptom manifestations, are regarded as more acceptable and are given more positive attention. A systematic collaboration among primary care physicians, mental health professionals, culturally accessible indigenous ethnic practitioners, and spiritual/religious organizations can further promote wellness among immigrant/refugee elders.
12. Ensure that services are available, accessible, and acceptable to the intended immigrant and refugee elderly population. Consider three major types of potential barriers to service utilization: (1) institutional or structural barriers, such as unavailability of services, eligibility restrictions related to noncitizen and illegal immigrant status, cost of service, and racism; (2) instrumental or functional barriers, such as the lack of transportation and service information, and (3) cultural and linguistic barriers, such as health beliefs, lack of English skills, and insensitivity to cultural norms of interactive behavior.
13. Actively reach out to the intended ethnic immigrant elderly population and provide information about available services in culturally and linguistically sensitive ways. It is especially important to have outreach workers who speak their language and who are, preferably, from the same ethnic background. Obtain the support and participation of community and religious leaders in the outreach effort. Use ethnic media and organizations, which are often the most effective means of information dissemination in many ethnic communities. Finally, translate the informational materials into the ethnic language and design the materials using a culturally attractive and familiar format.

CONCLUSION

Social work practice with immigrant/refugee elderly populations requires cultural competence and the ability to understand the target population's special issues and needs in service delivery, as well as an understanding of their cultural and immigration/refugee background. Special service delivery arrangements to overcome the language and cultural barriers, acknowledgement of the traditional methods of coping and healing, and demonstration of culturally appropriate interpersonal skills, in both verbal communication and behavioral aspects of interaction, can significantly increase effectiveness in meeting the service needs and thereby improving the well-being of the immigrant elderly. For example, the practitioner's effort to show respect for the client's culture and special needs, such as expressing an interest in and appreciation of the client's cultural background during the initial stage of relation formation, and speaking clearly and slowly and some-

times repeatedly, with patience, to clients with limited English can make a difference in gaining the client's acceptance and trust of the practitioner.

In this regard, although matching a practitioner and an immigrant elderly client by ethnicity often has the advantages of meeting the language need and gaining early acceptance of the client, the practitioner's ethnicity alone is no guarantee of the desirable cultural competence or responsiveness. Considering the growing heterogeneity not only among different immigrant/refugee elderly populations but also within the same ethnic group, practitioners must be cautioned against overgeneralizing and stereotyping groups and individuals solely based on their immigrant/refugee and ethnic background. A study of social workers' interactions with Iu-Mien refugees from Laos found that those who did not exhibit cultural competency made assumptions about the clients with regard to stereotypes, lack of appropriate care for elders, and lack of English-language acquisition (Schuldberg, 2001).

Multiplicity and complexity of ethnicity and culture demand a multidimensional approach to social work practice with the immigrant and refugee populations, whose culture and immigration-related factors are only some of the numerous factors to be considered in practice. Nevertheless, cultural competency enables practitioners to better understand "where the client is" and how best to meet the client's needs. In this regard, Cox and Ephross (1998) state:

Finally, it is imperative to recognize that all cultural patterns are based on a universal human need: to solve problems of human existence and find meaning in the face of physical, social, and technological ecologies. The framework for social work involvement must respect and legitimize the diverse ways in which ethnicity can influence the efforts to solve these problems. By working through a clear ethnic lens that recognizes the factors that can impede growth and functioning, while also recognizing cultural strengths and preferences, social services can enable ethnic persons and groups to obtain the benefits ascribed to others in society. Mistreated and Neglected Elders

18

CURRENT KNOWLEDGE

In the early 1980s, the phenomenon of elder mistreatment was introduced as a form of domestic violence—it was a latecomer to the field that had paid greater attention to child abuse, child sexual assault, woman battering, and rape. Many steps have been taken to deal with the problems: the passage of reporting laws in every state, education of practitioners, formation of multiagency consultation teams, and development of assessment tools and techniques for intervention, including criminal prosecution of some abusers. Conferences and forums devoted exclusively to elder mistreatment are held regularly, and research efforts have been made to understand the circumstances, profiles of victims and abusers, and extent of the problem.

Extent of a Hidden Problem

Estimates of elder mistreatment vary among studies due to differences in use of definitions, time frame, participant age, sampling and data collection methods, and objectives. Prevalence rates have been reported to be 3.2% by Pillemer and Finkelhor (1998), 4% by Podnicks (1992) in Canada, and 5.6% by Comijs, Smit, Pot, Bouter, and Jonker (1998) in Amsterdam. Pillemer and Finkelhor (1988) estimate that for every case known to a regulatory agency, an additional 14 cases are unreported. The National Elder Abuse Incidence Study derived an incidence rate of 1.2% (National Center on Elder Abuse, 1998; Thomas, 2000) and calculated that for every case reported to adult protective service agencies, five additional cases were known to community agencies. The actual rate of elder mistreatment is probably much higher than reported, because secrecy and isolation, common in all forms of intimate abuse, prevent an accurate count. The norms of American society make behavior inside the home a private affair, and even after mistreatment occurs, the rule of family privacy is so strong that it often works to prevent victims from seeking help.

Types of Elder Mistreatment

- *Physical abuse* includes physical force that results in bodily injury, pain, or impairment. It may include acts of assault, battery, and inappropriate use of restraints.

- *Sexual abuse* includes any form of nonconsensual sexual contact. Sexual abuse should be considered when elders report being sexually victimized or when there are symptoms that are commonly associated with sexual victimization: genital or urinary irritation, injury, or scarring; intense fear in reaction to a particular individual or to procedures that might involve the pelvic area, such as bathing or cleansing after incontinence; and trauma in the pelvic region.
- *Emotional or psychological abuse* is the willful infliction of mental or emotional anguish by threat, humiliation, or other verbal or nonverbal conduct.
- *Financial abuse* includes the misuse of trust to steal money from bank accounts, obtain credit cards to make unauthorized purchases, and embezzle large sums of money through refinancing the elders' home. In addition, exploiters may steal jewelry and cash, forge or alter checks, and add their names to elders' bank accounts or deeds to the house. Notarized documents, powers of attorney, quit claim deeds, refinance documents, and wills are some of the common tools used by financial abuse perpetrators (Sklar, 2000).
- *Identity theft* has recently been recognized as a serious financial crime as well. This involves accessing the elders' identifiers, including Social Security number, credit card, driver's license, and bank account numbers, for financial gain.
- *Undue influence* occurs when some people, often in their capacity as caregivers, use their position to exploit the trust, dependency, or fear of elders. Over time, exploiters may use fraud, duress, threats, and isolation to gain control over the elders' finances and decision making. Over time, dependency develops, and a "siege mentality" is created, with exploiters saying, "It's only you and me against the world" or "No one cares for you as much as I do. . . . I know what is best for you." Eventually, elders become fearful and are an easy target for financial and material exploitation (Nievod, 1992; Singer, 1992; Quinn, 2000).
- *Neglect* is the failure of caregivers to fulfill their responsibilities. It includes withholding the basic necessities of life, such as personal care, nutrition, medical attention or medication, and a safe, well-maintained environment. Neglect may be active or passive: in active neglect, the withholding of basic necessities of life and physical care is willful; in passive neglect, the withholding is usually due to lack of experience or information. In either case, neglect can lead to death just as abuse can.
- *Self-neglect* is the failure to adequately provide oneself with the basic necessities of life, including food, clothing, shelter, medical care, and medication. The lack of such necessities can threaten the elders' health and safety.

In all of these categories, whether an act is considered abusive or neglectful may depend on its intentionality, severity, intensity, frequency, and consequences (Daly & Jogerst, 2001).

REVIEW OF RESEARCH

Theories of Causation

The main hypotheses regarding the causes of elder mistreatment that is inflicted by others are: (1) elder dependency; (2) learned violence; (3) individual problems of the perpetrator; and (4) societal attitudes, including ageism, sexism, destructive attitudes toward the disabled, and greed. Although some of these hypotheses are popular, they are not supported by the research done so far. For cases of self-neglect, one theoretical explanation is that it is a social-psychological process to maintain identity and control.

With regard to the dependent-elder concept, in the late 1970s and early 1980s, during the first phase of research on elder mistreatment, several researchers noted that the majority of elder mistreatment victims were impaired—physically, mentally, or both (Block & Sinnott, 1979; Douglass, Hickey, & Noel, 1980; Steinmetz, 1978; Steuer & Austin, 1980). However, in the mid-1980s and later, second-phase research found that the victims were not more ill nor functionally disabled (Pillemer & Finkelhor, 1989) and that dependency of *abusers* was a stronger explanation for the mistreatment (Hwalek, Sengstock, & Lawrence, 1984; Phillips, 1986; Pillemer, 1985a, 1985b; Wolf & Pillemer, 1984, 1989). Abusers had a history of mental illness, psychiatric hospitalizations, or substance abuse problems or a combination of these three factors. They were dependent on the elder for money and housing. With these newer findings, it is *not* accepted that victim impairment by itself causes elder mistreatment.

Next, the hypothesis of the stressed caregiver has received a great deal of attention from researchers and clinicians, not only because it is the most readily acceptable explanation but also because it fits with interventions that have been pioneered by those working in the field of domestic violence, particularly in child abuse and neglect. With the finding that

abuser dependency, not elder dependency, is a significant factor in elder mistreatment cases, the stressed-caregiver concept has lost favor among those researching the problem. Also, the stressed-caregiver concept is not supported by empirical research (Phillips, Torres de Ardon, & Briones, 2000; Pillemer & Finkelhor, 1988, 1989; Reis & Nahmiash, 1997, 1998). Having emphasized this point, in very specific instances, caregiver stress may be a vulnerability, not a causal, factor. Homer and Gilleard (1990) found that physical abuse by caregivers was triggered by physical abuse or threats of violence by the patient, by incontinence, or both. The abusers identified elders' behaviors as the main problem, not physical impairment, financial problems, social isolation, or emotional strain. The abused patients were not more dependent but had more communication problems and were more socially disturbed than those who were not abused. The caregivers who admitted to physical and verbal abuse scored higher on the depression scale than the nonabusive caregivers.

Paveza and colleagues (1992), also recognizing that caring for persons with Alzheimer's disease and related disorders can be stressful enough to lead to violence, studied the frequency of violence and risk factors for violent behavior in the caregiver-patient dyad. Two variables were statistically associated with the violent patient-caregiver dyads: The caregiver was depressed and the patient was residing with relatives other than the spouse. As with Homer and Gilleard's study (1990), elder impairments were not predictive of violence among the dyads. Caregiver depression was related to violence: The caregivers who scored high on the depression scale were at three times greater risk for violence than caregivers who scored below the cutoff score.

Although still important, characteristics of the elder alone are insufficient explanations for the various forms of mistreatment. Characteristics of the abuser and the nature of the abuser-elder interaction, perhaps affected by elder behaviors, are emerging as primary theoretical explanations. Findings from these two studies compel social workers to ask caregivers about depression, lowered self-esteem, and fear of becoming violent, as well as assisting them in ways to alleviate their symptoms. Further studies will determine which factors will prevail as the strongest explanations. It may be that specific explanations apply to certain subgroups of the elderly but not to the general elderly population.

The concept of intergenerational transmission of violence is almost as popular as the concept of the

stressed caregiver, but it is not supported by the research on elder mistreatment. At this time, a paucity of empirical data makes it impossible to form conclusions on the use of this concept; it is not known whether grown children harm elders for retaliatory or imitative reasons.

Thus far, one of the strongest explanations for elder mistreatment has been abuser impairment. Research has found that abusers are dependent on their victims financially, emotionally, and for housing (Pillemer, 1985a, 1985b; Podnieks, 1992; Wolf & Pillemer, 1984). Some exhibit psychopathological features, and others have substance abuse problems (Anetzberger, Korbin, & Austin, 1994; Bristowe & Collins, 1989; Wolf, Godkin, & Pillemer, 1986). For example, neighbors may assume that the grandson who has moved in to live with the 85-year-old woman next door is being helpful and performing caregiver tasks, while in reality, the grandson is a drug-addicted, unemployed male who threatens harm and cashes his grandmother's Social Security check. With time and further research, it is possible that among perpetrators of elder mistreatment, impaired abusers will make up a smaller percentage, because in other areas of domestic violence, all demographic categories are represented among the perpetrators: males and females, high- and low-income earners, and college and high-school graduates.

One last explanation for other-inflicted mistreatment is that societal attitudes create an atmosphere that paves the way for elder mistreatment. Ageism includes myths and stereotypes about the old and the aging process. Old age has become synonymous with loss of personal power, disability, and lack of control over one's own life. In addition, female elder mistreatment victims outnumber male victims by a ratio of 2:1, and sexism may play a part in their mistreatment. Some elderly widows, lonely and with no relative available to help them with financial affairs, fall prey to strangers who offer help. Human greed is another attitude implicated in elder mistreatment. Some relatives may rationalize that because elders would have given them the money later, it is justifiable to spend these elders' money now for what is claimed to be an emergency.

Self-neglect, the most prevalent type of mistreatment, is a complex process with varying scenarios. Bozinovski's (2000) theoretical explanation is that elders are "geared toward preserving identity, protecting and remaining in preferred environments, staying in control of their worlds, and presenting themselves as competent social beings" (p. 54). Maintaining conti-

nunity, or trying to hold on to one's longtime environments, relationships, and activities, is very important to self-neglecters. Using a set of behaviors that are comfortable and usual to them, they preserve their lifestyles and protect their identities while perceiving their present problems to be the result of situations such as abandonment by divorce or death of significant others and pets (Bozinovski, 2000). Ironically, those self-preservation behaviors often are not socially acceptable and precipitate referrals to protective service agencies and offers of help. Rathbone-McCuan & Bicker-Jones (1992) add that the neglecters' saying "no" to help is a means of exerting control.

By the time they reach old age, self-neglecters have minimal supports and few attachments; past betrayals, abandonment, and other negative experiences create mistrust and alienation in later life. Their families report that these clients have "burned their bridges" due to their personalities and unsociable behaviors. These clients have a "reality discrepancy," or different perceptions of what are appropriate community standards or socially acceptable behaviors. They also have difficulty at "role taking" or grasping others' perspectives that are required for appropriate social interactions. These difficulties are compounded by impairments in hearing and mental faculties (Bozinovski, 2000).

The preceding hypotheses about the causes of other-inflicted elder mistreatment and self-neglect are not mutually exclusive. Elder mistreatment may be the result of a multiplicity of factors. Further research will refine, confirm, or take issue with some of these hypotheses. But for now, they provide a logical framework that can help social workers understand the phenomenon of elder mistreatment.

Victims and Perpetrators

The majority of cases reported to adult protective services involve neglect and self-neglect (Bozinovski, 2000; Teaster, 2003). Most studies have consistently found a higher percentage of female victims than male, amounting to a 2:1 ratio (Dimah & Dimah, 2002; Dunlop, Rothman, Condon, Hebert, & Martinez, 2000; Greenberg, McKibben, & Raymond, 1990; Lachs, Williams, O'Brien, Hurst, & Horwitz, 1997; National Center on Elder Abuse, 1998; Otiniano, Herrera, & Teasdale, 1998; Teaster, Roberto, Duke, & Kim, 2000). Other than finding that victims are mainly female, studies have not established a clear profile of an elder mistreatment victim.

Family members are usually the perpetrators of other-inflicted elder mistreatment. Studies based on reports to adult protective services and other agencies (Brownell, Berman, & Salamone, 1999; Greenberg et al., 1990; Lachs et al., 1997; National Center on Elder Abuse, 1998; Otiniano et al., 1998; Vladescu, Eveleigh, Ploeg, & Patterson, 1999) have found that adult children are the most likely perpetrators, whereas random sample studies report spousal abuse in greater frequency (Pillemer & Finkelhor, 1989; Podnieks, 1992). These reports found that sons are more abusive than daughters, and in reports on elder sexual abuse, sons are most likely to be the abusers of their mothers (Ramsey-Klawnsnik, 1991, 2003).

In general, there are many limitations in the studies from which information on victims and abusers has been obtained. Only a few studies have been large random sample studies; almost none used control groups; and some of the studies' conclusions were based on reported cases or a small number of victims.

Ethnic Group Information

Among professionals, it is generally agreed that elder mistreatment is not confined to a few countries or certain ethnic groups. Limited data based on reports to regulatory agencies in the United States indicate that African American and Hispanic elders are overrepresented and that reports are rarely made on Asians (except in Hawaii, where Asians make up a good portion of the population; Tataru, 1999; Teaster, 2003). Griffin (1999) found that African Americans were more susceptible to financial exploitation, and this finding is supported by Dimah and Dimah (2002), who found that among substantiated elder mistreatment cases at one agency in Illinois, older African Americans were more likely to be victims of financial exploitation and physical neglect. The majority of the perpetrators were daughters (75%) and sons (67%). It is not possible to make generalized statements with these data, because some minority elders may be referred preferentially and investigated due to their poverty status (Lachs, Berkman, Fulmer, & Horwitz, 1994), whereas others are not reported because individual wrongdoings are hidden within the community and victims are stereotyped as having caring families who would never abuse their elders (Tomita, 1999).

Research so far on minority elders indicate that some elders are not aware that others consider them to be victims (Moon & Williams, 1993), differ among themselves about the definitions of abusive behavior

(Anetzberger, Korbin, & Tomita, 1996; Hudson & Carlson, 1999; Moon & Benton, 2000), have varying levels of tolerance for abusive behaviors (Moon, Tomita, & Jung-Kamei, 2001), and also are unaware of sources of help (Moon & Evans-Campbell, 1999). Native Americans in one study reported that one incident of mistreatment was sufficient to warrant a label of elder abuse, in contrast to an expert panel's view that mistreatment was defined by repeated and frequent incidents. They also rated more vignettes as abusive than their European American and African American counterparts did (Hudson, Armachain, Beasley, & Carlson, 1998; Hudson & Carlson, 1999). In another study, Moon and Williams (1993) explored African American, European American, and Korean American elderly women's perceptions of elder mistreatment using 13 scenarios that involved a female elder as a victim and a family member as the perpetrator. Overall, a smaller percentage of Korean Americans (50%) than African Americans (73%) or European Americans (67%) perceived the scenarios as mistreatment, leading the authors to conclude that the Korean Americans were less sensitive to or more tolerant of abusive situations. Many in the Korean American group indicated that they would be reluctant to reveal the abuse or neglect to others, out of shame or fear of creating conflict. This corresponds with the greater cultural emphasis on community and family harmony than on individual needs or well-being within some cultures. The following sections provide social workers a guideline for assessment and intervention.

SOCIAL WORK ASSESSMENT AND INTERVENTION

Assessment Guide

The assessment of elder mistreatment begins when there is a suspicion that the elders' relationships are contributing to unnecessary suffering, or when elders hint at or directly report relationship problems. A variety of instruments are available to assess elder mistreatment, with shorter versions being more appropriate for such settings as an emergency room of a hospital (Fulmer, Guadagno, Dyer, & Connolly, 2004; Kahan & Paris, 2003; Quinn & Tomita, 1997).

Interview with the Elder Elders very rarely seek help for other-inflicted elder mistreatment; they often present themselves to an agency for resolution of other problems. If mistreatment is suspected, seize the op-

portunity to assess the situation. Take precautions to maximize privacy and confidentiality, for it is not uncommon to discover during an assessment that those accompanying elders are the alleged abusers.

In general, assessments review the risk of abuse and the elders' cognitive ability and ability to function independently. They may require several contacts over a period of time and should be conducted in a nonjudgmental manner. Although having a high index of suspicion is important in ruling out elder mistreatment, elders should not be diagnosed prematurely as being victims. Work assessment questions into a conversation in a relaxed manner. It is more problematic to assess self-neglecters because they rarely initiate the request for help; they would rather be left alone. The main task is to assess their capacity to make decisions for themselves before an intervention plan can be implemented. For elders who willingly disclose mistreatment, some of the questions suggested that follow may be skipped.

Collect pertinent data. Ask what type of transportation elders use to get to the center, what services they obtain in the home, and with whom elders live.

Ask elder about a typical day as a way of assessing activities of daily living. Find out how elders spend a typical day to determine the degree of dependence on others and who are the most frequent and significant contacts (e.g., "Who helps you with the laundry? How often does he take you out?"). Abusers are often among this pool of people mentioned by elders.

Ask the elder about expectations regarding care (e.g., "Does she do everything you want? Does she come on time?").

Have the elder report any recent crises in family life (e.g., "Have you been worrying about anything in particular in your family lately? Is something in your family troubling you?").

Ask about alcohol problems, drug use, illnesses, and behavior problems among household or family members (e.g., "Are you worried about that son? How long has he been out of work? Are you comfortable with him being in your home for three months?").

Ask the elder about abuse, neglect, and exploitation incidents (e.g., "Do you eat together? Is he good to you? Tell me how you've suffered. Have you been yelled at . . . shoved, shaken, hit . . . ? Then what happened? Show me how she did that").

Record the description of the mistreatment. When possible, record the statements in quotes and document in detail the incidents of mistreatment.

Determine the elder's current mental status. The elder's mental status can be assessed quickly with such

tools as the Mini–Mental State exam (Folstein, Folstein & McHugh, 1975). This adds credibility to elders' reports of elder mistreatment and can counter attempts by others to dismiss the allegations that the elders are senile or confabulating.

Address the elder's concerns about revealing the mistreatment. Fear of reprisals, loss of control over the elder's own environment, and ambivalent feelings toward abusers also may be expressed. Assure elders that their opinions and involvement in the strategy phase are of great importance and will guide the workers' actions.

In summary, because elder mistreatment is a hidden phenomenon, elders do not readily volunteer information about it. Warming up to the subject by first asking nonthreatening questions is helpful, followed by questions that focus on the elder's relationships, then questions about problems in the family, and finally questions about incidents of mistreatment. The term "abuse" is unfamiliar to many elders, so asking, "Is he good to you?" may elicit a response more easily than asking, "Did he abuse you?" Also paying attention to what is not said or someone who is not mentioned may provide clues about who the perpetrators are.

Interview the suspected perpetrators. Questions are less provocative if suspected perpetrators perceive them to be elder-centered and perceive workers as wanting to make a detailed assessment of the elder's situation rather than focus on the perpetrator's behavior or actions.

When possible, interview the suspected abuser immediately after the elder is interviewed in order to avoid collusion. First, assure elders that confidentiality will be maintained and that the perpetrators will not know what the elders have said. Use some of the following questions and statements:

"I am doing an assessment of your mother's current functioning and situation, in order to determine what services are appropriate at this time. I would like to spend some time with you and have you tell me your perception of how things are here."

"Tell me what you want me to know about your mother."

"What do you expect her to do for herself?"

"What does she expect you to do for her? Do you do those things? Are you able to do them? Have you had any difficulties? What kind?"

Assess the suspected perpetrator's degree of dependence on the elder's income, pensions, or assets:

"If you help your mother pay her bills, how do you do it? Is your name on her account?"

"Do you pay rent? Whose name is on the deed?"

"Do you have power of attorney? Does it have a durable clause? When did you get it?"

Interview the family and others. If the elders consent, collateral contacts must be made promptly before the suspected perpetrators attempt to collude with others. Concerned people who possess important information may be reluctant to get involved, and workers may need to appeal to them as "good Samaritans."

Determine Capacity

Once the assessment is complete, determine the elder's willingness for intervention and capacity to make decisions. Protective interventions are based partly on the elder's ability to understand transactions and withstand undue influence. One of the first questions raised during an assessment is, Did the elders understand what they were doing, and were they able to withstand undue influence tactics, for example, when the deed was signed over to the nephew.

Determine Willingness for Intervention

After determining the elder's comprehension of the incident, a second common set of questions raised by workers is, Does the elder have sufficient mental capacity to accept or to refuse help? Does the elder want outside help? The dynamics of elder mistreatment as a form of family violence, in which power and control play a big part, differ from being harmed by strangers. Often victims prefer to maintain some form of a relationship in spite of being victimized and would like workers to help stop the abusive behavior, not end the relationship. In such instances, the focus of the intervention is on correcting the power imbalance and on victim safety and abuser accountability.

Reporting Suspected Mistreatment

All states have mandatory or voluntary reporting laws (St. James, 2001). A point of emphasis is that, although reporting by workers is often mandatory, the receipt of services by victims is voluntary. Adult pro-

tective services must assess the situation and offer services, but elders have the option to say, “Yes, I am being mistreated by my son, but I don’t want your help—leave me alone.” Often referring social workers and the public in general, due to confidentiality protocols, may not realize that the victims have been offered intervention options and that the cases have been closed due to their refusal of services.

This unwillingness to receive help is probably the most confusing and frustrating aspect of intervention. Instead of “giving up” on victims who seem to choose their relationship with perpetrators over others’ interventions, workers should discuss with elders the factors influencing their choice of intervention options: fear, hope, love, low self-esteem, financial dependence, emotional dependence, isolation, duty, lack of proper help and support from outsiders, an assumption that the abuse is normal behavior, a tendency to be passive and avoidant in coping (Comijs, Penninx, Knipscheer, & van Tilburg, 1999), and the fact that the abuse is not severe enough to make them want to leave.

COUNSELING STRATEGIES

Other-Inflicted Mistreatment: Correct the Power Imbalance

Situations of other-inflicted elder mistreatment involve an unequal power distribution between elders and their abusers, often due to a lack of checks and balances in the relationship. Mistreatment continues when there are no consequences for the acts; when elders are unaware of their own power resources, blame themselves, and are selfless parents; when the elder-abuser dyad is isolated; and when there is support by a culture or community for the mistreatment behaviors.

In these contexts, victims may believe that the mistreatment is beyond their control and may stop trying to do anything about it. This “learned helplessness” (Seligman, 1975) creates fearfulness in victims, saps their motivation if they perceive that they are unable to influence events, and causes an inability for them to perceive success. Social workers have an important twofold role: to maximize the victim’s potential power—replacing the symptoms of learned helplessness with a sense of mastery over the elder’s own situation—and to minimize the abuser’s use of power resources, which consist of affection, verbal promises, threats, physical strength, and mobility.

Often elders do not realize that their own power sources easily make up for comparatively less physical strength and mobility: housing, the ability to remove themselves from the abusive situation, alliances and friends, agencies, professionals, income, and public knowledge of the mistreatment.

Power Balancing via Victim Advocacy and Abuser Accountability

Provide education and prevention. It is easier to get elders to receive difficult information by turning statements into questions: “Have you ever heard of the term ‘abuse’? When your son hits you, that is called domestic violence or elder abuse. . . . When he takes your money, that is financial abuse.” Or, “Are you aware that others consider you to be a victim of abuse?”

Identify and correct maladaptive thinking. Workers can represent a different reality and combat self-blame, excessive fantasies, and magical thinking—the idea that the mistreatment will end by itself. For example, say, “Accidentally using his towel does not justify a slap. No matter what you did, it is wrong to be hurt like that. No one deserves to be abused.” Remind elders of their *hardiness* and *powerfulness*, their ability to withstand adversity. Recount past events in which they survived and emphasize their ability to do so again.

Provide information and prepare for the next incident. Ask “What will you do when this happens again?” “Taking her name off your bank account is not difficult; we could go to your bank. . . .” “Let’s pack a bag and copy your important papers just in case. . . .”

Practice the intervention. Help elders dial the phone and speak into it: “I live at 1234 Elm St. and need help right now.”

Work on the expression and management of feeling. Help elders discuss their feelings instead of dismissing them as “hopeless.” For example, when workers say, “I believe you when you say you love your son. Even when he hurts you, you don’t want him to be arrested,” elders may reply eventually, “Well, maybe love isn’t worth this misery. . . . I should do something else.”

Restructure the elder’s environment and expand the social circle to maximize safety. Outside contacts and socialization diminish the chances of mistreatment. In approaching financial exploitation, acknowledge the strong bond between elders and perpetrators, but at the same time intervene to prevent elders from fur-

ther harm. Say, “I know John is your grandson and you love each other and always will. But he has taken advantage of you with regard to your savings. It isn’t your fault. He was clever and he was wrong. We must stop his taking advantage of you. That is why we must find someone else, perhaps your niece, to help you with your finances. This way, you can continue to have a relationship with John, and at the same time, be protected” (Quinn, 2000). A family conference mediated by the agency staff or an attorney may resolve financial issues quickly (Nerenberg, 2000). As with any intense relationship of a long duration, when the relationship is severed, elders often experience a severe sense of loss. It may be necessary to help elders 6 months or more to fill the void with activities and other, trustworthy relationships. If this phase is skipped, victims may very well return to the abusive relationship.

Suggest self-removal or disengagement for relief. The general rule of thumb is to provide services while maintaining elders in the least restrictive environment. Although domestic violence professionals advocate separation of victims from perpetrators, in elder mistreatment cases, most elders consider that to be a plan of last resort. Nevertheless, separation even for a few hours may defuse the situation and help elders have a sense of control. Ask, “Where can you go until you feel better?” With the elders’ permission, solicit help from such third parties as neighbors, apartment managers, and supportive relatives to prevent isolation and unwitnessed mistreatment.

Promote abuser accountability. Provide information to abusers: “Are you aware that others consider this behavior to be a form of elder mistreatment?” “Did you know that blaming and accusing your mother daily is a form of emotional abuse?” In addition, be insistent and gather details about the relationship, and put abusers on notice that the relationship will be monitored: “Tell me again what you do for your mother . . . how you spent the \$60 she gave you for groceries.” “We will visit regularly. . . .” “Yes, I know she has a memory problem, but I’d still like to talk to her.”

Educate possible victims and witnesses. Many elders do not realize that being forced to share their pension, food, and housing through power and control tactics (e.g., threatening to kill their pet) is a form of elder mistreatment. Encourage them to discuss such incidents with others and seek help. Also, educate families and elders about undue influence, as most people do not realize that it happens to people who are alert, competent, and capable. Surveys indicate that victims

are known to a good percentage of the general public. Neighbors and housing managers are in a position to overhear harsh words or elders crying or to notice that elders are seldom seen outside. If access is denied when a visit is attempted, or if persons answering the door or phone constantly say that the elders are sleeping or are not to be disturbed, a well-being check by relatives, law enforcement, or adult protective services may be necessary.

Create professional teams. Communities have benefited from the formation of multiprofessional and multiagency teams that meet regularly, discuss cases, and provide comprehensive services (see, for example, Aziz, 2000). A team may consist of representatives from law enforcement, the prosecutor’s office, social and protective services agencies, long-term care facilities, hospitals, and emergency phone (e.g., 911) networks. A detective may present a case to find out if the bed sores of the elder resulted from caregiver neglect; or a social worker, presenting a case of a self-neglecting elder whose house has been condemned, may ask others for intervention ideas not yet considered.

Self-Neglecting Elders: Respecting Control While Avoiding Harm

Social workers take on the role of “social influencers” with self-neglecters, who respond in varying ways to this outside social influence. Some elders may feel threatened and controlled, whereas others may welcome the intervention (Bozinovski, 2000). The worker’s job is made difficult by the conflict between society’s wish to protect vulnerable adults from harm and respect for individual autonomy (Mixon, 1991). Self-neglecters have a right to refuse services, but workers have a duty to protect them. During the assessment, have a thorough understanding of the underlying factors that led to the reported behavior. Next, decide on the intervention, which may range from advocacy to persuasion to finding a surrogate decision maker. If elders are capable and understand the consequences of refusing help, they have a right to refuse services. Involuntary interventions such as conservatorships or guardianships are justified when incapable elders face imminent harm (Mixon, 1991).

The intervention process with self-neglecters consists of the following steps: (1) establish trust and ally with the elder, focusing more on rapport than on the problem (Dubin, Lelong, & Smith, 1988); (2) find out how the elder processes information so that the worker’s messages are congruent with the elder’s

thinking and actions; (3) use exchange strategy—that is, state an expectation, find out the problem it poses, find ways to resolve the questions that the elder raises about the request, offer incentives to gain the elder’s cooperation, and find mutually acceptable solutions that allow control by the elder; and (4) provide one concrete piece of assistance, regardless of the current presenting problem, which may evoke some feelings of trust (Mixon, 1991).

SUMMARY

In summary, when social workers fight their own denial and avoidance, they can effectively intervene in cases of elder mistreatment; they can be prepared to take advantage of teachable moments with elders, correct the power imbalance, and consider themselves to be a power component that can enable elders to work on the mistreatment successfully. With self-neglecters, the focus is on assessing their capacities and assisting with making decisions that prevent further self-harm.

The biggest challenge is to identify and help victims in communities who do not realize that they are victims (Wood & Stephens, 2003), while neighbors and friends do not realize that they are witnessing acts of elder mistreatment. Workers may reframe as unacceptable those acts to which everyone has become accustomed and also reach out to ethnic groups, as well as to older lesbians and gay men, and educate them about power and control tactics used on elders. Current counseling practices need to be modified to accommodate cultural differences (Kosberg, Lowenstein, Garcia, & Biggs, 2002; Moore, 2000; Tomita, 2000; Vazquez & Rosa, 1999). For example, in some cultures, individual counseling is not a familiar concept; instead, the entire family or a family representative must be consulted before an intervention can be carried out successfully. In addition, elders who immigrate from other countries are especially vulnerable due to language barriers and cultural norms that discourage seeking help.

There is a dearth of empirical studies that focus on the outcome of social work elder-mistreatment interventions. One suggestion is for clinicians to pair up with academicians to find out what the current best practices are. With regard to male victims, there are greater numbers of males among elder mistreatment victims than are seen in the younger domestic violence victim population. More research needs to be done to help practitioners identify elder male victims

and understand their needs (Mouton, Talamantes, Parker, Espino, & Miles, 2001; Pillemer & Finkelhor, 1989). Using gender-neutral language in materials written for older persons, such as safety planning tools and legal advocacy, may help professionals reach more victims (Brandl & Cook-Daniels, 2002).

On a policy development and implementation level, challenges include varying definitions, methodologically weak research, fragmented program policies and services, lack of standardized protective services laws and procedures, and underfunded and unenforced directives related to interventions (Anetzberger, 2001; Bonnie & Wallace, 2002; Roby & Sullivan, 2000; St. James, 2001).

RONALD H. ADAY

Aging Prisoners

19

Older offenders committing violent crimes and being sentenced to lengthy periods of imprisonment has become an astonishing fact. The number of geriatric inmates in many state and federal prisons has been rising steadily since the early 1980s. Their numbers have jumped substantially over the past decade, both in absolute terms and as a proportion of states' entire prison populations. Of the 1.4 million inmates confined in state and federal prisons, 121,432 prisoners, or 8.6%, are over the age of 50 (*Corrections Yearbook*, 2003). With the graying of America, it appears that an increasing number of older adults will find their way into the criminal justice system as perpetrators. This dilemma, along with an increasing number of mentally ill inmates and an already overcrowded prison system, is creating a new challenge for our correctional system and those who must provide social and health services.

This chapter provides a greater understanding of the mental, physical, and social concerns facing aging inmates and those who must provide for their care. Also addressed are end-of-life issues resulting from mandatory sentencing practices that have produced policies to accommodate an increasing number of frail and dying inmates. Finally, a section on social work practice with this special population identifies useful approaches for practitioners as they develop specific case management strategies.

This comments in this chapter specifically focus on state and federal prison issues and avoid any discussion of jails. Whereas jails are utilized to house older offenders who commit minor offenses and as holding units for those who commit major crimes prior to sentencing, state and federal programs are more likely to experience the day-to-day challenges of providing appropriate housing for extended periods of time. As a result, greater attention has been given to the sentencing guidelines, health care delivery, end-of-life issues, and the economic impact that caring for the growing number of aging inmates can have on state and federal budgets.

DEFINING THE OLDER OFFENDER

The lack of consensus on what constitutes an “elderly” offender is one of the most bothersome aspects of comparing research outcomes (Fattah & Sacco, 1989; Forsyth & Gramling, 1988). A review of the literature finds that previous researchers have used a variety of age cutoffs when collecting and analyzing data. For example, Forsyth and Gramling (1988) de-

finer elder inmates as those 65 years of age or older; other researchers reported findings using age 60 (Aday, 2003; Douglass, 1991; Kratcoski, 1990); in yet other research projects, the ages of 50 and over were used (Aday & Nation, 1999; Falter, 1999; Colsher, Wallace, Loeffelholz, & Sales, 1992; Wahidin, 2004).

Whereas governmental programs typically recognize age 65 as the demarcation into old age, correctional officials usually consider “50 and over” as old (Aday, 1999). Correctional officials commonly agree that the typical inmate in his 50s has the physical appearance and accompanying health problems of someone at least 10 years older. House (1990, p. 398) supports this view of “early aging” when he states that “the lowest socioeconomic stratum manifests a prevalence of chronic conditions at ages 45–55 that is not seen in the highest socioeconomic stratum until after age 75.” Morton (1992) also stresses that age 50 is the ideal age to initiate preventive health care and the taking of other appropriate measures to reduce long-term medical costs for older inmates. Of course, although the declining health of many inmates substantiates the phrase “old before their time,” other inmates may remain in reasonably good health into their 60s and 70s. Although 50 and over are the ages used in this chapter, caution should be used when using chronological age exclusively to define the onset of old age.

OLDER OFFENDER CRIMES

The 50-and-older prison population is responsible for an assortment of crimes ranging from violent offenses, including homicides and assaults, to other crimes, such as forgery and crimes involving drugs. For example, 55% of Louisiana’s 3,321 offenders over the age of 50 are incarcerated for violent crimes, 23% for drug-related crimes, 11% for property crimes, and 11% listed under an “all other crimes” category (Louisiana Department of Corrections, 2004). Older homicide offenders are generally serving time for impromptu first offenses committed against younger relatives who had formerly served as caretakers to the assailants but who had relinquished caregiving responsibilities. The events, often alcohol-related, generally occur after altercations in the homes of the victims or the assailants. The crime may be the first offenses for older men who could no longer cope with age-related health or social losses, or they may be serious outward manifestations of low frustration tolerances that perpetrators had had throughout the life course. Only a few are “mercy killings” against

spouses. Nearly two thirds of older female offenders are serving time for nonviolent, often drug-related, offenses. However, about one third have committed violent crimes such as aggravated assault, murder, or manslaughter of a spouse or male companion. Although nearly three quarters are serving time for first (often violent murder and manslaughter) offenses, the number of older women sentenced for drug offenses, forgery, and theft is increasing.

A significant number of older male inmates are incarcerated for committing sexual offenses such as rape, pedophilia, and exhibitionism (Clark & Mezey, 1997). Crime statistics show that those over age 50 accounted for 10% of all sexual offenses, excluding forcible rape (U.S. Department of Justice, 2001). States report that anywhere between 25 and 35% of offenders over age 50 are incarcerated for sexual offenses (Aday, 2003). Older sex offenders are typically white married males who target minor children who are relatives, and the perpetrators frequently attribute these acts to having poor health or living in close proximity to the victim. Research findings have yet to conclude whether sex offenses are first offenses or offenses that have gone undetected prior to the perpetrator’s reaching old age.

HETEROGENEITY OF AGING PRISONERS

The majority of older offenders currently housed in state and federal prisons are non-Hispanic Whites. This population does, however, include a disproportionate number of African Americans (Krebs, 2000). Many of the southern states typically incarcerate a greater proportion of African Americans than states in other regions of the country. For example, of the 3,321 older inmates held in Louisiana prisons, 65% are African American, and the remaining 35% are European American. Similar to other prison population age groups, the older offender is also typically undereducated as a whole. Most older inmates come to prison having few coping skills and having made poor choices in structuring their lives on the outside. Many older prisoners are in poor health, have little support from family or friends, and have frequently abused drugs and alcohol. The following provides a summary of older offender attributes (Aday, 2003):

- The majority of older offenders age 50 and over are non-Hispanic Whites.
- The older-prisoner population includes a disproportionate number of Blacks.

- A substantial number of older inmates have sparse educational backgrounds.
- The average age of incarcerated inmates age 50 and over is 57 years.
- Males make up the overwhelming majority of the older prisoner population, with 95%.
- Only about one third of older offenders are married; the proportion is lower among females.
- A substantial number of older offenders are unskilled laborers or unemployed.
- A significant number of elderly prisoners have histories of poor health.
- About two thirds of older female prisoners have experienced some type of abuse.
- Approximately one half of 50-and-over inmates are serving time for a first offense.

Women represent approximately 5% of the 50-and-older prison population. Most women aging behind bars are unmarried Whites, have limited educational backgrounds, and have no prior employment history (Kratcoski & Babb, 1990). For example, Georgia, like many other states, reports that 77% have fewer than 9 years of formal education, and approximately 98% never completed high school. An overwhelming 66% have intelligence quotient scores below 70. Deficient in basic literary skills, a significant number have little ability to write letters home or pursue education programs without further training (Georgia Department of Corrections, 2003). In contrast, older females in Tennessee were more likely to be high school graduates, and one third had attended some college (Aday & Nation, 2001). However, nearly 60% were former victims of emotional, physical, or sexual abuse prior to incarceration.

MENTAL HEALTH NEEDS AND CHARACTERISTICS

The general population suffering from mental disorders is increasingly entering the prison system. Correctional facilities in the United States currently house more mentally ill individuals than hospitals and mental institutions (Ditton, 1999). A significant portion of the aged suffer from various mental or emotional disorders (Chaiklin, 1998). Whereas 15–25% of older adults in the general population have psychiatric disorders, the estimate of aging prisoners with mental health problems has been reported to be as high as 50%, depending on the populations considered and the diagnostic criteria used (Ditton, 1999; Douglass, 1991; Koenig, Johnson, Bellard, Denker, & Fenlon,

1995). Older white females housed in state prisons are more likely than other aging prisoners to suffer from mental illnesses (Ditton, 1999).

Disorders most prevalent among aging prisoners include organic brain syndrome, depression, anxiety, antisocial personality disorders, schizophrenia, and substance abuse. Although some of these issues result from declines in physical functioning, others can be attributed to the stressful nature of incarceration (Faiver, 1998; Vega & Silverman, 1988). Still others entered prison with psychiatric problems (e.g., organic brain syndrome) that contributed to the offenses committed (Clark & Mezey, 1997; Paradis, Broner, Maher, & O'Rourke, 2000). Although mental health problems are a growing concern among aging prisoners, a significant proportion (25–50%) do not receive appropriate treatment—a figure attributed to the stigma our society places on mental illnesses (Regan, Alderson, & Regan, 2002). Some of the more common mental health issues facing aging prisoners include (Aday, 2003; Tice & Perkins, 1996; Wahidin, 2004):

- Psychological stressors related to lack of privacy, inadequate prison structure
- Emotional problems and coping barriers related to drug/alcohol abuse
- Fears related to dying in prison, victimization, inadequate health care
- Grief reactions to losses such as physical health and life without parole
- Guilt and suicidal thoughts associated with crimes such as sexual offenses
- Symptoms related to prison shock and difficulties with late-life imprisonment
- Early states of dementia, Alzheimer's, and personality rigidity, anxiety disorders
- Loneliness, alienation, depression, and general low morale
- Coping with abusive histories, sleep disturbances, social withdrawal

Anxiety affects nearly one quarter of America's 65-and-older population, and the prevalence among older prisoners is expected to be much higher. Medical-related fears include seeing different physicians during each sick call, not receiving proper medical treatment, having heart attacks, and dying behind bars. Relatives who never visit; dwelling on the crimes committed; threats of financial exploitation, physical abuse, and ridicule by younger inmates; indeterminate sentences; noise; and lack of privacy may also heighten existing anxieties (Aday, 2003; Wahidin, 2004).

Depression affects 15–20% of older adults in the general population but as many as 70% of aging prisoners (Douglass, 1991; Eliopoulos, 1997). Missing outside friends and social life, not knowing when one will be released, and having limited opportunities to participate in age-appropriate recreational activities may lead many aging prisoners to feel bored and hopeless, to change their sleeping patterns, to lose interest in daily routines, to feel guilty about the behaviors that led to incarceration, and, in extreme circumstances, to contemplate suicide. Other symptoms of depression include feeling lonely and useless and describing life as dull. Older persons most often affected by this condition include those who have recently encountered declines in physical functioning or social losses, those who are under the influence of prescription medications, and those who are struggling with their own mortality.

MEDICAL NEEDS AND CHARACTERISTICS

Numerous studies have made valuable contributions to the understanding of the special health needs of the aging inmate (Aday, 2001; Colsher et al., 1992; Falter, 1999; Gallagher, 1990; Marquart, Merianos, Herbert, & Carroll, 1997; Smyer, Gragert, & LaMere, 1997). On average, these studies found a significant incidence of chronic illness for ailments such as arthritis (41%), heart disease (26%), menopause problems (33%), prostate problems (18%), emphysema (20%), stomach disorders (17%), diabetes (12%), cancer (6%), and stroke (8%). Previous studies have found that elderly prisoners suffer from three or more of these chronic illnesses (Aday, 2001; Douglass, 1991; Krebs, 2000) and consume an even greater number of medications. It has also been suggested that the health of the typical older prisoner tends to decline rapidly during incarceration (McCarthy, 1983; Rubenstein, 1984). This rapid decline or accelerated biological aging has been attributed to the following factors (Fabelo, 1999; Fattah & Sacco, 1989):

- Tendency to engage in high-risk behaviors (smoking, drugs, alcohol) prior to incarceration
- Lack of preventive health care prior to incarceration due to lack of access
- Unhealthy lifestyles fostered in prison, including poor diets and lack of exercise
- Greater rate of infectious disease than persons of the same age in the free world
- Harshness and stressors of prison life, especially in maximum security prisons

Other researchers see elderly inmates as experiencing a refuge from the traumas of life on the outside (Brogden & Nijhar, 2000). In this sense, the prison can serve as a haven and can potentially slow the aging process for vulnerable older offenders who experienced a destructive lifestyle and conditions of poverty prior to imprisonment (Fattah & Sacco, 1989).

Chronic illness has been reported to negatively affect a person's body image, psychological well-being, and social identity (Royer, 1995). At a minimum, for many persons, the diagnosis of a chronic illness forces an awareness of a permanent defect, however slight, that potentially reduces the accustomed level of functioning. As Table 19.1 illustrates, the ability of a group of 318 inmates over the age of 60 housed in Tennessee prisons to negotiate their environment is severely limited. When comparing the young-old (60–64) with the oldest (65–81) inmates, it was found that functional capabilities declined significantly for all indicators for persons in the latter age group. As they experience a more restricted life, chronically ill persons become cognizant of the fact that they cannot engage in many of the activities they valued and enjoyed in the past.

With some chronic illnesses, older adults first confront their own mortality, which may lead to greater uncertainty and profound fear. Inmates housed in correctional facilities at some institutions in remote areas may fear having a heart attack or some other sudden life-threatening symptom and worry about the response time for getting them to a medical facility where they could receive proper treatment. The presence of chronic illnesses can create a sense of vulnerability among aging inmates, who frequently have to rely on an unfamiliar or untrusting medical system for critical care. Of course, such chronic conditions also leave the aging inmate more vulnerable to victimization by younger inmates.

SOCIAL NEEDS AND CHARACTERISTICS

Understanding the social world experienced by older inmates requires a fundamental knowledge of Goffman's (1961) notion of "total institutions" and the extent to which prisons, as total institutions, strip inmates of former identities while placing them in settings with "undesirable" populations. Prison offers a new subculture, a new set of rules, and language that can be overwhelming for mentally fragile inmates. For the first time in their lives, older individuals are placed in a system in which they must submit to orderly rou-

TABLE 19.1. TDOC Inmates Over Age 60 With Special Health Care Needs

<i>Special Needs</i>	<i>Percent</i>
Requires ground-level housing	60.2
Requires lower bunk for easy access	68.9
Has difficulty walking long distances	48.6
Has difficulty standing up for 15 minutes	37.5
Independent but exhibits slow mobility	55.0
Requires special equipment for mobility	19.7
Incapable of ascending/descending stairs	51.4
Frail, brittle, unstable, or physically weak	43.3
High risk of victimization by other inmates	44.2
Possesses some vision problems	39.3
Possesses some hearing problems	72.9
Considered legally blind	12.9
Judged to have unstable chronic condition	33.0
Exhibits symptoms of confusion	10.5

tine and exercise very little self-determination. When entering the institution, correctional personnel immediately replace the inmate's name with a number, require him or her to relinquish all personal possessions, and strictly control the times during which inmates may eat, work, or receive visitors.

Despite more liberal visiting and correspondence policies in recent times, inmates still must relinquish substantial contact with family and friends while serving their respective sentences. As a result, imprisonment contributes to the weakening of relationships between inmates and their respective families and friends (Aday & Nation, 2001; Kratcoski & Babb, 1990). The fact that many older inmates are unlikely to receive visitors on a regular basis can stem from a number of factors:

- Some aging inmates may outlive their family members on the outside.
- Strict visitation requirements found in some institutions may create significant barriers.
- Aging inmates may be placed in special needs facilities that make it geographically impossible to maintain close family ties.
- Most inmates come from poverty-stricken backgrounds and unstable families in which there is little support.

- Poor health of inmates or family members may inhibit regular family visits.
- Aging inmates who commit violent crimes (sexual offenders and murderers) on family members often become estranged from the family.
- The shame of imprisonment in old age may serve to reduce the desire for family members (i.e., grandchildren) to visit.

In particular, Kratcoski and Babb (1990) found that older women are less likely to receive visitors than their male counterparts. Being separated from family members can prove to be difficult. Not being able to fulfill the role of parent or grandparent on a day-to-day basis can be frustrating. It can be a tremendous stigma for a grandmother to know that her grandchildren have known her only as an imprisoned person. Based on these shameful feelings, some older inmates prefer not to have visitors but rather to rely on letters and phone calls (Aday & Nation, 2001).

The break in the link with the free community can be a traumatic experience for the older offender already attempting to adjust to certain physical and emotional changes associated with aging itself. If the social attachments outside the prison decrease, this broken relationship may serve to make the older prisoner more dependent on the institution, especially if he or she has no immediate family or friends on the outside. When accompanied by a shrinking social environment, the length of institutionalization, as does old age itself, may serve to decrease the number of significant others on the outside. As a result, a significant number of aging inmates may experience what has been termed "institutional dependency." In this sense, prison becomes their home, and they are fearful, or in some cases unwilling, to return to the free world.

END-OF-LIFE ISSUES

The aging prison population has created a new panoply of end-of-life issues. Over a 12-year period, inmate deaths in state prisons have doubled, increasing from 1,630 in 1989 to 3,203 in 2000 (*Corrections Yearbook*, 2002). The percentage of inmate deaths due to natural causes has steadily increased, from 58.8% in 1996 to 80.0% in 2001. Overall, more than 2,500 convicted criminals now die of natural causes in state and federal prison each year (*Corrections Yearbook*, 2002). The mortality rate is expected to continue to increase primarily because of the graying of the U.S. prison populations and because an increasing number of of-

fenders are receiving sentences that will keep them imprisoned for the remainder of their lives.

Most inmates fear dying in prison, and these anxieties will become more commonplace as America's prison population continues to age (Byock, 2002). After anticipating and planning for release, terminally ill long-term inmates may fear dying in institutions that house aggressive inmates, hire uncaring staff, and restrict visits (Aday, 2003; Byock, 2002). Aging prisoners likely to fear death are those who report their health as poor, who have witnessed the deaths of their prison peers, and who rarely receive support from people other than uncaring paid prison staff (Aday, 2003). For those who have supportive friends and family, thoughts of leaving behind grief-stricken loved ones may also instill fears of death. Older prisoners cope with thoughts of dying in prison by gaining strength from religious beliefs, engaging in prison activities, and viewing death as the end of suffering endured while ill behind bars (Aday, 2003).

America's courts do not mandate prisons to release terminally ill older, infirm prisoners, but most federal and state prisons do provide compassionate release for inmates who have medical records and physicians' statements documenting their prognoses; low-risk security classifications; future economic security; and an established dwelling outside the institution (National Institute of Corrections, 1998). Sending minimal-risk, terminally ill inmates home to die reduces prison medical expenditures (Yates & Gillespie, 2000), but placing inmates in the care of others is not always possible. Aging relatives often do not have the strength, stamina, or time to adequately support the inmate, and many nursing homes do not want to assume the liability of caring for former prisoners (Aday, 2003). Therefore, correctional officials must provide in-house services for inmates who have no other option but to spend their final days behind bars.

SOCIAL WORK PRACTICE WITH OLDER OFFENDERS

About half of the states now provide geriatric facilities and programming for elderly inmates, ranging from separate facilities for the aged and infirm to selected clustering within a large prison setting (American Correctional Association, 2001). Numerous states are developing nursing home–like settings, which provide a greater degree of shelter and accommodation (Aday, 1999; Flynn, 1992). Grouping inmates with similar health care needs has been considered to be

more cost effective, as well as offering prison officials the opportunity to respond more efficiently to the unmet needs of elderly prisoners. Special facilities also provide aging inmates with a quieter living environment and one considered safer than living in the general prison population (Marquart, Merianos, & Doucet, 2000).

Geriatric facilities in Florida, Ohio, Pennsylvania, and North Carolina offer some of the more ambitious programs for older offenders. Among others, these states routinely provide inmates with geriatric walking programs, as well as other low-impact sports activities, including intramural basketball and softball for inmates 50 and over. Psychologists and social workers provide case management, counseling services, mercy parole recommendations, nursing home placement, and other special care. Services are offered so inmates can learn to deal with their reactions to health issues, problems with their spouses, adjusting to prison life, and strained relationships with children and grandchildren. Numerous states also provide hospice programs for the terminally ill and also arrange for appropriate aftercare to elderly inmates who are released.

There are, however, limitations in the implementation of new geriatric policies and programming efforts. Prison officials must be more imaginative in programming for this subgroup of inmates. In facilities designed solely for older, special-needs offenders, finding suitable work assignments for everyone may be difficult. Contacts with outside agencies can provide new opportunities for older, frail inmates. However, location of prisons in isolated areas can hinder such programming. On the other hand, many older inmates are incapable of successfully completing work assignments or training programs. Chronic health problems may prevent older offenders from participating in normal work assignments. Also, with the tremendous growth of the aging prison population, the number of beds dedicated to this population is far from adequate, and many aging inmates never have the opportunity to live in a special-needs environment. A system with a more careful monitoring process can allow inmates to be placed in an appropriate prison environment and prevent many of the negative outcomes associated with living in prison.

OLDER INMATE TYPES

Aging inmates are a diverse population, presenting a wide range of challenges for those providing services.

When developing strategies for working with older inmates, it is important to differentiate between three types. Approximately one half of older inmates housed in federal and state prisons are “new elderly” offenders who never intended to violate the law but committed first offenses (primarily murder and sex crimes) against younger relatives or close acquaintances after age 50. Formerly regarded as “model citizens,” these prisoners frequently have difficulties adjusting to life in prison—abiding by prison policies, living with a potentially violent population, and being away from family and former friends. The pains of imprisonment can leave some feeling guilty for disappointing loved ones, lonely, apprehensive about the future, and anxious about surviving in a total institution. As a result, many begin to exhibit symptoms of depression, withdrawal from prison staff and inmates, change in sleep and eating patterns, and suicidal ideations. Remorseful for the crimes committed, other “new elderly” offenders are appreciative of the free food, shelter, and clothing they now have and adjust rather well to institutional living.

A second group, the recidivist or habitual criminals, generally began a life of crime at a rather early age. Over the years, they have found themselves in and out of the criminal justice system and are now reincarcerated in later life. This group of offenders is generally well adjusted to the prison system, having an active support group of other inmates. Unmarried or divorced and abusers of drugs and alcohols, they have lived through hard lives on the outside and are typically in poor health. More times than not, they have committed a crime that will keep them incarcerated for 10 or more years, and many in this group will face end-of-life issues in prison. Due to their crime history, obviously habitual offenders are not considered a good risk for parole.

Another, smaller group who require unique programming include long-term inmates (lifers) who first offended early in life and received 20-plus-year prison sentences. Often young, uneducated, poor black men who pleaded guilty to the charges against them and never requested release have grown old behind bars. Since imprisonment, many have severed any contact they once had with members of the free world, and they would have no home where they could return if set free. Long-term inmates require special consideration, as many will lose motivation to participate in prison activities, obsess over visible signs of deteriorating health, and contemplate dying in prison. If these inmates were to receive parole and could tomorrow return to the free world, they would first require extensive release preparation, including assistance ob-

taining financial support, affordable lodging, and in-expensive health care services, because many have become heavily dependent on the institution to meet all of their needs for basic survival.

HELPING AGING PRISONERS ADAPT

As suggested by Gewirtz (1984), the goals, values, attitudes, knowledge base, and practice skills of social work provide a useful framework for working with the older inmate population. Research has demonstrated that those providing services to the geriatric inmate population need specialized training if they are to be effective (Kratcoski, 2000). Understanding that older offenders have the same rights as other clients in the free world is important. As suggested by Kropf and Hutchison (2000, p. 3), any special group of “elderly clients have the right to sensitive and ethical practice that preserves the greatest autonomy.” Although policies relating to medical care, social services, and parole planning for inmates have been hotly debated, there is a growing recognition that inmates should receive services consistent with prevailing community norms. Under the Eighth Amendment, not providing inmates programming conducive to their levels of cognitive, physical, and psychological functioning is considered “cruel and unusual punishment” (Krebs, 2000). According to Krebs, we must not merely permit older inmates permission to participate in existing programs but must also create new activities suitable to inmates with health limitations. Practitioners should be aware that they will likely encounter aging inmates requiring different types of intervention and assistance than other elderly clients.

For example, the entry into and adaptation to prison for late offenders can be a difficult transition, as can be the transition back out of society for long-termers after spending a considerable portion of life behind bars. To capture some of the unique problems facing aging prisoners, Kratcoski (2000) has suggested that special consideration be given to the following when working with older inmates in the prison context:

- Those who violate rules may not have understood the rules.
- Inmates may be forgetful, misinterpret instruction, or simply not understand the meaning of slang terms often used by correctional staff and officers.
- Older inmates will need more assistance and attention than younger inmates, as they may not be-

come involved in inmate subculture or be assisted by family members.

- Older inmates are more likely to have serious mental and physical problems.
- Some may be bed wetters, and others need to make constant trips to the bathroom.
- Many older inmates will need more encouragement to become involved in recreational, social, and education activities.
- Programming should be designed to elevate self-esteem rather than to prepare for a job.
- Lifers may be more fearful of being released back to the community.

In addition to prisoner characteristics, prison adaptation is also influenced by the prison environment in which they reside. The sheer physical condition and structure of the institution can create significant problems for older inmates. Few older men and women aging in prison report being satisfied with their living conditions (Aday, 2001; Kratcoski & Babb, 1990). Older, frail offenders often find the prison environment to be oppressive, with poor lighting and ventilation. Stale air from smokers, top bunking, and being housed too far away from the dining room and bathrooms have been viewed as significant environmental problems. Unlike people in the general population, who can generally adapt to oppressive housing arrangements, those aging in prison have no choice but to accept and find mechanisms to cope with the noise, limited recreational activities, lack of privacy, and potential victimization by other inmates.

Aging inmates typically benefit from involvement in some type of educational or social programming. As a broker (Kropf & Hutchison, 2000), a practitioner assesses both client needs and, in this case, environmental resources available in the prison and the community at large. To combat the many losses aging prisoners may experience, the empowerment model has been suggested as a way counselors and other mental health professionals can assist individuals in coping with their life changes and transitions (Waters & Goodman, 1990). Empowering older adults is practitioner oriented and includes establishing goals and supporting inmates in their efforts to adjust. In some instances the enabler role will serve to help aging inmates accept the fact that they will spend the remainder of their lives incarcerated. In other cases, emphasis may be placed on dealing with past abuses, offender behavior, or reentry back to the community. Life skills education programs are one way some correctional institutions have used to prepare older inmates for reentry to the community.

The program includes a number of referral activities and assistance in locating housing after release; in adjusting to having a criminal record; in reestablishing ties with family members; in obtaining financial resources such as food stamps, Medicaid, and Medicare; in developing social skills; and in taking care of personal hygiene. Preparation for reentry can be an onerous task for inmates who have spent 20 or more years separated from the outside world.

THE USE OF THERAPEUTIC GROUPS

As a planned programmed activity, working with the elderly in groups can serve as a valuable tool to help plan and implement effective intervention strategies in the prison environment. An important reason for conducting groups in correctional settings is that many inmates need socialization skills (Stojkovic & Lovell, 1997). Members learn from other members, and inmates feel reassured when they hear others sharing similar fears and concerns (Masters, 1994). According to Jacobs and Spadaro (2003), inmates are often distrustful of prison staff, but they may listen to their peers in a group counseling situation. The use of groups can be ideal in overcoming loneliness, dealing with guilt or grief issues, and, in general, facilitating positive personal changes. Toseland (1995, pp. 18–19) has identified numerous benefits of group participation:

- Groups provide feelings of belonging and affiliation that can help older adults to overcome the social isolation and loneliness.
- Group participation helps to validate and affirm the experiences of older adults.
- Groups provide members with an opportunity to share and to learn new information.
- Groups provide older adults with unique opportunities for interpersonal learning.
- Groups offer older adults the opportunity to resolve problems with the help and support of fellow members.

There are three basic categories of older adults for whom groups are particularly beneficial: (1) older adults who are socially isolated, (2) older adults who have interpersonal problems, and (3) older adults who need assistance in identifying and participating in new social roles. Older inmates transitioning into prison, as well as those coping with the effects of long-term imprisonment, can benefit greatly from effective

group participation. Remotivation, reminiscing, support, recreational, and psychotherapy groups have all been used productively in working with aging inmates (Aday, 2003). Table 19.2 is a modified list of support group topics frequently used with older incarcerated females, and most would be equally relevant for males.

It is essential for prison practitioners who work with older inmates to become thoroughly familiar with the process of grieving. Loss is a theme that fre-

quently reemerges when working with older inmates. Loss of freedom, health, work roles, identity, family members, marriage partners, or other prison acquaintances is quite common. Group therapy can provide the means for elderly inmates to accept and resolve long-standing attitudes and feelings related to their life in prison. Psychotherapy is also helpful, as it can expand older inmates' coping strategies.

EXPANDING THE ROLE OF PRACTITIONERS

The transition of the social work philosophy into the prison setting can be challenging. Although a significant number of states are providing special facilities to accommodate the needs of the aging prison population, numerous obstacles hinder service providers. For example, overcrowding and financial constraints frequently take first priority in states strapped for resources. The rising costs of health care inhibit some correctional systems from offering comprehensive services beyond the "medical model." Some facilities may have a small number of aging inmates, reducing the likelihood that special programming will be provided.

Some public sentiment remains against providing special therapeutic treatment or separate facilities for the older inmate. The public still disagrees about the ethical obligation to provide inmates with extensive services, such as palliative care or kidney transplants. Prison therapeutic programs may create high expectations that in a correctional setting cannot entirely be met. Identifying and meeting the special needs of aging inmates is a challenge filled with contradictions and pitfalls. Prisons as a rule have promoted conformity rather than individuality. Prison is a place where even simple platonic gestures are often discouraged. Simple human contact, such as touching a patient's hand or shoulder during assessment, is often frowned on. Some security and even medical personnel may have misperceptions about the mission and value of treatment programs.

Although researchers are beginning to address with more frequency the policy concerns associated with the aging prison population, the body of knowledge on elderly inmates is not extensive. Prison officials have stressed that indicators are needed to more clearly identify model programs to meet the needs of the elderly inmate (Edwards, 1998). For example, although a variety of programs and facilities have been introduced, a systematic way to evaluate them is

TABLE 19.2. Support Group Topics for Aging Inmates

<i>Topics Addressing Personal Growth</i>
Loneliness
Mortality
How to make each moment count
Self-esteem
Future fears and desires
Life transitions
Ageism
Drug/alcohol abuse
How to maintain independence
Energy level changes
Anger management
Lack of mobility
Feelings of isolation
Weight gain
<i>Topics Addressing Daily Life Issues</i>
Work activities
Learning to live in prison
Getting along with others
Learning to live with chronic illness, etc.
Legal issues
Financial concerns
Environmental stress
<i>Topics Addressing Family and Social Relationships</i>
Desertion by families
Children and grandchildren
Sexuality and relationships
Making prison friends
Family visits
Social issues
Abusive relationships
Death of family/friends

sorely needed. Important questions remain about their effectiveness in meeting the special needs of the aging prisoner. Also, little research has been conducted on aging prisoners themselves and the nature of their family relationships, the coping strategies of those entering prison late in life, or the utility of social networks in prison adjustment.

Prison administrators have pointed out the need for better-qualified staff to work with aging prisoners (Caldwell, Jarvis, & Rosefield, 2001). Selecting and training staff to deal effectively with older offenders will be an increasingly important challenge. Special sensitivity training may be necessary to adequately prepare staff to work with the aging population. Practitioners with background and training in gerontology can take an active policy role in educating the public about the important issues associated with the graying of American prisons. In addition to providing direct care to an increasingly frail aging prison population, social workers can take a leadership role in training administrative personnel, line security staff, and other prison staff to be more sensitive to the social, emotional, and health needs of aging prisoners. In effectively meeting these challenges, social workers will provide a valuable service to the correctional field.

SECTION IV

**Cultural Diversity and Social Work
Practice With Older Adults**

This page intentionally left blank

OVERVIEW

The concept of cultural diversity implies recognition by social workers of the differences in the life experiences of older adults. Differences may include but are not limited to cultural history, language, values, religion, ethnicity, nationality, regionality, immigration status, and sexual orientation. Both the National Association of Social Workers (NASW) and the Council on Social Work Education (CSWE) emphasize that social workers should be knowledgeable about the cultures of clients. These organizations of the social work profession also emphasize social workers' being trained to deliver culturally appropriate services to clients. To this end, this section addresses social work practice with diverse groups of U.S. older adults: African Americans and other Black populations; Asian Americans; gays, lesbians, bisexuals and transgender persons; religious and regional minorities; Native Hawaiian and Pacific Islanders; Latinos; and Native Americans.

In chapter 20, Chadiha, Brown, and Aranda focus on the largest group of U.S. elders of color—native and non-native Black Americans of African origin. Contrary to popular beliefs that the Black elderly population is monolithic, these authors note that the Black elderly population is a diverse group in ethnic composition and nationality. They also note variability within the Black elderly population and differences from other racial-ethnic elderly persons on social, demographic, economic, and health characteristics—factors that provide service providers with both challenges and opportunities when working with Black elderly persons. Further, Chadiha and colleagues identify three key informal sources of support—family, church, and religion—that help offset social, demographic, economic, and health challenges. They end with a discussion of different levels of interventions to address the special needs of elderly Blacks.

Min and Moon, in chapter 21, address the growth and diversity of Asian American elders—the fastest growing U.S. racial group. They cite 24 ethnic groups (excluding Pacific Islanders, information on which can be found in the last chapter in this section). Further, other elements of diversity and variability include language, immigration history (e.g., reason for immigration, age at time of immigration), length of stay and life experiences in the United States, religious affiliation, socioeconomic status, and level of acculturation—all factors that affect the well-being of Asian American elderly persons. These authors provide an illuminating discussion on issues of physical health status, psychological and mental health status,

and family and caregiving among Asian American elderly. They conclude from empirical studies that Asian American elderly persons underutilize services and end with recommendations aimed to help practitioners to practice culturally competent social work with these elderly persons.

In chapter 22, Butler profiles the diversity of one of the most invisible groups of elderly Americans—gay, lesbian, bisexual, and transgendered (GLBT) persons—in empirical research. She notes that precise numbers about the size of this population of elderly persons are unavailable, with figures ranging from 1 million to 2.8 million; however, the Administration on Aging estimates population growth to 6 million by 2030. Butler outlines GLBT elders' history of oppression and invisibility, as well as what is known about them on the basis of "few studies" and "small nonrepresentative samples." Butler ends with an informative discussion on the unique strengths and challenges of GLBT elders and the implications of these strengths and challenges for practitioners to consider when working with GLBT elders.

Chapter 23 by Aranda focuses on elders of Latino/Hispanic descent, another diverse group in "language, culture, sociopolitical history, acculturation, cumulative life experiences and opportunities." As do prior chapters in this section, Aranda also discusses social, demographic, and cultural characteristics, as well as physical health and disability among Latino elders. She anchors her discussion of these characteristics in issues of mental health, specifically late-life depression, for Latino elders. Through prior literature she clearly establishes the relatively high risk of depressive disorder and low service utilization among older Mexican Americans. The chapter ends with a case example that illustrates practice strategies for working with Latino elders.

Barusch, in chapter 24, addresses the history and demographics of the Native American elders, of their current living conditions, and of forced assimilation and colonization. She elucidates the negative impact that prior federal policies had on dislocating Native Americans and the extent to which such dislocation has meant that contemporary urban-dwelling Native elders lack access to services that are provided by Indian Health Services. Barusch ends this chapter with strategies to support and empower Native American elders. Further, she also addresses the need for increased numbers of trained Native American professionals to work with Native elders.

Whereas prior chapters focus on diverse groups based on race, ethnicity, and sexual orientation, the

last chapter in this section, written by Browne and Richardson, focuses on elderly persons in “other minority groups”—groups that represent “marginal religions and regions.” Specifically, these authors address the demographics, health (physical and mental), and cultural values of elderly persons of Jewish faith and elderly persons of Muslim faith. Correspondingly, they address the demographics, health (physi-

cal and mental), and cultural values of elderly persons residing in the Appalachian Mountain region and the Pacific Islands. Each discussion of a religious or regional group is followed by a set of innovative recommendations for social work interventions that take into consideration the unique characteristics of these “other minority groups.”

Older African Americans and Other Black Populations

20

The Black elderly population (i.e., African Americans, Caribbean and African immigrants) ages 65 years or older comprises the largest group of elders of color in the United States. Growth in population size, as well as in age and cultural diversity, of the Black elderly population presents both challenges and opportunities for effective service delivery by social workers to these Americans. The purpose of this chapter is to address the special concerns of social work practice with older Blacks while taking into account the ethnic diversity within the U.S. Black elderly population. In order to address such concerns, it is essential to preface them with a discussion on certain salient issues in empirical literature on the older Black population. These issues, which form major subheadings in this chapter, include the expansion and subsequent cultural heterogeneity of the older Black population; social, demographic, and economic characteristics; physical health and mental health status, as well as access to health care; and family, church, and religion as sources of informal support to older Blacks. Extant literature, including government documents and other empirical research, provided evidence for addressing these issues. We use the knowledge from this evidence to draw implications for social work practice with older Black adult populations living in the United States. Throughout this chapter, we use the terms Black and Black Americans to refer to native and non-native Americans of African descent.

GROWTH AND HETEROGENEITY OF THE ELDERLY BLACK POPULATION

A little over three decades ago 16.6 million elderly people lived in the United States. This figure had more than doubled by 2000 to 35 million elderly people (Angel & Hogan, 2004). Of these elderly persons, 16.4% were persons of color (i.e., Black, Asian, Native American, or Hispanic). Elderly Blacks (8.4%), persons of African, Caribbean, and European ancestry, composed the majority of these elderly persons of color living in the United States in 2000. The percent of older Blacks ages 65 years or older in the U.S. Black population is expected to almost double (16.1%) by 2030, reaching 20% by 2050 (Angel & Hogan, 2004).

The U.S. Black elderly population comprises primarily native-born persons of African descent, typically referred to as African Americans or Black Americans. Growth of the Black elderly population is attributed to the rising longevity that has come as a result of improved health status and medical care. The Black elderly population is a diverse group in ethnic

makeup, nationality, language, and religious orientation (Sotomayor, 1997). Immigration trends during the 20th century, especially in the latter part of the century, portend that unprecedented numbers of non-native-born older Blacks will constitute the future population of older Black Americans. Since 1965, the year marking an increase in the number of persons of African descent migrating to the United States (Allen, 1997; Ross-Sheriff, 1997), millions of Black immigrants from the Caribbean and the continent of Africa have settled in the United States. For instance, by the turn of the last century, “1.4 million Blacks (3.9%) had at least 1 foreign-born parent” (Lucas, Barr-Anderson, & Kington, 2003, p. 1740). Although non-native Blacks share the same marginal social status of native-born Blacks, non-native Blacks possess higher levels of human capital (i.e., education; Djamba, 1999) and report better overall health than native-born Blacks (Lucas et al., 2003). However, non-native Black men are less likely to be insured than either native-born Black or White men (Lucas et al., 2003). These contrary findings suggest that the current population of non-native Blacks represents a changing landscape of aging among U.S. Black residents.

SOCIAL, DEMOGRAPHIC, AND ECONOMIC CHARACTERISTICS

The social, demographic and economic characteristics of elderly Black U.S. residents add another dimension of heterogeneity. Data for characteristics, including age, gender, marital status, living arrangements, and poverty, represent the general Black population because data are unavailable by origin of Black elderly people. The number of persons reaching 85 years of age and older is a distinguishing feature of the general U.S. elderly population, reflecting increased heterogeneity in population aging (Siegel, 1994). The number of Blacks 85 years old or more increased from 67,000 in 1960 to 322,000 in 2000, with an expected increase in this number to 2.1 million by 2050 (Angel & Hogan, 2004).

The gender composition of the elderly population is a consequence of differences in the survival rates of men and women across the life course (Angel & Hogan, 2004). As people age across the life span, the sex ratio (i.e., the number of males per 100 females) declines with increasing age. For Blacks ages 65–74 years old in 2000, the sex ratio was 70 males per 100 females (Angel & Hogan). Further, the number of males to females continues to decline with increasing

age in the elderly population. For instance, in 1995 the sex ratio for elderly Blacks was approximately 40 males per 100 females (Siegel, 1994). The two main reasons for the existence of more females than males in the elderly Black population are a higher male than female mortality rate over the life course and a lower number of male births to female births (Siegel, 1994). Regardless of the reasons for a gender imbalance in old age, it has consequences for marital status, living arrangements, and poverty among Blacks in old age.

Regarding marital status and living arrangements among elderly Blacks, a substantially greater number of females than males live outside a married household. Using data from the 2000 U.S. Census, Angel and Hogan (2004) report that 24.3% of Black women, 42.4% of White women, 41.3% of Asian women, and 36.9% of Hispanic women lived in married households. Similarly, among elderly men, Black men living in married households (53.5%) lagged behind White men (74.3%), Asian and Pacific Islander men (72.0%), and Hispanic men (66.8%). Paralleling patterns of living arrangements in the general older adult population, more older Black women than Black men lived alone. Still, substantially greater numbers of elderly Black men (25.9%) than elderly White men (17.0%) and elderly men of color (6.6% Asian and Pacific Islander; 14.0% Hispanic) lived alone (Angel & Hogan, 2004).

These demographic and social characteristics have consequences for the economic circumstances of Black elderly. According to Angel and Hogan (2004), older persons of color experience more severe poverty (i.e., being 100% below the poverty threshold) than older Whites. A greater percentage of women living alone (41.5%) are impoverished than either unmarried males (29.3%) or female heads of households living with other individuals (23.6%). The lowest percentage of impoverished persons in the older Black population is married couples (9.1% husbands; 9.3% wives; Angel & Hogan, 2004). These economic data reflect the relationship between demographic and social patterns such as age, gender, marital status, and living arrangements of elderly Blacks. They direct social workers to the relationship between various factors that affect the well-being of Blacks in later years of life.

HEALTH ISSUES

Physical Health

Health is a complex phenomenon that is more than a physical status; it also includes mental and social well-

being (Johnson & Misra, 2001). A discussion of the physical and mental health of older Blacks is based on data for the general Black population because we have not found health data by ethnic origin for older Black adults. One can gain an understanding of the physical health status of older Blacks through an examination of such factors as life expectancy, mortality, and chronic health conditions.

Life Expectancy Despite the fact that people of all races and genders are living longer and healthier lives, longevity is not the same among all people. There is great variability in longevity by gender and by race: Women outlive men and Whites outlive Blacks (National Center for Health Statistics, cited in Rooks & Whitfield, 2004; Siegel, 1994). With regard to Black Americans, a Black female born in 1950 had a life expectancy of 62.9 years compared with her Black male counterpart, who had a life expectancy of 59.1 years, reflecting a gap of almost 4 years. A Black female born in 1999 could expect to live to almost 74.7 years of age, compared with 67.8 years for her Black male counterpart, reflecting a gap of 6.5 years. These figures show improvement in life expectancy of both Black females and males. Interestingly, the gender gap is wider in 1999 than in 1950, with Black males having a substantially lower life expectancy than Black females. A Black female born in 1950 could expect her White counterpart to live 9.3 years longer, reflecting a life expectancy of 72.2 years. A Black male born in 1950 could expect his White counterpart to live 7.4 years longer. By 1999, black females had a life expectancy of 74.7 years, compared with 79.9 years for White females. Black males had a life expectancy of 67.8 years, compared with 74.6 years for White females (Angel & Hogan, 2004). An exception to this pattern of longevity is the “Black-White mortality crossover” around ages 75–85 years, reflecting a reversal of the pattern of mortality pattern between races. After age 75, older Blacks have a chance of higher life expectancy than Whites. Explanations of the Black-White mortality crossover range from reporting inaccuracies of age to adaptation and selection processes that predispose heartier Blacks to longer lives (see Rooks & Whitfield, 2004, for explanations and debates on the Black-White mortality crossover).

Chronic Disease, Morbidity and Mortality The leading chronic diseases for Black elderly persons are hypertension, heart disease, stroke, and end-stage renal

disease (Mouton, 1997; National Academy on an Aging Society, 2000c). More older Blacks contract and die from heart disease and stroke, particularly those in the age range of 65 to 84, than older Whites (Rooks & Whitfield, 2004). The risk of having heart disease and of dying from it for older Blacks must be considered along with other widespread risk factors of heart disease and stroke, such as hypertension, obesity, and high cholesterol—factors known to be influenced by social (e.g., socioeconomic status) and individual (e.g., sedentary lifestyle) factors (Federal Interagency Forum on Aging-Related Statistics, 2004; Rooks & Whitfield, 2004). Differences in heart disease rates between Blacks and Whites tend to reverse for Blacks ages 84 and over. Further, prostate cancer strikes disproportionate numbers of older African American men, and more of them die from prostate cancer than men of any other racial/ethnic group (see review by Pierce, Chadiha, Vargas, & Mosley, 2003).

Other Risk Factors and Access Issues Personal or individual factors such as lack of exercise, overeating, smoking, and alcohol consumption are part of the equation of risk factors that affect the health of older persons. Curtailing or eliminating these risks may mean that older Blacks reduce the risk of developing chronic conditions and mortality from disease complications and also enhance the quality of their lives. Further, people of low socioeconomic status (SES) are more vulnerable to risk of chronic conditions (National Academy on an Aging Society, 1999). Older Blacks generally have disproportionately low incomes, thus suggesting an association between health and SES among older Blacks (Sotomayor, 1997). Drawing on the work of House and colleagues, Williams and Wilson (2001) note a curvilinear relationship between SES and health that is “small in early adulthood, increases markedly in middle and early old age, and decreases in late old age” (p. 165). One explanation offered by House and colleagues (cited by Williams & Wilson, 2001) for a decreasing relationship between SES and health in late old age is entitlement programs that have helped ameliorate social circumstances and lower adverse affects of low SES on health. Although Williams and Wilson acknowledge this as a plausible explanation, they also contend that racial disparities in access and quality of medical care for older Blacks play a critical role in the continuing racial disparity in health. Research corroborates these contentions by documenting racial disparities in the quality of health care received by Medicare enrollees,

as well as other elderly persons (Escarce, Epstein, Colby, & Schwartz, 1993; Schneider, Zaslavsky, & Epstein, 2002). Further, social explanations of racial disparities appear to outweigh genetic and biological explanations (LaVeist, 2004; Williams, 2004; Williams & Wilson, 2001).

Functional Status Concomitant with an aging U.S. population, a substantial number of elderly persons experience disability associated with a decline in functioning, including limitations in activities of daily living (ADLs; e.g., bathing and grooming) and instrumental activities of daily living (IADLs; e.g., traveling to the doctor and preparing meals). Besides these limitations, many elderly persons also experience a decline in social functioning. The Forum Report (Federal Interagency Forum on Aging-Related Statistics, 2004) on age-related statistics indicates a decline in disability rates for both males and females: From 27% of females and 20% of males in 1982 to 25% and 16%, respectively, in 1994. This report also notes Black-White differences in functional disability involving physical tasks. For instance, more older Blacks than older Whites are unable to perform physical activities such as walking up steps, lifting and carrying a heavy load, reaching overhead, and so on. Substantial numbers of older Blacks are also disproportionately affected by arthritis, a condition that does not lead to death but makes it challenging for older adults to lead active and productive lives (National Academy on an Aging Society, 2000a).

Cognitive Status With increasing longevity of older Blacks, more knowledge is accumulating on their experience with dementia. Although a high prevalence of hypertension and stroke among older Blacks would imply that they are susceptible to vascular dementia associated with these health conditions, many older Blacks with increased longevity now risk developing dementia of the Alzheimer's type, a degenerative disease of the brain (Alzheimer's Association of America, 2001). Whether or not African Americans have a greater likelihood than Whites of having Alzheimer's disease is equivocal. For instance, a recent prospective study of 1,079 African Americans, White, and Hispanic Medicare recipients in New York documented that the likelihood of African Americans and Hispanics developing Alzheimer's disease by age 90 years in the absence of an apolipoprotein allele increased significantly over the likelihood of Whites developing

the disease by a similar age (Tang et al., 1998). Further, these results were found independently of effects of sociodemographic variables such as age, education, income, marital status, and employment status. However, in the absence of this allele, all three groups had similar likelihood of developing Alzheimer's disease by age 90 years. These findings contrast with information reported by the National Academy on an Aging Society (2000b) that indicate that a disproportionate number of Whites (85%) relative to Blacks (9%) and persons of other races or ethnicities (6%) are affected by Alzheimer's disease. With the population aging among older Blacks in the 75–85 year old group and without a cure for this disease, we are likely to witness a substantial rise in Alzheimer's disease in the Black elderly population. The economic and psychosocial cost of the disease to elders and their caregivers can be staggering, requiring as much support as professionals can offer families who care for elders with Alzheimer's disease.

Besides the aforementioned objective health status evidence in the older Black population, self-rated health status is an essential piece in their health equation. Self-rated health has not been without criticism and controversy (see the review by Gibson, 1991). Yet researchers, policy makers, and practitioners recognize that older people's perceptions of their physical health are crucial to understanding their health and overall well-being. Data in a recent report indicate that positive self-rated health reports declined across age groups (i.e., 65–74; 75–84; 85 or older) for both Black and White elderly, as well as for males and females ("Older Americans 2000," 2000). However, older Black males and females of any age group were less likely to rate their health status as good than were Whites. The gradient of self-rated health for Blacks was more similar to that of Hispanics than to that of Whites. Black females and males reported nearly comparable levels of health status across age groups.

In sum, data on the life expectancy, mortality, chronic conditions, and physical and cognitive disabilities of older Blacks, principally for native Blacks, indicate both improvements and lack of improvements when Blacks are compared with older Whites of similar age. Comparative data for native-born older Blacks and non-native-born older Blacks for these health indicators are seriously lacking; however, studies on younger cohorts of native-born and non-native-born Blacks indicate within-race difference on physical health. For example, Lucas et al. (2003) report, after adjusting for age and controlling for SES, that non-native-born Black men were less likely to

report fair or poor health and less likely to report a functional limitation than native-born Black men. Further, the health status of non-native-born Black men was more similar to or better than the health status of native-born White men. Non-native-born Black men were less likely to report risky health behaviors such as smoking. The likelihood of non-native-born Black men smoking, however, increased with longer stay in the United States. Native-born men were more likely to report health insurance coverage than non-native-born men. Findings from the study by Lucas et al. (2003) direct the attention of social work practitioners to the growing ethnic heterogeneity and potential health disparity within the black elderly population.

Mental Health

The mental health status of the older Black population is also an essential piece of the fabric of their health and overall life quality. Poussaint (1990) has proposed that the mental health of Blacks is less about mental disorders and more about their life situation in old age, such as their relatively poor physical health, poor functioning, and low socioeconomic status due largely to a lifetime of cumulative social and economic disadvantage.

A recent Report of the Surgeon General (U.S. Department of Health and Human Services [USDHHS], 2001) notes that most older people experience “good” mental health, with only about one in five adults ages 55 years old or older likely to experience mental disorders. Ranked by order of prevalence, anxiety disorders (e.g., phobias and obsessive-compulsive disorder) and mood disorders such as depression are the most common mental health conditions, whereas schizophrenia, as well as personality disorders, are least common in the elderly population 65 years or older. The effects of these common disorders on the overall health and function of older Blacks remains unclear. Baker (1994) notes that little is known about the prevalence rates of mental disorders in the older adult Black elderly population because of their underrepresentation in epidemiological studies.

Poor health, low socioeconomic status, social isolation, minority status, being unmarried, being female, and having low education are linked to depressive symptoms among elderly Blacks (Baker, 1994; Baker, Okwumabua, Philipose, & Wong, 1996; National Academy on an Aging Society, 2000d). However, research is mixed on the well-established

link between gender (i.e., being female) and depressive symptoms in old age (Baker et al., 1996; Brown, Milburn, & Gary, 1992). Additionally, Baker (1994) also notes that older Black people are at risk of being diagnosed with mental disorders related to taking prescribed medications for their physical health and from environmental stress such as living in unsafe neighborhoods. A high prevalence of chronic conditions such as diabetes, particularly among older Black women, and functional limitations in chronic illness in older Blacks may generally predispose individuals to depressive symptoms and depressive illness (National Academy on an Aging Society, 2000d). Older persons with impaired cognitive ability may be more susceptible to depression, dysphoria, and comorbid conditions (Baker, 1996).

In conclusion, it is reasonable to assume that older Black Americans, like older adults generally, enjoy relatively good mental health. Still, literature documents depressive symptoms as an important mental health issue for older Black Americans. Contributing factors to depressive symptoms among Black elderly include a high prevalence of specific chronic health conditions, comorbid and co-occurring in old age. They also include side effects of consuming multiple medications, psychosocial stressors (isolation and loss due to death of significant others), and environmental stressors. A caveat about the literature on mental disorders among elderly Blacks is the underreporting and misdiagnosis of mental conditions in the elderly population, as indicated in the 2001 Report of the Surgeon General on mental health of older persons (U.S. Department of Health and Human Services, 2001).

INFORMAL SOURCES OF SUPPORT— FAMILY, CHURCH, AND RELIGION

A discussion of the social, economic, physical, and mental health issues of older Black Americans has highlighted the many challenges they face in late life. To gain fuller understanding of the situation of older Blacks, one also needs to consider their sources of informal support from family, church, and religion.

Family members are an invaluable source of informal support to elderly Blacks. For instance, older Blacks are embedded in an informal network of multiple sources of support flowing from family, church, and friends (Taylor & Chatters, 1986). Family members, typically women, rank first in the line of unpaid helpers (Chatters, Taylor, & Jackson, 1986; Dilworth-Anderson, Williams, & Cooper, 1999), providing as-

sistance to frail and severely ill Black elderly persons (Chadiha, Proctor, Morrow-Howell, Darkwa, & Dore, 1995; Stommel, Given, & Given, 1998).

Support from family members engages multiple caregivers—persons having most of the care responsibility for elderly persons and also persons having less care responsibility for elderly persons (Dilworth-Anderson et al., 1999). Further, Black family caregivers report high rewards and low burden in caring for their elderly relatives (Knight, Silverstein, McCallum, & Fox, 2000; Picot, 1995; Picot, Debanne, Namazi, & Wykle, 1997). However, a concern involving family caregiving is that it can be a demanding role contributing to negative well-being of Black caregivers—especially women (see Chadiha, Adams, Biegel, Auslander, & Gutiérrez, 2004). Many older Blacks, particularly grandmothers, are providing care to grandchildren (Fuller-Thomson, 2000; Minkler & Fuller-Thomson, 2000; Whitley, Kelley, & Sipe, 2001). Although there is evidence that custodial grandparenting may have negative outcomes for older Black women's physical health (Whitley et al., 2001), research on the consequences of custodial care to grandchildren is in its infancy stage, and it is inconclusive what such consequences are for older Black intergenerational caregivers.

Research shows that older persons who engage in religious activities report better physical and mental health than elderly people not engaged in religious activities (Levin, 1996). Historically, church and religion have been a source of inspiration and assistance to Blacks generally, providing invaluable resources to cope with problems of secular life, such as racial and economic discrimination. Not only does the church provide a base for the informal support networks among older Blacks, but it is also the source of much informal support from church members, along with family members and friends (Taylor, Chatters, & Levin, 2004). The importance of religion in the lives of older Blacks does not start in old age. Rather, it is a critical source of social support to Blacks over the life course (Williams & Wilson, 2001). Williams and Wilson argue that “religion may be especially salient in the lives of minority elderly,” providing them with spiritual, social, and oftentimes financial resources that are not accessible through the formal service sector.

Researchers acknowledge that religious coping, like other informal sources of support, has its downside, such as promoting avoidance and acceptance of a negative condition rather than facilitating a proactive or problem-solving approach (Taylor et al.,

2004). Further, a heavier reliance on informal systems of social support such as the family and the church may place older Blacks at risk of poor health outcomes (Williams & Dilworth-Anderson, 2002), particularly if members of those systems lack the prerequisite health care skills and training needed to meet the health needs of impaired elderly Blacks. Acknowledging these contradictions does not negate the overwhelming evidence that the church and religion are strong, positive, and natural helping systems that have a significant impact on the lives of elderly Blacks.

CULTURAL DIVERSITY AND SOCIAL WORK PRACTICE WITH BLACK ELDERLY

A working definition of culture is that it includes language, values, religion, societal norms, and a person's worldview (Landrine & Klonoff, 1992). The growth and heterogeneity of the Black population due to the increase of immigration from various countries has augmented cultural diversity within the older Black population. Yee (2002) defines diversity as recognizing differences, including ones that are uncomfortable for us, and “recognizing barriers that prevent access to our social systems and building a broader community infrastructure” (p. 6). Irrespective of origin, older Blacks living in the United States share racial oppression and may face similar barriers to accessing services due to continuing societal biases directed at persons of African descent. Still, older native-born Blacks and non-native-born Blacks differ in language, nationality, and religious orientation—differences that direct attention of social work professionals to the ethnic and cultural diversity within older Black adults. Such differences suggest that social work professionals must consider the principles of diversity and cultural competence that have been directed toward older people with origins in Europe, Asia, South America, and Mexico. For instance, Capitman (2002) notes that the challenge for social work professionals is how to deliver culturally appropriate (i.e., competent) services to old people in one setting so that social work professionals do not offend old people in another setting. Unfortunately, neither the field of aging nor social work has developed an accurate measure of cultural competency that would allow social work professionals to assess it or evaluate the effectiveness of culturally competent social work practice (Geron, 2002).

Regarding issues of social and economic disadvantage, as well as issues of racial disparity, in access

to mental and physical health care, prior works suggest directions for professionals to pursue when working with older Black adults. Ford and Hatchett (2001), for instance, in a treatise on social work practice with older Black adults, note three levels of intervention that are applicable to older Blacks. Primary intervention is necessary to promote the social, economic, and health-related well-being of older Blacks over the life course. A life-course perspective recognizes linkages between the present and past lives of people; it also recognizes that individual life histories are shaped and intertwined with social histories, such as passage of laws and social changes (Hatch, 2001). Viewed through the lens of a life-course perspective, it suggests that efforts on behalf of social workers to prevent social and economic disadvantages, as well as health inequalities, in the older Black population must be dealt with over the life course prior to old age. Underscoring this point are the words of Wallace, Enriquez-Haass, and Markides (1998): “The health and economic problems of older minorities are rooted in historic practices of discrimination” (p. 338). Therefore, in the absence of social work professionals’ ability to correct the mistakes of the past, a special concern of contemporary social work practice with older adults will be to ensure that policy initiatives such as Medicare and Social Security that greatly benefit older Black adults are kept intact (Wallace et al., 1998). Social work practitioners will further benefit from considering a political economy of health care explanation for reducing racial disparities in health. Wallace (1990) and Williams (2004), for instance, note the role of structural factors involving residential segregation, racial discrimination, and a medical care system that values profit over patient care as contributing factors to Black-White health disparities.

A secondary level of intervention in social work practice with older Black adults would address social, economic, and health problems and issues (Ford & Hatchett, 2001). Here, an example from empirical literature is applicable. Many older Black Americans with chronic physical conditions and declining mental health may fail to seek care, even when services may be available (USDHHS, 2001). Social workers’ knowledge of barriers to seeking help (e.g., stigma, denial, access barriers, financial barriers, and service fragmentation and gaps in health care) is an essential first step of the secondary level of intervention. Another essential practice step to take with older Black Americans is to assist them in managing their own health conditions through partnering with elders and their families to develop and implement suitable programs.

A third level of interventions focuses on mitigating the effects of chronic disease and disabling functioning on older Black adults and their family members (Ford & Hatchett, 2001). As others have suggested, the implementation of case management procedures such as linking older Black adults to community resources, matching their needs with resources, and advocating for them are appropriate for working with older adults at all levels (Ford & Hatchett, 2001; Yagoda, 2004). Such services may be useful at the tertiary level of intervention, particularly when the social, economic, and health care needs of older Blacks may be more challenging for the informal network to meet (Ford & Hatchett, 2001). Recognizing that older Blacks are not a monolithic group and taking this into consideration are crucial steps in the case management approach. Older Blacks experience within-race heterogeneity due to nativity status, gender, residential context, and age. When it comes to serving older Blacks, Dancy and Ralston (2002) report barriers to accessing health care in the older adult Black population due to rural residence and differences in attitudes between women and men, as well as between relatively old versus relatively young-old persons.

Evidence of social support from family, church, and religion for older Blacks directs attention of social work professionals to natural support systems that older Blacks trust and rely on for care. On the other hand, knowing the risks of long-term caregiving for Black women caregivers and the challenges they experience with social inequalities, as well as racial disparities in health and income, alerts social workers to these caregivers’ vulnerability to powerlessness and the applicability of an empowerment approach to practice with them (Chadiha et al., 2004).

In conclusion, older Black Americans are living longer and healthier lives than ever. Unprecedented numbers of non-native Black elderly have come and will become of age in their adopted homeland, thus contributing to growing ethnic diversity within an aging Black population and the service delivery system that serves them. This ethnic and age diversity of the older Black population is expected to present the field of gerontological social work and workers with both opportunity and challenge to deliver services to an unprecedented number of elderly Blacks. Thus, as Ford and Hatchett (2001) have noted for the general population of older Black Americans: “Only by combining practice and research can gerontological social workers begin to address the multi-faceted needs of older [African Americans and other Black] adults” (p. 152).

Older Asian Americans

21

The United States Census 2000 identified at least 24 Asian American groups, excluding Pacific Islanders. It included both nationally and ethnically defined groups: Asian Indian, Bangladeshi, Bhutanese, Burmese, Cambodian, Chinese, Filipino, Hmong, Indo-Chinese, Indonesian, Iwo Jiman, Japanese, Korean, Laotian, Malaysian, Maldivian, Nepalese, Okinawan, Pakistani, Singaporean, Sri Lankan, Taiwanese, Thai, and Vietnamese (U.S. Census Bureau, 2002).

Although the elderly among these Asian American groups may share some common background, values, and issues, considerable diversity prevails between and within the groups, as each individual has brought with him or her a distinct blend of culture, language, and history of the country of origin. Although most of the Asian American elderly came to the United States after the passage of the Immigration and Naturalization Act of 1965, considerable differences still exist among them in their immigration background (e.g., U.S. or foreign born, refugee or recent immigrant), reason for immigration (e.g., family reunification, fleeing from war, economic opportunity, educational opportunity for their children, or political turmoil in the country of origin), age at the time of immigration, and length of residence in the United States. Besides historical diversity, they also differ in religious affiliation (e.g., predominantly Christian Filipino and Korean, Hindu Asian Indian, Muslim Indonesian, and Buddhist Cambodian and Laotian American elders), socioeconomic status, acculturation, English proficiency, and life experience in the United States, all of which affect their well-being.

These variations make it difficult to generalize about relevant issues and their implications for social work practice with the 24 diverse groups of Asian American elders. Nevertheless, this chapter presents central cultural and social issues important to social work practice with Asian American elders and suggests a set of practice guidelines intended to enhance cross-cultural understanding and culturally sensitive social work practice with these populations. It begins with a review of the demographic and socioeconomic characteristics of selected Asian American elderly groups and is followed by discussion of major issues and challenges confronting them. Finally, practice guidelines for communication, assessment, and intervention with Asian American elders are presented.

GROWTH AND DIVERSITY OF OLDER ASIAN AMERICANS

For the third decade in a row, the Asian American population grew faster than any other racial group in the United States. The U.S. Census counted 11.9 million Asian Americans in 2000 (10.2 million “Asian alone” plus 1.7 million “Asian in combination with one or more other races”), an increase from 1990 by 48% (using the “Asian alone population”) or 72% (using the “alone or in combination population”). These percentages are significantly higher than the 13% increase in the total population during the same period (U.S. Census Bureau, 2002).

The elderly Asian American population grew at a rate even faster than the total Asian American population and the overall elderly population ages 65 and older. As shown in Table 21.1, the U.S. Census 2000 counted 843,543 Asian Americans ages 65 and older (782,994 “Asian alone” plus 60,549 “in combination with other races”), a remarkable increase of 78% (Asian alone) or 92% (combination with other race), compared with a 12% increase in the total elderly population, between 1990 and 2000. Among 10 separate Asian ethnic groups with 1990 (U.S. Census Bureau, 1992) and 2000 (U.S. Census Bureau, 2002) census data, two groups more than doubled their elderly population: Vietnamese (205%) and Asian Indian (170%). As a result, the proportion of the elderly in each of these census-selected Asian American groups has increased from 1990 to 2000, except the Hmong elderly, whose share of the overall Hmong American population fell from 2.8% to 2.6%, reflecting an even faster growth of the nonelderly Hmong population.

Despite this rapid growth in the elderly Asian American population during the past decade, they represented only 2.3% of the 65-and-older age population in 2000, excluding Pacific Islanders. Furthermore, whereas individuals of age 65 or older constituted 12.4% of the total population, Asian American elders accounted for 7.7% of the total “Asian alone” population, or 7.1% of the “combination” population. Table 21.1 shows substantial variation among 16 Asian American subgroups in terms of the representation of older adults in the respective populations, ranging from lows of 1.5% and 2.0% for Malaysian and Bangladeshi Americans, respectively, to highs of 9.8% and 20.4%, respectively, for Chinese and Japanese Americans.

Using the Census 2000 “Asian alone” data, Chinese elderly constituted the largest group, representing almost 30% of all elderly Asian Americans,

followed by Filipino (20.8%), Japanese (20.8%), Korean (8.5%), and Asian Indian (7.9%) Americans. Whereas approximately 78% of the Asian American elderly were foreign born, the foreign-born percentage exceeded 90% for 14 of the 16 subgroups, excepting the Japanese (29.2%) and Chinese (86.7%) American elders. Among the foreign-born elderly, the average length of residence in the United States was 23 years as of 2000, ranging from 12 years for the Bangladeshi and Malaysian to 40 years for the Japanese Americans (Ruggles et al., 2004).

Table 21.2 presents English use/ability, educational attainment, and poverty status of the Asian American elderly. Focusing on the “Asian alone” data in 2000, an average of 18.6% spoke English “only” at home, and almost 60% spoke English “less than very well” or “linguistically isolated,” a number almost nine times greater than that of 6.7% of the overall elderly population. The percentage of the Asian American elderly with English-language barriers varied substantially among subgroups: 28.8% for Japanese, 42.8% for Asian Indian, 52.8% for Filipino, 77.1% for Korean, 84.5% for Chinese, and over 90% for Cambodian and Laotian American elders.

A similar bimodal pattern is evident in the level of educational attainment: over three quarters of elders Hmong (93.9%), Cambodian (81.3%), and Laotian Americans (80.8%) had less than a high school education, whereas over 40% of Filipino (44.4%), Malaysian (46.6%), Indonesian (51.8%), Sri Lankan (50.5%), and Taiwanese (56.7%) American elders had some college or more education. As a group, 43.6% of Asian American elders had less than a high school education, 22.4% finished high school, and 34% had some college or more education.

As shown in Table 21.2, 12.3% of the older Asian American population lived in poverty in 1999, slightly higher than the 9.9% of the overall elderly population living in poverty. Among the 16 Asian American elders subgroups, 4 reported their poverty rate lower than the overall average: Filipino (6.3%), Malaysian (7.4%), Japanese (9.7%), and Asian Indian (9.8%). In sharp contrast, four subgroups exceeded a level of 20% of elders living in poverty: Hmong (37.8%), Bangladeshi (36.2%), Cambodian (28.6%), and Laotian (23.7%) American elders.

The diversity and variability in the demographic and socioeconomic characteristics among and within the 16 Asian American elders subgroups examined so far caution against the danger of overgeneralizing about “Asian American” group. Wide variability in these factors suggests diverse needs between groups

TABLE 21.1. Demographic Characteristics of Asian American Elderly in the U.S., 1990 and 2000¹

Group	Population Size (65+)			% of 65+ per Total Population		Age Subgroup (%) in 2000			% of Foreign Born in 2000

Source: U.S. Bureau of Census, 1992, 2000; Compiled from PCT₃ (Sex by Age), Summary File 4 (SF-4), Census 2000. Since information on foreign-born population for Asian subgroups aged 65 years and older was not available in Summary File 4, 5% iPUMS Census data (<http://www.ipums.org>) was used to obtain percent of foreign-born for Asian subgroups. Figures are based on SF-4 File and slightly different from those based on Summary File 1 (100% data), because SF-4 estimates are based on sampling. For example, SF-1 figure for the U.S. population of 65+ in 2000 is 34,991,753, Asian American alone 800,994, and Asian American combination 861,725. For detailed information, please refer to Technical Documentation at <http://www.census.gov/Press-Release/www/2003/SF4.html>.

Notes:

1. Census 2000 added a separate "Other Asian" response category with a write-in area for respondents to indicate specific Asian groups not included on the census questionnaire. Data on some Asian groups not included, as separate response categories in the earlier census questionnaires became available in 2000 census data. This, to large extent, explains the 300% decrease in the number for the "Other Asian" category in Table 21.1. It is important to note that unlike previous censuses, which obtained individuals' race information based on self-identification, the 2000 census collected race information using two broad categories, one race or more than one race ("Asian American alone" or "Asian American combination" in Tables 21.1 and 21.2), allowing individuals to indicate combination of races (e.g., Asian and White and American Indian). Because of these changes, the 2000 census data on race/ethnicity are not directly comparable with data from the 1990 census. Therefore, changes in the two censuses' data must be interpreted with caution.

2. Figures for each subgroup of Asian American elderly presented are based on Asian alone, excluding those reporting two or more races (combination).

3. AA subgroup's figures may not add up to a total number of AA alone, since info on one group, "Asian or Asiatic in general term" is not available.

and between individuals. It also suggests that many factors may affect provision of social services to Asian American elders and their families, including history of the country of origin, immigration background, socioeconomic status, language, cultural values and norms governing family roles and relations, health, and religious beliefs. Given the rapid increase of older people in these Asian American groups and in the population in general, social work practitioners must be prepared to assess a wide range of background factors and needs among older Asian American groups.

PHYSICAL HEATH STATUS AND ISSUES

Asian Americans are generally portrayed as a healthy minority, even healthier than White Americans (Tanjajiri, Wallace, & Shibata, 1995). A few studies conducted in the 1980s and the early 1990s documented that older Asian American groups tend to be healthier than other ethnic groups in terms of perceived health status, health-promoting behaviors, and exposure to health risk factors (Chen, 1993; Lubben, Weiler, & Chi, 1989). A study of California's Medicaid recipients

found that low-income immigrant elderly Asians engaged in healthier habits related to physical health than did low-income non-Asian elderly. For example, Asian elders tend to avoid detrimental health habits such as smoking and drinking (Lubben et al., 1989). Another study shows that the prevalence of some cardiovascular risk factors is lower in several Asian American elderly groups compared with Whites (Chen, 1993). Additionally, some Asian American groups, particularly Chinese and Japanese, are known to have longer life expectancies than White Americans.

However, the notion that Asian American elders enjoy better health than other elderly populations is largely based on lower health service utilization rates among elderly Asian Americans, along with some national health statistics that portray slightly lower rates of coronary heart disease and cancer-related deaths among selected groups of Asian American elders than in the population at large (Takata, Ford, & Lloyd, 1998; Zane, Takeuchi, & Young, 1994). The lower incidence of major diseases documented by a limited number of studies and longer life expectancies among some older Asian American groups have been generalized to all Asian American elderly populations regardless of the differences that exist between and within immigrant elderly Asian groups (Takata et al., 1998).

A reliable estimate of disease prevalence is hard to establish because of limited national-level health data for Asian American elders (LaVeist, 1995). Published findings from various sources (Kagawa-Singer, Hikoyeda, & Tanjasiri, 1997; Lum, 1995; Douglas & Fujimoto, 1995) indicate that, although they experienced a lower mortality rate than Whites, Asian Americans experienced significantly higher levels of chronic conditions than their White counterparts: diabetes among Japanese Americans (Lum, 1995), cardiovascular disease among elderly Korean Americans (Kim, Juon, Hill, Post, & Kim, 2001), and hypertension among elderly Chinese and Filipino immigrants (Kagawa-Singer et al., 1997). A study conducted in Los Angeles using a probability sampling method found that elderly Korean immigrants, compared with non-Hispanic Whites, perceived their health to be poorer and reported higher rates of hypertension, arthritis, kidney disease, and functional limitation (Villa, Wallace, Moon, & Lubben, 1997).

Identifying and reducing health disparities among racial groups in the United States has been one of many national agendas, as indicated in *Healthy People 2000 and 2010* (U.S. Department of Health and Human Services, 1995; 2000). Although many practice and policy efforts have been made to address such

disparities, inequality still persists in health status and access to health care among racial/ethnic groups in the United States (U.S. Department of Health and Human Services, 2003). According to the *National Healthcare Disparities Report* (U.S. Department of Health and Human Services, 2003), Asian Pacific Islanders are more likely to be subject to physical restraints in nursing homes than are non-Hispanic Whites, and more Asian elders (55%) than White elders (47%) have difficulty in understanding health care information provided by their physicians.

Human health, as a complex system, is affected by multidimensional factors, including personal, sociopolitical, environmental, and cultural components, throughout life (Pender, 1996). Culture, in particular, influences people's perceptions of health and disease, as well as their health-care-seeking behavior. Many ethnic-cultural minority groups in the United States view health as a product of continuity and balance in life or a long-term and continuous manifestation of changing relationships in the family, in the community, and in nature (Emami, Benner, Lipson, & Ekman, 2000; Ell & Castaneda, 1998). Although it is difficult to generalize the multiplicity and varying degrees of health beliefs between and even within older Asian American populations, their traditional health beliefs include the Yin-Yang equilibrium or balance (Yee & Weaver, 1994) and a fatalistic worldview of the cause of health and illness (Kitano, Shibusawa & Kitano, 1997) that may contribute to suppressing the pursuit of services from health care professionals. Religion and spirituality also play an important role in that some Asian American elders, especially immigrants from Southeast Asia, tend to rely on spiritual leaders for healing of illnesses. Therefore, it is important for health care practitioners to be aware of, to respect, and to incorporate indigenous health beliefs and practice in treatment plans for Asian American elders.

Many immigrant Asian elders seek both Western medical services and indigenous health care services, predominantly herbal and acupuncture treatment in their ethnic communities. For example, a study showed that 42% of Korean American elders in Los Angeles reported using a traditional healer, including herbal and acupuncture treatment, in the past year (Pourat, Lubben, Wallace, & Moon, 1999). Another study of almost 3,000 Southeast Asian refugee adults (Cambodians, Hmongs, Laotians, Vietnamese, and Chinese Vietnamese) in California also found traditional health care methods to be an important part of overall health care services, although all five groups

showed a significant increase in the use of Western medicine after they immigrated to the United States (Chung & Lin, 1994).

Individuals' autonomy and self-determination have been the major moral and legal tenet in the current U.S. health care system, as evidenced by the Patient Self-Determination Act (PSDA) and advance directives. However, there has been a growing concern that the dominant Western health practice based on individualistic decision-making styles may not be consistent with collectivistic values of Asian Pacific Islanders regarding health care decision making (i.e., shared or deferred decision making, filial piety, and silent communication; Blackhall, Murphy, Frank, Michel, & Azen, 1995; Kagawa-Singer & Blackhall, 2001; McLaughlin & Braun, 1998). When Asian American elders and their family face decisions regarding nursing home placement, end-of-life care, or communication and execution of advance directives, they are confronted with enormous challenges in dealing with the dilemma. According to Commonwealth Fund Health Care Quality Survey (McIntosh, 2001), Asians (41%) more frequently report underinvolvement in the decision-making process than Whites (22%). Furthermore, for some Asian American elders, patient autonomy is burdensome, rather than empowering (Blackhall et al., 1995), and they may feel disenfranchised in the health care decision-making process (U.S. Department of Health and Human Services, 2003).

In light of the cultural orientation of Asian American elders toward health care decision making, understanding their attitudes and preferences for health and long-term care services would be an important step in developing culturally sensitive services for them. Two studies, which examined attitude and preferences for long-term care services among Japanese (McCormick et al., 1996) and Korean American (Min, 2001; Min, 2005) elders, highlighted the importance of acculturation and adherence to traditional values in developing culturally appropriate long-term care arrangements and services for older Asian Americans.

FAMILY AND CAREGIVING ISSUES

Most Asian cultures are strongly influenced by Confucian teachings of filial piety and respect for older people: *oyakoko* among Japanese, *hyo* among Koreans, *utang na loob* among Filipinos (Browne & Broderick, 1994; Cheung, 1989; Kitano et al., 1997). In traditional Asian families, age is a symbol of author-

ity and wisdom, and thus older adults are expected to make important family decisions, whereas younger adults and children are expected to respect, obey, and care for their elderly parents or grandparents in an extended living arrangement. In such cultures, the family is the dominant source of support for older adults.

Immigrants from Asian countries bring with them their cultures and family values to the new homeland. In the process of settlement in America, however, many Asian immigrants not only adjust to the American social and familial norms of individualism and independence, as opposed to collectivism and interdependence, but also see the new opportunities and resources the American society provides for the care of their older family members. Although it is difficult to generalize the adjustment experience of Asian American immigrants, as they represent a wide range of immigration and socioeconomic background, the pace of acculturation to the American values and ways of life is generally faster for younger and female immigrants. Those who came to America in old age, compared with long-time immigrant elders, may take longer and find it more difficult to adjust to their diminished status and role in the family; they may also face more adjustment issues, including loneliness, language barrier, and unfamiliarity with the new social and cultural environments.

Traditional cultures, American culture, and opportunities play roles in shaping Asian American family life and relations. The traditional norm and practice of filial piety, in terms of living with and caring for elderly parents and providing emotional and financial support, has weakened, as has the status and authority of the elders in the family (Kauh, 1997; Pang, Jordan-Marsh, Silverstein, & Cody, 2003). On the other hand, most Asian American elders do not want to be a burden to their children, and in fact, many low-income elderly live independently in government-subsidized housing and receive Supplemental Security Income (SSI) and health care services through Medicaid and Medicare. Nevertheless, the fact that many Asian American elders live alone or with only a spouse may not necessarily mean erosion of filial piety or a lack of family support. In certain locales with concentrated Asian ethnic communities, such as Chinatown, Koreatown, Little Saigon, and Little Tokyo, many Asian American elders, especially those foreign born, prefer to live near their own ethnic community rather than in suburbs with their children, in order to socialize with people in their ethnic language and to have more ready access to various social, cultural, recreational, and health care services

provided by ethnic-specific agencies or professionals who speak their language and understand their culture (Cheung, 1989; Kim & Lauderdale, 2002; Yoo & Sung, 1997).

Although many Asian American families may not practice filial piety in a traditional sense, as there is reduced social pressure to do so and as alternative arrangements for care of their elderly relatives are available in the United States, family ties and family care are still strongly emphasized foundations of individual and family life among Asian Americans. A recent study of caregivers in the United States by the National Alliance for Caregiving and the American Association for Retired People (2004) estimated that although the proportion of older adults is significantly smaller among Asian Americans than Whites, 15% of Asian Americans, compared with 17% of Whites, provided unpaid care to someone 50 or older in the last 12 months, and the proportion of younger caregivers between the ages of 18 and 34 was 38% for Asian American caregivers, the highest among all subgroups (22% White, 35% African American, 33% Hispanic caregivers). The same study also found that Asian American caregivers were far more likely to indicate “old age” or “being old” as the main problem or illness of the person they care for (23%, as compared with 12% White, 10% African American, and 9% Hispanic caregivers) (National Alliance for Caregiving and American Association for Retired People, 2004).

Considering that over three quarters of Asian American elders are foreign born and that the majority of them are linguistically isolated, family caregivers of relatively recent immigrant elders, especially those from non-English-speaking countries, often face additional challenges. As older people become dependent on their children for many daily tasks, including going places and learning and adjusting to new places and systems, the prolonged dependence can create a sense of overburden and frustration, especially when the families have their own adjustment problems and other family issues, such as financial difficulty, crowded housing, and conflict with their children. Inability to provide adequate care for the elder due to a lack of time and family resources creates a feeling of guilt among family caregivers. Limited knowledge and accessibility of services, including supportive services available to family caregivers, and a lack of culturally appropriate coping skills and resources can result in the neglect of vulnerable immigrant elderly people.

Most research findings clearly suggest the importance and centrality of family in quality of life for

many Asian American elders. A study of Laotian and Vietnamese refugees 55 years of age and older found that the family was the most critical factor for an elder person’s satisfaction with life and living environment (Tran, 1991). In another study of Vietnamese elders in Texas, the family was almost the exclusive source of help with language, loneliness, and internal family problems (Die & Seelbach, 1988). A study of South Asian caregivers concluded that belief in filial piety norms among caregivers plays a significant role in lowering perceived levels of caregiver burden (Gupta & Pillai, 2002). Research on Korean immigrant elderly has found that a close family relationship improves the adjustment of elders to American society (Kiefer et al., 1985; Koh & Bell, 1987; Moon, 1996), increases level of morale (Moon, 1996), and mitigates the harmful impacts of life stress (Lee, Crittenden, & Yu, 1996). The family was also a critical factor for lower levels of depressive symptoms among Chinese and Korean immigrant elderly (Lee et al., 1996; Min, Moon, & Lubben, 2005; Mui, 1996).

PSYCHOLOGICAL/MENTAL HEALTH STATUS AND ISSUES

Unattended psychological/mental health issues can seriously and detrimentally affect mortality, morbidity, functional ability, and quality of life. Although there is no national estimate of prevalence data on mental health disorders for older Asian Americans and information on mental health care needs among Asian American elders remains limited and fragmented, growing evidence suggests that a higher proportion of Asian American elders suffer from mental health disorders than Whites and that most of them do not receive appropriate treatment (Browne, Fong, & Mokuau, 1994; Harada & Kim, 1995; Kang & Kang, 1995; Kuo, 1984).

Among many mental health issues, depression is the most studied among Asian American elders. An earlier depression study on Asian Americans, which examined 449 Asian Americans in Seattle, found that Chinese, Japanese, Filipino and Korean Americans were significantly more depressed than Whites based on the Center for Epidemiologic Scale of Depression (CES-D; Kuo, 1984). The study also revealed that among the four Asian American groups, Koreans, the most recent immigrant group, scored the highest rate of depression and that their depressive scores were higher among older than among younger respondents in their own ethnic group, whereas the scores

were lower for older respondents in the three other ethnic groups. In a two-wave panel study of psychological distress measured by CES-D between 172 older Korean immigrants and 157 White elders, the Korean respondents on average reported significantly higher levels of depression at both of the two time points (Min et al., 2005).

Several other studies further investigated depression and its correlates and effects for Chinese American elders (Casado & Leung, 2001; Mui, 1996, 1998; Stokes, Thompson, Murphy, & Gallagher-Thompson, 2001), Japanese American elders (Shibusawa & Mui, 2001), and Korean American elders (Lee et al., 1996). Other psychological constructs, such as post-traumatic stress disorder among Indo-Chinese refugee elders (Abueg & Chun, 1996; Lin, Tazuma, & Masuda, 1979; Ngo, Tran, Gibbons, & Oliver, 2001), and alienation and morale among elderly Korean immigrants (J. H. Moon & Pearl, 1991; A. Moon, 1996) were also examined. Significant correlates of depression, alienation, or low morale include shorter length of residency in the United States for elderly Korean and Chinese Americans (Kuo, 1984; Moon & Pearl, 1991; Stokes et al., 2001), lower levels of acculturation as measured primarily by limited English proficiency (Casado & Leung, 2001; Kuo, 1984; Moon & Pearl, 1991), poor self-assessed health and functional limitation (Min et al., in press; Moon, 1996; Shibusawa & Mui, 2001), living alone (Mui, 1998), and lack of family support and quality relationships (Casado & Leung, 2001; Lee et al., 1996; Min et al., 2005; Moon, 1996; Moon & Pearl, 1991; Shibusawa & Mui, 2001).

Multiple traumas experienced before emigration among refugees—such as torture, battlefield experiences, and loss of significant others—and various postimmigration stress and adjustment problems experienced by immigrant and refugee elders suggest that recent refugee and immigrant elders from Asian countries are high-risk populations for mental health problems, while at the same time they are less familiar or willing to use mental health services compared to U.S.-born and long-time immigrant Asian American elderly. An earlier study of the mental health status of first-wave Vietnamese refugees indicated that over half of study participants manifested severe psychological problems (Lin et al., 1979). A more recent study, however, found that the Cambodian, Hmong, and Mien refugees who arrived in the United States more recently represent the three most traumatized subgroups among Southeast Asian refugee groups (Abueg & Chun, 1996). Another study of adult Vietnamese Americans points to the positive effect of ac-

culturation on depression: premigration traumatic experiences had a strong effect on depression among those with lower levels of acculturation than among those who were highly acculturated (Ngo et al., 2001).

Data on suicide rates for some Asian American elderly groups also suggest need for serious concern. According to Lester (1994) and Kitano et al. (1997), suicide rates for Chinese and Japanese Americans ages 65 and older were the highest; 25.9 and 18.9, respectively, per 100,000 per year, whereas those of White and African American elders were 19.1 and 5.5, respectively. Yu (1986) reported that the suicide rate for elderly Chinese immigrants was almost three times higher than the rate for U.S.-born Chinese elderly in 1980. A more recent study of suicide rates between 1987 and 1996 among several Asian and other ethnic minority female cohorts in San Francisco showed that immigrant Chinese elders accounted for 89% of all elderly Chinese suicides and that Chinese women had a higher suicide rate than women in all other racial/ethnic groups, including Japanese, Filipino, African, Latino, and Native Americans (Barron, 2000).

Mental illness in most Asian American communities, especially among immigrant elders, is a stigmatized, if not a taboo, issue. The perceptions that mental illness is caused by unexplainable superpower, by spiritual forces, or by one's predetermined fate and that it cannot be cured by Western or medical treatment are strongly rooted in traditional Asian cultures and still prevail among many elderly Asian Americans. In fact, studies have shown that culture influences Asian Americans' perceptions, expression, and coping with mental illness and emotional or psychological problems (Braun & Browne, 1998; Douglas & Fujimoto, 1995; Fugita, Ito, Abe, & Takeuchi, 1991; Kagawa-Singer et al., 1997; Kleinman, 1980). In Japanese culture, as well as in many other Asian cultures, emotional and psychological problems are perceived as "craziness" (Fugita et al., 1991). Asian Americans in a focus group study believed dementia was part of the natural aging process about which nothing could be done (Braun, Takamura, Forman, & Sasaki, 1995).

Somatic complaints and distress are the most common expression of depression for older Asian Americans, partly because of their belief in the inseparability of affective and somatic systems (Browne et al., 1994) and partly because of a lack of experience in labeling, describing, and communicating about affect (Douglas & Fujimoto, 1995). Depression in Chinese culture is expressed mainly by symptoms of fatigue, low energy, and sleep disturbance, with little sign of dysphoria (Douglas & Fujimoto, 1995). A culturally

unique psychiatric symptom of *Hwa-Byung* among elderly Korean women refers to prolonged suppression of unbearable pain, suffering, loss, anger, or resentment, which develops into clinical depression, anxiety, and somatic symptoms (Lin et al., 1992; Pang, 1990). The most unique aspect of this *Hwa-Byung* is that Koreans label themselves as having this “illness” (or *byung* in Korean), and it is a commonly used and accepted expression of one’s psychological and physiological status.

Internalization and denial of existing mental problems in most Asian American cultures tend to undermine utilization of mental health services, which means that many people with mental health disorders go unnoticed and untreated, resulting in further and perhaps unnecessary deterioration. Among Japanese American elders, for example, *Gaman* (the internalization and suppression of anger and emotion, avoiding confrontation, and accepting the results of negative social interaction) and *shikata ga nai* (whatever happened cannot be helped or nothing more can be done to improve the situation) are common coping mechanisms, which amount to denial of a problem and of the need to deal with it (Fugita et al., 1991). This observation also prevails in other elderly Asian American groups. Because it is a stigmatized condition, many Asian Americans prefer to keep mental illness problems within the family, failing to take advantage of various treatment options available to them. In many cases, Asian American elders maintain modesty in their expression, suppress extreme feelings, control their emotions, and exhibit an unwillingness to reveal emotions to others. In some instances, such emotional control may be unduly considered as dysfunction or as treatment resistance. Therefore, social work practitioners should be knowledgeable and capable of demonstrating their understanding of the wide array of culturally defined perceptions of mental health issues among Asian American elders, including expression and communication styles, skepticism regarding treatability of mental illness, and reluctance to use formal mental health services.

HEALTH, MENTAL HEALTH, AND LONG-TERM CARE SERVICE UTILIZATION: PATTERNS AND ISSUES

A major finding that emerges from most studies on service use among older Asian Americans is *underutilization*. Research on various Asian American elderly

groups has generally found low rates of utilization of or participation in health services (Yee & Weaver, 1994; Shin, Kim, Juon, Kim, & Kim, 2000), mental health services (Browne et al., 1994; Harada & Kim, 1995; Matsuoka, Breaus, & Ryujin, 1997), and home, community, and institutional long-term care services (Choi, 2001; Lai, 2001; Moon, Lubben, & Villa, 1998; Tsai & Lopez, 1997).

For example, an analysis of national survey data found that the proportion of Asian American and Pacific Islanders who utilized mental health services at all types of public and private facilities was a third of the proportion of European Americans (Matsuoka et al., 1997). In addition, Asian American elders were significantly less likely to participate in home-delivered nutritional meal programs than White, African American, and Hispanic participants, primarily due to different food preferences and the lack of English proficiency among many recent immigrant elders (Choi, 2001). A comparative study of awareness and utilization of 15 community long-term care services (e.g., transportation; Meals on Wheels; congregate meals; visiting nurse, hospice, and mental health services) between Korean immigrant and White elders in Los Angeles clearly indicates that the lack of knowledge of existing services is the primary barrier to utilization of services. Korean elders were far less aware of all 15 services than Whites were. However, among those aware of services, the group disparities in service usage were much smaller, and in some cases, Koreans showed higher utilization rates than Whites (Moon et al., 1998).

Studies that examined service use in individual Asian American elderly subgroups showed that significant within-group variations exist (Kuo & Torres-Gil, 2001; Lai, 2001; Shin et al., 2000; Tsai & Lopez, 1997). In a study of Chinese immigrant elders, Lai (2001) found substantial underutilization of supportive services in general and identified three predictors of service use within the group: living alone, satisfaction with services, and fewer mental health symptoms. Another study of 240 elderly Taiwanese Americans found a higher number of doctor visits by those who used alternate medicine and preferred same-culture professionals (Kuo & Torres-Gil, 2001). The study also reported that a greater likelihood of using home- and community-based services was associated with living alone, longer years since immigration, preference for same-culture professionals, and higher functional limitations.

As mentioned earlier, culturally driven health beliefs, communication styles, coping mechanisms, and

attitudes toward use of formal services, especially for family and mental health problems, among Asian American elders people influence service utilization. For example, seeking help for psychological distress and problems from outside the family and disclosure of emotions to a stranger, even a professional mental health specialist, is still considered an act of weakness, resulting in loss of face to the family by many Asian Americans, especially immigrant elders. Loss of face or shame, as one of the central Asian values, may hamper help seeking among Asian American elderly (Casado & Leung, 2001; Kitano et al., 1997; Tsai & Lopez, 1997). Furthermore, many elderly Asian Americans seem to have little understanding of or confidence in the rule of confidentiality; they often worry that health and social service practitioners might tell others about their personal and family problems. Also, some Asian American elders might find it difficult to adopt Western-style help-seeking behaviors that may require them to be more assertive and proactive in seeking professional help (Kagawa-Singer et al., 1997).

In addition to cultural issues (and language problems for recent immigrant elders from non-English-speaking countries), various institutional and socio-structural barriers to service utilization exist in the Asian American communities. They include benefit/service eligibility restrictions to legal immigrants who are non-American citizens, as well as to undocumented immigrants; lack of awareness of and unfamiliarity with various supportive home- and community-based services, as well as mental health services; lack of transportation services; the stereotype that Asian American elders are taken care of by their families; and lack of culturally appropriate services and bilingual staffs.

GUIDELINES FOR SOCIAL WORK PRACTICE

In this last section, we translate reviewed empirical findings into concrete and useful practice guidelines for social work practice with older Asian Americans. Vastly diverse characteristics of many Asian American elderly subgroups (e.g., history, language, culture, immigration history and experience, socioeconomic status, and acculturation levels) make it impossible to provide a uniform set of practice guidelines applicable to all subgroups. Nevertheless, the very “diversity” within the Asian American elderly group warrants more efforts to refine a much-discussed notion of

“culturally competent practice”^{*} for the population. Kagawa-Singer and Blackhall (2001) argue that cultural competence is a law, not a choice, and it can be achieved. The following recommendations aim to help health and social service practitioners to conceptualize and practice cultural competence in their work with Asian American elders.

Communication and Assessment

Effective communication and accurate assessment of the needs of older adults are critical to effective social work intervention, regardless of the individual’s cultural/ethnic background, language, and socioeconomic status. Needless to say, a comprehensive biopsychosocial assessment (McInnis-Dittrich, 2005) should be conducted for every older client on his or her physical health, functional capacity, and psychological and social functioning. A fundamental principle of social work practice with the Asian American elderly is to recognize the importance of respect for them and to understand their cultural orientations, devoid of stereotypes and misconceptions (Kitano et al., 1997; Takamura, 1991).

The following suggestions are put forth for more effective communication and assessment in social work practice with Asian American elders:

- Language barriers hinder social worker-client relationship and communications. A priority should be set on assuring accuracy in communication and cross-cultural understanding.
- When working with clients with limited English proficiency and a cultural/ethnic background different from that of the practitioner, the practitioner should consider using an ethnic consultant (Mokuau, 1987; Takamura, 1991) or cultural broker (Valle, 1998) to ensure the client’s primacy and the sense of connectedness and effective communication between the client and the practitioner.
- Accurate assessment of individual Asian American elders should be made in the context of their historical experiences (e.g., internment experience for Japanese Americans), generational status, and immigration/refugee status (Fugita et al., 1991).
- Older Asian American clients often express their emotions in a nonverbal and indirect manner. Nonverbal communication and behavioral cues in some instances may be equally or even more important than verbal expressions (Moon, Tomita, & Jung-Kamei, 2001).

- Attitudes toward formal services and service preferences vary and need to be assessed (Moon et al., 2001; Shibusawa & Mui, 2001). Explain how formal services and professionals would be helpful to clients in concrete ways. Explain the confidentiality rule and its strict enforcement, assuring clients that violation of the rule is against the laws and professional code of ethics.
- Engage in cross-culturally informed nonjudgmental active listening (Valle, 1998) to identify Asian American elderly clients' culturally based meanings of dilemmas and of help. Incorporate clients' cultural perspectives in discussions of issues, problems, and service needs, as well as in intervention plans.
- Establish and demonstrate understanding of cultural and other aspects of clients' problems and needs, especially during the relation formation period, in order to gain credibility with, and increase the trust of, ethnic Asian American elders.
- Explore approaches to identifying and evaluating cultural influences in clients, such as the "attitudes, beliefs, context, decision making, and environment (ABCDE)" approach of Koenig and Gates-Williams (1995), later adapted by Kagawa-Singer and Blackhall (2001), or the "cultural mapping process" of Valle (1998).
- Adopt screening and assessment tools that are validated as culturally and linguistically appropriate for use with the target group (Stokes et al., 2001; Tran, Ngo & Conway, 2003).

Culturally Competent Intervention or Services

- Develop social work interventions and services that would have "cultural buy-ins" from the intended target elderly Asian American group. Start with the group's own understanding of issues, problems, needs, service goals, and preferred approaches to achieving the goals.
- Be aware of potential differences not only between different Asian American elderly groups but also within the same ethnic group in designing clinical and programmatic intervention services.
- Develop and expand community education and outreach programs that are linguistically and culturally effective in order to increase knowledge and usage of available services among Asian American elders. Such efforts should consider use

of (1) outreach workers who speak the language of the target group and who are preferably from the same ethnic background, (2) ethnic media and organizations, as well as respected community and religious leaders, to obtain support for the effort and cost-effective dissemination of information, and (3) informational materials written in the ethnic language, with pictures of elders from the target group, if necessary.

- In discussing and planning for intervention, terms and issues such as autonomy, self-determination, empowerment, and aggressiveness, especially as intervention goals, should be used with care with Asian American elders, because they may be interpreted as lacking concerns for harmony, interdependence, modesty, and consideration for significant others, values inherent in Asian cultures, thereby leading to miscommunication and misunderstanding between Asian American elders and professionals.
- Although no definite information is available as to whether nondirect counseling or directive and structured counseling style is more effective with or preferred by Asian American elders (Mokuau, 1987), flexible and eclectic practice approaches should be explored that consider an awareness of and sensitivity to a client's worldviews and values (Takamura, 1991).
- Social workers should be encouraged to participate in more cultural-sensitivity training on culture, values, acculturation, biopsychosocial aspect of the aging, and social work skills for working with elderly from different racial/ethnic backgrounds.

CONCLUSION

Older adults experience and adjust to a wide range of changes in biological, psychological, and social functioning (McInnis-Dittrich, 2005). They also cope with various kinds of losses in their physical and functional capacity, cognitive abilities, loved ones, work, and social status. In addition to these changes and challenges associated with the normal aging process, Asian American elders are at greater risk of experiencing multiple and compounding issues in their aging process due to their experiences of historical oppression, discrimination, and migration. Negative historical experiences resulting from discriminatory immigration laws, structural and cultural barriers, as well as lack of knowledge of available services, have meant that many

Asian American elders, especially monolingual recent immigrants and refugees, are underserved.

With a massive influx of immigrant and refugee elders from nearly all Asian countries during the past three decades, the growing number and increasing diversity between and within various Asian American elderly groups complicate our understanding of who they are, what they need, and how best to serve them, making it extremely difficult, if not impossible, to arrive at clear conclusions for effective social work practice with the population. Despite the complexity and limited knowledge of the rapidly growing older Asian American populations, however, this chapter attempted to describe some characteristics of growing diversity, influence of culture, research findings on major social work-related issues, and their implications for social work practice.

It is hoped that the growing diversity does not result in growing disparities in quality of life or access to services but instead contributes to a growing recognition of diversity and culture as an integral and natural part of consideration for service design and social work practice. Indeed, the “where the client is” principle as the most basic consideration for social work practice with any individuals or groups implies that acquisition of knowledge of, and culturally competent practice skills with, the intended ethnic group is not an option but a requirement for practitioners. This is impossible without reliable information. For this reason, the need for comprehensive, large-scale, and systematic research studies on older Asian American populations on the wide range of topics that affect older people and their families (e.g., dementia, end of life, family caregiving, service knowledge and utilization, effective assessment and intervention methods) is greater than ever before.

SANDRA S. BUTLER

Older Gays, Lesbians, Bisexuals, and Transgender Persons

22

Although the experience of aging for gay, lesbian, bisexual, and transgender (GLBT) individuals, in many regards, is indistinguishable from that of their non-GLBT counterparts, there are nonetheless special circumstances and a history of discrimination which bear noting when working with this population. There is considerable diversity within the GLBT community itself (e.g., Herdt, Beeler, & Rawles, 1997). Gay, lesbian, bisexual, and transgender elders vary in characteristics such as cultural, ethnic, or racial identity, physical ability, income, education, history of marriage and/or child rearing, and place of residence. They also vary in terms of the degree to which their GLBT identities are central to their own self-definition and their level of affiliation with other GLBT individuals and organizations (Meyer, 2001). Despite these differences, GLBT individuals of all ages share experiences related to stigma, rejection, discrimination, and, at times, violence. In most parts of the United States, it is legal to discriminate against GLBT persons in housing, employment, and basic civil rights, although selected cities, states, and businesses have nondiscrimination ordinances, laws, and clauses.

It is difficult to be precise when estimating the number of GLBT seniors. Conservative estimates of the prevalence of gay men, lesbians, and bisexuals in the U.S. population range from 3–8%; this is likely to be an undercount due to the ongoing taboo of identifying as gay, lesbian, or bisexual in an interview or survey (Cahill, South, & Spade, 2000). Using this estimated prevalence rate, Cahill, South, and Spade (2000) suggest that there are currently from 1 million to 2.8 million GLB individuals ages 65 or older, and, based on Administration on Aging estimates of elder population growth, they predict that this number will increase to 2 to 6 million by 2030. Only recently have there been preliminary efforts to estimate the number of transgender individuals in the United States—individuals who fall along the full range of sexual orientation from homosexual to bisexual to heterosexual and into many subcategories based on numerous factors (Witten, 2002); rough estimates suggest that at least 3% or more of the U.S. population is transgendered (National Association of Social Workers [NASW], 2003). The population of GLBT elders includes the same racial and class diversity as the larger U.S. population. Despite a widespread myth that gay men and lesbians are economically privileged, multiple studies have shown this not to be the case at all.

This chapter examines social work practice with GLBT older adults. The purpose of this chapter is to

introduce practitioners to information and resources so that they might better serve older GLBT individuals. It begins by tracing some of the historical events and circumstances which have shaped the lives of the current cohort of GLBT elders. The invisibility of GLBT elders will be discussed next, a phenomenon that has resulted from a history of discrimination and oppression. What we know about GLBT elders is constrained by this invisibility and the scarcity of representative empirical research; nonetheless, some observations and estimations can be made to describe this population, and they are presented here. GLBT elders bring certain unique strengths to the aging process; they also face some particular challenges. These are outlined, along with suggested practice guidelines. Resources for further investigation of this topic conclude the chapter.

It has been well documented that health and social service systems are often perceived as unwelcoming by GLBT individuals. For example, Brotman, Ryan, and Cormier (2003) enumerate the types of negative reactions gay men and lesbians may encounter from service providers, including embarrassment, direct rejection, hostility, excessive curiosity, pity, avoidance of physical contact, and breaches of confidentiality. Furthermore, Brotman et al. (2003) submit that discrimination toward GLBT persons may be particularly pervasive in the elder care system, which has gone largely unchallenged with respect to its treatment of this group.

Just as old age, by itself, is not a reason for social work intervention, neither are sexual orientation and gender identity generally the cause of intervention. Older GLBT individuals, similarly to all elders, become involved with social workers because of illness, frailty, disability, or life crises (Langley, 2001). However, although presenting problems may be similar to those of non-GLBT elders, solutions for the GLBT client need to be seen in the context of the individual's life experience. Social workers are ideally suited to work with GLBT elders given the profession's dual focus on the individual and his or her environment and that the nature of the work involves both direct service and advocacy for social change (Appleby & Anastas, 1998). Unfortunately, although it is quite certain that all social service and mental health agencies serving older adults have GLBT clients, many of these clients hide their identities; thus social workers and social service agencies must foster environments that promote trust from these elders so that their needs can be more fully understood and addressed (Gallance & Warshaw, 2004).

Definition of Terms

Homosexual—has largely been dismissed by the gay community because of its link to pathological diagnosis.

Gay—came into favor after the 1969 Stonewall riots and refers to men whose primary emotional and sexual connections are with other men. Although gay is an overarching term for homosexuality, it is generally used to refer particularly to men.

Lesbian—came out of the feminist movement of the 1970s as a substitute for the word gay and refers to women whose primary emotional and sexual connections are with other women. Some elder lesbians may refer to themselves as gay rather than lesbian.

Bisexual—refers to men and women who have sexual attractions to both sexes.

Transgender—came into usage in the 1990s and applies to people who resist gender stereotypes or who transgress sex-gender norms. Transgender individuals may identify as either gay or “straight” (i.e., heterosexual; Hunter & Hicker-son, 2003).

HISTORY OF OPPRESSION

The life experiences of older GLBT individuals differs quite markedly from those of younger cohorts (McDougall, 1993). Brotman et al. (2003) refer to this cohort as “preliberation” gays and lesbians, drawing attention to the context of their youth and early adulthood, which occurred prior to the gay liberation movement of the 1970s. The Stonewall rebellion of 1969 has been considered a watershed event initiating the movement for gay civil rights (Morrow, 2001; Kochman, 1997). The Stonewall Inn was a gay bar in New York City that was frequently raided by police in the 1960s. On June 27, 1969, the patrons did not acquiesce to the raid but rather fought back, resulting in three days of rioting; this pivotal event has been described as the point in gay culture at which active resistance replaced submission to antigay violence (Morrow, 2001).

Most of the current cohort of elder GLBT individuals grew up before this time of liberation, often in very hostile environments. *Homophobia* and *heterosexism* are the terms frequently used to describe the severe oppression that existed prior to gay liberation and which continues to permeate society today, though in a less blatant form.

Forms of Oppression That Affect GLBT Elders

Homophobia—the irrational fear of homosexuals and the hatred of GLB individuals based solely on their sexual orientation.

Heterosexism—an ideological system that denies, denigrates, and stigmatizes any nonheterosexual form of behavior, identity, relationship, or community; refers to beliefs and attitudes that favor opposite-sex over same-sex partnerships (Cahill et al.; Kochman, 1997; van Wormer, Wells, & Boes, 2000).

Transphobia—social prejudice against transgendered people; can be even more intense than homophobia (Cook-Daniels, 1997).

Liberal humanism—a concept which expresses tolerance or acceptance but denies the experience of GLBT individuals—a “sexually blind” approach (Langley, 2001).

Prior to the Stonewall riots, the first two editions of the *Diagnostic and Statistical Manual of Mental Disorders* (DSM-I, 1952 and DSM-II, 1968), published by the American Psychiatric Association (APA), labeled homosexuals as sexual deviants and classified them as child molesters, voyeurs, exhibitionists, and people who committed antisocial or destructive crimes (Hidalgo, Peterson, & Woodman, 1985). The societal impact of the gay liberation movement led to the APA’s historic removal of homosexuality from its official list of disorders in 1973. This action rippled through the helping professions, including the profession of social work. Prior to the APA revision, social work had been guilty of defining homosexuality as an illness and subjecting gay clients to conversion (to heterosexuality) treatment (Kochman, 1997). Since the late 1970s, the policy statements of the National Association of Social Workers (NASW) have reflected increasingly affirmative approaches to practice with and advocacy for gay men and lesbians and, since 2000, bisexuals and transgender individuals, as well (Hidalgo et al., 1985; NASW, 2003).

INVISIBILITY OF THE POPULATION

Given this history of oppression, it is not surprising that elder GLBT have become very practiced at concealment. In their youth and young adulthood, they learned to hide their orientation from family, friends, and employers; some chose heterosexual marriage and having children as one way to conceal their sex-

ual orientation from society—and perhaps themselves (D’Augelli, Grossman, Hershberger, & O’Connell, 2001; Sitter, 1997). Blando (2001) refers to elder lesbians and gay men as “twice hidden” and the most “invisible of an already invisible minority” (p. 87). Having grown up with the prevailing message that homosexuality is a sickness, sin, perversion, or arrested development, this cohort of elder GLBT individuals has been particularly vulnerable to “internalized homophobia,” resulting in a reticence to reveal their sexuality or gender identity to service providers (Langley, 2001). Smith (2002) submits that, compared with gay men and lesbians, people with a bisexual orientation are even less visible because they fear rejection by both the gay and straight communities.

Although older GLBT adults are invisible in part because they seek anonymity to avoid discrimination, they are also invisible because the dominant heterosexual society generally seeks to ignore their existence (Connolly, 1996). This attitude, sometimes described as “heterosexual assumption” (Healy, 2002), presents barriers to full disclosure by elder GLBT who have learned—with good cause—to live their lives “passing” as straight (Wojciechowski, 1998). Quam (1997) recalls asking a group of 15 to 20 social workers, who were both sensitive to gay and lesbian issues and practicing in long-term care, to estimate the number of gay or lesbian clients they had had in their careers; only one practitioner could recall any GLBT clients, and this social worker could only think of one: “he never exactly came out to me . . . but then I never asked him about it” (p. xv). Clearly this invisibility can affect quality of care. For example, Cook-Daniels (1997) notes that GLBT elders have so routinely taken extraordinary measures to protect their privacy that they are frequently unwilling to allow persons who provide personal care into their homes.

It is important to emphasize again the diversity that exists in the population of GLBT elders, a diversity which also encompasses degree of identity concealment. For example, some of today’s GLBT older adults have “come out” (i.e., assuming self-definition as gay, lesbian, bisexual, or transgender) in their middle age, and their experiences may be quite different from those who identified as GLBT in their youth, during the more oppressive preliberation years. Friend (1991) suggests that older gay men and lesbians fall along a continuum in terms of their cognitive/behavioral responses to heterosexism. One end of this continuum represents GLBT individuals who have internalized the negative societal messages, and the

other end represents individuals who have formed affirmative self-perceptions.

In addition to the heterosexism, homophobia, and transphobia that affect GLBT individuals across their life spans, ageism is an added insult for the GLBT elder. The GLBT community has not been immune to the youth worship reflected in mainstream U.S. society (Boxer, 1997; Connolly, 1996; van Wormer et al., 2000). Gay culture has been guilty of being particularly youth focused; what is old has been seen as less attractive and less worthy than what is young (Auger, 1992; Brotman et al., 2003; Cahill et al., 2000). For example, in a study conducted by Jacobs, Rasmussen, and Hohman (1999), GLB respondents reported greater levels of ageism in the gay/lesbian community than in the society at large. This issue of ageism may be particularly prevalent among gay males, for whom the gay identity is often focused on sexualized physical attractiveness, which is frequently associated with youth (Jones, 2001). Moreover, ageism in the GLBT community may be an extension of internalized homophobia, which, at times, affects GLBT individuals' self-acceptance and acceptance of other GLBT persons.

WHAT IS KNOWN ABOUT GLBT ELDERS?

Although there has been increasing research on GLBT elders in recent years, what we know is gathered from relatively few studies, which are based on small non-representative samples (Humphreys & Quam, 1998). The majority of these studies are of gay men, with a smaller number on lesbians, and very few include bisexual or transgender individuals. Furthermore, most investigations have utilized small samples that do not reflect the racial and economic diversity within the GLBT community (Cahill et al., 2000; Christian & Keefe, 1997). Meyer (2001) notes a range of obstacles that stand in the way of gathering knowledge about GLBT populations. Some of these obstacles are methodological, and "others are related to homophobia and heterosexism, which place GLBT studies outside the mainstream in terms of importance and allocation of resources" (p. 857).

In the seminal report, *Outing Age: Public Policy Issues Affecting Gay, Lesbian, Bisexual and Transgender Elders*, Cahill, South, and Spade (2000) synthesize current research. It appears that elder GLBT individuals are more likely to live alone than their heterosexual counterparts. They are also less likely to be living with life partners and less likely to have children than

heterosexual seniors (Cahill et al., 2000). For example, one New York City-based study found 65% of their sample of 253 gay and lesbian seniors to live alone; this was nearly twice the rate of living alone among the entire population of New Yorkers 65 and older (36%; Brookdale Center on Aging of Hunter College and Senior Action in a Gay Environment, 1999). Another study with a sample of gay and lesbian elders in the Los Angeles area found that 75% of their respondents reported living alone (Rosenfeld, 1999).

It is important to distinguish living alone from being lonely. There is a pervasive stereotype of GLBT elders as lonely and isolated. This caricature has been refuted repeatedly in the literature (Blando, 2001; Christian & Keefe, 1997; Dorfman et al., 1995; Whitford, 1997): GLBT elders are no more lonely than heterosexual elders or than GLBT younger adults (Cahill et al., 2000). Moreover, some have posited that GLBT elders may have a social advantage given their well-developed social networks of choice, which provide a broad base of support in times of loss and need (Barranti & Cohen, 2000; Butler & Hope, 1999; Healy, 2002). Committed partner relationships are important to many GLBT elders; surveys of gay and lesbian individuals have documented "a range of 40–60% of gay men and 45–80% of lesbians in a committed relationship at any given time" (Cahill et al., 2000, p. 10). Grossman, D'Augelli, and Hershberger (2000) found that partners provide the most support, as compared with friends and family, in GLB support networks.

PARTICULAR STRENGTHS OF GLBT ELDERS

Contrary to the myths of a pathetic and lonely old age, many gay men and lesbians approach their elder years with unique resiliency and particular strengths. Barranti and Cohen (2000) enumerate specific factors which may allow GLBT individuals to enter their elder years with greater ease than their non-GLBT peers:

- Coping skills developed through the process of accepting their sexual identity may help GLBT seniors in the acceptance of aging.
- Skills developed through the coming-out process and the management of the social perception of "difference" throughout life prepare GLBT individuals for society's perception of older people in a youth-oriented society.

- The stigma of being older is often experienced as less severe than the stigma of being “queer,” which gay men and lesbians faced in their youth.
- In part due to rejections by families of origin and/or procreation, GLBT individuals often create “families of choice,” which are able to provide extensive social support in times of need.
- Greater flexibility in gender roles exhibited by GLBT individuals can be helpful in the aging process.

These factors have been highlighted by numerous authors in the literature on GLBT elders (e.g., Butler & Hope, 1999; Healy, 2002; Humphreys & Quam, 1998; McDougall, 1993; Morrow, 2001; Quam & Whitford, 1992; Wojciechowski, 1998).

Despite these advantages, GLBT individuals do experience some obstacles in their latter years, some of which are not shared with their heterosexual counterparts. For example, GLBT older adults may face declining health, loss of partners and friends, ageism, and reduced income in their later years, just as many heterosexual older adults do. But they may also face barriers to services due to discrimination, reduced financial security when their partnerships are not recognized, and blatant homophobia from health and social service professionals, which may not be shared by their heterosexual counterparts. Although there is greater acceptance of gay and lesbian relationships and GLBT individuals in general in our society than existed 30 years ago, considerable discrimination, stigma, and overt hatred toward homosexuality remain (Brotman et al., 2003).

CHALLENGES FACED BY GLBT ELDERS

Heterosexism, homophobia, transphobia, legal discrimination, and the inability of GLBT partners to benefit from the advantages of being married spouses lead to many specific problems and barriers to service for GLBT seniors (Smith & Calvert, 2001). I enumerate a few of these challenges here, drawing largely from the work of Cahill, South, and Spade (2000).

Access to Services

There are very few organizations whose mission is specifically to meet the needs of GLBT elders. They exist in large cities with relatively visible GLBT communities. Nevertheless, the majority of GLBT elders

in the country do not have access to such specialized services and must seek services in more mainstream aging organizations such as the Area Agencies on Aging (AAAs). Most mainstream aging organizations are not sensitive to the needs of GLBT elders (Behney, 1994).

Lack of Recognition of GLBT Families

Legal marriage affords certain rights and privileges that are unavailable to same-sex partners. People of the same sex are not allowed to marry, and domestic partnerships are neither widely available nor as comprehensive as the rights and responsibilities of marriage (Cahill et al., 2000). Some rights generally unavailable to GLBT partners include Social Security benefits for survivors, employee health benefits, inheritance, housing, and hospital visitation.

Social Security and Gay/Lesbian Couples

Cahill and his coauthors suggest that Social Security’s treatment of same-sex couples may be the most blatant and costly example of institutionalized heterosexism in federal policy. Under the current Social Security system, married spouses, some divorced spouses, and children are eligible for survivor benefits; unmarried spouses (e.g., same-sex partners) are ineligible for these benefits no matter how many years they may have lived with and supported their partners. Similarly, minor children in unrecognized GLBT families are ineligible for benefits (Dubois, 1999). The Social Security Administration estimated that in 1998, 781,000 widows and widowers received an average of \$442.00 a month in survivor benefits, costing the Social Security system \$4.1 billion (Cahill et al., 2000). If only 3% of those individuals who survived their life partners were gay or lesbian, the failure to pay Social Security benefits to GLBT surviving partners would total about \$124 million a year (Cahill et al., 2000).

Nursing Homes and Homophobia

Although less than 5% of older adults over 65 reside in nursing homes at any one time (Hooyman & Kiyak, 2002), the fear of ending one’s life in a nursing facility is pervasive. This fear is particularly ubiquitous among GLBT elders who worry that their integrity

and life choices will not be honored as they become physically frail and/or mentally vulnerable (Auger, 1992; Butler & Hope, 1999; Connolly, 1996; Quam, 1997). When GLBT elders enter mainstream assisted living, nursing facilities, or retirement communities, they are frequently presumed to be heterosexual; their long-term partnerships may not be recognized or valued.

Other challenges described in the literature on GLBT aging include accessing quality health care (Barranti & Cohen, 2000; Brotman et al., 2003; Humphreys & Quam, 1998; U.S. Administration on Aging [AoA], 2001)—particularly for transgender elders (Donovan, 2001; Niedermayer, 2002; Witten, 2002); obtaining adequate housing (Humphreys & Quam, 1998; Langley, 2001); securing social support (Grossman et al., 2000; Humphreys & Quam, 1998; Jacobs et al., 1999); bereavement issues (Gallance & Warshaw, 2004; Kochman, 1997; McDougall, 1993; Wojciechowski, 1998); loneliness (Boxer, 1997; D’Augelli et al., 2001; Kehoe, 1991; Kochman, 1997; Quam & Whitford, 1992); and poverty (Quam & Whitford, 1992; AoA, 2001).

PRACTICE GUIDELINES

Given the strengths that GLBT elders bring to the aging process, as well as the extra challenges they face in a heterosexist, homophobic, and transphobic society, there are implications for both culturally competent practice and proactive policy change. In order to lessen and eventually eliminate both the subtle and blatant discrimination and oppression faced by current and future GLBT seniors, attention must be paid to micro, mezzo, and macro level practice. Affirmative practice with GLBT elders involves a framework that is based on clients’ strengths and that encompasses aspects of empowerment, ecological, and feminist approaches to practice (Hunter & Hickerson, 2003). Langley (2001) warns against the liberal humanist approach to tolerance, which fails to acknowledge the importance of understanding the life context of GLBT elders.

The following broad practice guidelines are a synthesis of suggestions offered by Berger (1985), Connolly (1996), Cook-Daniels (1997), Healy (2002), Humphreys and Quam (1998), and Morrow (2001):

- Engage in self-reflection and work through your own heterosexism and homophobia.
- Recognize diversity in the GLBT community.

- Protect privacy and confidentiality.
- Listen especially carefully and strive to connect with your client.
- Recognize that all presenting problems are not due to being old or being GLBT.
- Honor relationships and treat identified family as family.
- Assess your agency and combat heterosexist assumptions and homophobia.
- Utilize inclusive language and plan activities that are neutral with respect to sexual orientation.
- Educate yourself about special issues facing GLBT elders and resources in the community.
- Find respectful service providers to whom to make referrals.
- Assist the client in connecting with the GLBT community.
- Work to develop more GLBT-friendly resources.
- Include GLBT elders in program planning.
- Advocate to change heterosexist organizational, local, state, and federal policies.

Practitioners can look to the literature for ideas regarding affirmative activities and interventions with GLBT elders and training for culture change in organizations serving older adults. Examples include a program utilizing a buddy system for homebound elders (Jacobs et al., 1999); a community organizing approach to involving GLBT elders in program planning (Beeler, Rawles, Herdt, & Cohler, 1999); pet therapy with lonely GLBT elders (Kehoe, 1991); the use of support groups (Slusher, Mayer, & Dunkle, 1996); life-review workshops (Galassi, 1991); changing agency culture to be more GLBT friendly (Smith & Calvert, 2001); and providing staff training for more affirmative practice with GLBT clients (Metz, 1997; Senior Action in a Gay Environment [SAGE] and Brookdale Center on Aging, 2003).

Many challenges facing GLBT older adults will not be easily solved without policy change. As a profession, social work is committed to advancing policies that will improve the status and well-being of all GLBT persons (NASW, 2003). Cahill et al. (2000) provide a comprehensive list of recommendations for policy advocacy and activism with regard to GLBT elders. The reader is encouraged to access this sourcebook for detailed suggestions under the following broad categories: research; service, training, and caregiving; recognition of GLBT families; housing; health care; and discrimination and income support (Cahill et al., 2000, pp. 70–78).

Today's GLBT elders have lived through years of legalized oppression and discrimination. Although their numbers are significant, they are not always visible, having spent many years protecting their private lives, sexual orientation, and/or gender identity from public view. Social worker practitioners can be at the forefront of improving the quality of life for today's GLBT elders and for the elder generations to follow.

This page intentionally left blank

The population ages 65 and older of Latino/Hispanic descent numbered 2 million in 2002 and is expected to grow to 13.4 million by the year 2050 (Administration on Aging, 2003). Older Latinos/Hispanics will comprise the largest racial/ethnic minority group in this age group by the year 2028 (Administration on Aging, 2003). According to the U.S. Census Bureau:

[p]ersons of Hispanic origin are those who classified themselves in one of the specific Hispanic origin categories listed on the questionnaire—“Mexican,” “Puerto Rican,” or “Cuban”—as well as those who indicated that they were of “other Spanish/Hispanic/Latino” origin. Persons of “Other Spanish/Hispanic/Latino” origin are those whose origins are from Spain, the Spanish-speaking countries of Central or South America, or the Dominican Republic, or they are persons of Hispanic origin identifying themselves generally as Spanish, Spanish-American, Hispanic, Hispano, Latino, and so on.
(<http://www.census.gov/acs/www/UseData/Def/Hispanic.htm>)

People of Latino/Hispanic origin may be of any race, thus adding to an already existing ethnic diversity. Among older Latinos/Hispanics in the United States, the majority (50%) is of Mexican descent, 17% are Cuban, 11% are Puerto Rican, and 24% are other Hispanic (Angel & Hogan, 2004). Moreover, older Latinos/Hispanics (hereinafter called older Latinos), are considered a diverse group of persons differentiated by a plethora of contextual experiences such as language, culture, sociopolitical history, acculturation, cumulative life experiences, and opportunities (Angel & Angel, 1998; Bean & Tienda, 1987).

The purpose of this chapter is to discuss a selected group of sociodemographic and cultural indicators in the service of showing how these indicators are relevant to social work practice in the mental health arena. Alternately stated, what role do income, education, living arrangements, physical illness and disability, culture and language play in the development of culturally competent mental health practice with older persons of Latino descent? Thus the information presented here goes beyond describing the contextual realities of older Latinos to offer a bridge to the next stage of developing mental health services related to older adults living with psychiatric disabilities. In order to provide a more tangible discussion, the material is applied to the case of late-life depressive illness. Although in the past more attention has focused on the health status of older Lati-

MARIA P. ARANDA

Older Latinos: A Mental Health Perspective

23

nos, this chapter attempts to narrow the serious gap in the mental health literature, specifically in terms of treatment of depressive disorders in communities of color. Such information has important implications for practice, because social workers are typically the “front-line” providers of mental health services in the United States (Miller, 2002). Focusing on depression is also a public health concern given that depression is associated with increased mortality, comorbidity, health service use and costs, and overall quality of life (Murphy, Smith, & Slatter, 1988; Murray & López, 1996; Wells et al., 1989; Katon et al., 1990; Koenig & Kuchibhatla, 1998; Unützer et al., 1997).

LATE-LIFE DEPRESSION

Clinically significant depression affects between 15 to 20% of older adults in the United States (Koenig & Blazer, 1996; Lebowitz, 1997) or 5.2 million of the 35 million Americans over the age of 65. A recent review by Blazer (2002) highlights the phenomenal growth in understanding the prevalence, etiology, nature, trajectory, and treatment of depressive illness in late life. Of particular interest to social workers are the promising treatments or care strategies—biological and psychological—available to practitioners in their commitment to prevent or mitigate the consumer- and society-related consequences of depressive illnesses. Still, key questions remain: Do older adults of color have at their disposal the same access to timely information, evaluation, and treatments as do mainstream older adults? What type of modifications in evidenced-based treatments are needed in order to make these treatments not only more linguistically and culturally congruent but acceptable to a wider range of older minorities who also experience structural disadvantages in terms of access to mental health care? The following section discusses several sociodemographic and cultural indicators relevant to the discussion of depression care in older Latinos.

SOCIODEMOGRAPHIC INDICATORS AND IMPLICATIONS FOR DEPRESSION AND DEPRESSION TREATMENT

Income, Wealth, and Retirement

Latinos, like other adults, look forward to living a healthy and productive life in their later years. To what degree this comes to fruition is in part dependent on the person’s ability to accumulate sufficient

wealth and income to sustain himself or herself during the retirement years. Conversely stated, to what degree has the older person developed a “three-pronged” income profile composed of Social Security benefits, private pensions, and savings and investment income?

Having confronted significant cumulative educational and employment disadvantages during their earlier years, many Hispanics have been unable to accumulate sufficient financial resources to sustain themselves during retirement (Villa & Aranda, 2000). Older Latinos are less likely to receive income from Social Security, yet typically Social Security benefits remain the *sole* source of income for Latinos (Villa & Aranda, 2000). Second, Latino elderly individuals are less likely than Blacks or Whites to report receiving income from pension benefits or supplemental Medigap health insurance than non-Hispanics (Angel & Angel, 1997). Third, older Latinos are as likely as Blacks and much less likely than Whites to receive income from interest on savings and investments. Thus it comes as no surprise that the poverty rate for Latino older adults over the age of 65 is about twice that of the total older adult population (21% compared to 10%, respectively; Federal Interagency Forum on Aging-Related Statistics, 2004).

The implications of poverty and low economic resources during the retirement years are significant and numerous. The following discussion addresses the implications related to Latinos’ at-risk status for depression and low access to mental health services. First, the association between depression and lower income status (or financial strain) is well supported in population-based studies of preretirement and older adult populations (see Blazer, 2003; Cornoni-Huntley et al., 1990; Dunlop, Song, Lyons, Manheim, & Chang, 2003). This association has also been found in studies on depression in older Latinos. For example, using epidemiological data from the Hispanic Established Populations for Epidemiologic Studies of the Elderly (H-EPESE) study of more than 3,000 Mexican Americans in the southwestern United States, Black, Markides, and Miller (1998) found that both females and males have elevated rates of depressive symptomatology than those found among older adults in general (25.6% vs. 10%, respectively; Black et al., 1998; Blazer, Hughes, & George, 1987), as well in comparison with the 15.1% reporting the same symptom range in the primarily Anglo American New Haven EPESE (White, Kohout, Evans, Cornoni-Huntley, & Ostfeld, 1986). Similar results indicating higher rates of de-

pressive symptomatology were found by Gonzalez and his associates in the Sacramento Area Latino Study on Aging (SALSA) study of older Latinos in the Sacramento area (Gonzalez, Haan, & Hinton, 2001). Moreover, higher levels of financial strain were found to be associated with twice the risk of clinically significant depressive symptomatology for both males and females (Black et al., 1998). Additional data from the H-EPESE (Angel, Frisco, Angel, & Chiriboga, 2003; Chiriboga, Black, Aranda, & Markides, 2002) suggest that a “cluster” of economic stressors and conditions may play an enhanced role in the etiology of depressive symptoms in older Mexican Americans, namely annual income, acute financial event, and chronic financial strains. Work with non-Latino populations has also underscored the especially noxious effects of chronic financial strains on mental health due to its persistent and unrelenting nature (Krause, 1997; Krause, Liang, & Gu, 1998; Lincoln, Chatters, & Taylor, 2003).

Disaggregating the data by gender and Latino subgroup reveals that the most economically vulnerable among this population are older Latinas: 25% of Latinas live in poverty compared to 18.1% of their male counterparts (Proctor & Dalakar, 2002) while close to 50% of older Latinas living alone live in poverty (Angel & Hogan, 2004). Although prevalence studies of psychiatric disorders of younger Latinos indicate more favorable mental health outcomes for immigrant versus U.S.-born Latinos (see review by USDHHS, 2001), older immigrant Latinos (especially females) tend to be at higher risk (Black et al., 1998; Kemp, Staples, & López-Aqueres, 1987; Mendes de Leon & Markides, 1988). Taken together, these findings show that older Latinos are overrepresented in terms of low income and high financial strain, with older Latinas and immigrants being most at risk of developing depressive symptomatology.

The second implication of low economic resources is that, although older Latinos may be at risk for depressive disorders, they also tend to be low utilizers of specialty mental health care (López-Aqueres, Kemp, Plopper, Staples, & Brummel-Smith, 1984; Vega, Kolody, Aguilar-Gaxiola, & Catalano, 1999). Significant barriers exist that lead to limited access to—and utilization of—mental health services by older Latinos. System-level barriers are often found to be the most important barriers to mental health service utilization—barriers such as insufficient mental health resources, unavailability of bilingual/bicultural staff, long waiting time, lack of outreach, lack of transportation, lack of publicity or information, service

fragmentation, and low level of Medicare reimbursement (Abramson, Trejo, & Lai, 2002; Aranda & Torres, 1997; Biegel, Farkas, & Song, 1997; Padgett, Burns, & Grau, 1998). In a depression treatment study of primary care consumers, Latinos (as well as African Americans) reported substantially lower rates of lifetime and recent depression care (Unützer et al., 2003). Although the majority of the participants (all racial/ethnic groups) indicated a preference for psychotherapy rather than antidepressant medications, only 8% actually received counseling or psychotherapy in the months before enrolling in the study.

Limited financial means also translates into less available capital for purchasing services or accessing clinical services. For example, one out of two Mexican Americans over the age of 65 reported not having enough money at the end of the month to make ends meet (Chiriboga et al., 2002). Access to care is compromised given the person’s inability to pay for an adequate trial of depression treatment, such as pharmacological therapies, as well as sociobehavioral and psychosocial interventions. Drawing from the health services literature, racial and ethnic minority groups receive limited or inadequate mental health services (Cheung & Snowden, 1990; Hu et al., 1991) and are less satisfied with the quality of services they receive (Alegria et al., 2002; Smedley, Stith, & Nelson, 2003; Snowden et al., 2003). Although the first literature to address the disparity in Latino mental health service utilization appeared approximately 30 years ago (see Lopez, 2002), Latinos continue to utilize mental health services at lower rates than their non-Latino counterparts (USDHHS, 2001). As has been documented extensively, Latinos (35%) are more likely than Whites (14%) or African Americans (21%) to report being without insurance (Pew Hispanic Center & Kaiser Family Foundation, 2002).

Thus older Latinos may wait until their conditions worsen before seeking care or following up with their treatment regimens. Then what providers may be confronted with in terms of depression is dealing with consumers who have been affected by depression for a longer time without receiving services or with an episodic trajectory of services. This is unfortunate given the emerging work that indicates that low-income Latinos are able to respond favorably to depression care even with modest linguistic and cultural adaptations (Miranda et al., 2003) and, in some cases, supersede the effects found for their White counterparts (Unützer et al., 2003). Delaying appropriate treatment may have adverse effects in that low-income, older Latinos may accommodate to the symp-

toms of depressive illness and appear more fatalistic in their perceptions about being able to get better. Sometimes this sense of fatalism is misperceived as a cultural value, when in reality it is an accommodation and a survival strategy in the face of chronic strain (Aranda & Knight, 1997). Thus the social worker and other providers are typically faced with real-life situations that are at a crisis—or near crisis—level, that have gone unnoticed or ignored for many years. This increases the likelihood that the social work practitioner will be involved in providing therapeutic services, as well as case management and other forms of resource-enhancing, crisis-mitigating activities. The case management approach to depression care has received support in recent years as a viable component to a multimodal program of services (Dwight-Johnson, Ell, & Juan-Lee, 2005; Unützer et al., 2003).

Another issue is the complex interaction between depression, chronic illness, and medication adherence. For example, using multiple sources of longitudinal, population-based data on older adults, researchers (Heisler et al., 2004) found that patients with serious chronic illnesses experience adverse health events when they restrict their use of prescription drugs due to cost. Specifically, middle-aged and older Americans who cut back on their prescribed medications experienced a statistically significant decline in their self-reported health status, and among those with preexisting heart conditions, there was a 50% higher risk of subsequent heart attacks, strokes, and angina. For those older adults over the age of 72 who restricted the use of prescription drugs due to cost, there was a significant increase in the risk of more severe depressive symptomatology. Disparities in the ability to purchase medications has far-reaching implications for older racial and ethnic minorities, such that those who restricted buying medications were more likely to have lower annual income and educational levels and to have no insurance or insurance without full prescription medication coverage. Thus being uninsured or underinsured could result in not being able to initiate—or to continue—guideline-concordant pharmacological treatments, which in turn could have a deleterious effect on mental health outcomes for older individuals from ethnic and racial minorities who are at risk.

Perhaps having higher educational status in late life is important in order to be able to access the myriad opportunities and resources that can foster psychological well-being: ability to access tangible, emotional, and cognitive resources such as housing, transportation, medical care, self-esteem, self-effi-

cacy, cognitive flexibility, positive attributions, pleasant activities (religious, social, family, civic), and so forth.

Educational Level

Although the educational attainment among older Americans has increased in the last few decades, large educational differences exist among older Latinos and their non-Latino counterparts. Older Latinos represent one of the most structurally disadvantaged groups in the United States as a result of their low educational attainment. According to census reports (Federal Interagency Forum on Aging-Related Statistics, 2004), about 70% of older Hispanics fail to complete high school, compared with almost 30% of the overall older adult population. Only 5% of older Latinos have bachelor's degrees or higher, compared with 16% of the older adult population in general. Specific groups of older Latinos are disproportionately represented in terms of educational attainment, such that older Cubans, for example, have comparable high school completion rates to those of Whites (Villa & Aranda, 2000). Even when education levels are the same, Latinos often earn less than their non-Hispanic White counterparts (Council of Economic Advisers, 1998), evidence that occupational segregation and glass ceilings experienced by older Latinos and their family members are a stark reality.

Formal education is a key mechanism by which people develop more expansive cognitive strategies for learning and the acquisition of knowledge and vocabulary, as well as enlarge their repertoires of positive coping strategies and develop resources and increase access to a wider array of helping networks associated with adaptation and resiliency. This situation has implications for clinical social work practice and mental health. Lower education levels present a challenge to practitioners to the degree that many current evidence-based interventions were initially developed and refined based on certain types of peoples with certain sociodemographic characteristics.

Living Arrangements

Coresidence tends to be higher among older Latinos in comparison with the general older population. For example, living alone tends to be proportionately less common among both older Latino males and females, whereas older Latinos are twice as likely to live with a relative (nonspouse) as compared with the

general older adult population. For example, 25% of older Latinas live with other relatives (mostly adult children) as compared with 7% of females in the total older adult population. Similarly, 15% of older Latino males live with other relatives, compared with 4% of the male non-Latino population (Federal Interagency Forum on Aging-Related Statistics, 2004).

Coresidence has implications for the assessment of the extent and nature of the older consumers' natural networks, including family and significant others. Although coresidence is only one aspect of the consumer's network, it is nonetheless a measure of proximity to help when help is needed, as well as the nature of reciprocity between individuals living in the same household. Second, coresidence provides some gauge of the potential participation of significant others in the care of older consumers. For instance, in a current qualitative study of depression treatment among home health patients over the age of 65, family members or significant others perform a key gatekeeper function for the older persons' participation in depression treatment; not only are they distillers of information, but they also function as protective agents in terms of the consent process and treatment regimens (Aranda, 2001; Aranda & Ell, 2004).

Similarly, lower rates of institutionalization (nursing home use) by older Latinos have been attributed to various demographic (higher fertility, larger families, multigenerational households), cultural (familism, filial obligation, low acculturation) and economic (low income, financial strain) factors (see discussion by Angel et al., 2004). Regardless of the reasons for low institutionalization rates, families tend to absorb a lion's share of the responsibility for the older person's long-term care needs. This notion was supported by Angel and her associates, who found that among older Mexican Americans (who make up 50% of the older Latino population in the United States), "even when they exhibit serious deficits in functional capacity, though, older individuals are more likely to remain in the community than to enter a nursing home. Indeed, our data indicate that death is a more likely outcome than institutionalization as the result of seriously compromised physical and cognitive status" (2004, p. 13).

Still, current profiles in terms of living arrangements and family structure may be changing, as evidenced by other work that points to the changing availability of family to provide assistance. Some studies have found that Latino caregivers have identified fewer networks for support (Phillips, Torres, de

Ardon, Kommenich, Killen, & Rusinak, 2000), and others underscore the reality that for some Latinos, having a caregiver available to help them in the future may not be a consistently viable option (Talamantes, Cornell, Espino, Lichtenstein, & Hazuda, 1996). Thus, although previous generations of older Latinos have been described as surrounded by extensive and supportive networks, social workers are more likely to work with future cohorts of Latinos who have fewer caregiver supports available to them.

Physical Illness and Disability

There exists a consensus that depression coexists with physical illness and functional disability in older adults (Berkman et al., 1986; Gurland, Wilder, & Berkman, 1988; Hays, Wells, Sherbourne, Rogers, & Spitzer, 1995; NIH Consensus Development Panel on Depression in Late Life, 1992; Zeiss, Lewinsohn, Rohde, & Seeley, 1996). Moreover, depression is not only associated with the presence of disease but is also implicated in the development of disease and disability over time. Whereas mortality for certain conditions is equivalent to—and in some cases better than—that of non-Latino Whites, Latinos are disadvantaged for certain chronic conditions and have higher rates of disability than non-Latino Whites (Hazuda & Espino, 1997; Markides, Rudkin, Angel, & Espino, 1997). The evidence also suggests a higher prevalence of chronic medical conditions such as diabetes and its complications, obesity, certain cancers, Alzheimer's disease, and cardiovascular disease (especially in Latinas; Villa & Aranda, 2000; Espino, Burge, & Moreno, 1991; Perkowski et al., 1998). About 72% of Latinas and 42% of Latinos report a limitation in functional ability (Hazuda & Espino, 1997). This indicates a higher risk of functional impairment among Latinas over the age of 65. In developing depression care, it is important to address the role that physical illness and disability play in the etiology of depression, as well as in the ways that one approaches treatment.

Culture and Language

The goal of positive outcomes in mental health encounters is predicated to a substantial degree on the formulation of the consumer-provider relationship or alliance, regardless of the treatment orientation of the providers or service provided (Hepworth,

Rooney, & Larsen, 2002). A precursor to developing the therapeutic or care alliance is the ability of the consumer to express his or her situation in such a way that the provider can comprehend not only the spoken word but also culturally laden idioms, patterns of communication, and nonverbal gestures and cues (Aranda, 1999; Dyche & Zayas, 2001; Valle, 1998). Thus the language and ethnicity of both consumer and provider play a key role in the communication between both parties and the ability to formulate a helping relationship. In the mental health systems literature, one of the most studied hypotheses regarding the underutilization of services by Latinos is the lack of linguistically and culturally relevant mental health services (Lopez, 2002). These studies, mostly large-scale studies of mental health departments or centers in urban settings in large counties, have found that matching of consumers with same-language, same-ethnicity providers has for the most part resulted in more positive outcomes. What are less certain are the mechanisms and pathways that may account for the improved mental health of the consumers—for example, cultural expressions of mental health and illness, cultural explanatory models or notions of the etiology of psychological distress, personal and socio-centric beliefs regarding responsibility, help-seeking behaviors, the acceptance of and adherence to treatments, and so forth (Talamantes & Aranda, 2004; Lewis-Fernández & Díaz, 2002). Emerging work in clinical services research (Balsa, Seiler, McGuire, & Bloche, 2003; Cooper et al., 2000), especially more qualitatively driven efforts (Guarnaccia & Rodriguez, 1996), points to culturally laden beliefs and behaviors that may easily be misinterpreted by mainstream, professionally trained providers who make clinical judgments about who needs what type of treatment and the reasons why (Lewis-Fernández & Díaz, 2002).

CONCLUSION

Support for addressing the special mental health needs and strengths of older Latinos follows the principle of consumer- and family-centered services as set forth by the President's New Freedom Commission on Mental Health (2003). This chapter has addressed a selected set of sociodemographic indicators, along with cultural variables, and how these are related to the mental health needs and special circumstances of social work practice in the mental health arena. Older Latinos are at risk for depression, tend to underutilize

mental health services, and are least likely to be institutionalized even with higher levels of functional limitation. Although rates of coresidence are higher than for many other subgroups of older adults, the burden of caregiving may be more evident in subsequent generations of caregivers. With the aging of subsequent cohorts of U.S. Latinos, we can expect social workers to play a significant role in the delivery of mental health services to older Latinos and their families.

Native American Elders: Unique Histories and Special Needs

24

Although they represent a tiny fraction of the U.S. population, Native American elders' history and culture lead to distinct opportunities and needs. This chapter uses figures from the most recent census to examine the status of Native American elders in the United States. Following a brief review of current living conditions, it examines the history of forced assimilation and colonization and the impact of that history on Native American elders. This is followed by a discussion of service approaches that empower elders and improve their quality of life—and a suggestion that the pursuit of culturally appropriate interventions should begin with the employment of Native American service providers (Barusch & TenBarge, 2003).

Because this chapter focuses on harsh living conditions and special needs of this population, it is important to acknowledge the diversity and the strengths among Native American elders. As Weaver (1999) reminded us, “each tribe is different.” Many Native American traditions offer privileges and respect to their elders and assign them honorific titles and roles. Elders preserve heritage and wisdom, so can serve as healers, counselors, and leaders by virtue of their advanced age. Having lived through a violent and challenging history, some elders are the very embodiment of resilience (Weaver & White, 1997). These individuals present social work practitioners with opportunities, and they can serve as vital resources to strengthen and heal Native American families and communities. Other elders experience health and mental health limitations and may be victims of neglect or abuse. Given their distinctive history, these Native American elders have special needs that may (or may not) be met through social work intervention.

DEMOGRAPHICS

Prior to the 2000 census, the last careful count of the nation's Native American population was that mandated by the Dawes Act in 1887. Census counts during the interim undercounted the Native American population, and as a result much was written about the so-called “vanishing race” (Churchill, 1999; Johansen, 2002; Thornton, 1987, 1996). Using a strategy familiar to social work since the Settlement House days, the Census Bureau hired Native American people to collect data for the 2000 census. The need to cooperate with Census personnel was advertised, and Native Americans were encouraged to participate in the cen-

sus at powwows and other cultural events, urban Indian centers and clinics, schools and universities, and other settings. Images of famous Native American figures—Sitting Bull, Chief Joseph, Geronimo—were imposed on huge posters exhorting people to “stand up and be counted,” and Census personnel offered gifts—key chains, flashlights, pens, notepads, mirrors, posters, and t-shirts—respecting a universal Native American tradition.

They did a better job than usual with the count. In the 2000 census, more than 4.1 million people said they were at least partially Native American, which is double the 2 million who reported Native ancestry in the 1990 census and 14 times the official figure of about 300,000 a century ago (Johansen, 2002; Thornton, 1987, 1996, U.S. Census Bureau, 2002). By comparison, the total U.S. population grew by 13% between the 1990 and 2000 censuses (U.S. Census Bureau, 2002).

Most of the growth in the Native American population was due to a change in the census procedures. Census 2000 was also the first in which respondents were allowed to choose more than one race. A total of 1.6 million Americans identified themselves as part American Indian/Alaska Native, which accounted for most of the increase. But even when those identifying as part American Indian/Alaska Native are not included, Census 2000 documented a 25% increase in the number of Americans identified as Native American peoples since the 1990 census. The 2000 census also indicated which states were home to most Native American elders. Nearly half of Native Americans ages 55 and older lived in just five states: Oklahoma, California, Arizona, New Mexico, and North Carolina (Ogunwole, 2002).

CURRENT LIVING CONDITIONS

Federal recognition is critical for tribes seeking to establish services and provide benefits to their people. There are 562 federally recognized tribes in the United States and about 148 groups seeking federal recognition. The process of attaining federal recognition is difficult and arbitrary. During the 1950s and 1960s the federal government pursued a policy of “termination,” discontinuing recognition of several tribes (Churchill, 1998; Yellow Bird, 2001a). At the same time, a program of relocation dispatched Native American peoples from reservations to cities with the goal of forcing them to assimilate into mainstream society.

A direct result of this policy is seen today in the greater numbers of Native American peoples living off reservations. In 1900, over 99% of federally recognized Native Americans lived on reservations. By 1970, nearly half (44.5%) lived off reservations. Current estimates suggest that over half of Native Americans—between 55 and 70%—live off the reservation (Churchill, 1998; Walters, 1999).

Of course, elders are more likely than younger generations to live on reservations. Nonetheless, Native American elders live in diverse settings—in *hogans* in the deserts of Arizona, Utah, and Nevada, in concrete block houses on reservations, in urban apartments, and in suburban homes. Many Native American elders live in urban centers, such as New York and Los Angeles (Ogunwole, 2002). Urban elders generally enjoy greater income and better health than those living on reservations, although urban settings do not allow for access to Indian Health Service facilities. As Chapleski, Gelfand, and Pugh (1997) pointed out, this situation results in lower utilization of in-home care services among urban elders.

Native American elders are significantly more likely than Whites to live in rural settings. According to the 2000 census, only one in four non-Hispanic Whites lived in rural locations, whereas nearly half of Native American elders live in rural areas. These statistics led Share DeCroix Bane to observe that “Native American elderly are the most rural of the minorities . . .” (1991, p. 63). Reservation-based elders live on treaty-based, executive-ordered, and state-created reservations, as well as in bands not federally recognized. Although reservations offer greater access to tribal community and Indian Health Services, living conditions are extremely difficult. Many homes have no electricity, refrigeration, or indoor toilets. Transportation is also difficult on reservations, where many rely on poorly maintained dirt roads that become impassable in rain or snow. Finally, communication is a challenge, as most elders do not have telephones, receive newspapers, or have television sets (Bane, 1991).

Access to health care is problematic, even on reservations. As the National Indian Health Board (NIHB; 2004) noted, funding for the Indian Health Service has lagged behind need and even basic fairness. Indeed, the federal government spends nearly twice as much money for a federal prisoner’s health care as it does on a per capita basis for Native Americans and Alaska Natives. Per-person HIS expenditures were approximately \$1,900 last year, a figure that, when adjusted for inflation, represents a net decline compared with budgets of the mid-1970s (NIHB, 2004).

Harsh, impoverished living conditions and limited access to health care contribute to lower life expectancies for Native Americans. In 1980 John (1980) estimated the average life expectancy for Native Americans at 45 years, but this figure has improved. In the mid-1990s, life expectancy for American Indian/Alaska Native men was estimated at 66.1 years, and life expectancy for women was 74.4 years. This compares to life expectancies of 73.2 years for White men and 79.6 years for White women. Only African American men have shorter life expectancies (U.S. Department of Health and Human Services, 1998).

Despite this improvement, short life expectancy continues to limit the number of years that elders can access benefits widely available to older non-Native elders. A person with a shorter life has fewer years to collect Social Security and related benefits, even though he or she contributed to the system for as many years as someone who enjoys a longer life.

FORCED ASSIMILATION AND COLONIZATION

Any understanding of the lives of Native American elders must be informed by knowledge of the trauma imposed by forced assimilation and colonization. Assimilation refers to the process through which members of minority cultures give up their way of life and take on that of the dominant group. It is associated with the “melting pot” theory of cultural interaction. In the case of Native Americans, forced assimilation was the result of systematic policies designed to eradicate the Native American culture.

For example, the U.S. government set out to “kill the Indian in every child” by removing Native American children from their homes and placing them in government-run boarding schools (George, 1997, Churchill, 1998). These schools forced the children to wear the clothes, eat the food, speak the language, and practice the customs of the dominant culture. In the United States, this practice continued from the late 19th century until the middle years of the 20th century (George, 1997). Most boarding schools were closed by the 1960s and 1970s, although a number continue to operate.

Boarding schools were succeeded by perhaps a more insidious form of repression, the Indian Adoption Program. A joint venture of the Bureau of Indian Affairs and the Child Welfare League of America, this program placed Native American children in White adoptive homes located as far as geographically pos-

sible from their families of origin. Between the 1950s and the 1970s, an estimated 395 Native American children were adopted through this program (George, 1997). The general practice of placing Native American children in White homes was slowed about 25 years ago, with the passage of the Indian Child Welfare Act in 1978.

Religious sects were willing partners in government efforts to force Native American peoples to adopt the majority culture. Churches were given federal funds to establish and operate schools on reservations, and some engaged in aggressive proselytizing (Linn, Berardo & Yamamoto, 1998; McCarty, 1998). Religious conversion meant abdication not only of traditional religious practices but also of health practices, which in Native American cultures have a strong spiritual component.

Another policy designed to force assimilation was the Indian Relocation Act of 1953. Couched in the concept of “entitling [Native American peoples] to the same privileges and responsibilities as are applicable to other citizens of the United States,” this act initiated a process commonly referred to as “termination policy.” The purpose of the resolution was to end the protected trust status of Native American land and to withdraw the federal support of educational, health, and social programs promised in exchange for lands when treaties were signed. The resolution included plans for the immediate termination of tribes in California, Florida, New York, and Texas (Bonvillain, 2001).

Eradication of Native American languages is pivotal to the process of forced assimilation. As Fillmore (1994) pointed out, “the question of cultural identity is synonymous with the question of language” (p. 1; as cited in Linn et al., 1998). The U.S. government has long recognized the importance of language. In the boarding schools children were severely punished for using their native tongue. This policy was also pursued by the Kennedy administration during the Americanization of the western Pacific (Barusch & Spaulding, 1989). The result is what some linguists call “language extermination.” Roughly half of the Native American languages of California have no fluent speakers left at all (Hinton, 1998). As Teresa McCarty explained:

Native American languages in the United States are under siege . . . of the 175 Native American languages still extant in the USA, only 20 are being transmitted as child languages. The remainder are spoken by parental or grandparental

generations, and over a third are spoken only by the most elderly members of the community, often fewer than ten individuals. (McCarty, 1998, p. 27)

COLONIZATION

What assimilation does to culture, colonization does to political and economic power. Through the process of colonization, Native American people became second-class citizens and lost control of their land and other sources of wealth. The result of this process is seen in the financial poverty of Native American people. In 1999, for example, American Indian/Alaska Natives had the highest poverty rate of any ethnic group in the United States. Whereas 7% of non-Hispanic Whites lived with incomes below the federal poverty threshold, 25.9% of Native American people lived in poverty. Thus, in this country, Native American people have *over three times* the risk of poverty of the White majority (U.S. Census Bureau, 2000). Native American elders experience even higher rates of poverty. The Indian Health Service (IHS) reported that 31.6% of Native American elders had incomes below the poverty threshold, compared with 9.8% of Whites ages 60 or older (IHS, 1996).

The association between poverty and ill health is evident in the health and functional status of Native American elders. Assessments of functional status and need for long-term care consistently suggest that Native American elders suffer from more activity limitations than the general population (McFall, Solomon, & Smith, 2000). For example, Bane (1991) reported that “Native Americans experience the same limitations in their activities of daily living at age 45 as do non-Indian people at age 65” (p. 64).

In addition to greater functional impairments, Native American peoples experience high rates of many diseases. These include phenomenal rates of diabetes, with experts suggesting a prevalence of 40–50% among Native American adults (Roubideaux, 2002). Indeed, the Pima tribe in Arizona reports the highest recorded prevalence of diabetes in the world (Acton et al., 2002). This finding led one IHS doctor to remark, “I was often surprised to see a patient *without* diabetes” (italics added, Roubideaux, p. 1401). Native American peoples are more likely than others to die of tuberculosis, influenza, and pneumonia (Harris, 2002).

In addition to health problems, practitioners who work with Native American peoples see the legacy of forced assimilation and colonization in the behavioral and emotional problems they confront each day. In 1992, Maxwell and Maxwell conducted an ethnographic study of elder abuse on two reservations. The reservation with the highest rate of poverty and isolation also had the highest rate of elder abuse. Their findings underscored the role of social conditions in producing what some perceive as individual dysfunction. As they explained, “We attribute differences in prevalence of mistreatment of elders to variations in economic opportunities for younger residents” (1992, p. 3). Like the tribal respondents they interviewed, these researchers concluded that mistreatment of elders was the explosive result of perceived powerlessness, “a dysfunction in community health” (p. 3). As two leading Native American scholars write:

Historical trauma refers to cumulative wounding across generations as well as during one’s current life span. For Native people, the legacy of genocide includes distortions of Native American identity, self-concept and values. The process of colonization and varying degrees of assimilation into the dominant cultural value system have resulted in altered states of an Indian sense of self. (Weaver & Brave Heart, 1999, p. 22)

Similarly, Yellow Bird (2001b) argued that:

Today, more than ever, I am convinced that the disproportionate amount of substance abuse, family violence, and suffering within First Nations communities is a result of the continuing effects of European American colonialism. First Nations Peoples are the survivors of a massive and prolonged campaign of racial and cultural terrorism perpetuated by the United States of America. (p. 2)

A young person’s history is an old person’s lived experience. Many of today’s elders had direct experience in boarding schools and White foster homes. They carry the memory of having their mouths washed out with soap for speaking a language some considered “primitive.” Many have had to relearn their cultural practices late in life because they were unable to do so as children. Still others have had to learn to parent, having spent years moving from foster home to foster home. So Native American elders are especially sensi-

tive to the effects of historical trauma, and those who work with them must be, as well.

STRATEGIES TO SUPPORT AND EMPOWER NATIVE AMERICAN ELDERS

Observing that interventions designed to reduce elder abuse by treating individuals have proven ineffective, Maxwell and Maxwell (1992) argued for the potential efficacy of community-based interventions. They acknowledged that we tend to “slight trauma suffered by the community as a whole” and noted that “police do not arrest ‘conditions,’ they arrest someone naïve or unlucky enough to have drawn attention to himself by doing something disapproved of” (1992, p. 20). Further, interventions that target social conditions risk alienating those currently privileged as they inevitably require the reallocation of resources. Nonetheless, there are several promising community-based interventions.

Some interventions address the health needs of Native American peoples. The Indian Self-Determination and Educational Assistance Act of 1975 set the stage for tribes to manage health programs that had been under the Indian Health Service. Many tribes have taken advantage of this opportunity, and Yvette Roubideaux (2002) reported that “approximately half of the IHS budget is now managed by tribes” (p. 1402). Recognizing the growing need for long-term care, several tribes have, both in collaboration with the Indian Health Service and on their own, established nursing homes and home-health agencies on their reservations. Noting that “most elderly Indians who require nursing home care must leave the reservation and their families” (p. 181), Susan Mercer (1996) described the culturally sensitive care provided by a nursing home operated by the Navajo nation with primarily Navajo staff. Similar care is provided by the Navajo Area Home Health Agency (McCabe, 1988). The Alaska Native Women’s Wellness Project has successfully increased cancer prevention screening rates among Native American elders in its catchment area through respect for the individual and her culture (Stillwater, 1999). Napoli & Gonzalez-Santin (2001) described an intensive home-based wellness service based on Native American values that was developed for families living on reservations.

To address the weakening of intergenerational bonds, activists in New York established ELDERS (Encouraging Leaders Dedicated to Enriching Respect and Spirituality), a week-long gathering at

which elders teach youths the traditional ways of the Iroquois. Although primarily intended as a substance-abuse-prevention program for youths, this effort has the secondary benefit of offering meaningful activity and connection to local elders (Skye, 2002).

Language revival and restoration efforts have the dual benefits of salvaging language and empowering elders. The 1990 Native American Languages Act (PL 101-477) reflected the discovery that hundreds of native languages in this country were endangered. That is, they were spoken by only a handful of elders. Linguists have pointed out the importance of language diversity, not only for minority language speakers themselves but also for the nation as a whole, noting that “language loss is part of a much larger process of loss of cultural and intellectual diversity in which politically dominant languages and cultures simply overwhelm Native American local ones” (Linn et al., 1998, p. 63).

Several community-based interventions have been initiated to salvage the nation’s Native American languages. Christine Sims (1998) described one such intervention, designed to preserve and restore the native language of the Karuk tribe in northern California. Using tribal funds, a language-immersion camp was offered in 1992 for children, parents, and fluent-speaking elders. Both overnight and day-camp experiences were offered in which children learned the language of their elders in highly structured sessions. Sims reported that “language support and interaction that elders provide is a key element” of the program, establishing “the crucial intergenerational linkages necessary for language vitality” (1998, pp. 103–104). The tribe also established “master-apprentice language teams,” who devote at least 20 hours each week to language learning. Language interventions such as these not only help to restore cultural diversity to the United States but also add meaning and power to the lives of Native American elders.

THE NEED FOR NATIVE AMERICAN PRACTITIONERS

Although laudable, current efforts to develop cultural competency do not meet the needs of Native American elders in ways that are personally satisfying and culturally appropriate. Certainly, the White practitioner needs cultural knowledge and skills to even begin to provide support to a Native American elder, and certainly that support will be better than nothing.

But it would be more effective and more efficient to recruit and train Native American practitioners.

It is almost comic to consider advice that has been given to White practitioners (and researchers) seeking to work with Native American elders. For example, Ferraro (2001) identified “hurdles” faced by researchers seeking to collect information on elders in “Indian Country.” The first such hurdle “is gaining the trust of the native elder to actually want to participate in your study” (p. 314). He suggests that a “gift of tobacco” might be offered and warns the potential researcher that “in some Native cultures it is considered disrespectful to look someone in the eyes.” Similarly, McDonald, Morton, and Stewart (1992) offered suggestions for clinical practice with Native American peoples. The first piece of advice, “Begin and end each session with a handshake,” will poorly serve a practitioner working with the Navajo, for example, for whom such physical contact can be uncomfortable.

Indeed, most tribal people do not use the handshake as a greeting. It was thought (and still is to some extent) that in a handshake the other person might be trying to steal your soul and your energies. One didn’t know if that person was friend or foe, especially in the case of the White man. So physical contact involved risk of loss. The same thing applies, although to a lesser extent, to the reluctance to engage in eye contact with an unfamiliar person. That person could be an enemy or, as in Navajo stories, a witch capable of cursing you with her eyes.

CONCLUSION

Today’s Native American elders experience the consequences of yesterday’s efforts to eradicate Native American cultures (assimilation) and appropriate the resources of Native American peoples (colonization). They were victimized by policies that have since been abandoned: boarding schools, adoption by Whites, and language suppression. Many live in harsh and impoverished conditions—the direct result of colonization. A few are neglected and abused by family members.

Recognition of these devastating experiences yields a difficult conclusion: non-Native American practitioners working by themselves may not effectively meet the needs of Native American elders. Asking an elder to “trust” a White person who offers a gift of tobacco and a hearty handshake adds insult to injury. Native American elders deserve to receive care

from someone who does not remind them of past humiliations.

There is a crying need for Native American practitioners from all professions (doctors, teachers, social workers, counselors, rehabilitation specialists, administrators) to serve elders in rural areas. The Census Bureau figured this out when in a masterful stroke it hired Native American staff to count the nation’s Native American people. Non-Native American practitioners by themselves should be considered a second choice for direct service (on the dubious principle that “something is better than nothing”). First choice would be a well-trained, highly skilled Native American practitioner.

We also note the limited impact of interventions that punish individual perpetrators and recommend expansion of community-based programs designed to empower elders and enhance the quality of their lives. No doubt, the interested reader will add to our list of examples, which includes health services for Native American elders, as well as language restoration efforts in which the elders play a pivotal role. At the policy level, it is way past time for federal, state, and local governments to defer to tribal authority on matters affecting Native American peoples.

Older Adults in Other Minority Groups

25

Members of minority groups share a common identity and collectively experience subordination relative to the dominant culture. We typically define minority groups according to such criteria as race, gender, ethnicity, religion, and national origin in the United States. Previous chapters have addressed the most common minority groups based on race, gender, ethnicity, and sexual orientation. This chapter focuses on older adults from “other minority groups,” specifically those from marginal religions and regions. Our intent is to raise social workers’ awareness and understanding of these other older minority persons, highlight salient issues that social workers must address with these older adults, and introduce innovative interventions. First, we discuss older adults from Jewish and Muslim religions, and, second, we consider older Appalachians and Pacific Islanders.

RELIGION AND OLDER PERSONS

Religion is a central issue for many older persons (Kosmin & Mayer, 2001a). It provides people with meaning, support, and guidance in their daily lives, in their jobs, and in their relationships with family members, friends, and colleagues. Kosmin and Mayer (2001a) found that whereas 47% of adults over the age of 65 described themselves as religious, only 27% of younger adults described themselves this way. Although national census guidelines preclude gathering information on Americans’ religious preferences and characteristics, other organizations and research centers have conducted surveys that shed light on people’s religious affiliations. The American Religious Identification Survey (ARIS) included a random-digit-dialing telephone survey of more than 50,000 Americans in 2001. The survey revealed that although most Americans identify with the Christian religions, people represent diverse faiths in this country. In addition, people within these religious groups vary in their worldviews and religious beliefs. The Jewish and Muslim populations are especially diverse; they include individuals from different countries and various ethnic backgrounds.

JEWISH OLDER ADULTS

Demographics

The American Jewish population numbers about 5.3 million adults, including Holocaust survivors, Jews

from the former Soviet Union who recently immigrated to the United States, and those unaffiliated with Jewish organizations (Harel, 2001). Most older Jewish persons are U.S.-born, whereas others are first- or second-generation immigrants (Harel, 2001). About one-half of the Jewish population identifies with Judaism as a religion, whereas about 20% associate with no religion, and another 20% affiliate with a religion other than Judaism (Kosmin & Mayer, 2001a; United Jewish Communities, 2004).

The American Jewish population is older than the non-Jewish population in the United States; between 19 and 25% of the Jewish population is over the age of 65 (Kosmin & Mayer, 2001a; United Jewish Communities, 2004). Whereas the median age of the U.S. population in 2000 was 35, the median age of the Jewish population was 42.

Physical and Mental Health

Most older Jewish persons are in good health, but they are more likely than younger Jewish persons to report poor or fair health, to have lower incomes, and to live alone. Compared with younger Jewish persons, older Jewish adults more often participate in their Jewish communities. They more closely identify with their Jewish heritage and tend to have more Jewish friends, to feel more emotionally attached to Israel, and to more frequently regard being Jewish as being important than their younger counterparts (United Jewish Communities, 2004).

Elderly Soviet Jews, many of whom are non-English speaking, minimally acculturated, and without adequate economic support, are especially vulnerable and in need of social work services (United Jewish Communities, 2004). In addition, depression is more common among Russian Jews than among those born in the United States (Harel, 2001; Fitzpatrick, 2000). Older Holocaust survivors also require special attention. They have experienced anti-Semitism throughout their lives and often have lingering trauma, resulting in intrusive thoughts, associated with their Holocaust experiences (Harel, 2001).

Cultural Values and Social Work Interventions

Many organizations provide counseling and support to older Jewish persons, although this varies by region. These organizations include the Jewish Associ-

ation for Services for the Aged in New York (<http://www.jasa.org>), the Council for the Jewish Elderly in Chicago (<http://www.cje.net>), and the Jewish Council for the Aging in Washington, DC (<http://www.jcagw.org>), along with Jewish agencies in urban communities such as Jewish Family Services, Jewish Community Centers, and Jewish Homes for the Aged, which are excellent resources for these older adults. These programs offer adult day programs and other respite services for caregivers, congregate meal sites and meals-on-wheels programs (including hot kosher meals), various group programs, and home- and community-based services that can help older Jewish persons who want more support. Most agencies offer mental health services, including in-home assessments and interventions. Some, such as the Council for Jewish Elderly, provide Holocaust community services for aging survivors of Nazi persecution. Several national organizations, such as United Jewish Communities, actively advocate for national, state, and local aging policies and services.

As social workers increase their knowledge and appreciation of older Jewish adults and engage in culturally competent practice, they will more effectively help these older minority persons get the services they need. Cultural competence involves several components, including (1) knowledge and skills that are compatible with culturally diverse populations; (2) attitudes and values that honor diversity; and (3) a dual focus on the responsibilities of the provider and the institution to improve practice, policy, and research related to the culturally diverse (Lum, 1999; Mokuau, 1999). The Office of Minority Health (2001) has published standards for cultural and linguistic competence that emphasize culturally competent care (i.e., showing respectful care of diverse clients), language access services (i.e., providing bilingual staff) and organizational supports (i.e., maintaining demographic, cultural, and epidemiological profiles of the community; Office of Minority Health, 2001). Literature related to cultural competence and older populations, although severely limited, nonetheless supports these general concepts (Caplan, Wells & Haynes, 1992; Delgado & Tennstedt, 1997; Kosloski, Montgomery, & Karner, 1999).

The strengths perspective, as conceptualized by Saleebey (1997), is another useful approach that social workers can successfully use with older minority persons. This perspective emphasizes clients' assets, such as their talents, knowledge, capabilities, and strengths. When social workers combine the strengths perspective with culturally competent practice, they will be

more successful in empowering and fostering the resiliency of these older clients.

MUSLIM OLDER ADULTS

Demographics

Less than 1% of adults (between 2 and 5 million adults) identify themselves with the Muslim/Islamic religion in the United States; however, it is likely that this fact may be underestimated due to older Muslims' reluctance to respond to questions about their religion (Bukhari, 2003; Kosmin & Mayer, 2001a). The majority of Arab Americans are not Muslims, and the majority of Muslims are not Arab Americans (Kosmin & Mayer, 2001b). The Muslim population is similarly ethnically diverse, including about 20% who are from African American backgrounds, 26% who are Arabs, and 32% who are South Asians (Bukhari, 2003). About 17% have emigrated from Pakistan (Bukhari, 2003). Muslims over the age of 65 represent about 7% of the U.S. Muslim population, although these estimates vary depending on the sample and the survey used (Bukhari, 2003). Older Muslim adults reside in many cities, but especially in New York, Chicago, Los Angeles, and Detroit.

Samana Siddiqui, a Muslim social worker from Canada, describes three groups of older Muslims. The first group includes individuals who immigrated to the United States at the turn of the century and lived with younger family members. Intergenerational differences sometimes arise in these families. The second group is the parents of younger family members who accompanied them to America during the 1960s and 1970s. The third and smallest group, the most socially isolated older Muslims, are persons who have converted to Islam. Most older persons reside with younger relatives, but some live alone (Siddiqui, 1999).

Physical and Mental Health

Although Sengstock (1996) found few complaints in her study of older Muslims, some did need help with transportation, caregiving, and medical assistance. Others needed assistance with cooking, grocery shopping, taking medications, and socializing with others, whereas a few required help with self-care. Following the events of September 11, 2001, Muslims have experienced increased apprehension from other Ameri-

cans. Muslims who dress in their traditional garments or speak English with a foreign accent are harassed more often than older Muslim adults who conceal their cultural or ethnic identities (Salari, 2002). Social workers must advocate against such hostility and discriminatory practices and educate others about Muslims to eradicate stereotypical attitudes. Social workers should conduct needs assessments of older Muslims' physical and mental health to more effectively target services to these older adults.

Cultural Values and Social Work Interventions

Helping others is central to Muslim daily life. The help is usually informal and family based, but increasing numbers of social service agencies, such as Muslim Family Services, are emerging. According to Siddiqui (1999), many older Muslim families eschew formal help because of the stigma associated with seeking professional guidance, but social workers who practice culturally sensitive approaches with Muslim traditions and rituals will appeal more to older Muslims. In addition, many older Muslim persons feel more comfortable talking to social workers who share the same religious background. Social workers who partner with the natural, informal support systems in Muslim communities also will lessen the stigma many older Muslims associate with seeking formal help.

The oldest and largest Muslim social service agency is the Arab Community Center for Economic and Social Services, in Dearborn, Michigan, created in the mid-1970s, but smaller organizations are also emerging. These programs are usually organized around participants' ethnic and religious values and provide assistance to individuals in need of food, clothing, and/or money (Nimer, 2003). Social workers will more successfully consider older Muslims' ethnic and religious preferences when they collaborate with these agencies.

REGIONAL MINORITIES

Some older adults become members of other minority groups as a result of living in certain areas, such as in Appalachia or as indigenous peoples from the Pacific Islands. Older persons from Appalachia and the Pacific Islands maintain distinct social and economic characteristics and need support in various ways.

Appalachian Older Persons

Demographics

The Appalachian Mountains are a major mountain chain in the northeastern United States, covering 1,500 miles of land from the Canadian province of Quebec to northern Alabama. It includes several sub-regions: (1) northern Appalachia, which comprises areas in New York, Pennsylvania, Maryland, Ohio and parts of West Virginia; (2) central Appalachia, which incorporates nine southern counties in West Virginia, all of Appalachian Kentucky, and parts of Virginia and Tennessee; and (3) southern Appalachia, which encompasses areas in Virginia, Tennessee, the Carolinas, Georgia, Alabama, and Mississippi (Appalachian Regional Commission [ARC], 1974; see also <http://www.arc.gov>).

Although the Appalachian region is a diverse area, in 1964 the President's Appalachian Regional Commission concluded that the people who lived there demonstrated distinct social and economic characteristics (Pollard, 2003). The percentage of older persons in Appalachia, most of whom have resided in the region since birth, is higher and growing faster than in the rest of the country.

About 14.3%, or 3.3 million, older persons live in Appalachia, in contrast to 12.4%, or 35 million, in the rest of the country, and the highest percentage of older adults (16%) resides in the northern areas, in portions of Pennsylvania, eastern Ohio, and northern and eastern West Virginia. The percentage of older Appalachian adults will remain higher than that of the general population in the future (U.S. Census Bureau, 2000). Although the number of people over the age of 65 in the U.S. population is expected to reach 18.2%, or 63.5 million, in 2025, the percentage among similarly aged Appalachians should rise to 19.8%, or 5.1 million. The number of older persons over the age of 85 in this region will remain about the same as the rest of the population in 2025; about 1.7% and 1.5%, respectively (U.S. Census Bureau, 2003a).

The aging Appalachian population resembles national trends, but whereas many Americans' life expectancies have increased, they have remained the same in Appalachia. The demographic shifts in Appalachia are due mostly to emigration of young adults seeking jobs outside of Appalachia because of unemployment and other economic pressures. Few older persons, especially those in poor health, leave the area, in part because they maintain stronger attachments to the land and their communities than do

younger persons (Dorfman, Murty, Evans, Ingram, & Power, 2004).

Despite these lifelong connections, many older persons, especially older women, live alone in Appalachia. About 40% of older Appalachian women maintained single households in 2000, compared with about 36% of women over the age of 65 in the total population. Only about 18% of older Appalachian men lived alone, which is only slightly higher (17%) than the percentage in the rest of the country.

Many older Appalachian women who live alone also struggle with poverty. Whereas the poverty rate for women over the age of 65 in the general population is 20%, among similarly aged Appalachian women, it is 27.5%. Among older men, the percentages are 15% and 24%, respectively. More than a quarter of older Appalachian persons living alone are economically impoverished, in contrast to about one-fifth of older women and about one-tenth of older men in the rest of the United States.

Physical and Mental Health

Older Appalachian persons, especially Appalachian women, have high disability rates, as measured by their abilities to perform activities of daily living and instrumental activities of daily living. For example, compared with non-Appalachian women and men over the age of 85, who had disability rates at about 78% and 67%, respectively, the rates for similarly aged Appalachian persons located in eastern Kentucky were 81% for women and 91% for men (Haaga, 2004).

Lack of access to preventative care is one reason these disability rates are so high (Wilcox, Bopp, Oberrecht, Kammermann, & McElmurray, 2003). Many older persons live at great distances from hospitals and other clinics, and transportation to these places is often difficult. Another problem results from the decline in informal supports as increasing numbers of younger persons relocate. Traditionally, older Appalachian adults have relied on friends and family members to assist them in their later years, but when family members leave, many older persons become socially isolated (McCulloch, 1995). Gerontological social workers will become increasingly needed as these trends continue.

Although many researchers have investigated the physical health problems of Appalachians, few have studied their mental health. Susan Keefe, who published *Appalachian Mental Health* in 1988, found that many women, especially older women, sought treat-

ment for their “nerves” (Keefe, 1988), for which physicians frequently prescribed “nerve pills,” that is, Valium and other tranquilizers. Keefe (1988) observed that many Appalachian women felt stressed from constantly struggling to make ends meet.

Cultural Values and Social Work Interventions

Older Appalachians share many common values and lifestyles despite some cultural variations across the subregions (Pollard, 2003). For example, most older Appalachians maintain strong religious beliefs and emphasize self-reliance and hard work (Dorfman et al., 2004). Older Appalachian women are remarkably resilient and thrive on their friendships, which they value and nurture. Mutual self-help groups are especially efficacious in these settings. For example, McInnis-Dittrich (1997) organized an innovative program, referred to as “The Women’s Club,” based on these older women’s natural support systems.

The integration of social and medical services is especially crucial when assisting older clients, including Appalachian older persons, whose mental and physical conditions often interact (see Wilcox et al., 2003). Ritchie and colleagues (2002) found that case management teams composed of nurses and social workers that visited older persons in their homes, used state-of-the-art, standardized assessments, and implemented patient-specific care plans successfully enhanced older Appalachians’ mental and physical functioning. Keefe (1988) offers several suggestions for mental health professionals working in Appalachia. They include: increasing public awareness of mental health services; locating mental health agencies in accessible areas; adopting flexible services to accommodate low-income persons; involving Appalachians in the mental health system; familiarizing professionals with Appalachian culture; incorporating a family perspective; and encouraging more mental health research in Appalachia that will reveal the most effective interventions for these individuals and their families.

Advocacy is also important when assisting older Appalachian persons. Social workers must advocate for older Appalachians in several areas, but the most important involve: (1) increasing their economic resources, given the high rate of poverty among older persons in Appalachia; (2) expanding their physical and mental health care, which is often fragmented and difficult for many older Appalachian adults to access; (3) strengthening their social resources, especially for the most socially isolated older adults; and

(4) improving their transportation and other community services assistance for those who live alone and at great distances from services.

The 2002 reauthorization of the Appalachian Regional Development Act of 1965, which created the ARC, mandates increased funds for partnerships committed to improving Appalachian persons’ lives. These partnerships should include teams of social workers and other health professionals that reach out to the most impoverished and vulnerable older adults. Although older Appalachian elderly persons share a common region, they represent diverse cultural, racial, and religious perspectives. Social workers should tailor interventions by conducting comprehensive, holistic assessments that consider these older clients’ biological, psychological, social, and environmental influences and by implementing treatments that are sensitive to older Appalachians’ cultural and religious preferences and practices. Social workers will avoid stereotyping these older clients and more successfully address their concerns when they use culturally competent biopsychosocial interventions.

Older Native Hawaiian and Pacific Islanders

Demographics

The term *Pacific Islander* refers to those individuals whose origins are from the indigenous or original people of Hawai’i, Guam, Samoa, or other Pacific Islands (U.S. Census Bureau, 2003b). Native Hawaiian and Pacific Islanders (NHPI) make up 0.3% of the total population, which represents 874,414 persons, and only 5% of this population includes people over the age of 65, according to the 2000 U.S. Census reports. The NHPI are a relative young population, with a median age of 35.2 (U.S. Census Bureau, 2000). Nearly three-fourths of the NHPI residing in the United States and its territories live in the western states, and more than half live in two states—California and Hawai’i. Ten states—California, Hawai’i, Washington, Texas, New York, Florida, Utah, Nevada, Oregon, and Arizona—account for 80% of the nation’s NHPI population.

Native Hawaiians are the largest NHPI group, including 401,000 persons, or 46% of the NHPI population. This group consists of 141,000 respondents who report being Native Hawaiian and another 261,000 who report being Native Hawaiian and at least one other race. Five percent of these persons are

over the age of 65. The next two largest groups are Samoans (either alone or in combination with other races), comprising 133,000 people and making up 15% of the NHPI population, and Guamanian/Chamorro (either alone or in combination), consisting of 93,000 persons, or 11% of the population. Five percent of the Samoans and 2% of Guamanian/Chamorro include people over the age of 65. Twenty percent of NHPI did not report belonging to a cultural group but identified themselves as “Pacific Islander.” For various historical reasons, these NHPI had a much higher proportion of respondents who reported two or more races (U.S. Census Bureau, 2001). Native Hawaiians, Samoans, and Guamanian/Chamorro Pacific Islanders accounted for 74% of all respondents who reported a single Pacific Islander group and 71% who identified as Pacific Islander with race combinations (U.S. Census Bureau, 2001).

Older NHPI differ from the overall older adult population in the United States in several other ways. For example, the median household income and the per capita incomes for older NHPI are significantly lower than the incomes of older U.S. residents in general, although nearly the same proportion (10%) of NHPI and U.S. elders lives in poverty. Nearly 30% of NHPI elders do not list English as their first language, and 28% of these older persons report not speaking English fluently or at all. In contrast, less than 1% of U.S. elders state that English is not their first language, with only 12.4% of this group reporting that they don’t speak English fluently or at all. Additionally, NHPI elders rarely live alone compared with U.S. elders. The average household and family sizes are larger among NHPI than among Americans. In addition, contrary to popular opinion, NHPI families are less likely than the general population to live in rural areas (U.S. Census Bureau, 2004).

Older Pacific Islanders are composed of many cultures, including Polynesians (e.g., Hawaiians, Samoans, and Tongans), Micronesians (e.g., Chamorros, the indigenous people of Guam, and other groups), and Melanesians (e.g., Fijians). Each group represents a unique culture with distinct languages, values, lifestyles, histories, and patterns of adaptation to the United States (Srinivisan & Guillermo, 2000).

The heterogeneity among Asian Americans and Pacific Islanders in culture, language, and origin is one reason the U.S. Census separated Asian Americans (AA) from Native Hawaiians and other Pacific Islanders (NHPI) and created two distinctive racial categories (U.S. Census Bureau, 2001). The aggregated data tended to mask rather than illuminate the

mental and physical health issues in the Pacific Islander population (Srinivisan & Guillermo, 2000).

Physical and Mental Health

Although the leading causes of death for NHPI mirror those of other Americans—heart disease, stroke, and cancer—Native Hawaiians have one of the nation’s shortest life expectancies and have significantly higher death rates for these three diseases. A number of researchers have linked increased morbidity and mortality from chronic diseases among NHPI to the changes in lifestyle in the past century. Contrary to the traditional Pacific Islander diet of low-fat, high-fiber foods and active lifestyles, today’s NHPI have adopted a Western diet high in fats and refined foods and a sedentary lifestyle (Englberger, Marks, & Fitzgerald, 2003; Hezel, 2001). Others have attributed their poorer health to forced colonization of Pacific Islanders that robbed them of their land and spirituality and left them with high rates of poverty (Bushnell, 1993; Mokuau, 1996).

Pacific Islanders also are at greater risk for mental health problems than Whites, due to stressors such as immigration, adjustment to living in an alien culture, discrimination and prejudice, language barriers, economics, and educational and occupational stresses and diseases (U.S. Department of Health and Human Services, 2001). Many NHPI feel socially alienated and disenfranchised as a result of internalizing discrimination and others’ prejudiced attitudes toward them (Lee & Mokuau, 2002). NHPI also exhibit more psychological symptoms than the overall population, although few researchers have examined the mental health issues in this population (Prizzia & Mokuau, 1991).

Cultural Values and Social Work Interventions

Many social and historical factors have adversely affected NHPI mental and physical health (Braun, Yee, Browne, & Mokuau, 2004). These include international trade, military strategies, missionary influences, and the loss of sovereignty that were imposed on NHPIs and resulted in the replacement of local traditions and rituals with Western norms and practices (Bushnell, 1993; Braun et al., 1995; Mokuau, 1996). Other forces, such as diseases, migrations, economic ruins, and intermarriages between NHPI and non-NHPI have exacerbated these trends. Cultural values and social structures also contribute to many health disparities among NHPI and to problems they

have accessing and participating in various social services (Brach & Fraser, 2000).

Older NHPI are, however, resilient, and like many older minority persons, they have much strength that has sustained them during difficult times. For example, the majority of NHPI maintain strong spiritual beliefs, believe in holism, and revere nature and spiritual realism. They tend to value mutuality in relationships and the collective over individual needs (Mokuau & Tauili'i, 1998; Palafox & Warren, 1980). In addition, most NHPI, especially Native Hawaiians, Samoans, and Chamorros, believe in reciprocity and helpfulness (Alailima, 1996; Torsch & Ma, 2000; Mokuau & Tauili'i, 1998). Similar to many traditional cultures, NHPI also respect and admire elders for their strength, wisdom, and courage. They appreciate their older adults' skills as arbitrators and the knowledge they share with younger generations (Harden, 1999; Mokuau & Browne, 1994; Mokuau, Browne, & Braun, 1998). Despite varying levels of acculturation, many older NHPI maintain leadership roles in their families, churches, and communities. However, elders' roles and status in their families are undermined when poverty, discrimination, and poor health persist in their communities.

Like most older persons, NHPI adults struggle with rising health care costs, but they must also confront many culturally specific issues and barriers in the medical system. For example, NHPI elders have one of the shorter life expectancies compared with all other ethnic minority populations, and many struggle with English as a second language (Braun et al., 2004; Braun, Takamura, Forman, Sasaki, & Meininger, 1995; Braun & Browne, 1998). Social workers will appeal to more older NHPI by learning more about these problems. In addition, social workers must educate themselves about the cultural values and history of various Pacific Islanders and the relevance of these values and history to their health and social service utilization. Social workers who understand the association between NHPI's own illness and health to spiritual balance might collaborate with spiritual and traditional healers and use more holistic interventions when working with these older persons (Braun et al., 2004). Equally important is the need for social workers to empower NHPI elders by teaching them coping strategies, interacting with their extended families, linking them to appropriate services that counter and alleviate the adverse effects of poverty and poor health, advocating on their behalf in various contexts and situations, and enforcing non-hierarchical interactions, which is especially impor-

tant in creating an alliance with NHPI clients who have had long histories of oppression and unwelcomed interventions.

The anticipated growth rate of older persons from these and other minority populations underscores the need for more widespread social work training in the strengths perspective and in culturally competent practice that takes into account older minority persons' diverse resources and challenges. These demographic trends also support the need for more research about culturally competent interventions to guide practice and policy making. Social workers will encounter increasingly more older persons from various religions and residences, as older cohorts become increasingly heterogeneous. As social workers, our commitment must be steadfast in ensuring that all older persons receive quality care and services.

**Social Work Practice in Palliative
and End-of-Life Care**

This page intentionally left blank

OVERVIEW

The importance of the social worker's role in providing palliative and end-of-life care is well established. Social workers are uniquely qualified to work with clients and their families and caregivers in this field because of the profession's focus on psychosocial issues, group and individual work, advocacy, and linkages with the community. The following chapters, by Gutheil and Souza and Howe and Daratsos, examine social work's expanding involvement in providing end-of-life care in terms of settings, roles, skills, assessment, resources, legal issues, and bereavement support.

A discussion of the social worker's role in end-of-life care for older adults is complex. Longer life expectancy has led to a widening age range for older persons, with increased diversity and more chronic and life-limiting illnesses. Greater use of technology in health care has resulted in persons living longer with more disabilities and illnesses, sometimes resulting in longer and more complicated death trajectories. Thus advance care planning takes on major importance, with an imperative for social workers to provide education and counseling about advance directives with clients and their families before a health crisis strikes.

Social workers carry out multiple roles in palliative and end-of-life care, optimally within the context of the interdisciplinary team. These roles include, but are not limited to, administration, liaison, advocacy, clinical assessment, counseling, education, and research. Psychosocial assessment is particularly complex and crucial for clients facing life-limiting illnesses. For the dying person, psychosocial and spiritual issues are as important as physiological ones, and the social worker, representing the personal and social concerns of the dying person and family, plays a critically important role at this time. The social worker serves as the patient advocate and is often the person on the team who can help facilitate the patient's wishes and articulate them to the team. Furthermore, social workers understand the cultural issues for dying persons and their families and can facilitate recognition and incorporation of customs and

traditions surrounding death in the setting. The social worker is a resource to other members of the interdisciplinary health care team because of the profession's focus on the emotional and social aspects of care and human need. Finally, social workers are principal providers of bereavement and grief counseling, and we recognize that this is an area that needs further expansion.

In summary, the social work contribution to palliative and end-of-life care is a significant one and includes domains ranging from interdisciplinary team member to assessor to grief counselor to advocate to educator to administrator. As we look to the future, the role of social work in end-of-life and palliative care will be increasingly articulated and recognized, as has already occurred in the professions of nursing and medicine. The Social Work Summit on End-of-Life and Palliative Care held in 2002 helped to shape an agenda, and other professional activities are under way to develop competencies and information exchange among social workers in end-of-life care. For instance, the National Association of Social Workers recently issued *Standards for Social Work Practice in Palliative and End of Life Care*, based on the work of the Social Work Summit that brought together social work leaders and social work organizations in this field. These standards are geared to enhancing social workers' awareness of the skills, knowledge, methods, and attitudes necessary to effectively work with clients and their families (see the website www.socialworkers.org). Social work-based initiatives such as this are welcome and call for the inclusion of social workers in a range of practice settings given the broad impact and importance of palliative and end-of-life care. In addition, social workers must be included and must provide leadership in interdisciplinary training programs and initiatives. The Veterans Health Affairs Interprofessional Palliative Care Fellowship Program is one such example. It trains promising individuals during a 1-year fellowship in a range of disciplines, including master's-prepared social workers, to be future leaders in palliative and end-of-life care. Initiatives such as this put social work right in the middle of the interdisciplinary mix of palliative and end-of-life care, where it should be.

CONTEXT OF PALLIATIVE AND END-OF-LIFE CARE AND ROLE OF SOCIAL WORK PRACTICE

In recent years, there has been a movement to increase the availability of palliative and end-of-life care for patients and families. This is due in part to foundation and government support, media attention, and significantly increasing public and professional demand for more compassionate and appropriate care for those with life-limiting illnesses. Indicative of this groundswell was the Social Work Summit on End-of-Life and Palliative Care held in March 2002, aimed at developing a national consortium of social work leaders and organizations to shape an agenda for social work and end-of-life care and develop programs in practice, education, and research (Christ, 2002).

Social work is an essential and significant part of palliative and end-of-life practice. Whereas not all social workers practice in settings devoted to palliative or end-of-life care, all social workers will probably work with clients who are themselves experiencing or who have loved ones who are experiencing life-threatening illnesses, as well as people who are grieving (Kramer, 1998, 2002). Competent care for those facing life-threatening, serious illness is recognized to be multifaceted and holistic. By its nature, palliative care is an interdisciplinary area of practice, and hence the psychosocial domains of a client's well-being must be addressed in a comprehensive manner (National Consensus Project for Quality Palliative Care, 2004). As noted by Steinhauser and colleagues, "whereas physicians tend to focus on physical aspects, patients and families tend to view the end of life with a broader psychosocial and spiritual meaning, shaped by a lifetime of experiences" (Steinhauser et al., 2000). The social worker is often the key individual assisting patients, families, and caregivers in addressing the emotional, psychological, social, spiritual, cultural, financial, and environmental aspects of care.

The interdisciplinary team is the cornerstone of palliative care, and the social worker is a principal member of that team. For instance, the Veterans Health Administration (VHA; 2003) mandates that every VHA facility have a palliative care consult team (PCCT), at least 25% of whose members should be physicians, social workers, nurses, or chaplains, in addition to at least 25% administrative personnel (Veterans Health Administration, 2003). Social workers have specific roles and functions in working with clients, their families, and caregivers, requiring spe-

Roles of Social Workers in Palliative and End-of-Life Care

26

cific competencies in knowledge, skills, and attitudes. Palliative care social workers have a particularly important role in working with clients and families coping with impending loss of life, which is often experienced as yet another loss layered on a series of prior losses.

This chapter addresses the settings of care for social work practice in palliative care, the role of the social worker in delivering palliative care, the social worker's role in assessment and service provision, psychosocial and financial resources, cultural and spiritual issues, and bereavement support services.

SETTINGS OF CARE

Social workers practice in a range of settings in palliative and end-of-life care, including the hospital, nursing home, outpatient clinic or practice, hospice, and home. Although 90% of all individuals state their wish to die at home, in fact only about one in five individuals actually do. The National Mortality Follow-back Survey found that 56% die in the hospital, 19% in a nursing home, 21% at home, and 4% in other settings (National Center for Health Statistics, 2003).

Social workers are key individuals on the palliative care team in ensuring smooth transitions from setting to setting along the care continuum. Individuals with life-threatening illnesses may move frequently from setting to setting, and the social worker is often the team member who recognizes crisis points in the illness trajectory. These crisis points represent opportunities for effective social work intervention. Social workers are the team members with the expertise and training in community resources and referrals. They apply the tasks associated with discharge planning and merge that planning with their counseling skills to assist the individual and his support system in attaining the best available setting for palliative and end-of-life care.

Hospice may be defined as a model for quality and compassionate care for individuals facing a life-limiting illness. It involves a team approach to medical care, pain management, and emotional and spiritual support for patients, family, and caregivers. Hospice focuses on caring, not curing, and is usually provided in the patient's home, but it is also offered in other settings (see the National Hospice and Palliative Care website, <http://nhpco.org>). The holistic approach of hospice emphasizes social, psychological, and spiritual, as well as medical, needs. Medicare, which covers hospice care for those predicted to have less than 6

months to live, requires hospices to provide psychosocial and spiritual counseling services as a condition of participation. Many states have licensing or certification requirements as well, which reinforce this approach to hospice care. A recent study of state regulatory reports, however, found that often the role of social work was not adequately documented in assessment, care planning, bereavement, and interdisciplinary team meetings. The conclusion of this study was that social workers must improve their documentation to demonstrate their effectiveness as powerful team members in the hospice setting (Oliver, 2003).

Another recent study reports on the findings of a survey of members of the Association of Oncology Social Workers about the likelihood of social workers referring a terminally ill client to hospice. Although the social workers held very favorable attitudes toward hospice care, the average proportion of terminally ill clients whom they referred to hospice was just 49.5% (Becker, 2004). This finding suggests that social workers may need greater education about when a client is ready for hospice, better training to present the hospice option to patients and families, and the empowerment skills within the team setting to recommend that referral.

The recent *Clinical Practice Guidelines for Quality Palliative Care* note that palliative care is most effective when integrated into existing care settings, such as the hospital, nursing home, or home care. At the end of life, the proven model of care is hospice (National Consensus Project for Quality Palliative Care, 2004). The common organizational delivery models of palliative care, including hospice programs, are delineated in Table 26.1 (National Consensus Project for Quality Palliative Care, 2004).

Hospital

The hospital is frequently the host site for palliative and hospice care. There are a variety of models for care delivery, including freestanding hospice or supportive care units and palliative care consultation teams. Often, facilities have inpatient units, consultation teams, and outpatient clinics. These teams are charged with case-finding in the medical center to identify patients who require palliative and end-of-life care with the goal of making earlier referrals to hospices and decreasing the number of patients dying in the intensive care unit. The teams also facilitate development of goals for ongoing care. The social worker is an instrumental team member in ascertain-

Combined consultation team, inpatient unit, and outpatient clinic	Combined consultation team and inpatient unit	Hospice-based palliative care

ing when a transfer is appropriate for nonmedical reasons such as caregiver functioning and changes in the patient-family-caregiver triad.

Nursing Home

One in five Americans dies in a nursing home, with projections indicating that this number may increase to as much as 40% by the year 2030 (“Developing Quality Indicators,” 2000). For nursing home social workers, end-of-life care is an integral and day-to-day part of practice. Increasingly, nursing homes have palliative care teams, which include social workers.

Home/Outpatient Practice or Clinic

The outpatient practice or clinic serves two purposes for palliative care patients. For patients whose palliative care needs are just beginning to be identified, the clinic functions as a transitional care setting in which symptoms can be managed and recommendations for more intensive interventions can be identified and arranged. In the second instance, the outpatient setting will function as the provider of record for patients receiving hospice care at home. In this case, the outpatient clinic team works collaboratively with the hospice team to care for patients with minimal travel to and from the clinic. This is an advantageous arrangement because it allows the patients to have their care managed by their providers of choice and, at the same time, it integrates the expertise of the hospice team.

THE ROLE OF THE SOCIAL WORKER AND SCOPE OF PRACTICE

Quality of care at the end of life is highly individual and should be achieved through a process of shared

decision making and clear communication that acknowledges the values and preferences of patients, caregivers, and families. In an interdisciplinary team, social workers, chaplains, and others can aid with resolving psychosocial end-of-life issues (Steinhauser et al., 2000).

Social workers carry out multiple roles in palliative and end-of-life care, often in the context of the interdisciplinary team. These roles include:

- *Clinician.* The social worker provides the counseling to patients and families to help them cope with the changes in physical, cognitive, and emotional functioning and to cope with the anticipated death.
- *Educator.* The social worker, with an interdisciplinary educational foundation, can play a significant role in curriculum development and teaching in end-of-life and palliative care. There are increasing opportunities for leadership in this area with the emergence of advanced training programs. (See the websites <http://www.smith.edu/ssw/index1.htm>, <http://www.nyu.edu/socialwork/>, <http://www.va.gov/oaafellowships/palliative.asp>.)
- *Researcher.* The social worker can, and should, take the lead in palliative care and end-of-life research. As noted by the Social Work Summit on Palliative and End-of-Life Care (Christ, 2002), there is a pressing need for increased financial support for research in social work and end-of-life care, as well as the inclusion of social workers in research collaboratives. In particular, social work practitioners, with their unique, day-to-day perspectives, need to be included in the conceptualization and implementation of research in this area.
- *Team member.* The social worker, having advanced communication and facilitation skills, can play an important role on the interdisciplinary team in the areas of leadership, problem solving, and other team-building and maintenance tasks so critical to effective teamwork.

Skills Needed to Provide Services to Patients and Families

Comprehensive Assessment

Psychosocial assessment in palliative care appraises an individual's mental status, emotional stability, social resources, and ability to interact with others. Terminally ill patients often view their current experience as part of a broader life course trajectory. Measures used to assess end-of-life quality should account for a patient's emotional and spiritual growth in spite of the limited life expectancy. The work of Dr. Ira Byock, among others, has taught us that when biopsychosocial and spiritual needs are well satisfied, there are tremendous opportunities for healing and closure at the end of life for both the patient and the family (Byock, 1997).

Psychosocial assessment at the end of life is critically important for several reasons. The comprehensive assessment facilitates the development of a care plan specific to that patient and family (Blum, Clark, & Marcusen, 2001). The assessment also promotes the initiation of strong working relationships among the patient, family, and care team, facilitates articulation of goals of care and sets the tone by which these goals can be achieved (Cox & Stovall, 2001).

During the 20th century, the culture of death changed. With the location of death shifting to the hospital from the home, physicians assumed greater responsibility for interventions designed to postpone an individual's death. As a result, death is viewed as a physiological event. For the professionals and patients involved with care at the end of life, however, death carries a broader meaning. Psychosocial and spiritual issues are as important as physiological events. For most terminally ill older adults, two components are important in end-of-life events: generativity and the need to be treated as a whole person rather than a case or disease (Erikson, 1994). Caregivers and other members of the patient's support system have a need to feel that they have done whatever possible for the patient. The caregivers themselves also need emotional and practical support, as well as bereavement care.

The patient-family-caregiver unit rarely "speaks with one voice." Thus comprehensive assessment contains individualized assessments of the patient, the family as defined by the patient, and the informal caregivers involved, instead of a focus only on the patient. The multifaceted assessment provides important historical and developmental details about each person within the patient system. It documents financial, employment, and educational details. It

notes cultural, ethnic, and spiritual backgrounds and compares and contrasts the differences among the involved parties. Because of this broad scope, the assessment detects the subtle range of coping styles, behaviors, beliefs, and opinions within each involved individual who is assessed. This kind of assessment reveals varying abilities to cope with the patient's needs at the end of life (see list below).

Components of Comprehensive Assessment

- Needs and goals as expressed by the patient and family
- Strengths, competencies, and coping resources of the patient and the support network
- Life history and developmental needs
- Emotional issues, including death anxiety
- Impact of illness on patient's body integrity and concerns about dependence
- History of prior losses
- Perceptions about illness and prognosis and cognitive and emotional integration of diagnosis by the patient and family members
- Present pain and symptom management
- Potential treatment barriers and risk factors that may impede success of the plan of care
- Family history, structure, roles, and dynamics of the family network
- Financial, social, emotional, spiritual, and psychological resources and supports available to the patient and family
- Expressed educational, practical, health care, advance care planning, discharge planning, and support needs
- Safety issues and functional and environmental issues
- Concerns about sexuality and intimacy
- Cultural expectations and preferences
- Spiritual and/or religious beliefs
- Bereavement risk assessment
- Legal and ethical principles

Performing the assessment in this fashion takes time—something that palliative care administrators must respect. With the details also comes a commitment by the palliative care social worker and the team to attend to the presenting issues to the best of their abilities. We believe that this devotion to detail from the initial contacts with the patient system will lead to a deeper understanding of the presenting issues, an appropriately detailed plan of care, and a more rapid

response from the palliative care team to meet these needs and to help the patient system negotiate their differences.

Identification of Psychosocial Resources

The specific information gained from the psychosocial assessment will lead to an understanding of the patient system's strengths and areas for further address. Social work education's fundamental tenet is to view people in the contexts of their environment. The palliative care social worker's training integrates the practical considerations with the emotional reserves, which, when taken together, uncover the available psychosocial resources.

In the last stages of life, when patients are likely to be in health care settings, the psychosocial assessment and subsequent recommendations for intervention, executed by a competent social worker, can restore or maintain hope in both the patient and the survivors. Hope, in the context of palliative care, takes on a particular meaning. Early on, when news of any advanced disease is first learned, there is nearly always a hope for a restoration of health. Palliative care social work, with its emphases on continuity of care, competency-based practice, and smooth transitions from setting to setting, can allow the patient and family to develop a new definition of hope. Palliative care social work can lessen patient and family anxiety and thus "prove" to the patient system that they have the internal strength to sustain themselves during this phase of the life cycle. Social workers who specialize in palliative care can attest to receiving heartfelt thank-you notes from grateful patients and families for assistance given even though the social worker will feel as though she or he had done very little. It is that offering of active listening for which the families express thanks.

In addition to the psychosocial counseling that the palliative care social worker provides, there are several other sources of professional and peer counseling that patients and their caregivers can pursue. Some organizations provide individual and group counseling over the Internet and by telephone to people who, for whatever reason, cannot leave their homes. Among the most well known of these agencies is Cancer Care.

The use of technology to bring counseling to people in their homes has been an enormous advance toward reducing distress among the homebound. In many instances, caregivers are also homebound either because of their own physical issues or because the

terminally ill patient cannot be left alone. In underserved communities, whether urban, suburban, or rural, the telephone and the Internet provide specialized psychosocial counseling where this skill set might not exist. Consider, as well, a few of the many reasons why mobility within the community is reduced at the end of life for both the patient and the caregiver: self-perception about physical changes, lack of transportation, and medication side effects. Group counseling promotes formations of new relationships with similarly situated people under circumstances that would ordinarily isolate people. Some Internet formats are ideal for patients and families to access emotional support and social bonding according to their own scheduling needs. With some planning, the counseling can continue even as the patient moves from setting to setting. The success of these formats in providing counseling is based on reducing the social and emotional isolation that advanced illness fosters. Social workers who work with families who are facing terminal illness should recognize what value these two resources have and should encourage clients to use these referrals whenever appropriate.

Providing Linkages to Financial Resources

Regardless of the patient's income level and age, terminal illness can be a tremendous financial burden on a patient and family. Medical expenses may have mounted before the patient became designated as in need of palliative care. Besides hospital bills, all medical treatment, even hospice care, can include many direct and indirect expenses that public and private insurance do not cover, such as medications (hospice does not pay for medications not related to the terminal diagnosis), transportation (for the patient as well as the caregivers), some home care and nursing home costs, child care, and so forth. Fear of financial problems can also be related to physical symptoms, as is the case in which patients forgo needed services or treatments because of a perception that medical care will adversely affect the household (Francoeur, 2001). Among working-age patients and caregivers, consideration for lost wages, time away from work, the real or perceived threat of job loss, and the presence or lack of a financial safety net can cause a financial crisis for the family.

There can be no doubt that the threats of debt and impoverishment are sources of emotional distress. Social workers working in palliative care set-

tings often encounter situations in which the patient had been the primary breadwinner and provisions had not previously been made to obtain access to checking and bank accounts so that critical monthly expenses such as rent and utilities can be paid. The oldest patients may be reluctant to use their savings to pay for care out of the false belief that government programs such as Medicare and the Veterans Health Administration cover all expenses related to illness. Distress related to financial issues is an area in which social work training, with its emphasis on counseling and accessing resources, can be of enormous assistance to the patient, his or her family, and the palliative care team. Palliative care social workers must know the available resources to assist patients and families in obtaining relief. They additionally need to use their counseling, negotiation, consumer, and advocacy skills in helping patients and families to access these resources in a timely and appropriate fashion.

Some patients and families might observe an initial barrier of privacy that prevents a social worker from obtaining a complete financial assessment. The resulting delay may prevent that aspect of the care plan from developing and going forward. Some patients and families, on hearing of the news that the illness is terminal, attempt to seek financial assistance from unrealistic sources, such as attempting to purchase life insurance when the patient is *in extremis*. As noted, some patients and families initially do not believe that the government resources will not pay for the total costs of care. For others, the crisis of the illness makes it difficult to mobilize their energies to follow through with gathering the necessary documentation or keeping required appointments. It may be necessary, for example, for the palliative care social worker to help the patient and family to review his or her health insurance policy and, when present, disability policies to better understand the available coverage. When the palliative care social worker facilitates this focused financial review, anxiety about the patient's needs can be reduced, even if the review does not yield a financial windfall. Instead, this work demonstrates a concern about how the family might continue to go on living in spite of the severity of the illness and the expected outcome. The following list presents some organizations and agencies that can be resources to the palliative care team and to the patient and family.

- Financial assistance and tips for meeting other practical needs are available through some disease

organizations such as the American Cancer Society, Cancer Care and the Leukemia and Lymphoma Society.

- The Department of Veterans Affairs can provide a variety of financial, medical, and other assistance to qualified veterans. To find the local VA, contact 1-800-827-1000 or www.va.gov.
- Pharmaceutical companies have medication assistance programs to help patients obtain certain prescription drugs. Palliative care social workers can help to obtain the necessary information about access these programs and can help advocate to obtain this benefit.
- Palliative care social workers should be knowledgeable about sources of support in the community. They should be able to research religious, ethnic, and cultural communities that can help patients and their families. These organizations can assist with an array of supportive services.
- For patients over 60 and disabled, the local or state agency on aging can locate sources of assistance, such as Meals on Wheels, home repair, and local home care assistance programs. To find local Area Agency on Aging and other online elder resources, visit the Administration on Aging: Information for Older Persons and Their Families website at www.aaa.gov.
- For information regarding Social Security, disability, and Medicare benefits, see www.ssa.gov.
- For information about Medicaid, the state-administered health insurance program for those in need, visit www.hcfa.gov/mcaicnsm.htm or the local welfare agency. These sites provide information on local Medicaid eligibility.
- For information about food stamps, public assistance, or emergency cash grants, contact the local welfare office.
- To provide assistance with hospital expenses, the palliative care social worker can develop a working relationship with the financial counselor in the business office of the hospital to help develop a monthly payment plan. Such a working relationship also helps demonstrate the role of the social worker in promoting appropriate revenue collection.

If the family cannot meet its daily living expenses and has outstanding credit expenses, the palliative care social worker can assist the patient and family by directly contacting these creditors to work out a payment plan before these obligations become critical.

Identifying Cultural and Spiritual Resources

The need to recognize the role of both cultural and spiritual issues at the end of life is obvious to social workers involved with palliative care. At the same time, palliative care social work continues to deepen its understandings of these areas. Although it is often a challenge to incorporate spiritual care into health care, particularly within secular organizations, the relevance of spiritual care at the end of life has been increasingly recognized as critical (O'Connell, 1999).

Palliative care social workers recognize that the rewards for meeting the challenges posed by increasing awareness and understanding of spiritual and culturally appropriate care are great. The Joint Commission on Accreditation of Healthcare Organizations (JCAHO) and National Council of Hospice and Palliative Care Professionals (NHPCO) both support spiritual and cultural competence among staff members. There are many ways in which social workers can factually learn about spiritual and cultural practices of different religious and ethnic groups. In general, professionals can improve their ability to provide spiritual care by:

- Being open to multiple interpretations of reality and ways of believing and being
- Having a desire to learn about self and others
- Being aware of biases
- Becoming nonjudgmental
- Welcoming challenging experiences that allow for personal growth
- Being aware of one's limitations

To truly master these domains of palliative care, social workers must look inward to ascertain their cultural and spiritual identities. Along with this self-reflection comes self-care, as the social worker contemplates the effects of this work on all aspects of his or her life. Replenishing one's own vessel in culturally and spiritually renewing ways is important in supporting the health professional's caregiving potential to clients, team members, families, communities and ourselves. This enables the social worker to come to the bedside with a strong healing presence and true compassion, as well as sensitivity to the cultural and spiritual needs of patients and families. Regardless of what we practice, no doubt we will recognize the value of the therapeutic use of self and improve our listening, presence, and commitment to nonabandonment. We will be able to make referrals to pastoral care not as a way of passing along a task that we define as being

“not our job” but rather with the level of understanding that the spiritual domain deserves.

Identifying Bereavement Support Resources

The palliative care movement has made a significant contribution to how people are cared for at the end of life. One area of needed expansion is bereavement support services. On intake and at critical points in the patient's care, hospice programs do assess how the caregivers and extended family are likely to cope with the patient's death. Hospices are also charged with continuing bereavement care for survivors 1 year after the patient's death. In general, the bereavement services of hospice programs are separate departments, reflecting that the delivery of bereavement care is a specialty. Unfortunately, that level of understanding of the impact of loss is evident only within the palliative care community.

Intrapersonal, cultural, ethnic, and spiritual needs are ignored by the community at large after the time just following the death. This could be viewed as an abrupt change from the spiritually and culturally competent care and practices provided by the palliative care team that supported and sustained the patient system during the illness. Cable (1998) notes that because social support networks are now not necessarily confined to a specific community or geographic region, the bereaved are very often isolated in their communities. In contrast, before there was great mobility and easy communication in the United States, families lived close to one another and communities mourned deaths as a shared experience (Cable, 1998). Currently, few employers offer designated time off for the death of a loved one, and when this benefit exists, it tends to be defined in terms of the familial relationship rather than by the significance of the deceased to the survivor. Most employees would be expected to use vacation days or leave without pay to attend funerals. Furthermore, there is a general expectation that when the person returns from time off for the death, the survivor will be able to resume his societal roles.

The generalized expectation that death should be attended to in a discreet manner runs counter to the experience of suffering a loss. According to Rando, grief is the personalized biopsychosocial reaction to the loss (Rando, 1993). This reaction takes place over a time frame unique to the individual. Rando defines mourning as the display of grief, which is expressed

through the bereaved's behaviors. Over time, the bereaved adapts to the loss.

All social workers, regardless of their settings, will work with people who are bereaved. Thus all social workers should have a basic training in grief work appropriate to the age, culture, and spiritual backgrounds of the population served. This aspect of the work will model sensitivity to the issues presented in the workplace and will make referrals to grief specialists. Having and using the training will create a culture of caring and concern so needed by the bereaved, one that has become absent in the community at large. The atmosphere of understanding does not minimize the loss based on degree of kinship to the deceased or the time that has passed since the death or any other domain. It tolerates expressions of emotion and at the same time demonstrates concern for the person's well-being and conveys a sense of hope that the pain of the loss will lessen. By acknowledging the bereavement issues in the workplace and spearheading the facility's approach, the social worker will yet again exert valuable leadership and coordination skills and demonstrate her or his keen understanding of how the person fits into the environment.

CONCLUSION

As the World War II and baby boomer generations age, social work practice in the area of palliative and end-of-life care is becoming increasingly complex. Social workers are involved in palliative care no matter what setting or what population they find themselves in, because death and dying are universal experiences. The social work contribution to palliative care touches on many domains, from interdisciplinary team member to administrator to educator to therapist to researcher to peer support leader. Social workers who have an interest in this work are encouraged to share their experiences and lessons learned with their colleagues on their teams, within their practice settings and beyond, in regional and national venues. It is exactly this sharing that will continue to deepen the knowledge base, improve the level of practice, and promote the leadership role of the social worker.

Psychosocial Services at the End of Life

27

Although in many ways dying has become a medical and legal issue, it is and always has been a profoundly personal and social event. Because social workers focus on psychosocial issues and are trained to work with individuals and families, as well as with larger systems, they are uniquely situated to work in end-of-life care. Social workers view people from a holistic perspective and have expertise in helping facilitate communication, addressing taboo topics, and mediating between individuals and organizations. All of these skills are essential to effective end-of-life care. Social workers have been identified as critical to the health care team (Csikai, 2004), involved in patient education (Baker, 1995, Christ & Sormanti, 1999), and actively involved in working with family members in end-of-life planning (Werner & Carmel, 2001).

This chapter, which addresses dying and older adults, does not seek to develop universal principles. Although general guidelines are presented, the concept that dying is a personal event related to the choices and values of the persons involved, especially the dying person and his or her family, is paramount. The setting in which the social worker intersects with the dying person also affects the available roles and interventions. Within this context it is the responsibility of the clinician to listen for and to elicit the needs of the persons involved and to seek to respond to these needs as much as possible. The social work roles of broker, teacher, mediator, enabler, and advocate (Compton & Galaway, 1999) provide a direction for the actions of the worker in addressing goals based on the needs and wishes of the involved persons.

A critical first step for all social workers in end-of-life care is awareness of the losses in their own lives and the meaning that death has for them. Social workers must be aware of their beliefs, their values, and their own needs to ensure that these do not influence their work with the dying person and his or her family. Although self-reflection is an essential component of all work, dying raises particular problems because of the larger social and cultural environment that seeks to keep death at a distance. Despite the growing attention paid to dying in recent years, continuing limitations in our society's ability to comfortably address this topic (Moller, 1996) affect the scope of work for the social worker.

In addition to self-knowledge, social workers in end-of-life care have a responsibility to be knowledgeable about the stages of the dying process, illness-related issues, the manifestations of pain, advance directives, and the range of settings that provide care

at the end of life (National Association of Social Workers [NASW], 2004).

DYING IN OLD AGE

The diversity and widening age range among older persons makes discussion of end of life and older adults a complex topic. A grandmother of 67 confronted with terminal illness, who is raising her grandchildren and still employed, has vastly different needs than a 90-year-old infirm and demented resident who has spent the last 5 years of her life in a nursing home. Both persons and their families may require professional but different types of assistance in dealing with and coming to terms with the finality of a terminal illness. Regardless of the age or condition of the older person, death represents a finality and loss to the person and to those who are connected to him or her.

Death in older adults may be poorly dealt with because, in the natural progression of the life cycle, it is inevitable. Care providers may minimize the intensity of the experience and its importance to the participants. This diminishes the centrality of lifelong relationships and neglects the importance of parental ties, however complicated, and of grandparent relationships. It also can diminish the loss of a spouse who has been a life companion for decades. Although death for some older persons is welcomed, for many older persons and their families, death is still a dreaded experience that they try to hold at bay for as long as possible.

Understanding death as simply the “natural” next step in old age may result in unrealistic expectations that persons be accepting of it. Often clients who are grieving reveal that other family members or friends try to soothe their grief by indicating they should be grateful that the person had a “long and good life.” At a viewing for his recently deceased mother a physician stood by her coffin. In her mid-80s, she died after a difficult adjustment to dementia and nursing home placement. As the physician began to recite how she had had a good, long life and all the appropriate responses about what is best, he sat in a chair, put his head down, and said “So why do I feel so bad?”

ADVANCE DIRECTIVES

The increased use of technology in medicine has resulted in persons with increased disabilities and mul-

tipl illnesses living longer, at times resulting in long and difficult deaths. Although it is imperfect and often fraught with difficulties, advance care planning can help older persons discuss and plan for their own health care decisions in the event they are unable to speak for themselves. Consequently, the social work role in end-of-life care should begin long before major illness or crisis strikes.

The importance of providing individuals with information about end-of-life decision-making tools and advance directives has been well documented (Gutheil & Heyman, 2000; Meier et al., 1996). Advance directives are legal documents that individuals can use to name someone to make medical decisions for them (health care proxy) or specify instructions for care (living will) should they become unable to speak for themselves. Although, in the past, attention had focused on working to increase the completion rate and developing the best forms, more recently attention has turned to the process of end-of-life planning and decision making (Souza, 2004; Teno, 1998). Effective planning for end of life must be grounded in a process of communication. Older adults need to be provided with adequate information about advance planning and with opportunities to discuss their concerns and wishes with family, with the individual they will name as their agent, and with their health care providers. Because these discussions may be difficult for all parties involved, social workers can play important roles in helping individuals overcome resistance to discussing upsetting topics and fostering communication by serving as teachers, mediators, and enablers.

The health care proxy, the most widely recognized advance directive, is used to give one individual (the agent) the authority to speak for the incapacitated person. Even under the best of circumstances, when the older person has had extensive conversations with and carefully conveyed her wishes to the health care agent, problems may develop. Other family members may disagree with the agent’s choice of actions, or health care providers may fail to act on the agent’s decisions. Social workers may need to bear in mind that advance directives have also become a means to protect medical providers from litigious concerns (Souza, 2004). Acting as a mediator or advocate, the social worker can help the health care agent carry out awesome and, at times, overwhelming responsibilities.

Carefully thought-out advance care planning and in-depth communication about concerns and wishes can help older persons ensure that they are cared for

as they wish during their dying. Careful planning can also help families more comfortably make difficult decisions and deal effectively with medical care providers. However, even the best advance planning communication between older adults and their family members does not guarantee that there will not be problems when illness or crisis occurs. Clinical support and empowerment are essential at this time.

Another difficulty is that practitioners may focus on the medical and legal language of advance directives. Consequently, they may fail to hear or listen to the ways in which persons talk about life choices. Focusing on issues of feeding tubes, resuscitation, and intubation and requesting that forms be completed may meet with resistance. At times, focusing on the legal aspects of directives and the tension associated with the completion of these documents in a timely manner may lead to discomfort for both the medical provider and the family.

Concern that participants will not sign the documents that medical practitioners deem appropriate is particularly troublesome when the participants are ambivalent about what is occurring. A mistaken notion often exists that because dying persons and their families remain hopeful in their communication and plan for the future, they have not accepted the terminal condition or the impending death. Most persons aware of impending death do maintain a hopeful demeanor despite their understanding of the proximity of death and the choices they have made regarding refusal of aggressive treatments.

Communication is a key factor in ensuring that end-of-life wishes are understood and respected. Practitioners need to be attentive to the ways in which older adults express their wishes for care. When older persons observe care being rendered to another in a debilitated condition and remark that they would not want that to happen to them, there is a need to follow up with open-ended and general questions to find out what they would and would not want. Social workers need not only to be alert to those types of communication as indications of a direction for care but also to instruct and support direct-care staff members in facilities to be alert for remarks that indicate a resident's thoughts about treatments and interventions.

Because an advance directive cannot spell out wishes for every potential situation, family members, often the decision makers, may have difficulty being certain what their older relative would want. As they struggle with the responsibility of making life-and-death decisions, the social worker can help with cues that may jog their memory concerning prior conver-

sations and utterances made about how people die. Questions such as "When family members died, did your mother remark on the type of death that occurred, and did she say how she felt about it or what she thought about it?" can be helpful. Another approach is to bring up nationally known figures; for instance, "When Karen Quinlan (or others) was in the news did your father say what his opinion was and what he felt should occur?" These conversations that people have informally may reveal end-of-life choices more directly than the formal language of an advance directive.

Because many older adults have multiple illnesses for which they have continued to receive treatment for a long period of time, the decision to discontinue, stop, or not pursue a particular treatment makes visible the reality that death is timed and a choice that is made. It is difficult to know when is the correct time to stop and prepare for death. The roles of enabler, mediator, and advocate are essential in this context, as social workers use their listening skills accompanied by supportive techniques to help older persons and their families reject or request interventions according to their needs. Advance care planning usually focuses on the elimination of treatment, but it is also meant to provide treatments that patients and families may need and want.

When health care agents hesitate to authorize a DNR (Do Not Resuscitate order) or to refuse treatment that staff members deem inappropriate as they carefully sort out the options and choices available, staff members may suggest that the family members "can't let go" or "make up their minds." Often the focus of social work intervention can be on enabling the family to complete the documentation for the discontinuation of treatment by helping them work through the struggle inherent in such painful decision making. Refocusing on where the older individual and family are in the process and being in that place with them are critical skills. Workers may come to recognize that the rationale for refusal has profound implications for the family at some point in time and may need to communicate to the staff the importance of family events and process. Social workers must also be alert to the changing decisions that dying persons make.

CARE AT THE END OF LIFE

Palliative care and hospice acknowledge and validate the holistic needs of dying persons. However, at times,

these programs may tend to focus on nursing and medical needs, seeking to provide comfort and symptom control from what may be painful and difficult physical processes that occur in long-term illness. This approach to comfort is often essential to dying persons and their families, but it must not obscure other, less visible needs that at times may have greater significance. Addressing these needs will not take away the pain of loss experienced by all in the process of dying, but it can enable an acceptance or an accommodation that helps survivors eliminate needless and ongoing guilt after death has occurred. It can also empower a person who is dying to complete the last act of life on her or his own terms.

SOCIAL WORK ASSESSMENT

Although social work assessment is a generic skill, there are some aspects of work in end-of-life care that demand specific attention. Assessment in end-of-life care considers relevant biopsychosocial factors, as well as the needs of the dying person and the family (NASW, 2004). This section considers some specific assessment issues.

The first and foremost assessment task of social workers in end-of-life care is to identify the different clients. The social worker's primary clients are generally the dying person and the family. The assessment of the needs of the dying person and his or her family generally begins at a concrete level. These needs may include information, help with advance directive completion, or brokering arrangement of services. These needs often have emotional components. If assessment prematurely ends at the concrete level, critical needs may be overlooked. Often dying persons are unable to assert their needs or articulate them directly. Therefore, the needs of the family may take precedence over the dying person's, with an implicit assumption that they are coterminous. Although the needs of the dying person and family may be compatible, social workers must be attuned to the discrepancies that may exist. Discomfort about death and the difficulties involved in communicating with dying persons may result in work with the family inappropriately taking precedence over work with the person who is dying.

Death is usually the result of a deteriorating condition that may have either a continual and rapid downward spiral or continuing acute episodes that leave the individual in an increased debilitated condition after each episode. This disabled and dependent

condition leaves the person at a disadvantage in relation to the ability to articulate needs. Being attuned to nonverbal communication and the responses and reactions of the dying person can assist the social worker in recognizing her or his needs.

Dying persons may become objectified as the process of disengagement is promoted by health care professionals. Consequently, it is essential that the social worker constantly be aware of the context of care for the dying person and family. The social worker must understand the functioning of the organization providing services and the impact it has on care to the individual and on attention to the concerns of family members. Too many times, family caregivers are seen as impediments to care rather than essential members of the care team (Levine, 1998).

Social workers are in the unique position of operating as part of both the health care team and the larger system, while at the same time needing to step back and evaluate how this larger system is affecting clients and how the client is affecting the team. Each member of the team operates from a different perspective. The social worker's viewpoint should be to represent the personal and social concerns of the dying person and family. Social workers may need to call on all of their skills to give other care providers the perspective of the dying person and, if it becomes necessary, to act as mediators between their clients and the health care team. Because of their focus on the emotional and social aspects of care and human need, social workers can also be a resource for the medical team, whose training and practice may limit their ability to recognize or validate their own personal responses to the dying process.

EMOTIONAL LOSS

Loss is a critical component of dying for all persons involved. The dying person faces the loss of a future and continued participation in the life cycle. The family is diminished. Even when the dying person is not a highly regarded member of the family, or when the person was lost long ago to dementia, the family members still face the physical absence of that person in their lives. When a family member provided care for the older adult, that member loses the caregiver role. The experience of loss, although universal, is experienced in each family and by each family member in a unique way. One of the challenges the social worker faces is assessing the meaning of the loss to all involved. A death reveals to all persons involved their

own mortality. The worker must be accepting of all feelings and recognize that not everyone will be saddened by the loss of their family member or be able to communicate their sadness.

SOCIAL SUPPORT

Assessment of the social resources of the dying person is critical. Some older persons have no families or are estranged from their families. Unless they have others intimately involved in their lives, they may be bereft of social resources, facing the end of their lives alone.

When family is present, there may be strong inter-familial support or there may be discord. The discord may be long-standing, or it may be the result of differences in how to best deal with the current situation. A head of an intensive care unit commented that he often sees family members who were not actively involved in elder caregiving suddenly show up at the hospital with their own ideas of how end-of-life care should be handled.

Finally, it is important to understand the support available from outside the family. Many families have strong connections to individuals or organizations in the community, such as churches, that can serve as resources to them. Death is a time when families need to be encouraged to avail themselves of their informal resources so that they can meet the needs of the dying person, as well as their own needs.

FINANCIAL CONCERNS

Financial concerns are an unwelcome but powerful participant in health care provision. Funding sources and family finances often determine what care is available and where care is provided. Financial concerns may influence decision making by dying persons, families, or care providers. Social workers need to be attentive to the power of financial concerns, even when they are unspoken.

Social workers need to be attuned to the formal and informal resources available to participants and creatively help dying persons and their families make choices based on their needs whenever possible by finding ways to meet those needs. They can empower the dying person and family by having a well-developed list of resources, and they may need to use advocacy or their informal networks to help families access these resources.

RELIGIOUS AND SPIRITUAL NEEDS

As in any practice setting, social workers need to be aware of religious and spiritual needs. Although it is often a source of strength, the importance of religion differs among families. These differences must be recognized and respected. A belief that the future is “in God’s hands” can limit an older individual or her or his family’s involvement in end-of-life decision making. In such situations, it may be the state and not a higher power that will make the decisions if they relinquish their rights.

Death can cause a spiritual crisis for the dying person and family members. The social worker needs to evaluate whether religious assistance is needed. She or he can help broker the connection to enable spiritual help to be enlisted. However, social workers also need to be willing to discuss spiritual concerns and needs and to recognize when the spiritual aspect of an individual’s life is a source of strength in the absence of religious beliefs. The dying person or family may want a safe place to talk about the meaning life has for them and how to find strength in the face of death. These essential conversations do not necessarily require the assistance of a spiritual person.

CULTURAL NEEDS

Social workers understand the importance of sensitivity to the cultural differences of dying persons and their families and the need to adhere to specific customs and traditions that bring meaning to the dying process. Equally important is the particular way the dying person culturally believes the world should work and the need for consistency with the values he or she holds concerning life. The way in which the dying process is assisted or inhibited as this process and individual beliefs intersect within the individual’s and family’s culture is something the social worker must keep in mind.

Expectations of dependence and independence may be major cultural issues. In the United States, where independence is a strong value, most older persons attempt to maintain their independence as long as possible. When they are no longer able to do so and become increasingly in need of assistance, they look to family and formal resources in the community to meet their needs. In contrast, Japanese adults, expecting as they grow older to become dependent, develop and maintain familial and other informal arrangements that they foster during their lives to assure

reciprocity as they age and become dependent (Hashimoto, 1996). These expectations continue as death becomes imminent, and the way these expectations are met can influence the comfort or distress the dying person experiences. In other cultures social pressure can be placed on family members in an attempt to ensure that the expectations of care are provided to older adults and dying persons (Catedra, 1992).

In end-of-life literature, much research has focused on cultural variations in relation to issues of advance care planning and directives (Blackhall et al., 1999; Hofmann et al., 1997). Although the focus is on the completion of these documents, there is recognition that a variety of approaches are required to assist completion. This cultural sensitivity must be extended to the context of the dying process and to the larger issues of role expectation, dependency, and other areas in which dominant values are not shared.

Social workers cannot be expected to have expertise in all cultures and the diverse ways in which their clients incorporate cultural values into their lives. However, using skills of open-ended questioning, exploring in depth and clarifying, as well as curiosity and naivete (Dyche & Zayas, 1995), can ensure that these cultural dimensions will be expressed in an environment that is open to accepting diversity and not labeling it as pathological.

QUALITY OF LIFE AND DEATH

Every effort must be made to ensure that the quality of life of the dying person is maintained up to the end. Some dying persons choose to forgo optimal pain medication in order to be able to remain as alert and involved with life as possible. Others may make a different choice. The important task is to create an environment in which the choice can be heard and will be respected. For quality of life to be maintained, social death cannot occur before physical death. Seeing and dealing with the older individual as a person and responding in a manner that accepts physical and mental losses without having those losses diminish the person, who is still alive, provide a model of behavior and an approach to the dying person for family and staff members to emulate.

Symptom management provides comfort to the dying person and often comforts family and professional caregivers as well. They are assured that they are doing the correct thing. The social worker is challenged to listen to ways in which the dying person ver-

bally and nonverbally expresses his or her needs, as well as the needs expressed by family and staff members. These can be put together with a focus on the dying person as the central client. The social worker may work with family members to help them accept the primacy of the dying person's needs. In addition, staff members may need help in letting go of their own wishes to manage the situation.

SOCIAL WORK INTERVENTIONS

The previous sections have illustrated ways in which social work interventions can be used in end-of-life work. Here we review those processes in a more systematic and chronological way, using as a framework the five interventive roles outlined by Compton and Galaway (1999; see Table 27.1).

Teaching and enabling are essential skills in assisting persons in the completion of advance care planning tools. In helping individuals complete the health care proxy, social workers need to evaluate an older person's ability to complete this document when dementia is present. The completion of this document does not require the same level of capacity as other documents with legal standing, and it is important to ensure that an individual who is capable of choosing an agent be given the opportunity to do so. Generally dementia is less evident in the early morning hours, so the social worker should investigate whether the individual has times when she or he is more lucid. The individual's behavior may illustrate choices. Resistance to an intervention may be a nonverbal way of communicating. If the person is in a facility, education for direct-care staff members is needed to help them understand how the words older persons use and their behavior when referring to interventions for themselves or others can provide insight into their choices.

Broker, mediator, and enabler roles are used to assist individuals with terminal illness and their families with concrete care needs. Connecting to the services that persons need; assisting them with acceptance of a deteriorated status, loss of appetite, loss of energy, and so forth; and assisting family members to accept increased care needs and to provide or supervise the care are essential social work tasks. Helping families deal with the losses they experience as their loved one's condition deteriorates enables them to provide their presence or respond to care needs. When death occurs, although it is still painful, guilt may be lessened.

TABLE 27.1. Social Work Interventions in End-of-Life Care

Broker

- Locating the services that meet the specific family's and dying person's needs
- Arranging concrete and other services both formally and informally as needed
- Negotiating with various systems to meet the person's and family's specifically expressed wishes
- Helping families to negotiate with their informal systems for emotional support and needed assistance
- Assisting in operationalizing advance directives
- Connecting dying persons and/or family to spiritual resources as requested or in times of spiritual crisis

Teacher

- Educating about advance care planning
- Educating about the illness
- Educating about persons' medical rights to pursue or reject medical interventions
- Providing information about the dying process
- Assisting persons to focus on their concerns regarding health issues
- Discussing ways in which to communicate with the health care team
- Helping clients to prepare written lists of questions for the health care team
- Modeling styles of communication and approach to different team members
- Informing others about the differences in resources and various referrals
- Providing information about cultural differences to the health care team
- Helping the team to understand the unique needs of a dying person and his or her family
- Modeling communication with family members for the help care team
- Helping families find ways to communicate and respond to the dying person

Mediator

- Negotiating the needs of the dying person with the available family members' resources
- Assisting both the dying person and health care providers to listen and respond to each other
- Facilitating communication between family members and health care providers
- Encouraging open communication between family members for mutual support and understanding
- Negotiating the provision of appropriate and necessary concrete services from formal providers and/or family members
- Assisting in the resolution of long-standing family difficulties as needed
- Assisting family members with diverse opinions to listen and hear each other and resolve the resulting tensions

Enabler

- Empowering dying persons
- Empowering family members
- Working with the health care team to understand and respond creatively to each unique situation
- Affirming staff members' emotional needs and responses to death
- Assisting dying persons to be socially alive and connected as long as possible
- Supporting the multiple and mixed emotional responses the person and family have to the dying process
- Supporting and encouraging family to respond to the person during the dying process with words or touch
- Encouraging social and medical services to be responsive to the diverse needs of dying elders and their family members
- Providing bereavement services that enable survivors to integrate the person who has died into their ongoing lives
- Normalizing the diverse feelings of survivors
- Assisting survivors to develop personal, meaningful rituals for memorialization of the deceased individual

Advocate

- Interceding for the dying person with the organizations providing services

(continued)

TABLE 27.1. Social Work Interventions in End-of-Life Care (*continued*)

-
- Interceding for the family with the organizations providing services
 - Advocating for the dying person or family with members of the health care team as needed
 - Providing voice to the dying person's needs and wishes
 - Mobilizing services
 - Encouraging medical practitioners to communicate clearly and directly with older persons who are in the terminal phase of life
 - Assisting the dying person to be recognized as a social person while she or he is actively dying
 - Helping families ensure that the dying person's wishes are being carried out
-

At some point in the trajectory of long-term illness, decisions may need to be made about limiting treatment. At times, particularly when treatment has already continued for multiple medical issues and lessened physical functioning, persons may decide that comfort instead of continued pursuit of curative medicine is appropriate. Social workers need to evaluate whether depression is present and is causing an individual to give up, whether untreated pain is the cause of the depression, and whether the person understands the situation and chooses to focus on comfort, recognizing that these choices may hasten death. At times, medical practitioners pursue interventions based on assumptions of the hopefulness of the person. Social workers in these situations need to be cognizant of changes, help clients to think about their needs, and assist medical staff to understand these changing needs. If clients choose comfort over treatment, they may need a mediator and, in some cases, an advocate. On the other hand, if clients want to pursue treatment against the advice of medical personnel, they may also need an advocate.

PSYCHOLOGICAL NEEDS

To some extent, the aforementioned interventions address the mechanics of end-of-life care, although they also address psychosocial needs. Often, the essence of the social worker's contribution is addressing the psychosocial needs of dying persons as they approach the end of their lives. A comparison of Lawton's (1997) ethnography of a hospice in England with de Hennezel's (1997) work in France underscores how recognition and validation of the dying person's psychosocial needs avert a social death before the physical death and also provide a sense of completion of one's life. Notwithstanding that death is a time of loss and pain, the process of dying can complete one's life, if recognition and affirmation of that life are made.

In addressing the psychosocial needs of dying persons and their families, social workers may assume the teacher, mediator, enabler, or advocate roles. For example, helping participants understand the dying process and anticipate the feelings that may be engendered may help them normalize their reactions. Creating an environment in which the dying individual and his or her family can talk freely about concerns and fears may help ease angry interactions, hurt, and blame. Assisting the dying person and family to prepare for the death and burial arrangements together (Jenkins, 2002) can provide a sense of control to the dying person and relief to the family. Respecting the words that individuals and families use can limit the insistence that those personally involved discuss dying in the way the medical team does. Representing the dying individual's view at team conferences may ensure that care providers hear her or his voice.

Social work interventions may take a range of forms, including individual counseling, family counseling, group modalities, case management, and system advocacy (NASW, 2004). Because each individual and family is unique, the choice of intervention is based on the needs of the dying person and his or her family. The social worker may be challenged to be creative when the needs call for help that is not readily available. For example, it may be necessary to develop a support group specifically for health care agents who have made decisions to withdraw life-sustaining treatment and are struggling to deal with the awesome responsibility this decision entails.

BEREAVEMENT AND GRIEF COUNSELING

Family members may need help integrating the lost person into their ongoing life after the death (Klass, Silverman, & Nickman, 1996). Grief is normal when dealing with loss and needs to be validated and af-

firmed. Providing opportunities for its expression through rituals that have meaning for the family can help the process. For example, friends of a deceased person may go to a casino on her birthday to celebrate it annually in the way she would have if she were alive.

Because sadness for the loss of someone of extreme old age or who has been demented for many years is not widely sanctioned in our society (Moss & Moss, 1989), families may need help with their grief. Persons who have experienced grief often need an opportunity to talk about the deceased. Unfortunately, family members and friends who encourage someone to “move on” may limit this. Groups or individual sessions provide a place for remembering the deceased individual.

Family members may continue to cherish objects, talk to the deceased individual, identify with him or her, and continue to make decisions with him or her in mind (Klass et al., 1996). A mature couple, both widowed, made a toast at their marriage proclaiming that the four of them would now be “living” happily together (cf. Moss & Moss 1996).

CONCLUSION

The role of the social worker in end-of-life care starts before illness or crisis strikes and continues after death occurs. Social workers may enter this continuum at various points, depending on the practice setting. This chapter has provided an overview of social work practice in end-of-life care. In highlighting psychosocial components, as well as the concrete needs, it underscores the valuable and diverse roles that social workers perform in working with dying persons and their families.

SECTION VI

**Family and Intergenerational Social Work
Practice in Special Caregiving Situations**

This page intentionally left blank

OVERVIEW

This section includes six chapters that address special caregiving situations. It is well recognized that caregiving is a heterogeneous phenomenon, with some caregivers experiencing significant physical and mental health difficulties, whereas others seem to thrive and derive considerable gratification from similar circumstances. In this section, we consider the context of family caregiving to attempt to understand the sources of the heterogeneity of outcomes experienced by family caregivers.

Specifically, the section focuses on the following six key issues: (1) caregivers to older adults in general, (2) grandparents who are raising their grandchildren, (3) older adults who provide care to a family member with developmental disabilities, (4) aging Latino family caregivers, (5) rural African American caregivers, and (6) caregivers who are at a distance from their family care recipients. The landscape covered by these six chapters is overlapping, as well as distinct, due to the commonalities and unique qualities of the caregiving experience.

The first chapter, by Greenberg, Seltzer, and Brewer, is a general overview of caregiving to older adults. Fully 12.1 million Americans need long-term care, and thus caregiving is a major public health issue. It is well documented that caregivers have poorer mental and physical health than their age peers who are not in caregiving roles, but many also experience the rewards and gratifications of caregiving. Thus caregiving is a role with heterogeneous outcomes. Many factors can explain this degree of heterogeneity, including the context of caregiving, the level of caregiving stress, and the social and psychological resources available to caregivers. Among these, the type of illness or disability is a prominent source of heterogeneity of outcome, with disabilities that are characterized by cognitive impairments and behavior problems leading to the poorest outcomes in caregivers. In addition, women experience more difficulties with the caregiving role than men do. The evidence suggests that caregiving effects are not static over time but rather unfold over the course of the caregiving career.

The second chapter, by Kropf and Yoon, addresses the phenomenon of grandparent caregiving. Fully 2.4 million grandparents in the United States have primary responsibility for taking care of their grandchildren, and 6 million children in the United States live in grandparent-headed households. This rate has doubled over the past 30 years. Grandparent care-

givers have elevated rates of physical and mental health problems as compared with their age peers, and there is evidence that these difficulties get worse after the entry into the caregiving role. Grandparent caregivers also experience elevated rates of financial and legal difficulties. The circumstances leading to grandparent caregiving derive from challenges experienced by the adult children of the grandparents—death, drug abuse, incarceration, and HIV/AIDS are among the most prominent. The chapter also includes suggestions for social work interventions and policy considerations relevant to grandparent caregiving.

The third chapter, by McCallion, focuses on older adults who are caregivers for persons with developmental disabilities. Because individuals with developmental disabilities now have nearly average life expectancies, the period of family caregiving is currently much longer than it was in the past. Important issues pertinent to this type of family caregiving include sources of stress and gratification, sources of heterogeneity in caregiving well-being, planning for the future, and dealing with grief and bereavement.

The fourth chapter, by Magaña, deals with aging Latino family caregivers. Latinos are currently the largest minority group in the United States. Therefore, the unique caregiving challenges and resources of this group warrant investigation. The chapter explores five themes: (1) the well-being of Latino family caregivers, including the high rates of depression that they experience; (2) stress and coping processes, including the role of religion and spirituality in this group; (3) family support and the cultural value of familism, as the individual is strongly influenced by family well-being; (4) service utilization patterns, as Latinos underutilize services possibly because of culturally insensitive services; and (5) interventions, which must be adapted for Latino family caregivers.

The fifth chapter, by Carlton-LaNey, examines rural African American caregivers. These individuals face critical and potentially life threatening problems, including poverty, lack of transportation, inadequate child care, substandard housing, inadequate health care, and insufficient child care. Although these challenges are formidable, rural African American caregivers can also draw on unique cultural resources, including the mutual-aid system that permeates African American culture, the importance of extended family, including fictive kin, religion, and the value of neighbors and the local geographic community. In this population, social support and caregiving

are overlapping concepts. Implications for social work practice are discussed.

The last chapter in this section, by Parker, Church, and Toseland, examines caregiving at a distance. As many as 7 million family members provide distant care for an elderly relative. These numbers are expected to double in the next 15 years. Distance complicates the quality and quantity of care provided, as care recipients prefer to live near but not with their adult children. “Near” is defined as within one hour’s drive, but many caregivers live quite a bit further

away. Military personnel represent a case in point of distant caregivers and are a focus of this chapter. Interventions for distant caregiving within faith-based communities are offered in this chapter, as are lists of national and state resources for distant caregivers.

The sum total of these chapters reveals the heterogeneity of the caregiving experience in later life. Social workers may be faced with the full range of these special circumstances, and they must recognize the unique needs of each. Commonalities, as well as unique needs, are highlighted within this section.

Caregivers to Older Adults

28

Rapidly growing numbers of individuals in society are in need of care due to Alzheimer's disease, severe mental illness, long-term disability, chronic illness, terminal illness, other age-related diseases, or social dislocation. It has been estimated that 12.1 million Americans need long-term care from others to carry out everyday activities (Henry J. Kaiser Foundation, 1999). Most but not all of these persons are ages 65 and older. Family members provide the vast majority of this care. Almost two-thirds of older persons living in the community and in need of long-term care depend on family and friends as their only source of help, and another 28% receive a combination of informal and formal care. Indeed, were it not for the efforts of families, formal systems of care would be overwhelmed by service requests (Biegel, Sales, & Schulz, 1991). Thus family members provide a significant service to society by sustaining vulnerable members. However, these contributions do not come without cost, as family caregivers are at risk for mental health problems, physical illness, and social isolation (Schulz, O'Brien, Bookwala, & Fleissner, 1995; Schulz, Tompkins, Wood, & Decker, 1987; Seltzer, Greenberg, & Krauss, 1995). The resultant health and mental health problems of family caregivers, which may impede the capacity for continuation in the caregiving role, have become a major public health concern (Lebowitz & Light, 1996).

Over the past two decades, considerable effort has been devoted to documenting the experiences of family caregivers of frail elders, in particular those with Alzheimer's disease. Researchers have more recently begun to focus on special populations of caregivers. The first section of this chapter reviews the general research on caregivers to older adults using Pearlin and his colleagues' (Pearlin, Mullan, Semple, & Skaff, 1990) stress process model as a framework for organizing this literature. The second section of the chapter explores special populations of caregivers, specifically male caregivers, end-of-life caregivers, and aging parents as caregivers to adults with disabilities.

CAREGIVERS TO OLDER ADULTS

Caregiver Outcomes

Researchers have consistently found evidence for the toll that caregiving takes on the mental health of family members. A growing number of cross-sectional studies comparing caregivers with age peers who do

not have caregiving responsibilities have found that caregivers report poorer mental health than noncaregivers (e.g., Baumgarten et al., 1992; Dura, Stukenberg, & Kiecolt-Glaser, 1991; Kiecolt-Glaser, Dura, Speicher, Trask, & Glaser, 1991; Russo, Vitaliano, Brewer, Katon, & Becker, 1995; Schulz & Beach, 1999; Schulz et al., 1995). For example, in a comparison of caregivers and noncaregivers, Baumgarten et al. (1992) found that 38.8% of the caregivers had Center for Epidemiologic Studies of Depression (CES-D) scores above the cutoff for clinical depression (a score above 15) compared with 16.5% of noncaregivers. Dura et al. (1991) administered the Structured Clinical Interview for *DSM-III-R* (SCID), the gold standard in psychiatric research for making a research diagnosis, to a group of caregiving adult children and a noncaregiving comparison group matched on key sociodemographic variables. Among caregivers, 18% met the criteria for a current depressive disorder and 9% suffered from an anxiety disorder compared with no cases of depression or anxiety disorders in the comparison group. In addition, researchers have established that caregivers are more likely than noncaregivers to be using psychotropic medications (Baumgarten et al., 1992; Grafstrom, Fratiglioni, Sandman, & Winblad, 1992). Thus the body of cross-sectional research comparing caregivers of older adults to noncaregivers provides compelling evidence of the considerable toll that caregiving takes on the psychological well-being of those providing care.

However, longitudinal research suggests that over time few caregivers experience further declines in their mental health, and, in fact, some report improved psychological well-being. In a study of daughter caregivers, Li, Seltzer, and Greenberg (1999) found that 65.2% of the caregivers' CES-D scores remained stable over an 18-month period and that another 21% showed a clinically significant (defined as 5 or more points) decrease in depressive symptoms. Townsend, Noelker, Deimling, and Bass (1989) reported that 58% of the adult children caregivers had a decrease of at least one point in depressive symptomatology over a 14-month period and that 8% showed no change. Schulz, Williamson, Morycz, and Biegel (1992) reported that 74% of the caregivers showed little change in depression over an 18-month period, with change defined as a difference of one standard deviation or more. Thus, although caregivers have greater psychiatric morbidity than noncaregivers, they appear to adapt to the new challenges that they confront as the caregiving career unfolds over time, at least during the short run.

Research on the effects of caregiving on the physical health of care providers is less conclusive. On one hand, caregivers rate their health as significantly worse than noncaregivers do (Baumgarten et al., 1992; Grafstrom et al., 1992). Kiecolt-Glaser and colleagues (1987) found caregivers had weaker immune responses than noncaregivers. Also, Schulz and Beach (1999) found higher rates of death in caregivers than among noncaregivers. On the other hand, Kiecolt-Glaser et al. (1991) did not find differences between caregivers and noncaregivers in the number of illness episodes, alcohol consumption, smoking, caffeine use, or nutrition. Baumgarten et al. (1992) found that the number of chronic health conditions experienced by caregivers was comparable to that of noncaregivers and that caregivers actually consumed less alcohol and smoked less than noncaregivers. Thus the current research suggests that the effects of caregiving on physical health are much weaker than on mental health and not consistent across different health domains.

Although research has primarily focused on the deleterious effects of caregiving on the mental and physical health of care providers, there is a rapidly expanding body of research on the rewards and gratifications of caregiving. A number of studies have identified these rewards of caregiving; they are many and include a sense of satisfaction or pleasure in fulfilling the caregiving role, feelings of personal growth, a renewed sense of purpose in life, closer relationships with family and friends, political advocacy, and greater insight into the struggles of persons with disabilities (Harris, 2002; Kramer, 1997; Lawton, Moss, Kleban, Glicksman, & Rovine, 1991; Miller, 1989; Motenko, 1989; Worcester & Quayhagen, 1983). Estimates of the percentage of caregivers who experience rewards in enacting the caregiving role have varied widely, ranging from approximately 50–90% of the caregivers sampled (Farran, Keane-Hagerty, Salloway, Kupferer, & Wilken, 1991; Hinrichsen, Hernandez, & Pollack, 1992).

Predictors of Caregiving Outcomes

There is great individual heterogeneity in the experience of caregivers. Whereas some caregivers appear overwhelmed by the challenge, others are able to maintain or show gains in their well-being (Kramer, 1997). A major goal of caregiving research is to understand the factors that help to explain why some cope well with the daily stress of caregiving whereas

others do not. A stress and coping model, based on the work of Pearlin and his colleagues (1990), provides a useful framework for understanding the reasons for individual differences in the caregiving experience. Pearlin et al.'s (1990) model focuses attention on the caregiving context in which the caregiving role is enacted. The caregiving context, defined by characteristics of the caregiver and care recipient, affects each step of the stress process, including the individual's exposure to stress, the resources available to mitigate the effects of stress, and ultimately how distress is expressed. The stressors of caregiving are conceptualized as sources of chronic strain that have the potential to cause distress. However, whether stress produces distress or results in positive adaptation and outcomes depends on the capacity of the individual to mobilize social or psychological resources that may counteract, moderate, or mediate the effects of caregiving stressors on well-being.

Caregiving Context

Factors that define the context of caregiving include the relationship of the caregiver to the care recipient (e.g., spouse, adult child, in-law); the caregiver's age, gender, race, and socioeconomic status; whether the caregiver and care recipient live in the same household; and the nature of the care recipient's diagnosis. In the section of this chapter on special populations, we discuss, in the context of male caregivers, how gender influences the caregiving experience. The impact of race and ethnicity in shaping the caregiving experience is the topic of several other chapters in this volume and thus will not be reviewed here.

The provision of assistance usually begins with the individual closest in proximity to the elder; thus spouses are natural primary caregivers (Zarit, Birkel, & Beach, 1989). If the elder is widowed, separated, or divorced, the elder typically turns first to an adult daughter, and then to an adult son, and finally to other family members (Cantor, 1983). Adult children as caregivers are more likely to receive assistance in the provision of care from another family member than are spousal caregivers. Stone, Cafferata, and Sangl (1987) found that whereas 60.4% of wives and 55.4% of husbands were the sole caregivers, only 23.0% of daughters and 10.8% of sons reported being the sole caregiver. Tennstedt, McKinlay, and Sullivan (1988) reported that spousal caregivers render up to four times the amount of care provided by non-spousal family caregivers. Spouses are involved in a broader range of caregiving tasks and activities than

are filial caregivers, and they provide this care in the face of their own declining health and increased frailty. They are more likely than other caregivers to report a lack of alternative roles and social activities outside the home that might function as a buffer against caregiving stress (Barber & Pasley, 1995; Hong & Seltzer, 1995).

Generally, spouses report greater burden and distress than other groups of family caregivers (Brodsky & Hadzi-Pavlovic, 1990; Deimling, Bass, Townsend, & Noelker, 1989; Fengler & Goodrich, 1979; George & Gwyther, 1986; Neal, Ingersoll-Dayton, & Starrels, 1997; Strawbridge, Wallhagen, Shema, & Kaplan, 1997; Zarit, Todd, & Zarit, 1986). McFall and Miller (1992) studied 940 spouse and adult child caregivers. Spouses reported higher levels of caregiver involvement, personal burden, and problems in personal activities related to caregiving than did adult children. However, adult children reported higher levels of interpersonal burden and problems in the relationship between themselves and the ill family member. Also, Hoyert and Seltzer (1992) found that the well-being of daughter caregivers declined over time, whereas the well-being of wife caregivers remained constant.

There has been a growing appreciation of the different challenges faced by caregivers depending on the nature of their loved one's diagnosis and the trajectory of the illness (Clipp & George, 1993). Some illnesses, such as Alzheimer's disease, have insidious onsets and progressively deteriorating courses, whereas other illnesses, such as heart disease and stroke, have abrupt onsets but relatively stable courses following the initial insult (Clipp & George, 1993). Biegel et al. (1991) pointed out that medical illnesses also differ in the degree to which they impair the mind and body. Whereas Alzheimer's disease attacks the mind but leaves the body intact until the end, other conditions, such as cancer and stroke, often destroy the physical being while leaving cognitive abilities intact. In an effort to understand how the nature of the care recipient's illness affects the caregiver's experience, researchers have conducted studies comparing different populations of caregivers for older adults, typically caregivers of persons with dementia, with caregivers of persons who are functionally but not cognitively impaired. In a study comparing 272 caregivers of persons with dementia to 30 caregivers of patients with cancer, Clipp and George (1993) found that Alzheimer's caregivers were more adversely affected, as indicated by more doctor visits in the previous three months, poorer self-rated health, lower positive affect, and higher negative affect. In another

study of 25 caregivers of adults with Alzheimer's disease, 25 caregivers of stroke patients, and 25 noncaregiving individuals, both groups of caregivers showed elevated levels of stress, with the health of caregivers of those with Alzheimer's disease being even more compromised than that of caregivers of those with a stroke (Reese, Gross, Smalley, & Messer, 1994). Also, caregivers of persons with Alzheimer's disease had fewer social contacts and reported more loneliness and higher levels of burden than stroke caregivers. Similarly, Karlin and Bell (1992) compared caregivers of persons with dementia with caregivers of persons with terminal illnesses such as cancer and emphysema but who did not suffer from dementia. They found that caregivers of persons with dementia reported higher levels of burden than caregivers of persons with chronic but nondementing illnesses. In a large, national sample of 1,500 dementia and nondementia caregivers, Ory, Hoffman, Yee, Tennstedt, and Schulz (1999) also found that persons caring for an individual with dementia experienced more physical and mental problems and more family conflict and had less time available for family and leisure. Li (2000) compared daughter caregivers of parents with a cognitive impairment, daughter caregivers caring for a parent with a functional but no cognitive impairment, and daughters whose parent had no impairment. Daughters who provided care to a parent with a cognitive impairment had a poorer quality of relationship with the parent than daughters caring for a parent with a functional impairment or daughters whose parent had no impairment.

However, other studies report no differences between caregivers of elders with dementia and other caregiving groups. Liptzin, Grob, and Eisen (1988) found no differences in burden between caregivers of patients with dementia admitted to a geriatric psychiatric inpatient unit and caregivers of depressed patients. Dura, Haywood-Niler, and Kiecolt-Glaser (1990) compared spousal caregivers of persons with Alzheimer's disease and spousal caregivers of persons with Parkinson's disease with dementia with a group of married control participants matched for sex, age, and education. Both groups of caregivers showed greater distress than the comparison group, but the two groups of caregivers did not differ from each other in levels of distress. Cattanach and Tebes (1991) compared three groups of daughter and daughter-in-law caregivers: 39 caregivers to elders with cognitive impairments, 30 caregivers to elders with functional impairments, and 33 caregivers to elders with no significant cognitive or functional impairment. They

found no significant differences between the groups in levels of depressive symptoms, perceived stress, social support, self-esteem, and perceived control. In a study comparing spousal caregivers of hospice patients with lung cancer or dementia with a group of their age peers without caregiving responsibilities, Haley and his colleagues (Haley, LaMonde, Han, Naramore, & Schonwetter, 2001) found that the two caregiver groups showed higher depression, lower life satisfaction, and poorer physical health compared with noncaregivers, but the two groups were not significantly different from one another. Finally, Rabins, Fitting, Eatham, and Fetting (1990) also contrasted caregivers of patients with dementia and cancer. Although a significant number of caregivers reported high levels of emotional distress, the nature of the patient's illness did not affect the presence or severity of caregiver symptoms.

What might explain the conflicting nature of the findings in studies comparing caregivers of those with Alzheimer's with other groups of caregivers? The Dura et al. (1990), Rabins et al. (1990), and Haley et al. (2001) studies all sampled caregivers late in the caregiving career. It is possible that initial differences between caregiving contexts decrease as caregiving approaches the final stages of the role because both functional and cognitive impairments are likely to be present as the end of life nears. In addition, Liptzin et al. (1988) sampled persons whose depression was sufficiently severe to require hospitalization. Older adults with severe major depression often experience cognitive and behavioral symptoms that mimic Alzheimer's disease. Thus inconsistencies in the findings from studies comparing caregivers of persons with Alzheimer's disease to other groups of caregivers may be explained, in part, by whether the selection of the comparison group provided a sufficiently distinct contrast to those with Alzheimer's disease. In general, the available research indicates that up until the last stages of the illness, caring for an individual with a cognitive impairment is more distressing than caring for a frail elder who is functionally but not cognitively impaired. As will be discussed, however, the stress may be due to behavior problems associated with the cognitive impairment rather than the cognitive impairment itself. End-of-life care appears highly distressing regardless of the nature of the care recipient's diagnosis.

The research on the effect of other characteristics of the caregiving context on caregiver distress is inconclusive. Older age of caregiver has been shown to be related to lower levels of distress in several studies

(Baumgarten et al. 1992; Clipp & George, 1990; Hoyert & Seltzer, 1992; Nijboer et al., 2000; Parks & Pilisuk, 1991; Russo et al., 1995) but unrelated to caregiver burden in other studies (Draper, Poulos, Cole, Poulos, & Ehrlich, 1992; Dura et al., 1991; Neundorfer, 1991; Schulz & Williamson, 1991; Semple, 1992). Most studies report that lower socioeconomic status (SES) is associated with higher levels of depression or distress (Barusch & Spaid, 1989; Dura et al., 1991; Morrissey, Becker, & Rubert, 1990; Robinson, 1989; Schulz & Williamson, 1991; Semple, 1992). Yet some researchers find either no relationship or a positive relationship between SES and caregiver burden (Nijboer et al., 2000; Russo et al., 1995). Hoyert and Seltzer (1992) found that daughter caregivers were more distressed the longer the duration of caregiving but that duration had no effect on the well-being of wife caregivers. Some researchers have found higher burden when the caregiver and care recipient live in the same household (Aneshensel, Pearlin, & Schuler, 1993; Brodaty & Hadzi-Pavlovic, 1990; Grafstrom et al., 1992; Zarit & Whitlatch, 1992), whereas others have not found any relationship between coresidence and burden (Cohen et al., 1990; Dura et al., 1991; Kiecolt-Glaser et al., 1991; Russo et al., 1995). Thus there is little consistency in the findings across studies on the relationship between how background characteristics of the caregiver affect levels of caregiving distress.

Stressors of Caregiving

The stressors of caregiving have most often been defined in terms of the functional and cognitive impairments of the care recipient and related behavioral problems that may be difficult to manage. Although many demands of caregiving arise when an individual has limitations in activities of daily living, most studies have not found that the amount of caregiving assistance is related to the caregiver's level of depression (e.g., Clipp & George, 1990; Russo et al., 1995). As noted previously, whereas researchers generally find that caring for an individual with a cognitive impairment takes a greater toll than caring for an elder who has a functional but no cognitive impairment, the relationship between the severity of cognitive impairment and levels of caregiver depression is less clear (Baumgarten et al., 1992; Boss, Caron, Horbal, & Mortimer, 1990; Brodaty & Hadzi-Pavlovic, 1990; Kiecolt-Glaser et al., 1991). However, researchers have consistently found that caregivers are at greater risk for depression and burden when they are faced regu-

larly with the challenge of managing their relative's problem behaviors (e.g., Baumgarten et al., 1992; Hoyert & Seltzer, 1992; Pruchno & Resch, 1989a; Schulz & Williamson, 1991). Variations from diagnosis to diagnosis in the type, severity, and frequency of behavior problems might better explain diagnostic-group differences in caregiver well-being than differences in severity of cognitive impairments.

It has been long recognized that the primary stressors of caregiving produce additional stressors in the lives of caregivers, such as financial stress, work-family strains, and family conflicts, a process that Pearlin et al. (1990) refer to as stress proliferation. Although caregivers typically spend an average of \$200 in a typical month on the recipient's care, the great majority of caregivers say they feel little or no financial hardship as a result of providing care (National Alliance for Caregiving and American Association of Retired Persons [AARP], 1997). Most caregivers are employed at some time during their caregiving career (National Alliance for Caregiving and AARP, 1997). Approximately 60% of employed caregivers report making work-related adjustments as a result of caregiving responsibilities. Caregivers who are working report more stress than employees without caregiving responsibilities (Marks, 1998; Neal, Chapman, Ingersoll-Dayton, Emlen, & Boise, 1990; Scharlach & Boyd, 1989). However, several studies have found that occupying multiple roles, including the work role, has positive consequences for the psychological well-being of caregivers (Hong & Seltzer, 1995; Scharlach, 1994; Stoller & Pugliesi, 1989).

It is not surprising that family conflicts often arise in the process of caregiving. The source of these conflicts may be disagreements over the equitable distribution of caregiving tasks or differences in perception of the needs of the care recipient (Semple, 1992). Family conflict is related to an increased risk for depression among caregivers (Ory et al., 1999; Semple, 1992; Strawbridge & Wallhagen, 1991). Other secondary strains, including role captivity and role overload, are related to greater levels of caregiver distress (Aneshensel, Pearlin, Mullan, Zarit, & Whitlatch, 1995). Thus the available research indicates that the full impact of caregiving cannot be understood without taking into account the proliferation and pileup of other life stressors.

Social and Psychological Resources

Intervening between primary stressors and secondary strains on the one hand and the outcomes of stress on

the other are psychological and social resources. Social resources may take the form of informal support from friends and family or of services and programs from the formal service sector. The receipt of emotional support from family and friends is generally associated with lower feelings of depression or burden (e.g., Aneshensel et al. 1995; Franks & Stephens, 1996; Haley, Levine, Brown, & Bartolucci, 1987; Sutor & Pillemer, 1992; Wilson, Moore, Rubin, & Bartels, 1990). Aneshensel and her colleagues (1995) suggested that different kinds of support are related to different outcomes. When caregivers receive help with care tasks from family and friends, they are less likely to experience feelings of overload. Aneshensel et al. (1995), however, did not find that this type of help was related to improved psychological well-being. In contrast, they found that emotional support was associated with improved psychological well-being but had no effect on role overload. Li, Seltzer, and Greenberg (1997) found that social support had different patterns of effects on depression for wife and daughter caregivers. For both groups, emotional support buffered the effects of stress emanating from the behavior problems of the care recipient. However, social participation had a main effect on depressive symptoms for daughters but not for wives. Thus the relationship of social support to caregiving outcomes is complex and likely depends on the goodness of fit between the type of stressor, the type of support, and nature of the outcome of interest. Li et al.'s (1997) research suggests that whether the fit is optimal or not may further depend on the relationship of the caregiver to the care recipient.

Research on the relationship between the use of formal services and caregiver burden has been quite limited. The continuous stress of caring for a relative with dementia suggests that respite services would be a priority for caregivers and should contribute to improved well-being. However, studies examining the effects of respite services, including adult day care, have found very modest effects on caregiver well-being as measured by burden and depressive symptoms (Bourgeois, Schulz, & Burgio, 1996). Lunderbold and Lewin (1987) found that respite care decreased caregivers' feelings of isolation and enhanced their feelings of control but did not affect feelings of burden, depression, or stress. Lawton, Brody, and Saperstein (1989) found that respite services allowed caregivers to maintain the care recipient in the community about one month longer than those who did not receive respite care but that they had no effect on caregiver well-being. Montgomery

and Borgatta (1989) speculated that family caregivers often delay seeking help from the service system until a crisis is looming, which may explain the modest effects of respite services in reducing caregiver burden.

In addition to respite services, caregivers are often thought to benefit from support groups, which may be peer or professionally led and typically involve both an educational and support dimension (Toseland, Rossiter, & Labrecque, 1989). The majority of studies find that caregivers are highly satisfied with support groups. In a mailed survey of 301 members of 47 different Alzheimer support groups, Gonyea (1989) found that caregivers valued the information gained from the peer support. Also, Gonyea and Silverstein (1991) found that caregivers participating in support groups were more likely to use community services. However, as Toseland and Rossiter (1989) concluded, based on the meta-analysis of 19 support-group interventions, support groups have only modest effects in reducing feelings of burden. In a more recent review of effective interventions with caregivers, Sörensen, Pinquart, and Duberstein (2002) concluded that support groups have significant but moderate effects in reducing caregivers' burden and increasing caregivers' knowledge but have no impact on caregivers' depression or well-being. Programs that combine a psychoeducational approach or a psychotherapeutic cognitive-behavioral approach appear more effective than support groups or respite care alone (Sörensen et al., 2002). The most effective approach is likely a combination of different strategies (e.g., psychoeducational, respite care, support group) that complement one another to produce beneficial effects across a range of caregiver outcomes (Sörensen et al., 2002).

Psychological resources are individual characteristics that increase the person's resilience or capacity to cope with stress. In the search for psychological resources that enhance caregiver functioning, attention has focused on coping strategies and an individual's sense of mastery. When people are faced with stressful situations, they are sometimes able to avoid psychological distress by using effective coping strategies. Lazarus and Folkman (1984) defined two major types of coping strategies: problem-focused coping and emotion-focused coping. Problem-focused coping involves cognitive and behavioral problem-solving strategies aimed at altering or managing the stressful situation. Emotion-focused coping, on the other hand, involves cognitive and behavioral efforts to reduce or manage emotional distress that are not focused directly on solving the problem. Cross-sectional

studies find that caregivers who use emotion-focused coping strategies in fact have higher levels of depression and distress (Haley et al., 1987; Patrick & Hayden, 1999; Seltzer et al., 1995). In contrast, the evidence from studies on the effectiveness of problem-focused coping is less conclusive. The preponderance of evidence suggests that the use of problem-focused strategies results in improved well-being (Aldwin, 1991; Essex, 1998; Haley et al., 1987; Kling, Seltzer, & Ryff, 1997; Seltzer et al., 1995). However, Pruchno and Kleban (1993) found that problem-focused coping was unrelated to levels of distress.

Mastery refers to “the extent to which people see themselves as being in control of the forces that importantly affect their lives” (Pearlin, Lieberman, Menaghan, & Mullan, 1981, p. 340). Higher levels of mastery are related to lower levels of depression in caregivers (Boss et al., 1990; Parks & Pilisuk, 1991). In a longitudinal study of daughter caregivers, Li et al. (1999) found that mastery had no direct effect on changes in depression over time but had an indirect effect by influencing how individuals coped in stressful situations. Daughters who had high levels of mastery were more likely to use problem-focused coping strategies, which led to decreases in depressive symptoms over time. In addition, daughters with high levels of mastery were less likely to rely on the use of emotion-focused coping strategies, a type of coping related to increasing levels of depression. These findings are consistent with the general literature on the relationship between mastery and coping (Aldwin, 1991; Elliot, Trief, & Stein, 1986; Folkman, Chesney, Pollack, & Coates, 1993) and suggest the importance of mastery in understanding the conditions under which different types of coping strategies are effective in reducing the negative effects of caregiver stress.

In summary, the care of older adults brings both gratifications and frustrations. The gratifications are many and include a sense of personal growth, a deeper appreciation of the struggles of persons with disabilities, and the satisfaction of performing a role well (Kramer, 1997). But there are many costs or strains associated with caregiving. Rather than the stress resulting from the physical demands of care, it is the stress of managing behavior problems associated with dementia that take the greatest toll on the caregiver’s well-being. In addition, Aneshensel and her colleagues (1995) suggest that these caregiving strains have rippling effects, producing new stressors and strains such as financial strain, family-work strains, and family conflicts. If left unchecked, these

strains of caregiving have a wear-and-tear effect on the caregiver’s mental health and, to a lesser extent, on the caregiver’s physical health. But it is clear that many, if not most, caregivers make a highly successful adaptation to the role. What distinguishes these caregivers from those who are less successful in adapting to the demands of caregiving? Research suggests that caregivers who show a pattern of resiliency receive higher levels of emotional support, maintain a strong sense of mastery, and use problem-focused coping and avoid the use of emotion-focused coping strategies. Also, there is some evidence that caregivers who are struggling can be helped, albeit modestly, by participating in psychoeducational programs and, to a lesser extent, by using respite services and by joining support groups.

SPECIAL POPULATIONS OF CAREGIVERS

Male Caregivers

Approximately 40% of all caregivers are men, typically the husband or son of a female care recipient (National Alliance for Caregiving and AARP, 1997). Many have speculated on the unique ways that men approach the challenges of caregiving. Fitting, Rabins, Lucas, and Eastham (1986) suggested that men utilize a “work” paradigm in approaching caregiving and focus on the task at hand. In addressing sons as caregivers, Pleck (1993) argues that sons are more likely to segment their lives to take on a caregiving role by clearly separating boundaries of work and caregiving (Thompson, 2002). In fact, the data suggest that there are few observable differences between male and female caregivers. Although sons may be more hesitant to take on the caregiving role, once involved they commit to it with the same intensity as women. Men and women seem to provide care for the same reasons and experience similar difficulties (Fisher, 1994). They perform similar numbers of caregiving tasks, although there may be slight differences in the nature of the tasks men and women perform (Barusch & Spaid, 1989).

Researchers, for the most part, have focused on how male caregivers of frail elders differ from female caregivers and not on understanding the natural variation existing among the experiences of men as caregivers (Kramer & Thompson, 2002). In comparison with male caregivers, female caregivers report higher levels of burden and depression (Fitting et al., 1986; Parks & Pilisuk, 1991; Pruchno & Resch, 1989b; Rose-

Rego, Strauss, & Smyth, 1998; Tennstedt, Cafferata, & Sullivan, 1992; Wallsten, 1998). In one of the first studies of gender differences, Barusch and Spaid (1989) found that women reported higher levels of burden than men but that the two groups did not differ on measures of physical health. In a meta-analysis of 14 studies of gender differences in caregiving, Miller and Cafasso (1992) reported that women were more likely to report greater caregiver burden than men. In a more recent meta-analysis, Yee and Schulz (2000) concluded that there is overwhelming evidence that women caregivers experience more psychiatric morbidity than male caregivers. However, one must be cautious in interpreting these results, as almost all of these studies are cross-sectional. In a longitudinal study, Zarit et al. (1986) found that even though women initially reported greater burden, they reported less burden over time, so that by the second wave of interviews there were no differences between women and men. Longitudinal studies are needed to investigate whether gender differences found in cross-sectional studies persist over the course of the caregiving career.

In their meta-analysis, Miller and Cafasso (1992) concluded that gender differences explain approximately 4% of the variance in caregiver burden. Several researchers have searched for explanations of why women appear more distressed by caregiving than men do. In addition to gender differences in depression in the general (i.e., noncaregiving) population, with women showing higher rates of depression than men, the available evidence suggests that caregiving may be more disruptive to the lives of women than it is to men. Kramer and Kipnis (1995) found that women were more likely than men to be distracted at work and forced to use sick days to fulfill their caregiving responsibilities. A higher proportion of women than men reported that caregiving limited their time with family and interfered with leisure activities. Thus men may experience less distress because caregiving demands may be less likely to spill over into other areas of their lives.

Several other hypotheses have been offered to explain lower levels of distress in male caregivers. There is some evidence that male caregivers may be more tolerant than female caregivers of the care recipient's behavior problems. Zarit et al. (1986) found that husband caregivers expressed greater tolerance and were less distressed by the behaviors of their wives with dementia than did wife caregivers of husbands with dementia. Others point to differences between men and women in their style of coping, with men more likely

to employ problem-focused coping and women more likely to use emotion-focused coping strategies (Pruchno & Resch, 1989a). Another theory is that men are more likely to receive assistance with caregiving than women (Stoller, 1990, 1992; Stoller & Cutler, 1992). Others often come to the aid of male caregivers because men in our culture are not expected to take on a caregiving role. In support of this hypothesis, researchers have found that men receive more informal support than women from friends and family with caregiving (Ingersoll-Dayton, Starrels, & Dowler, 1996; Stoller & Cutler, 1992). Horowitz (1985) found that married sons who were caregivers had more support from their spouses than did married daughters who took on the caregiving role. There is some evidence that male caregivers receive more formal support than female caregivers (Stoller & Cutler, 1992). These studies suggest that the caregiving networks of men and women are quite different. Whereas male caregivers may be supported by a network of secondary caregivers, female caregivers are often the sole providers of care, which may explain, in part, why men report less distress than women caregivers.

In summary, it is well documented that, on general psychological measures of well-being, male caregivers fare more favorably than female caregivers. But within the male caregiving population, there is considerable heterogeneity, which goes uninvestigated in studies comparing male and female caregivers. The next generation of research on male caregivers should focus on understanding the heterogeneity within the population of caregiving men, which will shed light on their unique caregiving challenges, as well as encourage the design of new psychosocial interventions targeting those men who provide care at great personal cost (DeVries, Hamilton, Lovett, & Gallagher-Thompson, 1997).

End-of-Life Care

Biomedical and technological advances in recent years have prolonged the lives of millions of Americans, while at the same time extending the dying process. The care of the dying is emerging as a major public health concern (Field & Cassel, 1997; Haley et al., 2002). Emanuel et al. (1999) found that 96% of primary caregivers of the terminally ill are family members and 72% are women. Caregiving at the end of life poses unique challenges because of the intensity of care often needed. The specific caregiving demands relate to the nature of the patient's disease and

functional ability but often include controlling pain, coordinating the multiple formal and informal systems of care likely to be involved at the end of life, and coping both with the patient's grief and the anticipatory grief of family and friends (Schulz et al., 2003).

Although family caregiving has been widely studied over the past two decades, only a few studies have been conducted on end-of-life caregivers. Emanuel and colleagues (Emanuel et al., 1999; Emanuel & Fairclough, 2000) documented the high level of assistance provided by family members of terminally ill patients and the very high levels of burden and depression they experience. In the most comprehensive study to date, Schulz and his colleagues (2003) followed 217 family caregivers of persons with dementia during the year before the patients' deaths and also for an average of 15 weeks after the patients' deaths. Prior to the patients' deaths, caregivers spent an average of 46 hours per week assisting the patients with activities of daily living (ADL) and instrumental activities of daily living (IADL) tasks, a number that is almost three times the average number of hours caregivers typically spend weekly in the caregiving role (National Alliance for Caregiving and AARP, 1997). Of the 56 caregivers who were employed outside the home, 27 (48.2%) had to reduce their work hours because of the demands of caregiving. Schulz et al. (2003) found elevated levels of depression within the 3 months prior to the death and around the time of the death, but within one year after the death, the levels of depression were substantially lower. The researchers concluded that end-of-life caregiver interventions might have their greatest benefit during the period immediately preceding the patient's death, not after it. The majority of caregivers were able to make a satisfactory adjustment to the death of the patient but struggled with the complex and multiple caregiving demands associated with the last few months of life.

Ageing Parents as Caregivers to Adults With Disabilities

A less common but increasingly recognized type of family care is provided by aging parents who have continuing caregiving responsibilities for a son or daughter with disabilities (Greenberg, Seltzer, & Greenley, 1993; Seltzer & Krauss, 1989). The emergence of this type of caregiving has resulted from several trends, including the increased longevity of persons with disabilities (Eyman, Grossman, Tarjan, & Miller, 1987), the aging of the baby-boom generation (Greenley, 1990; Janicki & Wisniewski, 1985), and

social policies of deinstitutionalization (Fisher, Benson, & Tessler, 1990; Fujiura & Braddock, 1992). It has become the norm for parents of adults with developmental disabilities and mental illness to be providing or overseeing the care of their adult children.

In an effort to understand the long-term toll of lifelong caregiving on aging parental caregivers, researchers have compared the experience of parents caring for a child with mental retardation with that of parents caring for a child with mental illness. Parental caregivers of adults with these two disabilities face overlapping yet distinct sets of stressors. Their experiences are similar with respect to feelings of grief and a sense of loss that their child may never achieve normal developmental milestones. Both mental illness and mental retardation are chronic conditions requiring long-term parental support and involvement. Finally, for both groups, parents are most concerned about what the future holds for their son or daughter after the parents' deaths.

Yet there are distinct differences. First, whereas mental retardation is ordinarily diagnosed at birth or in the first few years of life, mental illness generally occurs during adolescence or early adulthood. Therefore, the onset of the caregiving role comes at different points in the lives of these two groups of parent caregivers. Second, there is less predictability in the life of a parent whose child has mental illness because of the cyclical nature of the disorder compared with the relative stability of mental retardation. Third, whereas in recent years parents of adults with mental retardation have been welcomed as collaborators in the process of coordinating services for their sons or daughters, parents of adults with mental illness are still often kept at arm's length by mental health providers. Thus comparisons of family caregivers of adults with mental retardation with parental caregivers of adults with mental illness provide an opportunity to explore whether the effects of caregiving are generalizable across different caregiving environments or whether they depend on the specific context in which caregiving takes place.

The available evidence suggests that, whereas aging mothers caring for a child with mental retardation appear to adapt to the demands of lifelong caregiving, aging mothers caring for an adult child with mental illness show a wear-and-tear pattern. In a study based on a nonprobability sample of 107 maternal caregivers of adults with mental illness and 461 maternal caregivers of adults with mental retardation, Greenberg, Seltzer, and colleagues found that maternal caregivers of adults with mental illness reported

significantly higher levels of caregiver burden and depression, were more pessimistic about the future, and felt less close to their child than similarly aged mothers caring for an adult child with mental retardation (Greenberg et al., 1993; Seltzer et al., 1995). Using data from the Wisconsin Longitudinal Study (WLS), which is a probability sample of approximately 15,000 participants who were interviewed when the respondents were 18, 36, and 53 or 54 years old on average, Seltzer, Greenberg, Floyd, Pettee, and Hong (2001) compared 165 parents who had adult children with developmental disabilities and 53 parents who had adult children with mental health problems with a comparison group of 218 parents who had nondisabled and healthy children. Whereas there were no differences in well-being between parents of adults with developmental disabilities and parents in the comparison group, parents of children with mental health problems had elevated rates of depression and alcohol use and more physical health problems than parents in the comparison group. Pruchno and her colleagues (1996a, 1996b) similarly found that mothers of adults with schizophrenia reported greater levels of distress and poorer quality of relationships with their sons or daughters than mothers of adults with mental retardation.

The findings from this body of comparative research on aging parents of adults with mental illness and aging parents of adults with developmental disabilities has some parallels with findings reported earlier in the chapter, suggesting that caregivers of persons with Alzheimer's disease appear to fare less well than aging caregivers of adults with other types of disabilities. Although Alzheimer's disease and mental illness present quite different sets of challenges to caregivers, they are similar with respect to the high degree of uncertainty arising in part from the unpredictable nature of symptoms and behavior problems associated with these disorders. Both groups of caregivers must cope with cyclic periods when symptoms are relatively quiescent and other periods of increased symptoms requiring constant vigilance. This body of comparative caregiving research suggests that the very uncertainty or unpredictability of the caregiving context may help explain why caring for certain populations appears to take a greater toll on the caregiver than others.

An emerging research literature is examining differences between aging mothers and fathers caring for adult sons or daughters with disabilities. In a study comparing 251 aging mothers and fathers of adults with disabilities, the majority of whom had develop-

mental disabilities, Pruchno and Patrick (1999) found that mothers felt closer to their children with disabilities than fathers did. Mothers reported both higher levels of burden and greater satisfaction from the caregiving role than fathers. In contrast, Essex, Seltzer, and Krauss (1999) found that mothers and fathers of adults with mental retardation experienced similar levels of subjective burden and depressive symptoms. However, mothers reported feeling closer to their adult children with mental retardation than fathers did (Essex, 2002). Studies comparing mothers and fathers caring for adults with mental illness have found that mothers reported higher mean levels of subjective burden and depression than fathers (Cook, 1988; Greenberg, 2002).

In addition, researchers have begun to identify which characteristics of the caregiving context have similar effects and which characteristics of the caregiving context have differential effects on the well-being of mothers and fathers. Many of the same characteristics of the caregiving context are significant predictors of stress for mother and father caregivers of adults with disabilities. For instance, Pruchno and Patrick (1999) found that the child's living arrangements, emotional stability, functional ability, and parent health similarly predicted caregiver burden in mothers and fathers. The behavior problems of the adult with disabilities was a predictor of subjective burden for both mothers and fathers in studies of aging parental caregivers of adults with mental illness (Greenberg, 2002) and aging parental caregivers of adults with mental retardation (Essex, 1998).

However, several studies reveal that mothers and fathers are affected by different aspects of the caregiving context. For instance, Tessler and Gamache (2000) defined two modes of caregiving stress within objective burden: care and control. Care was operationalized as providing assistance for problems with self-care, and control was operationalized in terms of providing supervision. Their findings indicated that fathers were more distressed by the need to provide care and mothers were more distressed by the need to provide control. The authors argued that because the fathers were less likely to assist with these "care"-related tasks during the years of typical development, they might experience more distress when faced with these tasks later in life (Tessler & Gamache, 2000). Pruchno and Patrick (1999) found that the quality of the parent-child relationship was a predictor of burden for mothers, but not for fathers. Investigating whether different coping strategies had differential effects on parental caregivers of adults with mental re-

tardation, Essex et al. (1999) found that whereas problem-focused coping buffered the impact of the child's functional status on the mothers' depressive symptoms, there were no significant buffering effects for fathers. These studies suggest that fathers might be more vulnerable than mothers of adults with disabilities to the stressors of caregiving because, for fathers, social and psychological resources appear to have fewer beneficial effects in counteracting or buffering stress.

CONCLUSION

In conclusion, the research literature on the effects of caregiving on the caregiver leads to three overall conclusions. First, caregiving effects are generally not static. They vary over time, either resulting in the adaptation or the further depletion and wear and tear of the caregiver. Second, a great deal of evidence suggests that the heterogeneity in caregiving effects can be explained by the severity of the care recipient's behavior problems and by the extent of symptom unpredictability. A related point is that differences in adaptation versus distress among caregivers of individuals with different diagnoses may similarly be accounted for by distinct profiles of behavior problems and degree of behavior unpredictability. Third, although it may be useful from a policy perspective to separate out special populations of caregivers (such as male caregivers, or parents of adults with lifelong disabilities), the factors that affect their well-being and patterns of adaptation and distress are very similar to the factors that affect women as caregivers and caregivers of persons with more prevalent age-related disorders, such as Alzheimer's disease, cancer, and stroke.

We have a fairly clear understanding of how personal resources, such as mastery, coping, or social support, can alter the impact of caregiving and how the caregiving context influences outcomes. Missing from the available literature are insights into what *external* resources can ameliorate the distress of caregiving. We need to investigate and determine what formal supports and services have the potential to substantively reduce caregiving distress. With the aging of the baby-boom generation, the aggregated financial, social, and psychological toll of caregiving will increase dramatically. Our efforts to develop strategies to counteract these negative effects therefore warrant high priority.

WHO ARE GRANDPARENTS WHO RAISE GRANDCHILDREN?

As a hidden segment of America's caregiver population (Fuller-Thomson & Minkler, 2003), the number of grandparents raising grandchildren has dramatically increased. Several sources provide information about the incidence and prevalence of these caregivers and families (American Association of Retired Persons [AARP], 2004; Fuller-Thomson & Minkler, 2001; Lugaila, 1998; U.S. Census Bureau, 2001), including:

- An estimated 60 million grandparents currently live in the United States, with 2.4 million taking primary responsibility for their grandchildren.
- More than 1 in 10 of them have raised a grandchild for six months or longer.
- More than 6 million children under 18 live in grandparent-headed households (or with other relatives).

The number of children raised in grandparent-headed families has more than doubled over the past 30 years, from 2.2 million in 1970 (3.2% of all children) to more than 4.5 million in 2000 (6.3% of all children) (Bryson & Casper, 1999; U.S. Census Bureau, 2001). All data indicate that this family form has increased dramatically and includes significant portions of children and adults.

A profile of caregiving grandparents has been produced from a number of large data sets (Chalfie, 1994; Cox, 2000; Fuller-Thomson, Minkler, & Driver, 1997; Pebley & Rudkin, 1999; Szinovacz, 1998). These studies demonstrated that the characteristics of grandparents raising grandchildren transcend socioeconomic groups, geographic areas, and ethnicities:

- Grandparents come from all racial and ethnic groups. Although most grandparent caregivers are White (between 50 and 60%), a higher proportion (29%) than in the general population are African American. In addition, about 10% of the grandparents are Hispanic (any race), and 1–2% represent other groups (Chalfie, 1994; Fuller-Thomson et al., 1997).
- Geographically, grandparents predominantly live in urban areas, especially inner cities (Burnette, 1997; Minkler & Fuller-Thomson, 1999). However, the South is disproportionately represented, and significant numbers (approximately 25%) live in rural communities (Bryson & Casper, 1999; Robinson, Kropf, & Myers, 2000).

Grandparents Raising Grandchildren: Who Are They?

29

- The ages of grandparents range from mid-adulthood to old age. The average age of grandparent caregivers is 55 to 57 years (Burton, 1992; Dowdell, 1995). About one-fifth (21%) are older than 65, and 15% are younger than 45 (Bryson & Casper, 1999).

These characteristics indicate that grandparents who are raising grandchildren represent a varied segment of the population. As public recognition of intergenerational caregiving has increased, grandparents raising grandchildren should be highlighted as a critical social phenomenon in social work and aging (Kropf & Kolomer, 2004). The remaining sections provide an overview of the consequences of caregiving for the grandparent, the pathways and context of caregiving, and interventions to promote stable and effective functioning within these families.

OUTCOMES AND CONSEQUENCES OF CAREGIVING FOR GRANDPARENTS

A body of empirical literature has consistently demonstrated that many grandparent caregivers experience a multiplicity of social, physical, emotional, financial, and legal problems (Burton, 1992; Caputo, 2001; Dowdell, 1995; Emick & Hayslip, 1999; Minkler & Fuller-Thomson, 1999; Whitley, Kelley, & Sipe, 2001; Woodworth, 1996). Grandparents who are faced with the need to raise their grandchildren have health risks that could jeopardize a stable family environment established for their grandchildren. Both qualitative and quantitative research indicates that caregiving grandparents are vulnerable to a host of health and social challenges, including depression, social isolation, and poverty.

Physical Health

Taken collectively, the research on grandparents who are in caregiving roles indicates that their health status is compromised. Specific conditions include poorer self-assessed health status, considerable comorbidity, delayed help seeking, and a frequent tendency to “play down” the severity of personal health problems (Dowdell, 1995; Minkler & Fuller-Thomson, 1999; Minkler & Roe, 1993; Whitley et al., 2001). In addition, negative health practices, such as

smoking and alcohol consumption, exacerbate preexisting physical illnesses (Whitley et al., 2001).

Specific health conditions are especially problematic for custodial grandparents. Minkler and Roe (1993) found that 28% of the caregivers reported that their health had deteriorated during the previous year, and, more important, 38% reported that their health had worsened since assuming full-time parenting responsibilities for grandchildren. While custodial grandparents often experience deteriorating health, they also tend to ignore their health problems to appear “up to task” (Pinson-Millburn, Fabian, Schlossberg, & Pyle, 1996). In spite of physical limitations or symptoms, many of the grandparents caring for their grandchildren evidenced a high sense of perseverance and determination to continue their responsibilities (Minkler & Fuller-Thomson, 1999).

Mental Health

Research on the mental health status of grandparent caregivers also indicates negative outcomes as a result of undertaking care of grandchildren. Custodial grandparents express feelings of personal losses, which include loss of their freedom, loss of their own child, and loss of a peer group. Furthermore, social isolation from their own families, friends, and communities may lead to higher levels of depression and anxiety (Hayslip, Shore, Henderson, & Lambert, 1998; Kolomer, McCallion & Janicki, 2002; Minkler, Fuller-Thomson, Miller, & Driver, 1997; Minkler, Roe, & Robertson-Beckley, 1994). In fact, psychological indicators suggest that a substantial portion of these grandparents suffer from mental health issues that are clinically significant (Burton, 1992; Kelley, Whitley, Sipe, & Yorker, 2000; Minkler, Fuller-Thomson, Miller, & Driver, 1997). In a study of different caregiver roles, grandparents who were providing care for grandchildren reported higher rates of depression than either spousal or adult-child caregivers (Strawbridge, Wallhagen, Shema, & Kaplan, 1997).

Financial Difficulties

Financial problems have been commonly documented in studies with grandparents raising grandchildren (Burnette, 1999; Flint & Perez-Porter, 1997). Overall, about one-fourth (26%) of custodial grand-

parents have income below the poverty level (Fuller-Thomson et al., 1997). However, poverty rates differ among various types of households in which grandparents are raising grandchildren (Bryson & Casper, 1999). If a grandfather is present, there is less probability that the household is classified as poor. In families in which both grandparents are present, about 14% of households are poor, with a household average income of \$41,709. Twenty percent of grandfather-only households are poor, with an average income of \$43,476. Single grandmothers, however, have a higher poverty risk. In grandmother-only households, 43% are classified as poor, with an average household income of \$19,750.

Grandparents experience financial strains from expenses assumed as a consequence of care provision. Added costs are a result of expenses, poverty, and underemployment (Jendrek, 1994). Custodial grandparents assume added costs for educational, medical, dental, housing, food, and clothing expenses for grandchildren. Underemployment often occurs when grandparents are unable to earn sufficient income because of age-related discrimination in the labor force, competing demands of work and child care (e.g., taking part-time vs. full-time employment), or health consequences that compromise their ability to work (Sands & Goldberg-Glen, 1998). In addition, grandparents without full legal authority over grandchildren are not automatically entitled to receive financial benefits and may have difficulty establishing eligibility for assistance (Flint & Perez-Porter, 1997).

Legal Problems

Grandparents may encounter numerous types of legal problems in raising grandchildren, chiefly due to the informal arrangements of caregiving. Voluntary legal custody requires permission from a custodial parent, and such permission can be difficult for grandparents to obtain from an already troubled adult child who refuses to consent, such as the case of a parent with an addiction (Flint & Perez-Porter, 1997; Jendrek, 1994). Discussions about grandparental custody may intensify ongoing conflict with an adult child and erode familial relationships. Further, temporary guardianships make the relationship between grandparent caregivers and their grandchildren tenuous and insecure for both generations (Waldrop & Weber, 2001). Custody battles, court appearances, and legal fees are the cause of extra financial burdens for many families.

CIRCUMSTANCES OF CAREGIVING

The circumstances under which grandparents assume the primary caregiving responsibility for their grandchildren are often very complex. Several reasons have been cited as etiological factors, including substance abuse (Burton, 1992; Fuller-Thomson et al., 1997; Minkler & Roe, 1993; Minkler et al., 1994), HIV/AIDS (Linsk & Mason, 2004; Schable, Diaz, Chu, Caldwell, & Conti, 1995), incarceration (Dressel & Barnhill, 1994), mental illness (Dowdell, 1995), and teen pregnancy (Kropf & Robinson, 2004). The three most prevalent—addiction, HIV/AIDS, and incarceration—are explored more fully in terms of family situations and consequences.

Drug Addiction

An initial factor in the increase in grandparent caregivers was the crack cocaine epidemic, especially in major metropolitan areas. When a parent's life is ravaged or ended by involvement in crack, caregiving for the children is most often assumed by the grandmother (Roe, Minkler, Saunders, & Thomson, 1996). The highly addictive nature of this drug, the lack of available treatment programs, and the social context of crack addiction often leave the drug user and the family in a prolonged cycle of violence, desperation, and fear (Minkler & Roe, 1993).

Although crack cocaine is a dangerous substance, other types of addiction are also involved in this family situation. Rural communities in particular face a dramatic increase in methamphetamine use. "Crystal meth," "crank," or "ice" is a substance that is easily manufactured with over-the-counter ingredients, and remote locations are a perfect context for "meth labs." In California, a major production site, 3,900 pounds of methamphetamine were seized in 2003, which represents a 50% increase over the previous 3 years (Jewett, 2004). In another high-manufacturing state, Missouri, state troopers reported that 200 labs had been shut down in one county alone during the first half of 2004 (Hathaway, 2004). Methamphetamine is an especially popular choice for women, many of whom are involved with the manufacturing and distribution of the drug as well (Gorman et al., 2003; Strauss & Falkin, 2001). As greater numbers of families experience the negative aftermaths of this potent addiction, greater numbers of grandparents in rural communities are expected to be in caregiving roles for their grandchildren.

The intermittent cycle of substance abuse can create problems within the family system beyond the addiction. When parents are in periods of sobriety, they may initiate contact with their children. This experience may lead to problems such as confusion over familial lines of authority or the experience of reabandonment when the parent leaves again. These issues create caregiving and intergenerational challenges within the family system (Ehrle & Day, 1994; Goldberg-Glen, Sands, Cole, & Cristofalo, 1998).

Incarcerated Parents

Maternal incarceration increasingly contributes to the number of children placed in kinship care arrangements (Dressel & Barnhill, 1994; Young & Smith, 2000). Recent laws to fight drug-related crime have further contributed to the sharp increase in the number of incarcerated women (Gentry, 1998). At midyear of 1998, roughly 83,000 women were estimated to be in federal and state prisons, which translates to 6.4% of all prisoners (U.S. Department of Justice, 1999). Although the exact number of children affected by maternal incarceration is not well established, estimates indicate that female inmates in state prisons had an average of 2.18 children younger than age 18 (U.S. Department of Justice, 1994). Approximately 195,000 children younger than age 18 are affected by their mothers' incarceration (Young & Smith, 2000).

Women in prison, their children, and the children's caregivers present a special population with unique life experiences that warrant the attention of practitioners from several fields. Particular issues related to grandparents who are raising grandchildren of incarcerated parents include the emotional challenges of fostering the parent-child bond during the period of separation. In addition, some grandparents report emotional difficulties of managing attachment to their grandchildren, knowing that the parent will regain custody upon release from prison.

HIV/AIDS

The HIV/AIDS epidemic has also increased the number of grandparent caregivers as infected parents become incapacitated or succumb to the disease. Caregiving by older family members to HIV-infected adults and children has been common in this country

from the beginning of the epidemic (Joslin, 2000; Linsk & Mason, 2004; Poindexter, 2001). At least half of informal caregivers for adults with advanced HIV disease are older relatives (Joslin & Brouard, 1995). At this point, grandparents are typically the care providers who assume responsibility for these "AIDS orphans," many of whom may also have health problems related to their own HIV + status (Calliandro & Hughes, 1998; Poindexter & Linsk, 1999).

As with other pathways into caregiving, the emotional toll for the grandparents is high. Several studies report that older caregivers suffer from HIV stigma themselves. In addition, these caregivers experience grief reactions from anticipating or experiencing the death of an adult child from AIDS (Calliandro & Hughes, 1998; Joslin, 1995; Poindexter, 2001). In spite of the high levels of resilience that are documented in this group, HIV-affected grandparent caregivers report that HIV-related stigma leads to increased social isolation (Poindexter, 2002), and they fear rejection, practice secrecy, lack trust, and report reduced social supports (Joslin, 2000; Linsk & Mason, 2004).

SOCIAL WORK INTERVENTIONS

With the increases in grandparents who are raising grandchildren, social workers in a variety of service settings will work with members of this family form. Therefore, a great need exists for awareness among professionals about the unique problems that grandparents encounter when raising their grandchildren. Most program and service goals are to decrease the grandparents' psychological stress and improve their physical and mental health, social support, and family and legal resources. The following section addresses services and social policies that specifically relate to grandparents who are raising their grandchildren.

Direct Practice Interventions

The most pervasive type of intervention for grandparents who raise grandchildren is a group format. Groups, led by both professionals and nonprofessionals under the auspices of churches, schools, voluntary, and public agencies, have been widely available. Some groups have a more psychoeducational framework and deliver a set "curriculum" with

the participants (Burnette, 1998; Cox, 2002, 2003). Others, however, function as support groups and provide a safe environment for grandparents to discuss the issues that are most important. More than 500 such groups are registered by the Grandparent Caregiver Information Center (AARP, 2004).

Groups are a useful, cost-effective way to meet the educational and support needs of caregiving grandparents. Support groups can help to reduce feelings of isolation, as well as play instrumental roles in providing information. The impact of these groups is underscored by the finding that grandparents have described them as their most valuable resources (Kolomer, McCallion, & Overendyler, 2003; Minkler & Roe, 1993). Support groups provide a safe environment for grandparents to increase their knowledge about child care and augment their social support network with others (McCallion, Janicki, Grant-Griffin, & Kolomer, 2000).

Another direct practice intervention is case management. Using a case management approach, social workers can help caregiving families to mobilize both internal and external resources. For grandparents in more remote locations—for example, those who reside in rural areas—the new experiences of having a child again can be overwhelming, as limited assistance may be available within their communities. Grandparents may lack understanding of how to connect with community programs and may benefit from supportive assistance in learning these skills (Myers, Kropf, & Robinson, 2002). In addition, case managers can help the family identify and develop those resources that exist within the family, such as strong, supportive sibling relationships or good coping resources. An example of a community-based intervention program, Project Healthy Grandparents (PHG), has been implemented in one state as a way to promote strength-based services to these care providers (Kelley, Whitley, Sipe, & Yorker, 2000; Whitley, White, Kelley, & Yorker, 1999). In addition to a primary case manager, a multidisciplinary team (social workers, nurses, lawyers, and others) partners to improve the social, psychological, physical, economic, and legal status among grandparent caregivers.

Social Policy Issues

Changes in social policy are required to make programs more accessible and responsive to the needs of grandparent caregivers. Within public welfare, a

growing number of TANF (Temporary Assistance to Needy Families) recipients are grandparents and other relatives (Larrison, Nackerud, & Risler, 2001). TANF has had a particularly onerous impact on grandparents, with confusion over their benefit eligibility and the work requirements (Fuller-Thomson & Minkler, 2000; Mullen, 1998).

Secondly, the Older Americans Act (OAA; Public Law 106-501) was amended in 2001 to include the National Family Caregiver Support Program (NFCSP). NFCSP distributes funding to the states to work on developing partnerships with Area Agencies on Aging (AAA) and community service providers to develop five basic services for family caregivers: information, assistance in gaining access to support services, counseling, respite care, and supplemental services (Administration on Aging [AoA], 2004). States may use up to 10% of these funds to support services for relative caregivers ages 60 and over who have children in their care.

Several key policy components have been put forth by Generations United (GU), a national coalition that promotes intergenerational programs and policies, especially relative caregivers (Generations United, 2001). In particular, GU has advocated for additional residential options, given the low-income status of a substantial number of grandparents. One program that could alleviate these difficulties is the designation of intergenerational housing that is specifically designed for custodial grandparents (U.S. Department of Housing and Urban Development, 2000). These programs eradicate some of the existing barriers in public housing, such as maximum occupancy rates and space limitations (Kauffman & Goldberg-Glen, 2000).

In summary, the number of grandparents who have responsibility for raising grandchildren has increased dramatically. Various reasons account for this growing number, including increased addiction rates, incarceration of women, and the number of families affected by HIV/AIDS. Grandparents within caregiving roles experience physical, emotional, social, and economic stress. Various interventions, especially support groups and case management, provide grandparents with information, social support, and access to needed resources. However, policies need to be modified to sufficiently address more macro level issues associated with these caregivers.

Future research on grandparents who are raising grandchildren can add to the existing literature about this family form. In particular, the following areas are logical “next steps” in developing the knowledge base:

- *Additional outcome studies about effectiveness of interventions.* Currently, research outcomes have been limited to certain types of interventions, as well as particular groups of grandparents. What interventions are effective with grandparents who reside in rural areas? Besides group interventions and case management, what services or programs can provide education and support to custodial grandparents? What interventions are effective in reducing psychosocial stress in grandchildren who live with grandparents?
- *Longitudinal research designs.* To date, most research has been descriptive or cross-sectional. As grandparents age, how does the caregiving role affect their own aging process? How do children raised by grandparents perform in adult roles, such as intimate relationships, or as parents themselves?
- *Construction of theoretical models of family development.* Are there particular “risk junctures” in the family life course for intergenerational families? How do divergent pathways into caregiving affect family dynamics and functioning? How do grandparents enact their grandparent role with noncustodial grandchildren?

Although knowledge about grandparents raising grandchildren has increased, these additional areas of research will provide information that will be helpful in both understanding and intervening with intergenerational families.

The success that the aging of persons with developmental disabilities (DD) represents also means challenges for families who must provide longer term and new forms of care. In addition, traditional views of family caregivers, particularly older parents as caregivers, must be expanded to include other relatives, such as siblings and grandparents. The aging of persons with DD and their caregivers requires all social workers to renew perspectives, tools, and approaches. The increasing complexity of life history and experiences, health needs, and life transitions also require that a holistic and multidisciplinary perspective be embraced. Drawing on the related research and practice literatures, this chapter outlines key demographic issues for adults with DD and their families and describes changing family caregiving constellations. Suggestions are offered for the assessment and management of life transitions and of grief and bereavement issues that are increasingly a feature of the older years of both caregivers and persons with DD.

THE DEMOGRAPHICS OF AGING

Adults with DD are experiencing increased longevity, and concerns have been raised that this means increased needs for family caregivers and a demand for services and special attention that many jurisdictions are ill prepared to address (Seltzer & Krauss, 1994; Braddock, 1999). When persons with DD were not expected to live into old age, there was a reasonable expectation that parents would outlive their offspring and offer a lifetime of care. The reality that most care was provided in the home also meant that services for persons with DD in their older years were not developed or provided (Ludlow, 2002). For the first time we have sizeable groups of individuals with DD aging and needing related services. Also, the caregiving life of families is now spanning multiple decades and is increasingly a feature of advanced old age for parents and grandparents and of old age for siblings (McCaron & McCallion, in press).

In the United States, it is acknowledged that there are no mechanisms for complete counts of people with DD; reliance is only on estimates. Life expectancy for persons with DD is estimated to have increased from an average of 18.5 years in 1930 to 59.1 years in 1970 to an estimated 66.2 years in 1993 (Braddock, 1999). Based on analyses of New York State data generalized to the United States, Janicki and colleagues go further, projecting continued growth to match life expectancy of the general population (Jan-

PHILIP McCALLION

Older Adults as Caregivers to Persons With Developmental Disabilities

30

icki, Dalton, Henderson, & Davidson, 1999); by 2020 the number of persons with DD ages over 65 is expected to have doubled (Janicki & Dalton, 2000). There are reports of similar growth in the United Kingdom, in other European countries, and in Australia (Hogg, Lucchino, Wang, & Janicki, 2001).

For all of us, aging is a time of transitions, and although it may be compromised by ill health, successful aging may be sustained. However, it will require a different set of services and supports than was true in our younger years. This is also true for people with DD. As much as the aging of persons with DD is a credit to the sustained efforts of families, providers, communities, and professionals to improve their lives, aging also presents its own challenges. Looking at U.K. trends, Holland (2000) speculated that those who survived into old age were probably healthier and harder than those who did not, but he expressed concern about their potential to develop additional aging-related disabilities, such as those associated with strokes, arthritis, and the consequences of chronic illness, and about the lack of preparedness of service networks to address these concerns (Holland, 2000). This is a concern echoed by Cooper (1997) and one that should also be raised for the families who are frequently continuing to provide care (McCarron & McCallion, in press).

DEMOGRAPHICS OF OLDER CAREGIVERS

For all the attention paid to out-of-home care, the majority of people with DD are cared for at home. Estimates from the United States are that 61% of persons with DD are cared for by families and that only 10% live in out-of-home placements. An additional 14% live in their own households, and 15% live with a spouse (Braddock, 1999; Fujiura, 1998). There are aging trends among the caregivers to which attention must be paid; already over 26% of family caregivers are themselves reported to be over age 60 (Braddock, 1999; Fujiura, 1998). Given demographic trends, there is every expectation that a majority of those with DD who are currently being cared for by older caregivers will themselves be over 60 by 2020, that they will likely be cared for by the same but much older caregiver, and that those currently being cared for by caregivers in their 40s and 50s will by 2020 still be cared for by these individuals, who will then be in their 60s and 70s. Finally, even when care has transferred from parents to siblings, they too are likely to be older care-

givers as the persons with DD they are caring for also age (McCallion & Kolomer, 2003).

REWARDS OF CAREGIVING

Effective social work with family caregivers of aging adults with DD requires an understanding of the experiences of those families. Social workers and other professionals face the danger of seeing caregiving families and aging only in terms of needs and deficits (McCallion & Toseland, 1993). Often this occurs because service providers may have limited contact with families, and professional staff members are only brought in when problems are being experienced (McCallion & Tobin, 1995). It is important for social workers to recognize that despite or maybe because of the demands of caring for an adult with DD, there are also rewards associated with being a caregiver. For example, older mothers caring for adults with mental retardation have been reported as having high morale and as rating their health as good or excellent (Seltzer, Greenberg, Krauss, & Hong, 1997). Also, in contrast to mothers caring for an adult child with a mental illness, mothers caring for an adult child with DD tended to report more social support, less subjective burden, and more effective coping strategies (Greenberg, Seltzer, Krauss, & Kim, 1997; Seltzer, Greenberg, & Krauss, 1995; Seltzer et al., 1997). It appears that a history of addressing DD-related concerns builds strengths and confidence in many families (Seltzer et al., 1997).

The research reported on families caring for adults with mental illnesses does suggest that, for mental illness and for care of persons with other disabilities that are not of lifelong duration, the protective effect of a lifelong caregiving experience may not be present. The differences found may also reflect that mental illness brings behaviors that are more difficult to manage and more unpredictable, increasing caregiver strain. Even with caring that has been lifelong, rewards are likely but should not be assumed. One way for social workers and other professionals to anchor their work with families, then, is to begin with an understanding of caregiving strengths by measuring the extent to which families feel in control of their caregiving situation (McCarron & McCallion, in press).

CAREGIVING STRESS

Families with members who have DD are also reported to endure stresses that other families do not

experience. In a review of the available research and clinical literatures, McCallion and Toseland (1993) found that these stresses result from or are expressed in emotional strain, marital discord, sibling conflicts, difficult developmental transitions, unresponsive service delivery systems, and permanency planning concerns.

Although caregivers generally work through initial feelings of stress and strain over giving birth to and caring for a child with disabilities to a stage of adaptation and reorganization, for different members of the family this grieving can reoccur, especially when particular events—for example, increased infirmity and loss of previously learned independence in older age—remind family members of the individual's disability and the changes and sacrifices they have had to make (Ellis, 1989; Gilson & Levitas, 1987).

The presence of a child with DD has been found in some families to exacerbate both conflicts and joys and can place great stress on a marriage; this is often a major reason for caregivers requesting out-of-home placement (Sherman & Coccozza, 1984). Their own old age may be a time of retirement for one or both of the parents, that is, a time anticipated to be one of reduced responsibilities. This expected scenario may not be the case when there is an adult with DD in the home, increasing the potential for discord (McCallion & Toseland, 1993).

The needs of the person with DD may have monopolized the family's resources. Other siblings may have resented the expectation that they should spend large amounts of time caring for a sibling with a disability. These feelings and concerns may reoccur as increasing age of the parents requires that decisions be made as to whether a sibling will now assume caregiving responsibilities (Bigby, 1996).

Job loss, career changes, divorce, retirement, aging, relocation, deaths, and similar transitions in the family's life cycle can also be particularly stressful when a member with DD is present (Gilson & Levitas, 1987). In addition, if caregivers found that the people (including social workers) they turned to for help when their child with DD was born (or experienced other transitions) were unsupportive and that they had to work things through alone, they are more likely both to rely on their own resources during later transitions and to relive earlier stresses (Cook, 1990).

Families of persons with DD have often experienced service delivery systems as unresponsive, fragmented, and dehumanizing. When caregivers face difficulties in obtaining needed information and services, their relationships with professionals become

an additional source of stress. That stress will reoccur when, in the older years of the family, they must reengage with professionals (McCallion & Toseland, 1993). The increasing longevity of people with DD has raised issues of permanency, futures, or long-term planning for persons with DD who outlive parents and even siblings (McCallion & Kolomer, 2003).

DIFFERENT CAREGIVERS, DIFFERENT NEEDS

Traditional caregiving of persons with DD is affected by several important trends: the dramatic increase in single-parent families and lowered birth rates, which reduce the size of caregiving networks; greater participation by women in the workforce, which increases the potential for conflict between work and caregiving responsibilities (Doty, Jackson, & Crown, 1998); and delayed childbearing by siblings and increased age of parents, together increasing the likelihood of multiple coincident caregiving demands on siblings. Caregiving demands are increasingly being placed on all available family members, and family caregivers are increasingly likely to be stressed by their multiple responsibilities (Kaye & Applegate, 1990; Sanborn & Bould, 1991; Toseland, Smith, & McCallion, 1995).

However, responsibility for the care of an adult with DD is rarely shared equally by all family members. It is primarily, but not exclusively, a female responsibility—usually that of the mother—and generally there is one primary caregiver. The identification of a primary caregiver has led many social workers to focus attention solely on this family member. However, there is increasing evidence of the importance of the additional secondary support provided by grandparents (McCallion et al., 2004); fathers (McCallion & Kolomer, 2003); siblings (Connidis, 1997), including brothers and brothers-in-law (Archer & MacLean, 1993; Harris, 1998); and by nephews and nieces (Beach, 1997). When a mother or father is no longer able or available to provide care, persons with DD generally do not have spouses or children to assume care, as do many other aging persons, so the responsibility falls to siblings, if not to out-of-home placements.

Research to date suggests that support by siblings is expressed in a variety of ways. Most often siblings provide emotional, affective support—for example, through telephone calls and visits to an adult with DD (Seltzer, Begun, Seltzer, & Krauss, 1991). Siblings are less likely to provide hands-on or instrumental care.

Indeed, parents are reported to be more likely to expect their other children to take on the role of overseer rather than hands-on care provider to their sibling (Seltzer, Begun, Magan, & Luchterhand, 1993). As social workers engage with siblings as older caregivers, therefore, the workers must be careful not to assume that the siblings will simply continue traditional family care.

Although disabilities occur in all cultural groups, persons of diverse cultures with DD and their caregivers have been found to be underrepresented among those enrolled for and receiving publicly funded services (Grant-Griffin, 1995). The cultural background of a family contributes to decisions about caregiving. Culture, that is, the values, beliefs, customs, behaviors, structures, and identity by which a group of people define themselves (Axelson, 1993), has been found to have an impact on caregiving and on the use of services, but its effects may be difficult to discern and may vary across families. One series of focus groups held with families of persons with DD and culturally based service provider organizations (McCallion, Janicki, & Grant-Griffin, 1997) offered recommendations that culture be assessed family by family if culturally competent interventions are to be initiated. The participants agreed that families often attribute conflict they experience to workers' insensitivity toward cultural concerns and to a lack of recognition of the need to build up trust sufficiently so that families feel comfortable discussing cultural and family issues with them. Some concerns offered were that workers are rarely open to family structures and ways of caring that are different from their own, that they need to avoid stereotyping family members by virtue of their gender or by society's or even their own culture's expectations, and that they must also be open to recognizing that different values and structures may mean that different services are called for. These findings emphasize the critical need for culturally competent practice in work with caregivers of persons with DD (McCallion & Grant-Griffin, 2000).

LIFE CHANGES

Reviews of studies of the self-identified needs of caregivers of persons with DD report that fears about future care when the family caregiver is no longer able to provide it was the highest rated need (Bradley, 1991; McCallion & Kolomer, 2003). Permanency, long-term, or future planning in the DD field, for both the

family member with DD and the family caregiver, is related to such management-of-life transitions in later stages of life as establishing future arrangements for the person with DD in the areas of residential living, legal protection, and financial well-being (Smith & Tobin, 1989). Examples of residential-living permanency planning would be consideration of independent living; of shared households with siblings, with other relatives, or with family friends; and of transitions into supervised apartments, adult foster care, or group-home programs. Legal protection issues include consideration of legal guardianship and conservatorship of person and property issues, including the drafting of wills and other documents. Financial issues include developing arrangements that will ensure continued financial eligibility for needed services for the person with DD while providing for a safety net of resources if those services are not available or are insufficient (McCallion, 1993).

Developing a future-care plan requires effort and collaboration by workers from many disciplines. Social workers play a key role in ensuring that recommendations for care are consistent with the need for a plan, that they merge in a joint rather than a discipline-specific approach, and that they help engage and support families and the person with DD through a difficult process. Despite the potential for traumatic transitions on the death of a caregiver, parents and other aging caregivers are often averse to creating detailed future care plans for their adult children with DD, and many do not involve the person with DD himself or herself in such planning (Heller & Factor, 1991; McCallion & Tobin, 1995). Stress, concerns for safety, and anxiety all contribute to caregivers' reluctance to make concrete plans, and their concern about how the person with DD will feel and his or her ability to understand is used to justify not involving the person with DD in any planning that does occur (Bigby, 1996, 1997; Freedman, Krauss, & Seltzer, 1997). For example, Heller and Factor (1991) found that almost 75% of family care providers for persons over 30 years of age with DD did not make future living arrangements for their family member. Often, too, there is a reluctance to speak of future living arrangements with other family members. Therefore, the expectations that other family members will assume care responsibilities were often implied rather than formally documented (Bigby, 1996). This is the reality, then, in which social workers must address future planning.

However, families who successfully utilize respite and other services have been found to be more likely

to consider residential placement (Caldwell & Heller, 2003). Therefore, one role for social workers may be to encourage and facilitate such related service use. Key services for social workers to be familiar with include: in-home respite care, out-of-home respite or vacation programs, home health aide services, transportation assistance, and day and recreation/leisure programs.

Several manualized approaches to future planning are available that social workers may access for more information and as a basis for developing formal programs:

- The Family Futures Planning Project offers a 10-session curriculum addressing housing options, estate planning, home and community-based services, and caregivers' emotional, physical, and recreational health.
- The Planned Lifetime Advocacy Network (PLAN) offers a six-step approach to guide the development of a personal future plan: clarifying the vision, building relationships, controlling the home environment, preparing for decision making, developing wills and estate plans, and deciding steps to secure the plan.
- In the Family-to-Family Project, family support centers offer presentations on financial arrangements and wills, home ownership and consumer-controlled housing, and developing circles of support. A resource manual is available with information concerning funding sources, housing options, and legal issues (translated into several different languages) and suggestions on outreach to hard-to-reach families.
- The RRTC Family Future Planning Project uses paid facilitators and mentor families to provide information on available supports to both the family caregivers and the person with DD so that they can make informed choices. Information on all these programs, including references and contact information, are summarized in Heller (2000).

GRIEF, BEREAVEMENT, AND FAMILY CAREGIVERS

The increasing age of persons with DD and of their caregivers increases the likelihood of losing family members and other support. Some authors argue that families have been in a perpetual state of bereavement since the birth of an individual with DD (for a discussion, see Todd, 2002). Others suggest that, as the

person with DD ages, many families gain strength and are well adjusted (see, for example, Seltzer et al., 1997). It may be, however, that family members reexperience past senses of loss at major life transitions, such as the death of caregivers (McCallion & Toseland, 1993). Regardless, in work with families, social workers must recognize that there will often be considerable sensitivities and that many family members will resist informing the persons with DD about a death, particularly that of a caregiving parent.

There is both a long-standing belief that persons with DD do not experience the range of emotions that others do—including feelings of grief at the loss of family members and close friends or neighbors—and, conversely, the concern that they will not be able to “handle” the associated feelings (Yanok & Beifus, 1993). These beliefs and concerns are often used by family members to justify not informing persons with DD of the death of parents and for not involving them in funerals and other death and mourning rituals. Yet as they age persons with DD are likely to experience losses through death. The implications of such losses may be greater for persons with DD, as the loss may also mean they will have to move to a sibling's home or to an out-of-home placement (McHale & Carey, 2002). Furthermore, if they have not experienced death and mourning, they will be poorly prepared to understand death and for their own deaths (Clegg & Lansdall-Welfare, 2003).

Although death and bereavement have been poorly researched (Todd, 2002), there is evidence that persons with DD do indeed understand the finality of death and that they have often formed bonds with family members and others such that they feel personal loss and grief. What they do not often have experience in is how to express that grief (Yanok & Beifus, 1993).

Yet grief does surface. Symptoms of normal grief, as defined in the *International Classification of Diseases* (ICD-10), usually occur within 1 month of the bereavement and do not exceed 6 months' duration. For persons with DD, later onset and longer duration of grief symptoms are more likely (for a review of the research literature, see McCarron & McCallion, in press). Also, grief reactions in persons with DD are often manifested in behavioral difficulties. These are more likely to be viewed by family members and others as psychosocial concerns than as the expression of grief (Hollins & Esterhuyzen, 1997; McHale & Carey, 2002).

In many ways, too, the point at which the primary caregiver or another significant family member dies is

too late to be addressing issues of death and bereavement. Yanok and Beifus (1993) argue that, to help a person with DD understand death and the appropriate expression of grief, he or she should be prepared in advance. Such preparation may involve visiting funeral homes, cemeteries, and churches; helping the person to understand community standards regarding the expression of grief in public places; and teaching the person that death is inevitable and irreversible, as well as pertinent vocabulary words. Fauri and Grimes (1994) argue that, when possible, the person with DD should be prepared for death rather than simply left to react to it. An important role, then, for social workers is helping older caregivers develop an openness to dealing with grief and bereavement issues.

A number of formal programs offer suggested approaches and resource materials (see, for example, Blackman, 2002, Botsford, 2000; Cathcart, 1995; James, 1995). Also, the Scottish Down Syndrome Society offers booklets on explaining death and on dementia for persons with DD (available at www.dsscotland.org.uk).

CONCLUSIONS

Older family caregivers continue to provide the majority of care and support for community participation for persons with DD. They deserve the support of social workers in their own right, and the sustaining of family caregiving is an important societal outcome for social work services. This chapter has outlined critical issues involved in working with persons with DD and their aging families, with particular emphasis on those issues most likely to affect and involve social workers. The number of adults with DD is expected to grow further. Family caregivers are also likely to be older, and family care will most probably involve multiple supporters rather than traditional primary caregivers working alone, thus challenging preset notions about caregiving support. Also, social workers who previously saw themselves as working with children or young adults or focused on specific care populations such as the mentally ill or the elderly will find that older caregiver issues and the needs of persons with DD will be increasingly a feature of the families, clients, and systems they work with. For many social workers (and other professionals), this will be a cultural shift and may require that they renew their training to be effective. Future planning

and grief and bereavement are two areas that social workers must be equipped to address.

SANDRA MAGAÑA

Older Latino Family Caregivers

31

Aging family caregivers face unique challenges. These challenges include managing the demands of taking care of someone with a disability at a time in their lives when their own health care needs, responsibilities, roles, and abilities are changing. How these caregivers cope with and adapt to the caregiving process may depend on the caregiving context, including the relationship the caregiver has to the person with the disability, the type of disability the person being cared for has, socioeconomic status (SES), and the ethnicity and cultural characteristics of the family.

It is particularly important and timely to examine aging Latino family caregivers and the racial, ethnic, and cultural context that they provide. The reason is not only that Latinos have become the largest minority group in the United States (Cohn, 2003) but also that Latino families, and especially women, are very likely to be intimately involved with caring for family members who have disabilities across the life span. Many Latino caregivers are faced with challenges associated with low SES, such as poor housing, poor health, and limited access to health insurance and resources. In addition, although “Latinos” come from different countries of origin, with distinct political histories, practices, and customs, some evidence shows that cultural values and practices related to the family may provide a common experience for many Latino caregivers.

Other aspects of the caregiving context that are important to explore among Latino caregivers involve persons who care for family members with different types of disabilities and those who have different relationships to the care recipient. Although these caregivers may have much in common with each other, to what extent do these contexts lead to different adaptations? Caregivers who are parents or relatives of adults with mental disabilities, spouses or children of persons with dementia or Alzheimer’s, and grandparent caregivers of children with disabilities all have distinct and similar caregiving challenges. Those caring for adult children with developmental disabilities have been providing care for a disability that has been manifested since childhood, whereas parents caring for an adult child with mental illness are faced with a later and unexpected onset of mental illness. Caregivers who are spouses or children of persons with dementia, Alzheimer’s, and other aging-related disabilities are similar to the mental illness caregivers in that they are faced with a more recent and often more intense caregiving challenge, but the relationship to the caregiving recipient is distinctly different. On the other hand, grandparents who are caring for grandchildren

are often left to care for young children because the parent, for whatever reason, is unable to meet this challenge. They are different from the other caregivers and also deal with different systems, services, and needs related to children.

The terms *Latino* and *Hispanic* are often used interchangeably as a panethnic label. However, different Latino/Hispanic groups and individuals often prefer one term to the other. For the purposes of this chapter, I use the term *Latino* in general discussions, but when referring to specific studies, I use the terms chosen by the authors of those studies.

Based on the literature about Latino caregivers in these different caregiving contexts, five themes are addressed in this chapter:

1. The well-being of the Latino caregiver
2. Stress and coping among Latino caregivers
3. Family social support and the cultural value of familism
4. Service utilization by caregivers and their family members
5. Interventions with Latino caregivers

The majority of studies of Latino caregivers are of those who are caring for older adults with dementia and Alzheimer's disease. However, studies of older caregivers of persons with mental illness, developmental disabilities, and grandchildren are emerging and are included in this chapter. Because most studies refer to the primary caregiver, we first must explore who primary caregivers are in Latino families.

WHO ARE THE PRIMARY CAREGIVERS IN LATINO FAMILIES?

Similar to non-Latino caregivers, Latino primary caregivers are predominantly women. Studies of caregivers of persons with mental retardation have focused on mothers who tend to be the main caregiver (Magaña, Seltzer, Krauss, Rubert, & Szapocznik, 2002). With respect to family caregivers of persons with mental illness, mothers accounted for most of the primary caregivers, but sisters, spouses, and adult children were also primary caregivers in many cases (Milstein, Guarnaccia, & Midlarsky, 1995; Saldaña, Dassori, & Miller, 1999; Stueve, Vine, & Struening, 1997). In research on caregivers of persons with dementia and Alzheimer's disease, between 74 and 94% of the caregivers are women, with the largest proportion being daughters, and then spouses (Aranda,

Villa, Trejo, Ramirez, & Ranney, 2003; Cox & Monk, 1996; Gallagher-Thompson, Areal, Rivera, & Thompson, 2001; Ho, Weitzman, Cui, & Levkoff, 2000; Morano, 2003; Ranney & Aranda, 2001). A study of Latino grandparent caregivers found that more than 90% of grandparent caregivers are grandmothers (Burnette, 1999a).

Many of the Latino caregivers tend to be younger than caregivers in other ethnic groups, with study averages ranging from 48 to 70 years old (Cox & Monk, 1996; Guarnaccia & Parra, 1996; Ho et al., 2000; Magaña, Seltzer, & Krauss, 2004; Morano, 2003). This finding is partially due to the greater likelihood that middle-aged daughters are caregivers for Latinos with Alzheimer's and dementia. For Latinos with mental illness, many middle-aged sisters, spouses, and adult children provide care. Additionally, Latinos are more likely to be parents and grandparents at earlier ages than the non-Latino population.

With respect to SES, ethnicity matters. Studies of Cuban American caregivers find that they have similar levels of education and income to non-Latino White caregivers (Harwood et al., 2000; Morano, 2003), whereas studies that have included Mexican Americans, Puerto Ricans, Central Americans, and Dominicans show that they have significantly lower levels of income and education in comparison with either Cuban Americans or non-Latino Whites (Aranda et al., 2003; Burnette, 1999a; Ho et al., 2000; Magaña et al., 2002; Ranney & Aranda, 2001). The latter studies report that the majority of their Latino participants have less than a high school education.

Many studies that include Latino caregivers do not report language preference, immigrant status, or acculturation level. Five studies that reported whether caregivers were immigrants or born in the United States showed a range of 53 to 100% who reported having been born in a Latin American country (Aranda et al., 2003; Burnette, 1999a; Gallagher-Thompson et al., 2001; Magaña et al., 2004; Milstein et al., 1995; Ranney & Aranda, 2001). Six studies that reported language of preference of caregivers reported a range of 34 to 98% who preferred Spanish, with an average of 64% across the six studies (Aranda et al., 2003; Burnette, 1999a; Gallagher-Thompson et al., 2001; Magaña et al., 2004; Milstein et al., 1995).

In summary, Latino primary caregivers are more likely to be women across all caregiving contexts (similar to the general caregiving population). Latino caregivers of persons with dementia and Alzheimer's disease are most often daughters, and then spouses, and Latino caregivers of adults with mental and de-

velopmental disabilities are most often mothers, but sometimes siblings and spouses. Latino caregivers tend to be younger than caregivers from other ethnicities. They tend to have lower income and education than non-Latino White caregivers (with the exception of Cuban Americans). Finally, more than half of Latino caregivers (in studies that report this information) are primarily Spanish speaking and born in Latin American countries.

CAREGIVER WELL-BEING

Across all caregiving contexts and Latino ethnicities, research on aging Latino caregivers show that they suffer from high rates of depressive symptoms. This has been found for Mexican American caregivers of persons with dementia (Adams, Aranda, Kemp, Takagi, 2002; Ranney & Aranda, 2001), for Puerto Rican and Cuban American mothers of adults with mental retardation (Magaña et al., 2002), for family caregivers of persons with mental illness (Struening et al., 1995), and for grandparents caring for grandchildren with disabilities (Burnette, 2000).

Furthermore, compared with other groups, Latino caregivers appear to have higher rates of depression or distress. A study that compared well-being of spousal caregivers of persons with dementia from four ethnic groups (Mexican Americans, non-Latino Whites, African Americans, and Japanese Americans) found that the Mexican American caregivers were significantly more depressed and displayed more psychiatric distress than non-Latino White and African American caregivers (Adams et al., 2002). Although the mean number of depressive symptoms was higher for the Mexican American caregivers than for the Japanese American caregivers, this difference was not significant (Adams et al., 2002). Magaña et al. (2004) found that, compared with non-Latina White caregivers of adults with mental retardation, Puerto Rican caregivers reported significantly more depressive symptoms. A study of Hispanic and African American caregivers of persons with Alzheimer's disease found that Hispanic caregivers had significantly more personal and role strains than African American caregivers (Cox & Monk, 1996).

Findings are mixed regarding whether Cuban American caregivers exhibit more depressive symptoms than non-Latino Whites. In a recent study that included a fairly large sample of primarily Cuban Americans ($N = 184$), Harwood et al. (1998) found that the Cuban Americans were more depressed than

non-Hispanic Whites, whereas a study with a smaller sample of Cuban American daughter caregivers ($N = 13$) found that there were no differences in depressive symptoms between Cuban American and non-Hispanic White caregivers (Mintzer et al., 1992). However, given the small sample size of the latter study, it may have been underpowered. Studies also show that Latino caregivers tend to be in poor health compared with other groups (Adams et al., 2002; Aranda et al., 2003; Magaña, et al., 2004).

Only one study examined whether poor psychological well-being among Latino caregivers might be a function of caring for a person with a disability. Burnette (2000) compared grandparents who care for a grandchild with special needs with those who care for grandchildren without special needs and found that those who are caring for grandchildren with special needs had significantly more depressive symptoms. Because distress may be expressed differently across different ethnic groups, more studies are needed that compare caregivers with noncaregivers within the same ethnic group.

Whether cultural or other environmental factors interact with caregiving and lead to higher depressive symptoms among Latinos or whether high rates of depression are the result of some combination of cultural and environmental factors independent of caregiving is a question that needs further exploration. Magaña et al. (2004) found that, although differences in health status explained most of the differences in depression between Puerto Rican and non-Latino White caregivers of adults with mental retardation, an interaction between family problems and ethnicity explained some of the additional variance. Although the presence of more family problems predicted higher depression for both groups, the relationship was significantly stronger for Puerto Rican mothers than for non-Latino Whites. This finding suggests a cultural and environmental explanation: that a greater number of family problems brought about by the caregiving situation affect Latina mothers more than they do non-Latino Whites, possibly due to the cultural value of familism and a more collectivist mindset. Familism includes strong feelings of loyalty, reciprocity, and solidarity among family members (Marín & Marín, 1991). Collectivist cultures emphasize the needs of the group over the needs of the individual (Marín & Marín, 1991). The collectivist nature of familism implies that individuals who are from a familistic culture may be more likely to consider the well-being of the family before considering their own well-being. The combination of this cultural factor

and the poor health of the caregivers (which is highly related to low SES) compound the negative impact on emotional well-being. Other factors that could help explain ethnic differences in depression are the cumulative effects of environmental stressors that so many Latino caregivers face, particularly those who are immigrants. Immigrants face not only problems associated with poverty and low education but also many challenges dealing with immigrant status, language barriers, and lack of knowledge about North American service systems and culture.

To summarize this section on caregiver well-being, an important finding is that many Latino caregivers are at risk for depression across different caregiving contexts and Latino ethnicities. Additionally, Latino caregivers tend to show higher rates of distress than other ethnic groups. More research is needed to determine why. Because poor health is frequently reported for Latino caregivers, more research is needed on physical health as an outcome. Studies are needed that compare the health and well-being of Latino caregivers to those of noncaregivers in order to understand the impact that caregiving has on well-being.

STRESS AND COPING

Many studies on caregiving use stress process models, which examine the impact of environmental, caregiving, and cognitive factors on caregiver stress and which often include appraisals of stress, coping strategies, and resources that may mediate or moderate the effects of caregiving on the caregiver's well-being (Lawton, Kleban, Moss, Rovine, & Glicksman, 1989; Pearlin, Mullan, Semple, & Skaff, 1990). A few studies of Latino caregivers have used a stress-and-coping framework in their analyses (Adams et al., 2002; Cox & Monk, 1993; Cox & Monk, 1996; Magaña et al., 2004; Morano, 2003; Ranney & Aranda, 2001). However, even fewer studies have actually tested for mediation or moderation in their analyses (Magaña et al., 2004; Morano, 2003). Mediation refers to a factor or variable that helps to explain the pathway by which another factor affects the outcome. For example, if we were to say that more maladaptive behaviors of the person being cared for lead to depression in caregivers, we might wish to explain the mechanisms by which this happens. High levels of maladaptive behaviors might lead to an appraisal by the caregiver that he or she is very burdened, which would then lead to depression. We would say that the appraisal of

burden is a mediator between maladaptive behaviors and depression. Moderation often refers to a buffering or protective effect that a factor or variable might have. For example, if caregivers who are caring for someone with high levels of maladaptive behaviors also have high levels of social support, they might be expected to be less depressed than caregivers caring for someone with equally high levels of maladaptive behaviors who have low levels of social support. Social support would be considered a moderator of stress in this instance. Another way in which moderation can be conceptualized is as a variable that, when present at certain levels, actually exacerbates stress. Finally, moderation can also be used to test differences in the relationship of two variables for two groups of caregivers. For example, to test whether two racial or ethnic groups differ on the relationship of social support and depression, a moderation model can be used.

Magaña et al. (2004) hypothesized that family problems that result from caring for a son or daughter with mental retardation would function as a mediator in the caregiving process. They found, consistent with their hypothesis, that family problems mediated the effects of maladaptive behaviors on depression for Puerto Rican and non-Latino White maternal caregivers. This finding suggests that more maladaptive behaviors may lead to more problems in the family, which is then related to higher rates of maternal depression. They further found that there were no ethnic differences in this mediation pattern; however, as reported earlier, family problems were more strongly related to depression for the Puerto Rican mothers than for non-Latino White mothers (Magaña et al., 2004).

Morano (2003) examined appraisals of burden and satisfaction with caregiving and coping styles (e.g., emotion and problem-focused coping) as potential mediators or moderators of stress for Hispanic (primarily Cuban American) and non-Hispanic White caregivers. He found that for the pooled sample, appraisals of burden mediated the effects of caregiving stress on somatic complaints and burden, whereas appraisals of satisfaction moderated the effects of caregiving stress on personal gain and life satisfaction. This suggests a buffering effect in which the relationship of stress on outcomes was reduced for those with high levels of caregiver satisfaction. Research suggests that the presence of high levels of emotion-focused coping might exacerbate stress (Fingerman, Gallagher-Thompson, Lovett, & Rose, 1996; Lutzky & Knight, 1994). However, Morano

(2003) found that emotion-focused coping moderated caregiving effects on depression and life satisfaction in the opposite direction suggesting a buffering effect. Higher levels of emotion-focused coping reduced the relationship between stress and depression and stress and life satisfaction. Morano (2003) did not find mediating or moderating effects for problem-focused coping. Morano (2003) did not test for ethnic differences in the relationship of coping and appraisals to outcomes, so it is difficult to say whether non-Hispanic White and Hispanic caregivers in this study show the same patterns of stress and coping. Adams et al. (2002) found differential use of coping styles between Mexican Americans and other ethnic groups: Mexican American spousal caregivers of persons with dementia were more likely to use escape-avoidance coping than non-Latino White or African American spousal caregivers (Adams et al., 2002). The mediating or moderating effects of escape-avoidance coping were not examined in this study.

Other studies have examined aspects of a stress-coping framework, such as specific stressors, coping strategies and styles, and resources. In addition to coping styles, Adams et al. (2002) examined ethnic differences in different aspects of appraisal and found that Mexican Americans were more likely than non-Latino Whites to show positive appraisal and more likely than non-Latino Whites and African Americans to show pessimistic appraisal. This finding suggests that for Mexican Americans, positive and pessimistic appraisals are not necessarily on opposite poles from one another but represent different constructs. Mexican American caregivers also scored higher on spiritual appraisal than non-Latino White and Japanese American caregivers.

Spirituality has been found to be an important resource for Latino caregivers (Calderón & Tennstedt, 1998; Magilvy, Congdon, Martinez, Davis, & Averill, 2000; Milstein et al., 1995; Stueve et al., 1997; Thompson et al., 2002). Calderón and Tennstedt (1998) reported that Puerto Rican caregivers coped with the burden of caregiving by leaving the outcome in God's hands. Milstein et al. (1995) found that Hispanic caregivers of relatives with mental illness often had hope for a cure, which was linked to their faith in God. Magilvy et al. (2000) identified spirituality as a major theme with respect to health and healing in an ethnographic study of rural Hispanic elders and their caregivers. Stueve et al. (1997) found that Hispanic caregivers of relatives with mental illness were more likely than White caregivers to perceive religion as important in their lives. In a study of pleasureable activ-

ities and mood among dementia caregivers, Thompson et al. (2002) found that Latina caregivers reported obtaining more pleasure from spiritual activities than non-Latina White caregivers. Similarly, a representative study of informal caregivers (Navaie-Waliser et al., 2001) found that Hispanic caregivers were more likely to have experienced increased religiosity since becoming caregivers than non-Hispanic White caregivers.

To summarize this section on stress and coping, religion and spirituality has been found to be an important support factor for Latino caregivers. Some evidence suggests that coping strategies may manifest differently for Latinos than for other groups. The relationship between positive appraisal and burden needs to be explored, as they seem to coexist simultaneously for many caregivers. More research is needed that explores how coping styles and resources mediate or moderate stress and how these relationships are similar to or different from those of other groups. Finally, family variables as key constructs in stress and coping models need to be explored further for Latino caregivers.

SOCIAL SUPPORT AND THE FAMILY

The Latino family has been identified as central in social science literature on Latinos and is sometimes referred to in the context of the cultural value of familism (Aranda & Knight, 1997; Keefe, Padilla, & Carlos, 1979), which was briefly defined earlier. Behaviorally, familism is manifested through three mechanisms, each of which is reviewed in this chapter: support provided by the family, the individual's obligations to the family, and the use of relatives as referents (Sabogal et al., 1987). In the caregiving context, one might expect that support from the family for the caregiver and care recipient would be an important protective resource. Regarding obligations to the family, the obligation to care for a family member preferably in the home may be considered a cultural preference among Latinos. For many Latinas, the role of the caregiver as a cultural obligation becomes a primary role, which may conflict with other roles women play in modern U.S. society; but at the same time it may provide purpose and meaning to caregivers. Another aspect of familism, family members as referents, may be manifested by caregivers consulting with family members for advice on the care provided. This aspect of familism touches on the underlying value of collectivism, in which the good of the entire

family is considered, not just the good of the individual. In this context, the caregiver's perceptions of her or his own well-being may be based partially on the well-being of the family. If other family members' needs are being ignored because of the caregiver's required attention to the care recipient, or if the family is in conflict over some aspects of the caregiving process, the caregiver's own well-being may be jeopardized.

With respect to the first aspect of familism, support from the family for the caregiver or care recipient, some research has examined the extent to which other family members provide direct help in caregiving. In her study of Puerto Rican mothers of adults with mental retardation, Magaña (1999) found that, although the mother performed most of the caregiving tasks, a range of different family members also helped with these tasks, including siblings, fathers, cousins, nieces, and nephews. Similarly, in a qualitative study of caregivers across three ethnic groups, Calderón & Tennstedt (1998) found that the majority of Puerto Rican caregivers had other family members who helped with different caregiving tasks.

Other research has examined social support networks of Latinos and how they compare with other ethnic groups. Studies that compare Latino older adults with non-Latino White older adults report that the Latinos rely more on informal helpers and support than the non-Latino Whites (Mui & Burnette, 1994; Tennstedt & Chang, 1998). In her study of grandparent caregivers, Burnette (1999b) found that many of these older adults had large family networks and other adult family members who helped them in raising their grandchildren. In their study of caregivers of relatives with mental illness, Guarnaccia and Parra (1996) found that Hispanic caregivers had larger social support networks than African American and non-Hispanic White caregivers in the study. However, a similar study of family caregivers of persons with mental illness found comparable levels of support from informal networks across the same three ethnic groups (Stueve et al., 1997), and a study of African American and Hispanic caregivers of dementia patients found similar levels of social support between these two groups (Cox & Monk, 1996). A study of spousal caregivers found that Mexican American, Japanese American, and European American caregivers had similar levels of social support, whereas African American caregivers had higher levels (Adams et al., 2002). These researchers theorized that because the Mexican American caregivers had lower service utilization rates than other groups, those that come to the attention of service providers may be

those who have exhausted or have received minimal support from their social networks (Adams et al., 2002). Similarly, Mexican American caregivers of older adults reported having smaller social networks and using less of their social networks than non-Hispanic White caregivers (Phillips, Torres de Ardon, Kommenich, Killeen, & Rusinak, 2000). The authors theorized that because the Mexican American caregivers were more likely to be recent immigrants, fewer of their family members resided in proximity to them (Phillips et al., 2000).

How family and social support networks relate to caregiver well-being has been the focus of other studies. In the study of Puerto Rican mothers of adults with mental retardation, Magaña (1999) found that close to 90% of the mothers' social support networks were made up of family members and that larger networks and greater satisfaction with the network were related to lower depression among these mothers. Polich & Gallagher-Thompson (1997) similarly found that dissatisfaction with family support was related to higher depression among Hispanic caregivers of relatives with cognitive impairments. However, this was found only among bicultural caregivers, not caregivers who adhered to more traditional Hispanic culture. Cox and Monk (1996) found that the frequency of speaking with and seeking social support from relatives and friends was related to lower role strain among caregivers of relatives with dementia.

With respect to the second aspect of familism, obligation to the family, some research has focused on the commitment to caregiving among Latino caregivers. Calderón & Tennstedt (1998) found that the Puerto Rican women caregivers in their qualitative study felt a strong sense of responsibility and had a tendency to be self-sacrificing, fulfilling a cultural expectation for women. In a qualitative study of rural Hispanic elders and their caregivers, Magilvy et al. (2000) reported that one of the statements heard most frequently was "we take care of our own." These researchers reported that the importance of family and obligation was evident in interviews, observations, and photographic data (Magilvy et al., 2000). In her study of grandparent caregivers, Burnette (1999b) reported that many of the grandparents sacrificed their own well-being to care for family members over the course of their lives. Whether or not the care recipient lives with the caregiver can also be seen as an indication of obligation to caregiving. Some research has found that in comparison with non-Latino Whites, Latino caregivers are more likely to live with the care recipient (Ho et al., 2000; Mintzer, Rubert, & Herman, 1994). Interestingly, one study found that

more non-Hispanic whites caring for elders lived with their care recipient than did Mexican American caregivers (Phillips et al., 2000). This finding may partially be explained by the fact that the majority of Mexican American caregivers in this particular study were adult children, whereas the majority of non-Hispanic White caregivers were spouses. Most research, however, did not report on the coresidency of the caregiver and care recipient.

Little research has focused on the collectivist aspect of familism in caregiving, that of families as referents. This aspect has been examined with respect to advice and decision making by the family on behalf of the individuals and with respect to the fact that caregivers' identity and well-being are strongly linked to that of the group or family. Guarnaccia and Parra (1996) found that caregivers of relatives with mental illness were more likely to go to the family for advice and concerns than to other sources. As cited previously, Magaña et al. (2004) found that there was a stronger relationship between family problems and maternal depression for Puerto Rican mothers of adults with mental retardation than for non-Latino White mothers. These authors theorize that because of a familistic orientation among Puerto Rican mothers in which family needs are emphasized over personal needs, the well-being of the family is closely linked with the personal well-being of the mother. In other words, if the mother perceives that the family is suffering, her own well-being suffers as well.

In summary, research on different aspects of familism shows many similarities across caregiving contexts. With respect to support from the family, caregivers tend to rely on family members for advice, in addition to support. Informal social support networks of caregivers tend to consist primarily of family members. Research is mixed about whether Latino families have larger or smaller informal support networks than other groups. Some reasons for small networks among some Latino families may include the fact that recent immigrants often have left a large part of their family in their country of origin and that caregivers who seek out services may have exhausted many of their natural supports. Size of and satisfaction with social support networks is significantly related to caregiver well-being.

With respect to obligation to the family, some studies have emphasized the exceptional commitment of the Latino caregiver to her role. Some aspects of obligation and role fulfillment may differ based on the relationship of the caregiver to the care recipient. Caregivers who are spouses or parents may be more likely to live with the recipient and provide direct care

than caregivers who are adult children and siblings with their own family responsibilities. Although the primary caregiver performs most caregiving tasks, a range of family members help with these tasks.

With respect to family as referents, findings suggest that Latino families are more likely than other groups to seek advice from family members. In addition, research suggests that the well-being of the Latino caregiver's family is strongly linked to the individual well-being of the caregiver.

SERVICE UTILIZATION

Representative studies that compare formal service utilization of Latino older adults to that of non-Latino White older adults have found that Latinos report lower use of in-home services and nursing home care than non-Latino Whites do (Mui & Burnette, 1994; Tennstedt & Chang, 1998). Dementia-specific care services have also been reported to be underused by Latino caregivers (Aranda & Knight, 1997; Gallagher-Thompson et al., 1997). Because low service utilization often coexists with more reliance on informal family support, the phrase "we take care of our own" is often interpreted to mean that culturally Latino families prefer not to seek services and do not feel they need help. However, caregiver studies that have examined unmet service needs among caregivers have found that this assumption is not supported by the evidence.

In her study of grandparent caregivers, Burnette (1999a) found that although there was a high level of family support, grandparents reported many unmet service needs. Services they reported needing were support services such as toll-free hotlines, support groups, respite services, parent education, and legal services.

A similar analysis of unmet needs of adults with mental retardation and their caregivers was conducted by Magaña, Seltzer, and Krauss (2002). These researchers found that in comparison with non-Latino Whites, Puerto Ricans with mental retardation in the service system had more severe disabilities and lower functional skills. Despite more severe disabilities among the Puerto Rican adults, the number of services used was similar between the two groups. However, the Puerto Rican mother/caregivers reported significantly more unmet service needs. The types of services that Puerto Rican caregivers reported they most needed but had not received were occupational, physical, and speech therapy, respite services, and social and recreational services.

A study comparing service utilization of caregivers of older adults from different ethnicities (European American, African American, Chinese, and Latino) found that there were no differences in the total number of services received between groups. However, Latino caregivers reported more unmet service needs than both European American and African American caregivers (Ho et al., 2000). Latino caregivers reported a greater need for medical, social, and behavioral health services.

In a project that provides dementia-specific outreach and services targeting Latino caregivers, researchers found that by using culturally relevant outreach efforts the agency was able to increase calls to the program by 50% over the pre-outreach project period (Aranda et al., 2003). These efforts included Spanish and English language help lines, bilingual print and electronic media advertising, presentation to consumer and provider groups, community fairs, and consumer-to-consumer referrals. In addition, a bilingual outreach coordinator was hired who conducted face-to-face outreach in nontraditional outreach locations such as laundromats, beauty parlors, and botánicas. Caregivers in this project reported needing support groups, adult day care, respite, transportation services, legal services, and case management (Aranda et al., 2003). The fact that Latino caregivers in these studies are reporting a greater need for services contradicts previous assumptions that culture is somehow a barrier to service utilization.

With respect to barriers to receiving services, Aranda et al. (2003), Magaña, Seltzer, and Krauss (2002), and Burnette (1999a) all found that lack of knowledge about services was the greatest barrier reported by caregivers. Lack of knowledge about services may be linked to lack of culturally and linguistically appropriate outreach in the community, unfamiliarity with how or where to access services, and language barriers between potential recipients and service providers. Magaña, Seltzer, and Krauss (2002) found that an important predictor of fewer unmet service needs and higher use of services was participation in a Spanish-speaking support group. These authors suggest that this may be a culturally appropriate way to educate families about services and how to obtain them.

To summarize, research shows that Latino older adults and caregivers underutilize services. The main barrier to utilization as reported by caregivers is lack of knowledge about services and how to access them. Latino caregivers value services that help them provide better care to their family member, such as case management, respite care, information and educa-

tion, support groups, and day care programs. Culturally specific support groups may be an effective way to provide information about services and access, and outreach tailored to the Latino community can be effective in increasing service utilization.

INTERVENTIONS WITH LATINO CAREGIVERS

Only two published studies were found that test the effectiveness of interventions designed to reduce stress or burden for Latino caregivers (Gallagher-Thompson et al., 2001; Morano & Bravo, 2002).

Gallagher-Thompson et al. (2001) compared Latino caregivers of family members with dementia who received a psychoeducational intervention to reduce stress with Latino caregivers who did not and found that fewer depressive symptoms were reported for the intervention group. Although this intervention program was initially developed for non-Latino White caregivers, adaptations were made, such as translation of materials by a bilingual-bicultural panel, increased use of visual aids, and oral presentation of lessons with the written materials as backup.

Morano and Bravo (1993) conducted a study of Hispanic caregivers of persons with Alzheimer's disease using a psychoeducational model and found that the caregivers improved significantly on a survey of caregiver knowledge. Although no conclusions can be drawn due to the lack of a comparison group, the researcher learned about adaptations that were needed to make the group more effective. These adaptations included the need to be more flexible about strict starting and ending times, the need to include time for caregivers to socialize with and provide support to one another, and the importance of allowing caregivers to bring home-cooked treats.

Clearly, more intervention studies are needed with Latino caregivers, but the aforementioned studies suggest that with culturally relevant adaptations, already developed interventions can be effective.

CONCLUSION

Older Latinos are one of the fastest growing groups in the nation and will have increased by 300% between the years 1990 and 2020 (Administration on Aging). The Administration on Aging (AoA) reports that 27% of Latino households provide informal caregiving to a friend or relative (AoA,). Latino caregivers are diverse with respect to countries of origin, language,

culture, and religion and with respect to the persons they are providing care to. Not only is the number of older Latinos with chronic conditions expected to increase, but the number of Latinos with mental illnesses and developmental disabilities who need care will also increase with growth of the Latino population.

In this chapter, I examined caregiving across Latino ethnicities and across chronic conditions of the care recipients. I found more similarities than differences. Although the majority of studies were cross-sectional and used convenience samples, many of the results are consistent with one another across studies. Some of the most consistent findings are that Latino caregivers are often in poor health, face high rates of depressive symptoms, and report high levels of unmet service needs. Although informal support may be a strength for many Latino families, the extent to which it is available varies greatly, and caregivers who have large family networks still express the need for services. Emerging evidence shows that culturally adapted service outreach and interventions can be effective with Latino caregivers. More research is needed that uses representative samples, examines issues over time, compares caregivers with noncaregivers, and examines differences across type of care recipient and within Latino ethnicities. However, the evidence that there are pronounced needs among this group of caregivers is compelling. There should be no delay in expanding resources to provide services and interventions to Latino caregivers.

Support for the preparation of this chapter was provided by the Hartford Foundation and the Waisman Center at the University of Wisconsin-Madison.

IRIS CARLTON-LANEY

Rural African American Caregiving

32

In general there is a dearth of information about the rural elderly, particularly African Americans (Bullock, 2004; Carlton-LaNey, 1992; Ralston, 1993). Yet a sizable number of African American elders live in rural or nonmetropolitan communities. According to Coward, Netzer, and Peek (1998), 16.2% percent of African American elders live in rural areas, primarily in the southeastern region of the United States. Because of the small number of studies conducted on rural elder African Americans, the data are fragmented, leaving our pool of knowledge somewhat shallow. We do, nonetheless, know that elder African Americans who live in rural communities must cope with an array of critical and often life-threatening problems, including poverty, lack of transportation, inadequate child care, unemployment, substandard housing, inadequate health care, and insufficient elder care. Given these problems, images of spacious, safe, comfortable, relaxed rural communities ring hollow for many African American elders (Carlton-LaNey, Edwards, & Reid, 1999).

According to Arcury, Bell, and Carlton-LaNey (1998), much of the research on rural minority elders in the southeast has been conducted in North Carolina. Several reasons may account for this fact. First, many of the social scientists engaged in research on rural elder African Americans are housed in North Carolina universities. And, further, the state is home to a large population of elders, many of whom are poor, have aged in place, or have returned to the state as “return migrants,” providing a rich participant pool for these scientists. Based on their examination of research, Arcury and his colleagues conclude that future research on minority elders, who are overwhelmingly African American, must take history into account. Ergo, in discussing rural elder African Americans, the impact of blatant and overt racism within a historical context of rural community life is an essential factor that must be considered (Trotman, 2002). This historical backdrop, along with both physical and social isolation, has created barriers to formal services (Arcury, Quandt, Bell, McDonald, & Vitolins, 1998), causing people to avoid the uncertainty of requesting formal services and to instead create their own unique strategy for help seeking, care receiving, and caregiving.

Historically, caregiving among African Americans has existed as part of the fabric of life in those communities. In an article titled “Sitting with the Sick: African American Women’s Philanthropy,” Carlton-LaNey, Hamilton, Ruiz, and Alexander (2001) discuss the history of caregiving from U.S. African enslave-

ment and the slave doctor woman to the racially segregated old folks' homes to Marcus Garvey's Black Cross Nurses through the Great Depression and the Alpha Kappa Alpha Sorority's Mississippi Health Project of the mid-1930s and early 1940s. These authors discuss "sitting with the sick" as a metaphor for myriad caregiving services, including preparing meals for, housekeeping for, feeding, bathing, and generally visiting with individuals who are mentally or physically ill, injured, or grieving. Elders have participated as both givers and receivers of help, and African American women have been intimately involved in all aspects of the caregiving process (Chadiha, Adams, Biegel, Auslander, & Gutierrez, 2004; Trotman, 2002).

Caregiving among African Americans is part of the mutual-aid system that permeates the culture and is a fundamental part of the West African tradition that was replicated in this country (Blassingame, 1979). It was through this system that the slave community and later the community of freedmen and women were able to survive and thrive (Carlton-LaNey, 1999; Hamilton & Sandelowski, 2003).

Groger (1992) emphasized the importance of land ownership in the perpetuation of the mutual aid system. Groger's study of 35 African American informants in rural North Carolina described a series of six informal poverty-coping strategies, including (1) creating a compound, (2) joining a compound, (3) pooling resources in extended households, (4) sharing poverty/making do, (5) drawing on a lifetime of banked favors, and (6) educating one's children (p. 210). Creating a compound with others living on or near the land to which the elder holds sole ownership seemed to set the stage for developing a pool of helpers and for creating long-standing reciprocal exchanges. Scholars agree that this mutual-aid orientation has served African American elders very well by creating an available pool of people who have learned the art of self-help and can offer social support (Dilworth-Anderson, 1992; Hamilton & Sandelowski, 2003). Others note that the mutual-aid system has created a heavy reliance on informal assistance from family, friends, and neighbors and that that reliance, coupled with low income, has tied rural elders to geographic areas, cutting off their options to relocate and limiting their mobility (Koff, 1992; Skinner, 1992). Yet Griffin (1994) found that many rural African American elders acknowledge a commitment to the "homestead" as their primary rationale for preferring to live in their traditional hometowns. This commit-

ment reflects a strong family and community orientation and questions the desirability of relocating.

Within African American communities, family is defined relationally. It includes kin by blood line and marriage, as well as fictive kin. Fictive kin often become vital and important family members who are incorporated into the mutual-aid system. Furthermore, Dilworth-Anderson (1992) notes that within these families, boundaries are permeable and flexible, which fosters caregiving and social debt or a sense of obligation to the family group. The flexible boundaries mean that families are both temporal and stable and are, therefore, poised to meet members' needs as they arise. Elements of the African American worldview help to explain this family structure. This worldview, according to Exum and Moore's (1993) adaptation from Hilliard's work, emphasized the whole, not the parts; focused on acceptance and integration with the environment; favored approximations over accuracy; and valued people over things. This worldview has contributed to African American elders' resilience and has helped to structure their caregiving strategies.

Caregiving is an essential part of African American mutual aid and self-help that has historically permeated the community, providing much-needed service where gaps existed. There are several sources of caregiving for rural elderly African Americans. Table 32.1 identifies many of the major types of caregivers and their positions in the help-seeking journey that rural elder African Americans take. It is important to note that rural elder African Americans utilize a manifold informal helper system, as the table demonstrates. Essentially, they rely on a multifaceted network of informal unpaid helpers who share an array of responsibilities for the elders' care (Chadiha et al., 2004; Li, Edwards, & Morrow-Howell, 2004; Porter, Ganong, & Armer, 2000). These elders, however, are not simply passive recipients of care (Bullock, Crawford, & Tennstedt, 2003). Rather, they are active givers of care, as well. Hamilton and Sandelowski's research (2003) describes an intricate system of reciprocal mutual aid within the African American community that has helped generations to survive racial oppression and economic hardship. Their research findings suggest that there is a need to redefine social support as caregiving and caregiving as social support. They also concluded that the complex and dense nature of social networks function to link people with shared experiences, creating supportive relationships.

TABLE 32.1 Rural Elderly African American Caregiver Paradigm

<i>Personal Resources</i>	<i>Informal/Communal Resources</i>	<i>Formal/Professional Resources</i>
Self	Church (elders, stewards, deacons, church mothers)	Social workers
Nuclear family (spouse & children)	Church auxiliaries (Pastors' Aid committees, sick & shut-in ministries)	Physicians
Fictive kin	Secret orders (Masons & Eastern Star)	Other health care providers
Extended family	Folk healers	Agriculture & home economics extension agents
Friends	General stores (feed stores, seed stores, rural diners)	Social welfare services
Neighbors		Nursing homes

PERSONAL RESOURCES

Caregiving for African American elders begins with personal resources, including themselves, their families—nuclear, extended, and fictive—their friends, and their neighbors (Armstrong, 2000; Barnes, Given, & Given, 1992; Griffin, 1994; Jett, 2002; Porter et al., 2000). Rural elderly African Americans are notoriously self-reliant (Carlton-LaNey, 1993; Carlton-LaNey, 2003; Coogle, 2002). Their reliance on God for support and strength fortifies them and provides the impetus that they need to sustain themselves. Their tendency to call on God as they perform their daily tasks reflects their belief in God's omnipotence and omnipresence. Jett (2002, p. 373) found that it is not uncommon for elders to be heard uttering prayers such as "Oh Lordy Jesus make a way." Similarly, as an elderly African American North Carolina woman caring for her sick husband struggled to get herself out of bed, she invoked the Almighty, saying, "In the name of Jesus, I shall rise" (Kelley, 2004, p. 1E). Through God, these elders believe that they are able to care for themselves. Evoking God's name may also reflect a belief that illness is God's will and that God possesses the power to cure, not people (Reese, Ahern, Nair, O'Faure, & Warren, 1999; Wilson-Ford, 1992).

As mentioned earlier, the family, whether nuclear, extended, or fictive, is one of the rural African American elder's most important sources for care (Dancy & Ralston, 2002; Porter et al., 2000). Living in communities of kin extends the family network. Sengstock, Thibault, and Zaranek (1999) discuss two types of communities that reflect the lives of rural elderly African Americans. They include the "emotionally close communities" and the "geographic communi-

ties" (Sengstock et al., 1999, p. 83). The emotionally close community

continues to be found in the family, which ideally shares a sense of personal closeness, regardless of geographic distance that separates them or how infrequently they see each other. (Sengstock et al., 1999, p. 83)

For rural African American elders, the emotionally close community overlaps with the geographic community, which is the community in which the individual lives. Sengstock et al. (1999) and others note that people must interact, to some extent, with this community due to their common living arrangement. Yet residents may minimize their identity or extent of belonging with the others who live in that community. For rural elderly African Americans, many of whom are aging in place, the community, whether it is an emotionally close community or a geographic community, is a lifeline that professional helpers, including social workers, should learn to nurture.

Skinner (1992) recognizes that aging in place is not a racially or ethnically neutral phenomenon. He notes that African Americans and other minorities experience a unique form of aging in place. He identifies low income, racial segregation, and ageism as three interrelated variables that combine "to create formidable barriers to housing and the free choice or movement" (p. 50). In conclusion, Skinner notes that the aging in place phenomenon creates intense reliance on personal resources, as identified in Table 32.1. The family, friends, and neighbors are important to the survival of the elders in the community and are an essential part of the personal resources system.

Koff (1992) criticizes governmental policy for perpetuating a system of neglect to those elders who age in place in rural communities. He notes that governmental policies reflect a lack of interest in enabling rural elders to age in their residence of choice, in fact negating the provisions of the Older Americans Act of 1965 (amended in 1988), which proposes an array of services and programs to sustain people appropriately in their communities and homes. Koff concludes that a denial of funds has resulted in a de facto policy of differential services for rural and urban elders. As Koff explains it, the four service areas, transportation, health care, housing, and family support are all adversely affected by inadequate governmental funding. The transportation problem, for example, stems from the high cost of providing door-to-door services and of maintaining a bus route for elder passengers, whereas responsive health care is negatively affected by the relatively fewer number of physicians, specialists, and ancillary services in rural areas, along with a maldistribution of these providers. Adequate housing is an especially critical issue for elders in rural communities. Koff (1992) noted that 80% of rural elders own their homes but that the housing is substandard and federal funding to support these individuals has been cut. Further, family support has been affected by the aging of neighbors, along with the continued out-migration of younger family members, making informal help less viable and begging the need for culturally sensitive formal services.

It is important to note that the rural African American population is diverse and becoming more so each day. One group that is adding to the diversity is the return-migrant population. Return migrants are those individuals who migrated to cities in the northeast and midwest during their youth for employment and better opportunities and who, on retirement, are returning to their states and communities of birth (Waites & Carlton-LaNey, 1999). Return migrants present a special complication, as they are viewed as family members retuning home after living away for many years. However, this perspective ignores the fact that they are very different from their counterparts who have aged in place. Moreover, we know very little about them, because they are an invisible segment of the community. Hence we are unable to plan for them as they stream into our small towns and rural communities. Waites and Carlton-LaNey (1999) found, however, that they are active in their communities and that they make good neighbors and strong community advocates. They promise to be a good resource for social workers and for the

rural community overall. Yet they are an unmined neighborhood resource.

Jayakody (1993) has used the term “neighboring” to refer to the relationships and interactions occurring between people living in spatial proximity of one another.” She identifies neighboring as “perceptual and behavioral neighboring” (p. 22). Perceptual neighboring is the sense of caring and good will that is established between neighbors irrespective of contact. Behavioral neighboring involves contact such as visiting and is likely to occur among people who live in rural communities, as well as in mobile home parks, row houses, or ethnically homogeneous communities. Both perceptual and behavioral neighboring influence the type of caregiving that has evolved within the rural community.

Jett (2002) describes an intricate system of caregiving and care-receiving rules that she observed in her research with rural African American elders. The rules essentially state that the person must:

- (a) deserve help, that is, be sure to have lived a good life; (b) have needs that are both essential and genuine; (c) seek help only from those known to be capable of helping; (d) seek help from biological children first; (e) seek help along female bloodlines if biological children are not available or capable and willing; (f) maintain a proper attitude, that is, be humble and not make demands; (g) use the correct language, that is, asking without asking; and (h) trust and wait for people to do without asking (p. 378).

Researchers (Coogle, 2002; Hamilton & Sandelowski, 2003; Li et al., 2004) find that African American elders prefer to get help from those in their personal resource system. When these resources have been exhausted, elders may move to other systems of support, albeit with some reluctance. Behavioral patterns suggest that rural African American elders may use caregivers in the personal and communal system simultaneously or move back and forth between the systems as need arises (Jett, 2002).

INFORMAL/COMMUNAL RESOURCES

The informal/communal resources that are available to rural elderly African Americans include the church, church auxiliaries, secret orders, folk healers, and a network of people who congregate at local gathering

places such as the general stores at many crossroads in rural America (Dancy & Ralston, 2002; Parks, 1988.)

The church is an important part of African American life. It has traditionally served multiple functions, which include providing spiritual sustenance, a community gathering place, a political forum, a social service agency, and an emergency refuge. It continues to hold its place as the most important social institution in the African American community, second only to the family. In rural communities, the church may be small with limited concrete resources, yet it serves as a significant social support for elders. Through the church, elders, who often make up a majority of the congregation, receive compassion, respect, and social support that closely resemble those given by family (Boyd-Franklin, 1989).

Boyd-Franklin describes the church family as another extended family in which the minister is the central figure. The church family provides a support network for rural elders. Through the church family a number of informal social services may be provided. Using the Baptist church as an example, the church family includes the various church auxiliaries, from the deacon board to the Mothers of the Church to the usher board to the various choirs that make up the music ministry. Breakfast or dinner is often served at church—breakfast after the early morning service and dinner after the mid-morning service. If elders are not able to attend church services, church members who visit them may take a meal when they visit on Sunday afternoons. The visitation is also part of the church's outreach to the "sick and shut-in." Members of the church family also provide transportation for elders who are in need. Individuals may routinely take responsibility for taking elders to their doctors' visits or other regular appointments and errands, such as to supermarkets (Watson, 1990). Churches also sometimes have van services that provide transportation for elders who cannot get to church on their own. These vans are also used to transport elders to congregate meal sites that are sometimes located at the church or other governmental facilities.

Porter and her colleagues (Porter et al., 2000) identify two types of church families—the church family in the collective and the church family in the singular. The church family in the collective includes extended family members, friends, the pastor and his or her family, and a host of others. The church family in the singular identifies specific individuals who provide supportive services to an elderly person when needed. The personal assistance that the church family provides may also refer to services provided by a

specific individual who sees the provision of this particular service as part of his or her personal ministry. When the church and various auxiliaries cannot provide care, they are often able to direct the elder to the appropriate formal care system (Walls, 1992).

Secret fraternal orders are also an important supportive service to elders in rural areas. These groups are a significant part of the life of rural communities and have a long, rich history of service to their members. Secret orders include groups such as the Masons, the Order of the Eastern Star, the Grand United Order of Salem, the Sisters of the Tent, the Daughters of Rebeccah, the Daughters of Zion, and so forth. These groups have traditionally allowed people to hold leadership positions and to rise to an unprecedented level of community prominence. Ergo, they have given people the opportunity to develop leadership skills that are important in other aspects of community life. Part of the *raison d'être* of these organizations is to provide service to the members and their families. They are secret in ritual but benevolent in purpose. Historically, many of these groups provided burial insurance policies for members who were not allowed to purchase this type of insurance in the open market because of racial discrimination. The sisterhood and brotherhood that these groups create and perpetuate provides another type of extended or fictive kin system, expanding the elders' network of caregivers.

Folk medicine and folk healers provide a source of informal help for rural African American elders. These individuals provide care when people are ill or injured and cannot or will not seek health care from the formal system. African American elders in rural communities suffer from chronic conditions such as diabetes and hypertension more often than their urban counterparts and more often than Whites (Dancy & Ralston, 2002). They are also at higher nutritional risk, and women have a higher breast cancer mortality rate than their White counterparts (Altpeter, Earp, & Schopler, 1998). Yet they seek health care irregularly and may find it more difficult to secure because of poverty, lack of transportation, and a shortage of physicians within their communities (Dancy & Ralston, 2002).

In addition to the lack of available health care providers and a tradition of racial discrimination, health beliefs also influence rural African American elders' help-seeking choices. Reliance on folk healers, folk remedies, and home remedies often replaces a doctor's care (Taylor, Boyd, & Shrimp, 1998). Because physicians are more available to African Americans and discrimination is not as blatant today as it once

was, African Americans are less likely now to seek folk healers or to use home remedies. Dancy and Ralston (2002) note, however, that rural elders in isolated areas may continue to rely on folk medicine. Similarly, Wilson-Ford (1992) contends that rural elderly African American women continue to use home remedies and self-medication, including over-the-counter drugs, in lieu of physician care.

Caregiving is also provided in commercial community gathering places. Like the urban barber shop or beauty shop, the grocery store-service station equipped with a grill or diner at the rural crossroads (Petrow, 1982), the feed or seed store, or the feed mill are all places where European American and African American elders (usually men) gather on early spring and summer mornings or more frequently during winter months. These were at one time bustling places of business in small towns and rural communities, but as large corporate farming has grown and become more widespread and as the small family farms have died out and many rural elderly African American farmers and landowners have retired or sharecroppers have turned to day labor, these places are sometimes simply places to make small purchases, but mostly places to “sit and talk.” Talk, gossip, news sharing, and general caring for each other have replaced discussions of farming strategies and market information sharing. A cohort of men routinely gathers at these places to simply be together. These environments can become therapeutic settings worthy of note. Social workers and other helping professionals might find these settings strategic places to intervene.

The preceding discussion may appear to demonstrate social support rather than caregiving; however, as noted, Hamilton and Sandelowski (2003) contend that social support is a form of caregiving and caregiving is a form of social support. Social support literature, they contend, presents the typical elderly patient as a passive recipient of care given by one whose only function is that of provider. Their research with cancer patients showed, however, that these persons are in a variety of reciprocal relationships before they become ill and throughout their illness trajectory. They describe a reciprocal exchange that they liken to a “support bank.” They believe that individuals make regular deposits in this bank and “consciously or unconsciously keep mental records of what they have given and received from this bank over the years,” acknowledging the help that they receive as “withdrawing only from previously made deposits” (p. 670). This support bank is a version of the

mutual-aid system of support that has historically characterized the African American community’s response to need. It is critical to the provision of adequate service that professionals are aware of the community’s response to need and its structure, complexity, size, history, and effectiveness.

IMPLICATIONS FOR SOCIAL WORK PRACTICE

Social workers, physicians, agriculture and home economics extension agents, social service agencies, nursing homes, and other health care providers are all part of the formal, professional system of care. They constitute the last line of help that rural African American elders seek. All of these service providers have a professional obligation to meet the needs of this population. Some speculate that the underuse of formal services may result from feelings of vulnerability and powerlessness over resources in the service sector (Chadiha et al., 2004). Griffin (1994) notes that rural African American elders vividly remember the “double standards associated with racial segregation” and the humiliation suffered at the hands of White people that makes them avoid approaching public social institutions for help. Seeking help formally may also suggest family unwillingness to help.

Social workers cannot wait for these elders to seek our services. We must recognize that by the time we see these elders, they have probably exhausted their personal and communal resources. We must, therefore, be especially adept at serving this group, and we are uniquely positioned to do so. Because of the practice breadth, social workers are able to make multiple contributions to this group’s well-being. Social work’s person-in-environment focus, its client-centeredness, and its strengths-based perspective place the profession in a strategic position, beyond that of other professions, to empower and assist rural African American elders (Chadiha et al., 2004).

Social workers must understand the social context of caregiving for this group and engage in planned interventions at all three resource levels—personal, communal, and formal. Intervention at the personal resource level requires that social workers develop meaningful, trusting relationships with their elderly consumers in order to understand and support their caregiving system. Bullock (2004) notes that social workers must become aware of issues associated with preserving resources in African American families

and communities. This includes observing and documenting changes in community dynamics, politically, socially, and economically. It also means noting breakdowns in the personal and communal caregiving systems, such as the death of a caregiver, which can be observed simply by keeping one's finger on the pulse of the community through involvement in community life.

In order to keep our fingers on the pulse of the community, social workers must take time to listen to the members of the target community. This is the best way to learn the types of interventions that are needed and wanted and to develop them with cultural sensitivity and applicability.

Coogle (2002) notes that successful interventions for African American and rural caregivers must "reinforce the basic family infrastructure" (p. 60). She described the Families Who Care Project, which had the following four objectives:

- (1) to form a partnership of the most relevant and significant organizations that might address the continuing needs of African Americans and rural caregivers of elders with dementia, to be called Regional Needs and Resources Teams (RNRTs); (2) to develop a comprehensive, culturally sensitive training package, targeted to caregivers of elders with dementia and organized according to the progression of cognitive, social, and behavioral impairments; (3) to implement and test the train-the-trainer model as a mechanism for caregiver education; and (4) to evaluate the project and disseminate findings for replicability beyond the project period and beyond the geographical regions. (2002, p. 62)

Coogle (2002) found that the use of trusted community leaders as trainers of caregivers was one of the most notable aspects of the project. Through the project, individuals in the community were afforded the opportunity to develop competencies and to become known experts capable of helping families to deal with dementia.

Chadiha and her colleagues (2004) support Coogle (2002) and indicate that social workers should help caregivers to increase their capacity to acquire concrete problem-solving skills. Furthermore, they suggest that social workers aid caregivers to develop the needed political power to influence change at the macro level. Chadiha et al. (2004) also recommend that, when working with African American women

caregivers, social workers build on these individuals' natural strengths and resilience, help them to become empowered, share common ground with them, encourage them to use their own words when speaking, and help them to stay focused on social change.

As professional change agents, social workers must also stay focused on social change. For example, inadequate Medicare policies that do not reimburse for needed services such as patient care coordination, counseling, and education need to be examined, along with other federal, state, and local policies that do not function in the best interests of this population.

In addition to addressing varied social policy issues, social workers also need to examine their profession and to focus on ways to increase social work interest in aging, with special attention to a very vulnerable and neglected segment of that population, rural elderly African Americans.

Furthermore, social scientists need to focus more of their attention on issues that affect the quality of these individuals' lives by evaluating and validating strategies for problem solving. Avenues for further research with rural elderly African Americans include developing and evaluating interventions within a rural context to assist families in mobilizing their informal and community support. They also include utilizing and evaluating Chadiha and her colleagues' (2004) three-layered empowerment model that focuses on (1) raising critical group consciousness through storytelling, (2) teaching concrete problem-solving skills, and (3) teaching advocacy skills and mobilizing resources. And finally, social scientists must identify barriers to formal and informal services and present strategies for overcoming these barriers.

Within one month of Desert Storm and the deployment of American troops, a general assigned to a key position in Europe received a long-distance telephone call from his family priest in Middle America. During the priest's visit to the home of the general's mother, he noticed that she seemed oblivious to the smell of gas in her home and to the fact that the gas valve on her stove was open and not lighted. The general had made no plans for such a contingency and was greatly worried about the welfare of his mother while facing incredible responsibilities at work. (Parker, Call, & Barko, 1999)

Recent research by the National Council on the Aging and the Pew Charitable Trusts (1997), the Metropolitan Life Insurance Company (2004), and the National Alliance for Caregivers and the American Association of Retired Persons (AARP; 2004) suggests that maintaining contact with elderly parents and providing care for them from a long distance represent major challenges for a burgeoning number of families in the United States. According to the National Council on Aging (NCOA), approximately 7 million family members currently provide long distance care, and the NCOA estimates that these numbers will double in 15 years. Other estimates put the number of long-distance caregivers at more than 5 million (Metropolitan Life, 2004). Like the military officer in the opening story, many distant caregivers face an initial crisis with an elderly relative that brings them into contact with America's badly fragmented long-term care system. Such a crisis can signify the transition from "family member" to "caregiver" and the onset of a series of long-term care commitments for which distant caregivers (CGs) are unprepared. We define a *distant caregiver* as anyone (1) who provides informal, unpaid care to a person experiencing some degree of physical, mental, emotional, or economic impairment that limits independence and necessitates assistance; and (2) who experiences caregiving complications because of geographic distance from the care recipient, as determined by distance, travel time, travel costs, personal mobility problems, limited transportation, and other related factors that affect the caregiver's access to the care recipient.

The primary purpose of this chapter is to equip social workers and other human service providers with information that can be used to prepare and empower families who are geographically separated from their

Caregiving at a Distance

33

care recipients. First, we examine research on distant caregiving to provide an evidence-based context for interventions and an overview of key issues faced by distant caregivers. Second, we identify general guidelines, resources, and related issues and questions inherent in the practice literature. Next, we describe an intervention program designed for distant caregivers that has shown promising results in a clinical trial with military families and in a feasibility study with two faith-based communities. We supply important techniques and non-Web-based and Web-based resources from this program that can be used by practitioners in their work with this population, and we conclude with a focus on how professionals can help caregivers assess the merits of the growing number of Web-based resources.

GEOGRAPHIC DISTANCE

To the practitioner, “distant caregiving” may seem antithetical. How can someone provide “care” from a distance? Yet a growing body of research confirms that care is often provided by a growing number of caregivers from a distance. For example, a recent Metropolitan Life study (2004) indicates that nearly half of all long-distance caregivers spend time arranging for needed services or checking that care is being received and that almost three quarters spend time managing finances or providing or arranging for help with other instrumental activities of daily living, such as managing medications, transportation, cooking, or house cleaning. This and other studies indicate that distance complicates the quality and quantity of care provided. Given these considerations, what evidence-based measures of distance are best for practitioners to use in designing an intervention strategy?

Though research on elder caregiving has focused primarily on caregivers who live close to or with care recipients, a few studies have explored the impact of distance on patterns of intergenerational contact and care among current cohorts of caregivers (Wolf, Breslau, Ford, Ziegler, & Ward, 1983). Researchers have assessed whether caregiver contact is affected by the distance of a commute and whether it has a linear relationship with access to the recipient (e.g., Kwan, 1999). These researchers have often used distance and zone-based measures. Researchers using these measures assume equal accessibility within the same zone or distance. Yet this may be, in actuality, a poor indi-

cator of accessibility (Pirie, 1979). For longer distances, numerous other factors—such as the characteristics of the location, personal time budgets for travel, and “travel velocities” allowed by the transportation system—have all been found to affect accessibility (Miller, 1999). As a result, we do not have a clear understanding of the trajectories of contact and care among distant caregivers and their recipients. Furthermore, effective intervention strategies that target distant caregivers are only beginning to be tested (Myers, Roff, Klemmack, & Parker, 2004; Parker, Roff, Toseland, & Klemmack, 2003; Steffen & Mangum, 2003).

In the most recent national study of caregivers in the United States, the National Alliance for Caregivers (NAC) and the American Association of Retired Persons (AARP; 2004) utilized three primary distance categorizations: caregivers who live with the care recipient, caregivers who live less than one hour away from the care recipient, and caregivers who live more than one hour away from the care recipient. Although these measures were effective in discovering patterns of care, a practitioner might ask about a caregiver who lives 500 miles from the care recipient rather than more than one hour away from the care recipient. More than one hour away may not reflect the more typical, distant caregiver’s experience. For example, the National Council on Aging (NCOA) and Pew Charitable Trust’s study (1997) that found distant caregivers average 4 hours’ travel time to reach their care recipient, and the MetLife (2004) study reported that travel distance averaged 450 miles and 7.23 hours of travel one way. Also, if only the measure of *miles away* from the care recipient is used, this may not reflect the experience of someone living within a large city who may have a long commute to go a relatively short distance. Such a caregiver might live only 10 miles from the care recipient, but it might take considerable money (cab fare) and travel time (traffic problems) to respond to a care recipient’s crisis. Other care recipients might live in remote areas with limited accessibility by air or auto. Thus a threshold of more than one hour away from the care recipient seems a poor reflection of reality when considering the disadvantages a caregiver who lives 500 miles away would have in responding to a crisis.

Kart (1997) and Atchley (2000) concluded that almost all studies show that parents prefer to live near, but not with, their adult children. They defined “near” in functional terms as one hour’s travel time

rather than geographic distance. In keeping with a life course perspective, we posit that most caregivers and care recipients will move closer as issues of late life (e.g., chronic disease and disability, death of a spouse, retirement) begin to affect their trajectories of residence and patterns of migration. Future research should attempt to use cluster analysis and other methods to portray more accurately meaningful categories of distant caregivers for practitioners; however, the previously presented research clearly reveals that distance is a complicating factor that should be considered in some manner by the practitioner. Therefore, we recommend that practitioners be *aware* of the thresholds discussed but that they also *collect* the caregiver's actual miles from the care recipient, caregiver's travel time to the care recipient, the caregiver's primary mode of transportation to the care recipient, and caregiver's financial capacity to travel.

CAREGIVING AND WORK

Parent care is becoming an increasingly important personnel issue because it affects worker productivity, retention, and health (e.g., Neal, Chapman, Ingersoll-Dayton, & Emler, 1993). In the latest national survey, distant caregivers who live one hour or more from the care recipient are more likely to have completed a college degree or graduate work and to be working full time. Therefore, it was not surprising that 68% of distant caregivers report making more job-related adjustments than those who lived within one hour's travel from their care recipient (57%; NAC & AARP, 2004). In view of these findings, it is important to note that a review of 15 organization-based programs designed to assist employed caregivers found no evidence of specific assistance for employed, distant caregivers (Coberly & Hunt, 1995).

For many families, residential proximity of adult children to their aging parents is a complicating factor in decisions regarding career advancement. For example, some military personnel elect to retire or resign because of parent care responsibilities (Parker, Call, Dunkle, & Vaitkus, 2002). Those who choose to pursue career advancement options are often required to move farther away from their aging parents for extended periods, thereby decreasing their availability to maintain direct contact with aging parents (Parker, Call, & Barko, 1999). Conditions of distant caregiving add elements of complexity to the potential triple bind of work, child, and elder responsibili-

ties, particularly for working women. More women with children work full time in the United States than in any other nation in the world (Wisensale, 2002). As the full impact of this demographic and cultural change is experienced, the life course theme of elder care will be shared by a growing number of working women and men during midlife. However, competing commitments to parents, to nuclear and other extended family members, and to work make women who care for aging parents particularly vulnerable to stress and career disruption (Moen, Robison, & Fields, 2000).

In assessing the work-related issues for an employed, distant caregiver, the practitioner should gather information through pertinent questions that would explain a caregiver's personal availability and capacity to travel, remembering that an employed woman is more likely to be at higher risk than a man for role conflict and work spillover associated with caregiving responsibilities. For example, the practitioner might want to ask: Is the caregiver fully employed? Does the caregiver have more than one job? Does the caregiver have a work history of issues related to her distant caregiving responsibilities (e.g., being late to work, losing or giving up other positions or promotions, considering early retirement)? Is continued employment considered essential to the caregiver's family's well-being? The answers to these and other questions should help shape a distant caregiver's plan.

DISTANCE CAREGIVING AND FAMILY

The distance factor in family caregiving heavily influences who provides care and the nature and frequency of the care provided (Joseph & Hallman, 1998). In investigating this influence, researchers have defined frequency of interaction between distant caregivers and their care recipients in two ways. Some investigators view various forms of contact (i.e., telephoning, in-person visits) with parents as additive (e.g., Hogan, Eggebeen, & Clogg, 1993). These researchers have assumed that forms of contact are somewhat interchangeable, so that children who are likely to visit are also as likely to call when they cannot visit their parents (Bumpass, 1994). Others have suggested that the frequency and form of contact with parents depend, in part, on the geographic distance between parents and children (Climo, 1992; Baldock, 2000). These later researchers have suggested that distance alters

the nature of the contact with parents by reducing the frequency of personal visits while increasing other types of contact with parents. Call, Parker, Roff, and Toseland (2002) studied the effects of geographic separation from parents on adult children's relationships with their parents and on the nature and extent of parent-child contacts in American families using secondary analysis of data from the National Survey of Families and Households ($N = 3,352$). This research indicates that parent care opportunities are substantially affected by distance, again pointing to the importance of planning.

A major life-course transition, such as a parent's serious illness, may also require adult children to alter their relationship with their parent and to make emotional adjustments. As children perceive that their parents' health is deteriorating, a sense of duty may overtake affections (Abel, 1991); daughters, in particular, are reported to feel less close to parents experiencing poor health (Rossi & Rossi, 1990). Koerin and Harrigan (2002) reported that caregivers had great difficulty watching the deterioration of their parents and found that the greater the distance from parents was, the greater was the challenge to caregivers. Yamamoto-Mitani, Aneshensel, and Levy-Storms (2002) found that parental health status influences the nature and frequency of caregiver contact and support. A national Canadian study of 1,149 caregivers revealed significant, distance-decay effects in the average (weekly) number of hours devoted to elder care and that women were willing to travel farther more often than male caregivers (Joseph & Hallman, 1998). Kaufman and Uhlenberg (1998) postulated that critical life-course transitions affected family relationships, and Szinovacz and Davey (2001) found that retirement was associated with a complex pattern of change in parent-child contact that varied by geographic distance. Kart (1997), Rossi and Rossi (1990), and Logan and Spitze (1996) found that distance was a strong determinant of the frequency of contact between adult children and their parents. Because caregivers want to be there for the care recipient but need to balance that desire with the demands of their employers and their own immediate family members' needs, Baldock (2000) reported that children who live great distances from parents experience considerable emotional conflict and suggested that adult children cope by increasing their telephone and mail contact with their parents. Other researchers (e.g., Dewitt, Wister, & Burch, 1988) found that as distance increases and visits become more problematic, caregivers substitute other forms of contact to bridge the

miles and maintain strong intergenerational ties. Logan and Spitze (1996) found sizeable drops in numbers of visits and telephone calls if the child lived more than 5, 15, and 30 minutes away from parents.

The NAC and AARP (2004) found that distance measured by time-travel thresholds clearly affected caregivers' visits with care recipients. Only 16% of those who lived more than an hour away visited once a week or more, compared with 65% of those who lived less than an hour away. Distant caregivers (one hour away or more) were far more likely to hire a housekeeper to help with caring for their care recipient (50% vs. 36% who coreside), and they were more likely to make family adjustments, such as spending less time with their own families or giving up vacations (56%), to meet caregiving responsibilities than were those who lived less than one hour away from the care recipient (44%). Perhaps the most striking finding from this study was that more distant caregivers reported emotional stress (47%) than any other type of caregivers—that is, those coresiding (43%) or living less than one hour away (28%).

Overall, practitioners working with distant caregivers should consider the following familial issues in developing a long-term care plan: (1) the number of siblings and other relatives able to provide or currently providing assistance to the care recipient; (2) the nature of the caregiver's relationship with the care recipient and with her or his siblings, (3) the personality of the caregiver, (4) care recipient's and caregiver's awareness and satisfaction with current caregiving plans, (5) the caregiver's current pattern of visitation and communication with the care recipient, and (6) the care recipient's medical and functional status.

PRACTICE GUIDELINES, RESOURCES, AND PROGRAMS

When reviewing the practice literature for standard guidelines on work with distant caregivers, we identified some resources that might prove beneficial in such work. In 2003, a comprehensive review of the literature by a panel of national experts representing Caring from a Distance (CFAD), which is a nonprofit organization formed to assist distant caregivers, located over 1,000 books on the subject of caregiving, but only one, by Heath (1993), addressed the topic of distant caregiving. This book includes some potentially useful planning and organizing worksheets for

distant caregivers, but it does not contain newly created Web-based resources. Myers (2003) provides a critique of eleven contemporary books and four videos on the general subject of caregiving, and he includes excellent “encyclopedia-like” resource books for caregivers developed by interdisciplinary teams. We reviewed a variety of documentaries on the subject of caregiving that could be used by practitioners and educators and located only one on distant caregiving, by Patton (2004). Regarding resources under development, CFAD (2003) contacted the U.S. Census Bureau, the Administration on Aging, and the Department of Health and Human Services and concluded that distant caregivers were not on the “federal radar screen”; however, the National Institute of Aging is currently working on the development of a resource and information guide for distant caregivers.

Accepted practice wisdom with distant caregivers typically includes utilization of national elder care locator services, of local Area Agencies on Aging (AAA), of experienced hospital discharge planners and geriatric social workers, of worksheets that assist with the planning and organizing of caregiving tasks, and of geriatric care managers when not cost prohibitive (e.g., Franklin, 2000; Heath, 1993). With respect to geriatric care managers, states have not set comprehensive, uniform standards of conduct (e.g., codes of ethics) and competency (certification and licensure) for geriatric care managers. There are no systematic methods of monitoring geriatric care management for fraud and abuse at the state level, although more than 40 different certification designations related to geriatric care management have been identified (Stone, Reinhard, Macheimer, & Rudin, 2002). Although these and other guidelines are well intentioned, the evidence-based benefit of these directives remains in question. For example, we were unable to locate studies that examined the caliber of services available to distant caregivers with AAAs and the merits of the locator services in searching out the full range of services and resources needed for distant caregivers and their care recipients.

Our review of the overall, evidence-based literature located only four published studies and one conference presentation that evaluated the efficacy of a specific intervention program for distant caregivers (Myers et al., 2004; Parker et al., 2002; Parker, Call, Toseland, Vaitkus, & Roff, 2003; Parker, Roff, Toseland, & Klemmack, 2003; Steffen & Mangum, 2003). Preliminary research with distant caregivers suggests

that those with a parent care plan are at reduced risk for stress-related problems and that employed women, adult children without siblings, and caregivers providing care to parents with cognitive disorders are particularly vulnerable to stress from these responsibilities (Martin & Parker, 2003; Parker et al., 2002; Parker, Roff, et al., 2003; Steffen & Mangum, 2003).

In an effort to address the need for an empirically based comprehensive assessment and intervention program that simplifies the parent care planning process, Parker and an interdisciplinary team of geriatric professionals conducted, over a 5-year period, a series of cross-sectional, prospective, qualitative, feasibility, and clinical trial studies aimed first at military caregivers and their parents and later expanding to academic and faith-based groups (e.g., Jennings, Roff, & Parker, 2004; Myers et al., 2004; Parker et al., 1999; Parker et al., 2002; Parker, Call, et al., 1999; Parker et al., 2001; Parker, Roff, et al., 2003). In one study, Parker, Call, Dunkle, and Vaitkus (2002) explored variables that influenced the mental health of 277 officers at midlife. A structural equation model of mental health and parent care variables provided quantitative support to previous qualitative findings that satisfaction with a realistic parent care plan enhances the mental health of caregivers. In an ongoing effort, Parker (2002) compiled a comprehensive, geographically sensitive state of science and practice resource directory that can be linked conceptually to caregiving tasks. These results and other studies (Parker et al., 2001) provided the impetus for the development of the Parent Care Readiness (PCR) Program.

Parker (2002) and colleagues (Parker, Roff, et al., 2003) identified a total of 50 parent care tasks representing four domains (legal, medical, familial, and spiritual) by systematically surveying adult distant caregivers and a sample of interdisciplinary experts in gerontology and geriatrics (elder law attorneys, geriatricians, geriatric care managers, social workers, psychologists, registered nurses, etc.). Parker (2002) constructed a Parent Care Readiness (PCR) Assessment, the first element of the PCR Program, by combining these tasks psychometrically and using a unique set of scoring algorithms based on the trans-theoretical model of change (TMC; e.g., Prochaska & DiClemente, 1983) to score and to assess caregiver readiness to provide care. This assessment strategy, combined with other program elements (workshop, website, resource directory, expert consultation), was

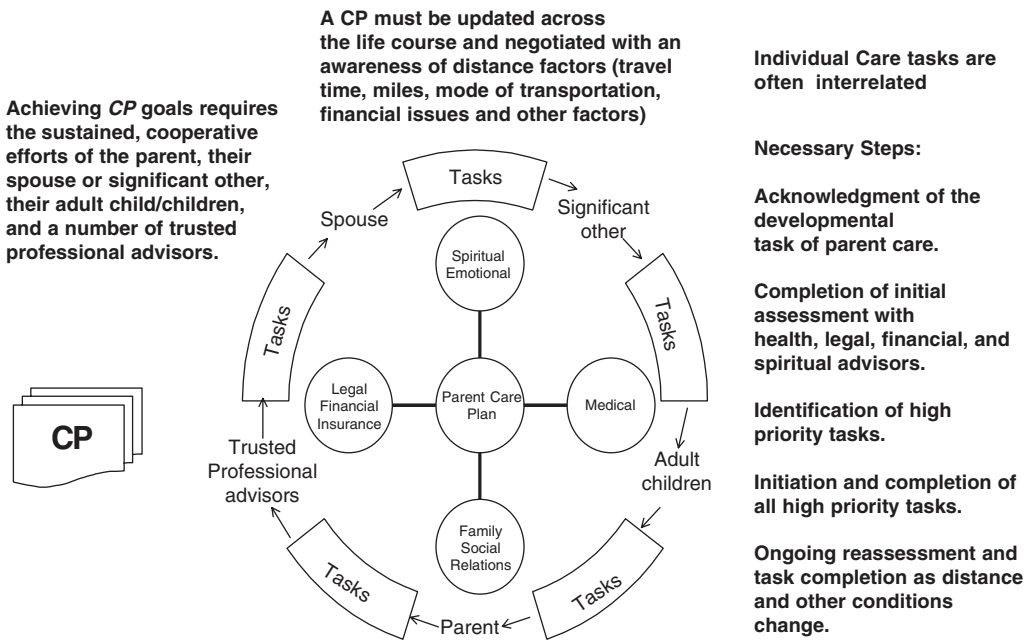

subjected to (1) a randomized clinical trial at the U.S. Air War College using a 2 × 2 partial rollover research design with military families and (2) feasibility studies conducted in Alabama and Texas with faith-based organizations (Myers et al., 2004; Parker, Roff, et al., 2003).

Caregiving Model

The distant caregiving program we propose is illustrated in Figure 33.1. The program consists of a comprehensive evidence-based assessment, computerized scoring and interpretation, and programmed linkage of assessment outcomes to state of science, practice information (prescriptions), and resources to aid caregivers in accomplishing high priority tasks. In short, the PCR Program provides an assessment that leads to a tailored intervention. Practitioners can use the PCR Program during family and individual counseling, and it can be easily augmented for didactic use

in workshops that address primary caregiving themes (medical, legal, spiritual, familial) associated with the task domains. We also recommend using Hollywood motion picture and television program clips taken from movies such as *Dad* or television series such as *JAG* that illustrate the importance of specific tasks and help to activate caregivers.

We view the development of a caregiving plan as a dynamic, ongoing process that involves the initial assessment of the landscape of possible tasks and the completion of specific tasks, followed by a reappraisal process as circumstances change. Using this approach, the caregiving plan consists of specific tasks that have been completed or are in the process of being completed. As the model illustrates, many of the tasks are complex and professionally intensive. For example, if the caregiver needs to find qualified geriatricians who live near her parent, the PCR Program provides a list of qualified geriatricians based on an extensive national and state resource directory that reliably captures this information and geographically

Parker & Martin, 2003

FIGURE 33.1. Model for Developing and Sustaining a Comprehensive Care Plan.

tailors the informational needs for the caregiver and her family. This information helps practitioners locate accurate distant information for their clients, and it may be particularly useful in assisting and directing underserved and disadvantaged caregivers who do not have access to as many resources.

In keeping with this model, the practitioner should emphasize that caring for a parent or elder represents a normal, age-graded (midlife) developmental responsibility that requires preparation. When caregivers are prepared for these tasks, they are likely to experience less anxiety and depression and more of the positive aspects of caregiving, such as the development of closer kinship ties (Kramer & Lambert, 1999; Parker et al., 2002; Parker, Roff, et al., 2003; Steffen & Mangum, 2003). Further, early and thoughtful parent care planning can minimize future barriers (e.g., onset of dementia) to task completion (e.g., durable power of attorney with a health care proxy).

The creation of a caregiving plan begins with a review of the full landscape of caregiving tasks. This is accomplished when the caregiver completes the PCR Assessment consisting of 50 tasks. The PCR Assessment is based on a systematic survey of distant caregivers and national gerontological experts in different disciplines (geriatricians, elder law attorneys, geriatric care managers, gerontological social workers, psychologists, nurses, and psychiatrists). The instrument was subjected to psychometric analysis, and it is scored using algorithms based on the TMC, a viable health intervention framework (Parker, Roff, et al., 2003; Prochaska & DiClemente, 1983). These tasks are listed in an abbreviated manner by domain in Table 33.1. It should be noted that not all tasks apply to all persons. For example, although spirituality and religion are very important to the current generation of older Americans, parent care tasks such as encouraging your parents' faith will not apply to all caregivers or care recipients (see Crowther, Parker, Koenig, Larimore, & Achenbaum, 2002; Crowther, Baker, Larimore, Koenig, & Parker, 2003; Tobin, 1999).

Each domain reflects a set of real-life challenges (specific parent care tasks) that potentially makes up an important aspect of a parent's care plan. For example, the newly automated version of the program has the capacity to identify qualified elder law attorneys who live in close proximity to the care recipient and thereby to facilitate the completion of high-

priority legal tasks (e.g., durable power of attorney). For example, care recipients and caregivers may need a health care power of attorney and advance directives for health care, a power of attorney to conduct business transactions for an incapacitated care recipient, or a "durable" power of attorney directive that endures through the parent's potential incapacity. If the parent has signed a power of attorney and later becomes incompetent by way of dementia, Alzheimer's, illness, or accident, the power of attorney is automatically terminated. In these same circumstances, a *durable* power of attorney would still be in effect.

If practitioners are working with caregivers without the care recipient, caregivers should discuss the outcomes of the PCR Assessment with their care recipients if possible, along with other family members and professionals with expertise in specific areas (geriatric-trained physician, elder law attorney, geriatric care manager). A preliminary feasibility study using this approach suggests that such a joint review fosters consensual forms of communication, minimizes redundancy, and clarifies tasks that require immediate attention (Myers et al., 2004). Examples of tasks listed on the assessment include "Determine the full extent of your parent's health/life insurance coverage as well as Medicare and Medicaid entitlement" and "Evaluate the safety of your parent's home situation (e.g., falls, isolation) and employ appropriate strategies to increase safety." The value of reviewing the full landscape of tasks minimizes the risk of leaving important tasks (e.g., durable power of attorney with a health care proxy) unattended or incomplete. Leaving important tasks unattended or incomplete may result in caregiver burden and depression and inadequate health care, family conflict, and financial exploitation or unintentional dissipation of assets for the care recipient (Campisi, Parker, Marson, Cook, & Moore, 2003; Parker et al., 2002; Steffen & Mangum, 2003).

The PCR Assessment helps caregivers prioritize caregiving tasks. After this process, practitioners can turn their attention to assisting caregivers with the completion of high-priority tasks. Outcomes from the PCR Assessment are linked to *prescriptions* (state of science guidance and resources) to help caregivers complete high priority tasks. As suggested, this process may involve contact with geriatricians and other providers (geriatric care managers) who live in close proximity to the care recipient.

When initially approached by family caregivers, some care recipients may be reluctant to engage in

TABLE 33.1. Domains of Parent Care and Associated Tasks

<i>Legal-Financial Tasks</i>	<i>Medical Tasks</i>	<i>Social-Familial Tasks</i>	<i>Spiritual-Emotional Tasks</i>
Discuss with your parents the advantages of completing and the consequences of neglecting to complete each of the following documents related to estate dispersion and management, advance directives, etc.	Discuss with your parents how involved or knowledgeable he or she would like you to be about their health conditions, diagnoses, medications, and functional status.	Together with your spouse, clarify your own values about where parents' care fits with your other life responsibilities.	Make peace with your parents.
Estate dispersion: <ul style="list-style-type: none"> • Will • Joint Ownership & Tenancy • Trust/Revocable living trust • Durable Power of Attorney • Preferred possession list 	Obtain access to results of comprehensive geriatric assessment.	Assess your relationships with your parents, siblings, and other relatives who would realistically be an acceptable resource for your parent's care.	Secure a video or oral history from your parents.
Advance Directives <ul style="list-style-type: none"> • Health care proxy • Do Not Resuscitate orders • Living Will 	Log information acquired from medical appointments.	Convene a family conference to formulate plans. Address who can and will do what, when, and how for your parents.	Investigate the nature of religious programs for seniors. available for your parents in their home community.
Secure accessible location for legal documents.	Compile a list of parents' health care providers and telephone numbers.	Make sure that you know the name, address, e-mail, and phone number of at least three people who live near your parents and who you could telephone if you could not reach your parents.	Consider active prayer with your parents, and cultivate prayer time with them by phone.
Rule out legal dependency of parents as a way to secure medical and treatment options.	Compile a list of current medications and obtain a copy of current medical records.	Develop a plan that would allow your parent to remain safely in his or her home and a plan that includes a move to another location if this becomes necessary.	Identify your parents' wishes for funeral and burial or cremation. If plans have been made, locate the documentation.
Assist parents in identifying assets, liabilities, income, and expenses.	Verify that primary care doctor or pharmacist is monitoring medications.	Discuss with your parent the possibility of a "panic button" service.	Establish a reliable point of contact of at least one member of your parents' church, synagogue, mosque, or religious organization.
Check parent's social security care for accuracy and review parents' credit history. If applicable, make sure mother has access to joint or separate credit.	Maintain a list of local emergency service providers (addresses, telephone numbers).	Understand the long-term care options available in your parent's home community (living options, in and out of home services).	Encourage your parents to complete a codicil to the will that represents what he or she would like to say to the next generation.

planning activities. Many of the strategies for formulating a family meeting are addressed in the PCR Program prescriptions located in the domain of family tasks. Caregivers should be aware that care recipients might see their attempts at planning as a transgression of their privacy or traditional parent-child boundaries. Care recipients may also view attempts at initiating planning as implying that they cannot plan for themselves or as a way for their caregivers to limit their independence and autonomy, especially with respect to control of their finances. Therefore, it is important for clinicians to help caregivers think through the nature of their relationships with their parents and their parents' likely reactions to engaging in the planning process. This will help caregivers to be sensitive to the likely reaction of care recipients and to think about how to approach the issue with care recipients and about what strategies are needed to prepare for different reactions from the care recipients. There is some preliminary evidence to suggest that a workshop format using the PCR Program provides a useful strategy for addressing these issues, particularly with faith-based groups (e.g., Myers et al., 2004).

The PCR Program model was applied in a 1-day, 5-hour workshop on parent care planning. Unlike a similar feasibility study conducted in Alabama, the Texas intervention was aimed at both adult children and their parents and thus provided an opportunity for members of both generations to address caregiving issues in the same setting. A PCR Assessment was developed for the parents, and the outcomes of the caregivers' and care recipients' assessments provided a valuable avenue for discussion. Whereas church assistance with child care is normative, parallel pro-

grams with older adults may be met with resistance, particularly when there is a cultural perception that finances, health concerns, and legal matters are private family matters. The favorable response and reactions of the older adults and their adult children appeared to be an indicator that open discussion of parent care can be effectively managed. Following a feasibility study, Myers et al. (2004, p. 51) described the PCR program as "a comprehensive map for developing an effective ministry innovation to congregational leaders who want to strengthen the family in later life and promote case readiness." The cultural taboo is that those matters are not spoken of publicly. The PCR Program and workshop for both parents and their adult children intentionally placed the generations together to address care readiness and offered an opportunity for the beginning of conversation about difficult topics introduced by the presenters and activated by mutual completion of PCR Assessments.

During workshops or during work with an individual family, the practitioner can approach reluctant care recipients by focusing on issues such as long-term care or by preparing a health care proxy, concerns that many care recipients may welcome addressing. Once these tasks have been successfully addressed, other, more controversial issues may be introduced as a way to complete the planning process that has been going along well up to that point. Another way to approach the situation is to talk with care recipients about their need for planning and to encourage care recipients to talk about their reactions to the planning process. Care recipients can be encouraged to choose only the types of tasks on which they would like to work. The PCR Assessment facilitates

this process because it reflects those tasks viewed as most important. When PCR Assessment information is available from the care recipient and caregiver, caregivers may also find that care recipients have some plans in place of which caregivers are unaware. This can be very helpful because then caregivers know where to look for documents or other evidence if the care recipients are incapacitated. Caregivers can also discuss with care recipients other tasks that have not been completed and how care recipients plan to address these tasks. Over the long term, this type of gradual approach can help care recipients get used to the idea that they need to plan and that caregivers are available to help them if needed.

In Tables 33.2 and 33.3, we present short lists of valuable national and state resources from this program. Table 33.2 gives important generic sites by task domain (e.g., legal links), and Table 33.3 contains a list of state commissions on aging and related Web addresses through which important links to local services within a state can be reliably identified. Both tables contain sites that address a broad range of caregiving tasks, such as the hiring of a caregiver or the locations of assisted living facilities or geriatric-trained physicians.

The PCR Program was standardized and tested with middle-class caregivers from military, academic, and faith-based communities. Though the efficacy of the PCR Program with underserved populations needs to be evaluated, focus groups and clinical trials are planned for residents of Alabama's Black Belt region, one of the poorest regions in the United States. Despite the preliminary nature of this research with caregivers from military and faith-based communities, the initial outcomes of these studies suggest that caregivers can be helped to prepare *proactively* for the tasks of caregiving using the PCR Program (Parker et al., 2002; Parker, Roff, et al., 2003; Myers, et al., 2004). Though this program has been described in some detail in this section, more explicit information is available (email: mwparker@sw.ua.edu).

The Internet and the World Wide Web

According to the most recent national survey (NAC & AARP, 2004), caregivers turn *first* to the Internet for health information (29%), followed by consultation with doctors (28%), family or friends (15%), and other health professionals (10%). Of those who use the Internet, nearly 90% search for information about

the care recipient's condition or treatment; more than half seek information about services available for care recipients; and 40% look for support or advice from other caregivers. More than 33% of respondents indicate that they need help with information about balancing work and caregiving responsibilities, and minorities are far more likely to request assistance and to experience financial stress related to caregiving.

Other research suggests that distant caregivers, particularly those in crisis, find it difficult to assess and digest the smorgasbord of largely untested informational sources available on the Internet (Parker & Martin, 2003; Setting Priorities for Retirement Years Foundation [SPRY], 2003). Further, those seeking help from local professionals often experience frustration because a paucity of trained professionals are available to assist them in the overall planning process (Martin & Parker, 2003; Parker, Roff, Myers, Martin, Toseland, et al., 2004). Finally, much of the caregiving information on the Internet and in lay-oriented books has not been subjected to scientific scrutiny (SPRY, 2003), and this process is further convoluted because caregivers must tailor the accessible information to the particular needs of their families (e.g., proximate vs. distance care) without the direct guidance of geriatric experts (Martin & Parker, 2003).

It is easy to see why many caregivers are experiencing an "information overload" when consideration is given to the sheer quantity of Internet resources. A recent review of caregiving and health information on three of the most widely used search engines revealed approximately 20,000,000 citations from Excite (www.excite.com), 32,000,000 citations from Alta Vista (www.altavista.com), and 1,346,966,000 citations from Google (www.google.com; SPRY, 2003). Although SPRY (2001) has developed a guide for older adults and caregivers to use in evaluating health information on websites, given these figures, it seems unlikely that caregivers will be able to systematically apply these criteria to potentially relevant sites. It is more reasonable for practitioners to assume this role. In this regard, practitioners should find the PCR and the SPRY-generated guidelines (e.g., Can you tell who created the content? Are you given enough information to judge if the author is reliable? Can you tell if the content is current?) helpful in evaluating caregiving sites before recommending them to caregivers. Eventually, we would like to see a SPRY stamp of approval or grade on all caregiving sites, but for now the

CONCLUSION

Although we are beginning to understand how distance complicates the provision of care to elderly relatives for some populations, we do not have a wealth of evidence-based programs that have been tested with different populations of distant caregivers. Rather than implementing carefully constructed plans that have been formulated on the best possible information and in consultation with the parent and trusted professionals, it would appear that most distant caregivers are not ready to provide care to their parents. Current and future research initiatives

should be aimed at automating assessment and intervention techniques, such as those described in this chapter, and testing the merits of these technological advances in a series of clinical trial studies with various groups, including underserved populations. Until these and other products are broadly available, informed social workers and other practitioners can help distant caregivers by facilitating early and thoughtful parent care planning using some of the resources reviewed in this chapter.

The views expressed in this chapter are the exclusive opinions of its authors, who gratefully acknowledge the assistance of the Gerontological Society of America and the John A. Hartford Foundation's Geriatric Social Work Faculty Scholars' Program, the Center for Mental Health & Aging at the University of

Practice in the Community: Settings for Practice

This page intentionally left blank

OVERVIEW

Unique to the profession of social work is our focus on the interface between an individual and his or her social environment or community. So most professional social workers who serve the elderly and their families practice in the community. These practice settings are varied, and the chapters in this section reflect that diversity. Each chapter considers the legal basis of social work practice in the setting under consideration, as well as the population served and the roles filled by social work professionals. This section offers a wealth of information about the broad-ranging functions that are filled by professional social workers.

Patricia Volland offers a description of social work practice in hospital settings, noting a shortage of professionals qualified to fill these important roles. This shortage is especially important for older Americans, themselves the highest users of hospital services. In an inpatient setting, social work professionals play key roles, not only through direct practice but also as advocates for patient safety and quality of life.

Ted Benjamin and Edna Naito-Chan examine the role of social workers in the development and delivery of home-based care. They note that home-based care is preferred over out-of-home care by most older adults and their families but bemoan the lack of outcome studies on the effectiveness of social workers in these settings. Benjamin and Naito-Chan argue social workers can enhance their status in home-based care through research, improved training, and redefinition of the social work role in this setting.

Pat Brownell tackles the practice of social work in public welfare and social services—settings from which the profession has retreated. She notes a survey by NASW that indicated less than 1% of membership worked in these public sector settings. Then Brownell goes on to describe historic and contemporary roles of professional social workers in public welfare and social services, including work in income maintenance, adult protective services, special housing programs, HIV/AIDS services, kinship care, and domestic violence programs. She offers an insightful description of the dilemmas and tensions inherent in these roles.

Carmen and Barbara Morano offer a description of social work practice in geriatric care management settings. They consider contemporary challenges that arise in these settings, including definitional issues around what constitutes “care management” as opposed to “case management,” the need for culturally relevant services, and developing professional credentials and identification in a relatively new area of practice.

Deborah Waldrop addresses the complex roles played by professional social workers in hospice settings. This chapter considers the history of hospice care, as well as recent trends that have improved care for people who are dying and their families. It includes detailed information about the availability and structure of hospices, as well as the Medicare and Medicaid regulations governing hospice care.

Traditionally underutilized by seniors, community mental health centers (CMHCs) are the focus of a chapter prepared by Sherry Cummings. Tracing the background of social work practice in community mental health centers, she notes the impact of deinstitutionalization and devolution. She notes an emerging focus on “behavioral health care,” and a role for CMHCs in managed care. Indeed, recent studies cited in this chapter suggest that nearly all CMHCs provide services to older adults, and a majority of centers now offer specialized geriatric services. Nonetheless, mental illness among older adults continues to be undertreated, and seniors continue to be underrepresented in these care settings. Cummings projects increased CMHC use by seniors in coming years and outlines the challenges this will pose for the setting itself and the professionals involved.

Philip Rozario presents a call to arms for underfunded and understaffed senior centers. This chapter presents senior centers as vital resources for improving the quality of life for older adults, and facilitating independence. He outlines the important contributions social work professionals have made in this venue and argues that senior centers have untapped potential to serve the aging population.

June Simmons and Susan Enguidanos have prepared a look at social work practice in managed care settings. This chapter offers an overview of managed care in this country, before outlining major debates about the impact of this care model on clients and professionals. Simmons and Enguidanos outline important ethical dilemmas that confront social workers in managed care, with a focus on retaining the core values of the profession while developing “the business acumen” necessary to communicate our effectiveness in this industry.

In a carefully crafted chapter, Robert Hudson examines the role of planning agencies at state and substate levels in improving the quality of life for older adults. He outlines the history of the aging network, with careful focus on the planning challenges professionals have confronted in these settings. Hudson emphasizes the emerging role of these agencies in the planning and delivery of long-term care, predicting

that this will define the identity of the network in coming decades.

Sheila Akabas and Lauren Gates examine the tensions of job and caregiving in their chapter on social work professionals in employment settings. This chapter outlines the cost to employers of failure to address the caregiving needs of their employees, as well as demographic trends that predict these costs will increase in coming years. Akabas and Gates outline the provisions of the Family and Medical Leave Act of 1993, as well as measures taken by individual companies to support family caregivers. They emphasize the potential roles social workers can play in making workplaces more supportive for employees who must care for disabled and dependent elders.

As with CMHCs, substance abuse settings have not traditionally focused their services on older

adults. In their chapter, Connie Corley, M. Gray, and R. Yakimo summarize epidemiological studies on the prevalence of alcoholism in older adults, as well as the diagnostic challenges presented by this population. They describe the service delivery network, and consider the role of Employee Assistance Programs (EAPs). Corley and her colleagues argue that the service delivery system is ill equipped to meet the needs of older adults who suffer from substance use disorders and calls for professional education to alert social workers in all settings to the signs of these problems.

Taken together, these chapters present the array of roles—from direct care to program development and advocacy—filled by social work professionals in our communities. They highlight some of the challenges involved in this work and offer suggestions for future practitioners.

The purpose of this chapter is to inform readers about the health care delivery landscape, with a specific focus on inpatient hospital settings. The chapter briefly describes older adults' use of acute care settings and the types of hospitals providing acute care, examines the payment mechanisms that older adults use to pay for this care, and outlines what special concerns older adults and their families have about acute hospital care. The chapter also includes an overview of the organization and delivery of social worker services in these hospitals.

OLDER ADULTS AND ACUTE HOSPITAL CARE

As Americans live longer, they require more health and social services to address the onset of acute and chronic medical conditions. Aging itself is associated with increased vulnerability to a variety of chronic physical and mental health conditions. Historically, health care in the United States developed around acute inpatient care in hospitals. However, advances in medical technology and increases in life expectancy have expanded care to community, home, and ambulatory settings.

Older adults are disproportionately high users of hospitals. Older people represent 13% of the population (Federal Interagency Forum on Aging-Related Statistics, 2000). Yet, they account for 35% of hospital discharges (Healthcare Cost and Utilization Project [HCUP], 2002). Older people have four times the number of days of hospitalization as those under 65 years of age (Administration on Aging [AoA], 2001).

Chronic illnesses such as hypertension, diabetes, heart disease, arthritis, and cancer are some of the more frequently reported medical conditions of the elderly (AoA, 2001). These conditions are episodic in nature and often require hospitalization to treat the acute episodes. As older patients move in and out of health care systems more rapidly than in the past, their interaction with all health care professionals, including social workers, is likely to be time limited and episodic (Shortell, Gilles, & Devers, 1995).

People age 75 and older experience an average of three chronic health problems at any one time (Gonyea, Hudson, & Curley, 2004). In addition to being at greater risk for chronic physical conditions, a significant proportion of older adults experience mental health problems. For example, older Americans with moderate or severe memory impairment range from about 4% among persons ages 65 to 69 to

PATRICIA J. VOLLAND
DAVID M. KEEPNEWS

Generalized and Specialized Hospitals

34

about 36% among persons ages 85 or older; 23% of persons ages 85 or older report severe symptoms of depression (Federal Interagency Forum on Aging-Related Statistics, 2000). In short, older adults are hospitalized for both physical and mental health episodes. Hospitalization itself can complicate recovery due to iatrogenic events such as infection and other adverse effects of being in a hospital.

TYPES OF INPATIENT HOSPITALS AND HOSPITAL SERVICES

Number and Types of Hospitals

The American Hospital Association (AHA) reported that, in 2002, there were 5,794 hospitals in the United States. The majority were community hospitals (4,927): Of these, 3,025 were nongovernmental not-for-profits, 766 were investor-owned for-profits, and 1,136 were state and local government community hospitals. In addition, there were 240 federal government hospitals, 477 nonfederal psychiatric hospitals, and 128 nonfederal long-term care hospitals (American Hospital Association, 2004).

The AHA defines *community hospitals* as all non-federal, short-term general, and other special hospitals. Special hospitals include psychiatric, obstetrics and gynecology, rehabilitation, and orthopedic hospitals. Community hospitals also include academic medical centers or teaching hospitals. Many hospitals are part of health care systems such as multihospital or diversified single-hospital systems; 2,261 community hospitals are in such a system. Hospitals are also part of *networks*—these are groups of hospitals, physicians, other providers, insurers, and/or community agencies working together to coordinate and deliver care to their community; 1,343 community hospitals are in such a network (American Hospital Association, 2004).

There are four types of hospitals: general, special, rehabilitation, and chronic disease or psychiatric. A hospital's primary function determines how it is classified by the AHA (see list below).

Types of Hospitals

- *General Hospitals* are institutions whose basic function is to provide patient, diagnostic, and therapeutic services for a variety of medical conditions.

- *Special Hospitals* are institutions that provide diagnostic and treatment services for patients with specified medical conditions, both surgical and nonsurgical.
- *Rehabilitation and Chronic Disease Hospitals* are institutions that provide diagnostic and treatment services to handicapped or disabled individuals requiring restorative and adjustive services.
- *Psychiatric Hospitals* are institutions that provide diagnostic and treatment services for patients who have psychiatric-related illnesses.

The bulk of federal government hospitals are those operated by the Veterans Health Administration (VHA). The VHA provides services to 6 million Veterans; 45% are ages 65 and older. The VHA is a community-based model of more than 1,300 sites of care that include 162 hospitals and 21 health care networks (Department of Veteran Affairs, Veterans Health Administration, 2002). The VHA provides care in all categories of hospitals and a wide array of community and ambulatory services.

Collectively, all U.S. hospitals have 983,628 beds; the majority of beds—848,565—are in general hospitals. Hospitals employ 97,931 physicians and dentists; 1,039,994 registered nurses; 151,684 licensed practical nurses; and 3,164,498 other salaried personnel, including social workers. These hospitals train over 90,000 medical, dental, and other trainees. Hospitals range from as few as 6 to well over 500 beds; 39% of hospitals have between 100 and 300 beds (American Hospital Association, 2002). Hospital utilization is projected to increase an additional 7% by 2013, due largely to the aging baby boomer population (Rodgers & Leutz, 2003).

Hospital Services

Services provided are generally similar in acute care hospitals, although the emphasis may be different based on hospital type, location, and governing auspice. For instance, rural hospitals generally provide fewer specialized services; public hospitals may serve larger numbers of underserved and/or uninsured patients. Every hospitalized patient has a physician and receives nursing care. Hospital care is generally focused on diagnosis and treatment of the acute circumstance that led to the hospitalization. Some older patients will require attention for more than one medical condition. Rehabilitation and psychiatric hospitals provide assessment and longer term, inten-

sive therapy services for patients recovering from disabling medical and psychiatric conditions.

Finally, specialized units in some hospitals provide specific types of services to patients, often including older patients. Both acute care hospitals and psychiatric hospitals might have separate geropsychiatric units for older patients with psychiatric disorders and/or behavioral problems. These units include evaluation and treatment from staff specialized in working with patients with dementia, Alzheimer's disease, and other mental disorders that are associated with advanced aging. The existence of specialized units changes based on the needs of the population served by the hospital, the expertise of the staff, and the financing available for specific diseases and treatments.

PAYMENT

The organization and financing of medical care services in the United States is complex; private enterprise and all levels of government are involved (Rice, 1995). Payment for the hospitalization of older adults is usually provided, at least in part, by Medicare and Medicaid or some form of private insurance. Of the total hospital discharges in 2002 (37,804,021), Medicare paid for 34.06%, Medicaid paid for 21.86%, commercial insurers paid for 36.33%, 4.8% were uninsured, and 2.85% were paid by other means (HCUP, 2002).

Medicare

Medicare is a federal health insurance program established by the U.S. Congress in 1965 as Title 18 of the Social Security Act. Medicare is designed to assist individuals ages 65 and older, some disabled individuals under 65, and patients with end-stage renal (kidney) disease. Medicare coverage is tied to Social Security Eligibility or Railroad Retirement Benefits. Individuals who retire before age 65 are not eligible for Medicare until age 65 (Centers for Medicare and Medicaid Services, 2004). There are two major types of Medicare coverage. *Part A* is mandatory and is called Hospital Insurance; it covers services received in hospitals. Thirty-four million older adults were covered by Medicare A in 1999 (Perloff, 2003); 40% of all hospital revenues come from Medicare (Beers & Berkow, 2000); 25% of all Medicare expenditures for a given year are spent during the last year of life of enrollees (Beers & Berkow, 2000). *Part B*, also called

Supplemental Medical Insurance, covers services of physicians and several other practitioners, including clinical social workers, under specific conditions. Part B is available on a voluntary basis to those who are covered by part A. Most Medicare beneficiaries accept part B coverage; over 96% of older adults covered by part A were also covered by part B in 1994 (Moon, 1996). Beneficiaries pay a monthly premium to Medicare for part B coverage (in 2004, the monthly premium was \$66.60).

Medicare pays only 53% of elderly Americans' healthcare costs (Davis & Raetzman, 1999). Beneficiaries face considerable out-of-pocket expenses for uncovered services, copayments, deductibles, and part B premiums. Some of these expenses are associated with outpatient rather than inpatient services (e.g., Medicare covers the cost of prescription drugs provided during an inpatient hospital stay). But there are also significant out-of-pocket costs associated with hospitalization. For instance, beneficiaries are responsible for a deductible for the first day of their hospital stay (in 2004, the amount was \$876) and for copayments for hospital stays beyond 60 days.

Many beneficiaries utilize one or another form of additional coverage to pay for or offset some of these expenses. These include employee health benefits (for both retirees and older adults who are still active members of the workforce), Medicare supplemental ("Medi-gap") plans, and Medicaid (described following; Goldman & Zissimopoulos, 2003). In many states, assistance with Medicare out-of-pocket expenses is available for low-income Medicare beneficiaries who do not qualify for Medicaid coverage through Qualified Medicare Beneficiary and Specified Low-Income Medicare Beneficiary programs (Centers for Medicare and Medicaid Services, 2004).

In most inpatient hospitals, Medicare part A pays for services on a prospectively determined rate—Prospective Payment System (PPS). As a result of the 1997 Balanced Budget Act, PPSs have also been developed for rehabilitation hospitals and psychiatric hospitals (Medicare Payment Advisory Commission, 2003).

Medicare uses different factors in determining payment rates for each type of setting. For inpatient hospital care, payment amounts are based primarily on the patient's diagnosis using a system of Diagnostic Related Groups. Payment is based on an estimate of the intensity of the patient's care needs, combined with factors that vary by geographic region (e.g., wages and the costs of goods and services) and some degree of risk adjustment (e.g., for age). Payment re-

flects an approximation of costs for the “average” patient with similar needs rather than reflecting the actual hospital costs. Services are bundled; the hospital is paid a “global” rate that includes all the services the “average” patient needs. Thus, variations in the types of services that individual patients receive usually makes no difference in payment (see example below).

Medicare Practicum Partnership Program— Case Example

■ Flora is an 83-year-old woman who is hospitalized with pneumonia. She spends 4 days in an acute care hospital. She is given a course of intravenous antibiotics and receives “routine” nursing care. She complains about stiffness in her left leg and is evaluated by a physical therapist. She is discharged soon thereafter. Sylvia, her best friend and next-door neighbor, also 83 years old, is admitted the following week with a similar diagnosis. She receives similar treatment, but she responds more slowly. She appears frail and weak and has substantial difficulty walking without assistance. Her son, who lives in a distant state, mentions that he has grown increasingly worried about her ability to take care of herself living alone. He has invited her to move to live with him and his family, but she has refused. A social worker is called in to assess her needs, talk to her family, and arrange for follow up and evaluation of her home situation. Together, the social worker, Sylvia, and her family, in conversation with the physician, agree that Sylvia will return home with follow-up home nursing care and that her ability to remain at home will be assessed periodically.

Flora and Sylvia received different services, but the hospital will most likely be paid the same amount for the care it provided to each of them. Medicare will pay for care based on the diagnosis, factoring in overall differences in labor and other costs for the area in which the hospital is located. That payment will not specifically reflect Flora’s physical therapy services and Sylvia’s social work services. However, without the social work services, Sylvia would probably have to remain in the hospital for several days more.

This payment system has important implications for all health care professionals involved in hospital care. Most physician services are paid separately and are not reflected in the hospital’s

Medicare payment. The other professional services that the hospital provides, including social work services, are not specifically associated with the Medicare payment that the hospital will receive. However, even though specific services such as social work services may not generate additional revenue, they may save the hospital money. Because the hospital receives the same level of reimbursement regardless of a patient’s length of stay, services that can facilitate earlier discharge can represent a cost savings. ■

Medicaid

Medicaid is a state/federal program that provides medical coverage for many poor patients. About 11% of Medicaid recipients are low-income elderly people (Perloff, 2003). In 2002, Medicaid paid for 21.86% of hospital discharges; 12.99% of those discharges were individuals ages 65 years and older (HCUP, 2002). Medicaid operates with a combination of federal and state funding and is administered by the states. As a condition of receiving federal Medicaid funding, states must provide the following basic services: inpatient and outpatient hospital care, physician services, nursing facility care for persons ages 21 and over, and home health services for persons eligible for nursing facility services. State Medicaid programs can offer many additional services; several state Medicaid programs include the services of clinical social workers and case management services, which, of course, are often provided by social workers. States also vary widely in how (and how much) they pay hospitals and individual practitioners. Some have PPSs, whereas other states pay based on costs and/or a negotiated rate (National Council of State Legislatures, 2005).

SPECIAL CONCERNS OF OLDER ADULTS WHO ARE HOSPITALIZED

No matter what type of hospital an older adult may need to use, many of the same concerns will arise. Paramount is having access to appropriate care and being able to pay for the care. Medicare beneficiaries with low incomes are at greater risk for experiencing difficulties in gaining access to care (Davis & Raetzman, 1999). Older adults and their families will be concerned about being able to successfully recuperate from the hospitalization and, while in the hospital, are concerned about being treated with respect and dig-

nity by the health care team. It is important that all patients, including older adults, are able to count on confidentiality and privacy. A number of regulations have been put in place to protect patient rights, as well as to protect confidentiality (Health Insurance Portability & Accountability Act, 1996; Knee & Vourlekis, 1995). In addition, older adults want to be active participants in decisions about their treatment in the hospital and their care after discharge (Zuniga, 1995). All decisions that will impact their independence need to include the preferences of the older adult patient. Frequently, end-of-life care decisions are necessary; older adults and their families seek guidance, compassion, and understanding to make the best decision. These decisions will focus on issues such as palliative care, do not resuscitate orders, and electing health care proxies—all decisions with serious ethical implications that require careful and thoughtful deliberation. Americans often view older adults negatively and as less useful because they do not work; this “ageism” is often subtle, but it can impact how health care providers consider alternative treatment choices for older adults. Older adults and their families should be able to expect all health care professionals to present treatment options without this ageism bias.

The percentage of older adults who are non-White or Hispanic is projected to increase to about 31% by 2040 from 11% in 1994 (Beers & Berkow, 2000). This increase in cultural diversity can create language barriers and can lead to misunderstanding if health care professionals, including social workers, do not understand language and religious and cultural beliefs of older adults. Older adults want to stay in charge of their own lives and want to remain independent for as long as it is feasible. Social workers are often the health care professionals most qualified to advocate for, and on behalf of, older adults and their families.

SOCIAL WORK PRACTICE

Social work practice has been an important component of health care since the early 1900s. Initially conceived as a service for poor and needy dispensary patients, social work services are now required by a diversity of individuals, both culturally and in terms of health status (Berkman & Volland, 1997). Social work with older adults in health care settings is the fastest growing segment of social work (Beers & Berkow, 2000). Employment of social workers is expected to increase more than 36% by 2012. Reduced length of stay in hospitals may limit the demand for

social workers in hospitals, but it will result in increased demand for social workers in home health services (*S. Rep. No. 108–81 at 219, 2004*). Social work practice with older adults in health care settings is focused on adapting to chronic illness, adjusting to disability and physical limitations, decisions about end of life, compliance with medical regimens, wellness, long-term care, and quality of life. Mental health social work practice focuses on the treatment of depression, substance abuse, chronic mental illness, cognitive deficits, suicide prevention, and adjusting to the changes that these conditions will require of the older adult patient and family (Clark, 2003). The broad scope of gerontological social work services is available in a National Association of Social Workers (NASW) document, “The Gerontological Social Work Spectrum” (NASW, 2004).

Social workers serve as part of the interdisciplinary team to evaluate the patient’s cognitive, behavioral, and emotional status, as well as his or her social support network. Interdisciplinary collaboration is recognized as an essential element to providing effective patient care and facilitating successful social work services (Mizrahi & Abramson, 2000). Working directly with geriatric patients and their families, social workers deal with social support factors that create or exacerbate problems in living (Beers & Berkow, 2000; Mizrahi & Abramson, 2000). Social workers are viewed as helping older patients and their families navigate systems of care and provide case management services that are designed to help older adults stay in charge of their lives.

Because of fiscal constraints and the advent of managed care, length of stay in all hospitals has been decreasing; this leaves less time for social workers to provide needed services. As a result, social work services in hospitals are often short-term crisis-based interventions (Aviram, 2002). Recognizing the hospital’s need to control costs, social workers have adopted strategies to provide care to older adults and, at the same time, help the hospital meet this goal. Such strategies include development of care maps and care management strategies (Berger, Robbins, et al., 2003). An expectation of these strategies is that social workers will be effective in helping patients manage the utilization of resources in a cost-effective way.

The functions of social work practice in health care vary by level of care and type of health and mental health setting. Social workers employed in acute hospital settings place the emphasis of their work on high-risk screening, brief counseling, bereavement services, discharge planning, collaboration, informa-

tion, referral, follow up, and emergency services on-call programs (Poole, 1997; Ross, 1997).

Social workers are usually assigned to specific medical or psychiatric services or specialty units in hospitals. Social work services are not routinely provided to hospitalized patients (whether they should be is another question). A number of methods for identifying patients who need social work services have been developed; these include high-risk screening (Berkman, 1996), attendance on rounds and in discharge planning conferences, referrals from other health care professionals—usually nurses or physicians, or patient or family referral. In one study of over 1,000 patients in 5 acute hospitals, 18% received social work services. Patients most likely to receive social work services were older, single women who lived alone, had physical limitations, and experienced long lengths of stay (Oktay & Steinwachs, 1992).

On specialty units, such as geropsychiatry and geriatric evaluation units, social workers usually provide at least an initial psychosocial assessment to determine the need for ongoing social work services. A study by Oktay and Steinwachs (1992) revealed that social work services (discharge planning) with older adults in hospitals is increasingly important; their study confirmed that older adults do benefit from social work services, but many older adults did not see a social worker during hospitalization, even though they reported needing this service.

Hospitalized older adults often need evaluation of psychosocial factors that determine where the patient will go following discharge. Factors such as caregiving needs and availability, family support, home and community environment, and financial supports need to be assessed and understood so that an older adult has the best chance of the fullest recovery possible. Often, social workers address financial/payment issues—including insurance coverage and arrangements for postdischarge services. This often requires case management to determine which postdischarge option best meets the patient's needs—home health care or longer term treatment in a skilled nursing facility, a rehabilitation facility, or other setting.

In the VHA system, social work services provided include evaluation and crisis intervention, as well as psychosocial case management and discharge planning (Becerra & Damron-Rodriguez, 1995). The VHA—one of the largest employers of social workers in the nation (employing over 4,000 graduate social workers)—defines *psychosocial case management* as including family relationships, community integration, and financial/legal/housing issues that impact health

and functioning and need for support (J. Manske, personal communication, 2004).

With the pressure on hospitals to reduce length of stay and control costs, social work services, like all professional services, have been impacted. Reduction in supervisory and management staff (Berger, Cayner, et al., 1996; Mizrahi & Berger, 2001), increased case loads, and a perceived lack of support from other staff (Kadushin & Kulys, 1995) have been the result of these pressures on hospitals. Organizational changes have also been reported; the traditional departments of social work are usually maintained with some departments being combined with other professions, such as nursing, as part of case management and discharge planning units (Mizrahi & Berger, 2001). Leaders in hospital-based social work are developing methods to support social workers in this challenging environment, including promoting professional staff (Blumenfield & Epstein, 2001).

There is a reported shortage of social workers trained to work with older adults in all settings; the U.S. Congress has directed the Department of Health & Human Services to prepare a report about this shortage (Department of Labor, Health & Human Services & Education & Related Agencies Appropriation Bill, 2004). The workforce shortage is not the only challenge facing social work leaders. The shifts in social work practice in health care settings have also led to recognition that recent graduates are not well prepared to help patients and families who need health and mental health services. One study has identified the need for increased synergy between the two components of graduate social work education—the field experience and the didactic instruction in the classroom as a method to increase the pool of skilled social workers to work in health care settings (Volland, Berkman, Phillips, & Stein, 2003). One such model—The Practicum Partnership Program (PPP)—is a part of the \$26.3 million Geriatric Social Work Initiative (GSWI, available at www.gswi.org/programs_services/index.html) funded by the John A. Hartford Foundation. The PPPs have already produced over 300 graduates competent to work with older adults in all settings (Damron-Rodriguez, Lawrance, & Lee, 2000–2003). The combined efforts of the GSWI—faculty scholars, PPP, doctoral fellows, faculty development, and geriatric enrichment programs—are having a positive effect on increasing the number of social work students being trained to work with older adults (GSWI, 2004; John A. Hartford Foundation, 2003).

Social workers who work with older adults in all hospital settings will be required to meet challenges that result from (a) the increased number of older adults, (b) the increase in chronic illness, (c) the changing systems of service delivery, (d) the increased diversity of the aging population, (e) the increased expectations for family responsibility in care, and (f) the lack of capacity in gerontological social work (Volland & Berkman, 2004).

The community of social work practitioners and educators is already preparing to meet this challenge. The GSWI is one example. Social work researchers have established priorities for research in gerontological social work that includes the development of evidence to support the positive outcomes associated with good social work practice (Burnette, Morrow-Howell, & Chen, 2003). This is compatible with development of evidence-based practice that has emerged as a part of hospital service delivery.

Quality-of-Care Issues

During the early part of the 1990s, significant concern arose in the health care system about the ability of providers and institutions to maintain quality of care in the face of growing pressure from managed care and in an environment of fiscal constraint. As a result, evidence-based practice emerged, and a literature has emerged on the “quality chasm” (Institute of Medicine Committee on Quality of Health Care in America, 2001; Rizzo & Rowe, 2003). The value of evidence-based practice rests on its systematic examination and appraisal of professional practices and outcomes, whether clinical, fiscal, organizational, or educational (Rosenfeld, 2003).

One method for ensuring the quality of social work services is through the establishment of standards. NASW has developed standards for social work practice in health care settings and for social work case management. Credentialing and specialty certifications are available for individuals as evidence that social workers have met these standards (National Association of Social Workers Credentialing Center, 2004). As older adults and their families become informed consumers, such credentials will be more important as evidence of quality practice.

The profession of social work is in the formative stages of developing evidence-based practices. Although there are studies that report high patient satisfaction with the care that social workers provide (Boult, Boult, Murphy, Ebbitt, Luptak, & Kane, 1994;

McNeill & Nicholas, 1998; Toseland, O'Donnell, Engelhardt, Hendler, Richie, & Jue, 1996; Toseland, O'Donnell, Engelhardt, Richie, Jue, & Banks, 1997; Williams, Williams, Zimmer, Hall, & Podgorski, 1987), there is also some evidence that older adults and their caregivers perceive the discharge planning process as negative and somewhat coercive (Clemens, 1995).

Evidence does articulate the effectiveness of social work with older adults in hospital settings. There is evidence that social work interventions result in positive care management; as a result of social work services, caregivers report decreased feelings of stress (Peak, Toseland, & Banks, 1995; Toseland, Labrecque, Goebel, & Whitney, 1992; Toseland, McCallion, Smith, Huck, Bourgeois, & Garstka, 2001), communications between patient/family and health care providers are improved (McCallion, Toseland, & Freeman, 1999), care coordination is improved, quality of social and health care is improved (Toseland et al., 1996; Toseland et al., 1997; Williams et al., 1987), knowledge of community resources is increased (Peak et al., 1995; Toesland et al., 1992; Toseland et al., 2001), and cost savings for hospitals can result (Rizzo & Rowe, 2003). The social work profession will need to continue to build evidence of effectiveness of practice and demonstrate the importance of its role in providing high quality and safe patient care to older adults who use inpatient hospital service.

SUMMARY

Social work practice in hospital settings is linked with social work practice with older adults (Berkman, 2004). The aging of the baby boomers will further stress hospitals and health care professionals who work in hospitals. Evidence of effective practice will be required to address the shortage of trained social workers to work with older adults in all hospital settings. Quality of care and patient safety will remain key focuses for professionals in hospital settings for the foreseeable future. Social workers will be essential as advocates for older adults who will require hospital care.

Home Care Settings

35

Social work plays an important role in the development and implementation of home care, which has become the preferred care option for growing numbers of disabled and chronically ill older adults. While professional social work knowledge, skills, and values are well suited to address the needs of home care clients and their caregivers, social work is often viewed as a professional service secondary to physician and nursing care, which are considered the primary home care services (Berger, 1988; Kane, 1987). Moreover, the lack of outcome studies on the effectiveness of social work services has contributed to this perception of social work as an ancillary service, and thus to the underutilization of social workers in home care (Lee & Gutheil, 2003). Nonetheless, the emerging field of home care provides opportunities for social work that can significantly expand its role and contribute to the health and well-being of older adults and their families. This chapter provides an overview of social work practice in home care, including a historical perspective on this practice arena, social work's current role and functions, and government policies and funding mechanisms for home care that have both shaped and constrained social work practice. We conclude with a brief discussion of some challenges involved in enhancing the visibility and role of social workers in home care and suggest some possible solutions.

DEFINITIONS

“Home care” refers to services provided by home care organizations, which include home health agencies, hospices, homemaker and home care aide agencies, staffing and private-duty agencies, and companies specializing in medical equipment and supplies, pharmaceuticals, and drug infusion therapy (National Association for Home Care & Hospice [NAHC], n.d.). Several types of home care organizations may merge to provide a wide variety of services through an integrated system. For example, a home health agency might also provide hospice care and homemaker services. This chapter will focus on home health care and homemaker service agencies, which are the most frequent users of social work services among home care organizations. Hospice care, in which social work plays an integral role, is addressed at length in chapter 38 in this book.

Home health care (HHC) is often associated with the type of care provided under the Medicare home health benefit. Medicare characterizes HHC as en-

compassing “a wide range of health and social services . . . delivered at home to recovering, disabled, chronically or terminally ill individuals in need of medical, nursing, social, or therapeutic treatment and/or assistance with activities of daily living” (Centers for Medicare & Medicaid Services [CMS], 2003a). Activities of daily living (ADLs) are self-care activities that include bathing, dressing, feeding, toileting, and transferring. Assistance with ADLs is known as personal assistance or care. Despite Medicare’s rather broad characterization of HHC, older persons actually qualify for home health care because of medical conditions and related assistance needs, and supportive care needs are considered secondary. *Homemaker service agencies*, on the other hand, employ workers who provide personal assistance, that is, help with ADLs, as well as homemaker and chore services, which include assistance with meal preparation, housekeeping, laundry, shopping, and transportation, termed instrumental activities of daily living (IADLs). The needs of older adults requiring these services tend to be ongoing and primarily related to functional impairment more than medical need; hence they are supportive rather than medically oriented services.

HOME CARE FOR AN AGING SOCIETY

The growth of the home care industry in the United States has been both dramatic and dynamic. The National Association for Home Care and Hospice (NAHC) reported that there were about 1,100 home care agencies in 1963. By 2001, this number had grown to more than 20,000 providers delivering home care services to about 7.6 million persons with acute or chronic health conditions, permanent disability, or terminal illness (NAHC, 2001). While the 1965 enactment of Medicare and Medicaid legislation accelerated the growth of the home care industry, the high risk of disability and chronic illness that are hallmarks of an aging society has made home care an increasingly attractive option for older adults and their caregivers. In 2000, about 26.1% of those 65–74 years old and 45.1% of those 75 years and over reported a limitation caused by a chronic condition. Moreover, the majority of older people have at least one chronic condition, and many have multiple conditions. The most frequently occurring conditions per 100 elderly in 1996 were (in descending order) arthritis, hypertension, hearing impairments, heart disease, cataracts, orthopedic impairments, sinusitis, and diabetes (Administration on Aging, 2002).

Disability is also experienced by a significant proportion of older adults. In 2000, approximately 42% (14 million) of the noninstitutionalized older population 65 years and over reported having at least one disability: 14.2% had a severe visual or hearing impairment; 28.6% had a physical disability that limits walking, climbing stairs, reaching, lifting or carrying; 10.8% reported a mental disability that impedes learning, memory, and concentration; 9.5% had difficulties in doing ADLs; and 20.4% reported having difficulties in leaving their homes to shop or visit the doctor’s office (Administration on Aging, 2002).

As the risk for chronic illness and disability increases with age, so does the need for assistance with ADLs. Data from the 2003 National Health Interview Survey (NHIS; National Center for Health Statistics [NCHS], 2004a) indicate that adults aged 85 years and over were more than seven times as likely as adults aged 65–74 years old to need help with personal care from other people (22.6% versus 3.2%). Moreover, the NHIS data also show that the proportions of older women and minorities who needed personal care assistance were higher than for older white men. For those 85 years old and over, 25.3% of women versus 17.3% of men reported needing ADL assistance; and the proportion of those needing assistance aged 65 and over was higher for Hispanic (10.1%) and non-Hispanic black (9.9%) elders than for non-Hispanic white elders (6.0%).

HISTORICAL PERSPECTIVE

A century ago, virtually all medical care was provided in the home, first by family members and other “natural” caregivers, and later by physicians making house calls and by visiting nurses (Benjamin, 1993; Cowles, 2003). The provision of services in the homes of clients is also not new to social work practice. Social work practice in home care is steeped in two relevant traditions—community-based “friendly visitor” services and hospital social work. Indeed, contemporary social work practice had its beginnings in the nineteenth century with “friendly visitor” services provided by charitable organizations on behalf of the ill and the indigent (Brieland, 1995; Romaine-Davis, Boondas, & Lenihan, 1995). Friendly visitations were part of “outdoor relief”—assistance to people who resided in their homes and outside of an almshouse, orphanage, or other residential facility (Barker, 2003). Friendly visitors, usually middle- and upper-class women, began as volunteers, then became paid employees of charity or-

ganization societies (COSs), and eventually became known as social workers. In general, the main duties of the friendly visitors were not very different from those of social workers in home care today: to investigate homes of indigent families; determine the causes of problems; provide guidance for solving problems; and, in some cases, provide material aid. The latter was rarely granted, since COSs stressed the morality of giving material assistance to only the “worthy” and not those who were considered able-bodied and thus employable, such as the “sturdy beggar,” alcoholic, or prostitute. As a result, “support went to the smallest number, at the least cost, and for the shortest time” (Brieland, 1995, p. 2247)—an approach to administering public assistance that continues to this day. Eventually, friendly visiting was replaced by the practice of professional social casework, currently referred to as “clinical social work,” as the friendly visitors developed greater professionalism, received better training, and improved understanding of the causes of health and social ills (Barker, 2003).

The other progenitor of social work in home care is hospital or medical social work. The role of the hospital social worker was initially modeled after that of the “friendly visitor” in its sympathetic and paternalistic attempt to alleviate social problems (Nacman, 1977). Richard Cabot, a physician at Massachusetts General Hospital in Boston, recognized the importance of psychological and social conditions that lead to illness and recovery. He is credited with introducing social work practice in a medical setting by adding social workers to his staff in 1905 for the purpose of “augment[ing] the physician’s treatment of patients by studying, reporting, and alleviating, to the extent possible, the patients’ social problems that interfered with the plan for medical care” (Cabot, 1915, as cited in Caputi, 1978). Cabot’s delineation of social work as an ancillary function to medical care continues to resonate to this day in most entitlement programs and health care settings. As a result of the efforts of Cabot and Ida Cannon, a nurse with social work training who was charged by Cabot to establish the nation’s first medical social work department at Massachusetts General in 1906, the American Hospital Association developed the first formal description of medical social work in the mid-1920s (Caputi, 1978; Nacman, 1977; Ross, 1995). It includes the augmentation role suggested by Cabot, along with other practice roles: liaison between the physician and patient; liaison between the physician and community resources necessary for continuing patient care; and educator serving as an agent of the physician to promote pa-

tient compliance in the medical treatment plan (Caputi, 1978).

During the decades prior to 1965, the importance of home care waned as the delivery of medical care and social services shifted from the home to hospitals and physicians’ offices in response to scientific advances and major socioeconomic changes like urbanization, industrialization, and immigration. But interest in home care reemerged as concern increased for the growing numbers of persons with chronic illnesses who began to occupy large numbers of hospital beds. Consequently, efforts to find suitable alternatives to institutional care would motivate federal home care policy development and reform for years to come (Benjamin, 1993).

By the mid-1950s, a commission of the U.S. Public Health Services called for organized home care programs to provide medical and social services to patients in their homes following hospitalization. Care was to be provided by a team of health care professionals through a range of services under a physician’s plan of care, including medical, nursing, social work, housekeeping, transportation, medication, and other benefits. The commission’s home care model was largely based on the first hospital-based home care service at New York City’s Montefiore Hospital, which was established in 1947 as a response to the limited home services then provided by visiting nurse organizations (Benjamin, 1993; Cowles, 2003; Goode, 2000). Some private health insurance companies—specifically Blue Cross-Blue Shield—were convinced that home care following hospitalization for certain patients could, under institutional and physician oversight, deliver high-quality and cost-effective care. As a result, the introduction of home care coverage by the “Blues” significantly enhanced the visibility and respectability of organized home care programs (Benjamin, 1993). The passage of Medicare (Title 18) and Medicaid (Title 19) legislation in 1965, which established federally funded health care for older adults and the medically needy, conclusively established the role of home care in mainstream health care. Moreover, the role of social work was formally established as an important professional service in organized home care programs.

HOME CARE POLICY AND FUNDING

In developing home care policy, federal planners embraced the range of services offered through the Montefiore home care model, but limited them to the kind

of coverage provided by the Blue Cross plans (Benjamin, 1993). Although nursing visits, home therapies (physical, occupational, and speech), medical social services, home health aide care, and medical supplies and equipment are included, the physician (who rarely makes home visits) is charged with establishing a care plan and providing the medical supervision consistent with postacute medical care. Various observers have conceptualized current home care policy and funding in terms of two models: the predominant medical or post-acute model represented by HHC, which is largely financed by Medicare; and the social-supportive model, which involves personal assistance and homemaker services typically covered by Medicaid and out-of-pocket payment (Benjamin, 1993; Dhooper, 1997).

Medicare and the Medical Model

Established as an age-based entitlement program to provide medical care for those 65 years and over, Medicare has played a significant role in the rapid growth of the home care industry. Medicare beneficiaries are the largest consumers of HHC. In 2000, over 70% of the 1.36 million patients receiving home health care were Medicare beneficiaries aged 65 and older (NCHS, 2004b, table 7). Medicare coverage of home health services is based fundamentally on the medical model, which approaches the beneficiary as a postacute patient with an illness that needs to be treated with medically oriented interventions (termed “skilled care”). Medicare’s home health benefit is not designed to address environmental factors that may influence illness and recovery or long-term care needs (Komisar, 2002). Thus, home care services are initiated by a physician’s order and are usually reserved for those who have been recently hospitalized and whose care needs are short-term and intermittent. A Medicare beneficiary can qualify for HHC if he or she meets all of the following conditions.

- Physician decides that beneficiary needs medical care at home, and makes a plan for care at home
- Beneficiary must need at least one of the following: intermittent (fewer than seven days each week or less than eight hours each day over a period of 21 days or less) skilled nursing care, or physical therapy or speech-language therapy, or continue to need occupational therapy
- Beneficiary must be homebound (unable to leave home unassisted)

- Home health agency providing care is Medicare-certified (CMS, 2003c)

An “episode of care” (i.e., length of benefit coverage) lasts 60 days. Because it is based on the medical model, Medicare home health coverage allows beneficiaries to receive medical social work services, home health aide services, and occupational therapy *only* when they are also receiving skilled nursing, physical therapy or speech therapy. Therefore, nonprimary services such as social work are not provided to all HHC patients, but are only required when ordered by the physician (Dhooper, 1997). In addition to skilled services, Medicare also covers medical supplies like wound dressings and equipment such as wheelchairs or walkers. However, Medicare coverage of HHC does *not* include 24 hour-a-day care at home, home-delivered meals, and homemaker services such as cooking, cleaning, and shopping. Prescription drug coverage, previously not provided under Medicare, is now available as a result of the passage of the Medicare Prescription Drug, Improvement and Modernization Act (MMA) of 2003.

Despite its status as an optional home health service, medical social work is characterized by Medicare as a service that is “necessary to resolve social or emotional problems that are or are expected to be an impediment to the effective treatment of the patient’s medical condition or his or her rate of recovery” (CMS, 2003a, chap. 2, para. 206.3). The services provided by HHC social workers can include assessment, community resource planning, counseling services (which includes discharge planning), short-term therapy (i.e., two or three visits) for the patient’s family member or caregiver to address problems that hinder effective patient treatment, and “other” services approved by physician’s orders, such as interventions related to suspected abuse/neglect and suicide risk.

Medicaid and Social-Supportive Care

Medicaid—the jointly financed federal and state health care program for low-income people—represents a small but growing portion of total payments for home care. In some states, Medicaid may also pay all or a portion of Medicare premiums, deductibles, and coinsurance payments for qualified low-income Medicare beneficiaries (CMS, 2003c). Medicaid payments for home care are divided into three main categories: the traditional home health benefit, which is required in all state plans and reimburses basic home

health care and medical equipment; and two optional programs—the personal care option and home and community-based waivers (NAHC, 2001). The availability of these two options varies from state to state and reflects the social-supportive model of home care. Both personal care and waiver programs involve “unskilled” care that assists clients with ADL, IADL, or homemaker tasks necessary to remain in their homes. Under this model, the need for home care services is determined by limitations in functioning due to chronic conditions rather than an acute medical episode. Supportive home care, therefore, involves longer-term services for individuals with chronic care needs and is heavily utilized by eligible older adults and younger people with disabilities (NCHS, 2004b).

In Medicaid-funded home care programs, social workers generally are less well-represented than in Medicare-funded programs, since Medicaid does not pay for social work services provided by home health care and homemaker service agencies unless the client is enrolled in a waiver program to reduce nursing home stays. Under Medicaid, clients deemed at high risk for nursing home placement may be provided personal assistance, homemaker services, meals-on-wheels, respite care, transportation, adult daycare, and numerous other services (Goode, 2000). Clients in waiver programs can also receive case management by social workers.

Funding Sources

Medicare is the largest single payer of home care services. In 1999, Medicare spending accounted for about 26.3% of total estimated home health expenditures, while Medicaid accounted for 9.7% (NAHC, 2001). Other public funding sources—the Older Americans Act, Title 20 Social Services Block Grants, the Veterans Administration, and the Civilian Health and Medical Program of the Uniformed Services (CHAMPUS)—funded 12.7% of home health care spending. Private sources accounted for 46.2%: 19% was paid by private insurance companies, while 27.2% was paid out-of-pocket. (About 5% comes from other sources, including philanthropy.) By 2010, Medicare and private payments for home health care are expected to grow to 28% and 53%, respectively (NAHC, 2001). Despite the increasing need for home care services among older people, this projected growth has been slowed considerably as a consequence of the Balanced Budget Act (BBA) of 1997, which marked a major policy change in home care financing.

Policy Changes: Prospective Payment System

Home care expenditures rose steadily during the 1980s and 1990s, and the number of Medicare-certified home health agencies peaked at over 10,000 in 1997 (NAHC, 2001). Total Medicare home health expenditures increased at an annual rate of 21% between 1987 and 1997, accounting for 9% of total Medicare spending in 1997, up from 2% in 1987 (Health Care Financing Administration [HCFA], 1999). To curb rising costs and increase efficiency, the BBA of 1997 introduced a prospective payment system (PPS) for home care organizations that changed reimbursement from fee-for-service to a flat rate based on classification of patient condition and associated needs (Cowles, 2003). As a result, Medicare spending between fiscal years 1998 and 2000 decreased by 34%, the number of Medicare-certified home health providers declined by 31.5% (NAHC, 2001), and visits per user were cut nearly in half (Liu, Long, & Dowling, 2003). Between 1997 and 1998, the reduction in home health care utilization was heavily concentrated among lower income Medicare beneficiaries (Zhu, 2004). Of great concern has been the impact on minority older populations, who already experience poverty in greater numbers and have lower utilization rates of community-based services (including home care), despite having higher service needs in terms of medical problems and functional limitations (Damron-Rodriguez, Wallace, & Kingston, 1994; Wallace, Levy-Storms, Kingston, & Andersen, 1998). Added to existing structural and cultural barriers to utilization, the PPS may result in lower home care utilization rates among ethnic elders.

Assuring Quality of Care

Several organizations are involved in addressing issues of quality in home care. In most cases, an agency must be certified in order to receive public funding. For example, HHC agencies must be certified by Medicare or Medicaid in order to receive reimbursement. Other efforts to assure quality include accreditation provided by nonprofit advocacy groups, which depend on industry-wide acceptance and the weight of public opinion to exercise influence (Romaine-Davis, Boondas, & Lenihan, 1995). The nation’s predominant accrediting body in health care is the Joint Commission on Accreditation of Healthcare Organizations (JCAHO), which evaluates more than 17,000

organizations, including hospitals, health maintenance organizations (HMOs), home health agencies, long-term care facilities, behavioral health care organizations, and ambulatory care providers. Other home care accreditation bodies include the Accreditation Commission for Home Care, Inc. (ACHC), the Community Health Accreditation Program (CHAP), and Homecare University.

Despite the presence of formal accrediting bodies, assessing the quality of home care services is complicated by the following factors: diversity of programs and services, goals, and clientele; the lack of provider controls in multiple home care settings; and the lack of valid patient outcome measures (Kane, Kane, Illston, & Eustis, 1994; Institute of Medicine, 2001). In home health care, these challenges are being addressed by introduction of the Outcome and Assessment Information Set (OASIS), an instrument utilized by Medicare-certified home health agencies to measure patient medical, functional, emotional, behavioral, and cognitive outcomes for purposes of outcome-based quality improvement (Hittle et al., 2003; Shaughnessy, Crisler, Schlenker, & Arnold, 1997). While critics have called for more information on the reliability of OASIS (Berg & Mor, 2001), the widespread dissemination and utilization of OASIS seems to be yielding an impressive set of outcomes data based on well-tested measures.

SOCIAL WORK ROLE AND FUNCTIONS

Constraints

The roles of social work in home care have been limited in two important ways by the design of health insurance, both public and private. First, predominance of the medical model limits the range of tasks that insurers will cover to those associated directly with acute episodes. Second, funding constraints perennially confronting the Medicare and Medicaid programs have pressured provider agencies to control costs, often by minimizing or eliminating services (like social work) not considered “core” in home care. For example, Medicare does not require social workers to see all home health patients or to participate in the planning of their care; it only requires that social work services be made available to patients (Dhooper, 1997). Consequently, within Medicare-certified home health agencies, social workers comprise only 2% of personnel, compared with 45% for nurses (see Table 35.1).

TABLE 35.1. HHC Personnel Mix, 2003

<i>Service</i>	<i>Percent</i>
Home health aides	38
Professional nurses	33
Vocational nurses	12
Physical therapists	5
Occupational therapists	2
Social workers	2
Other	8

Note: From *Health Care Industry Market Update—Home Health*. Baltimore: Centers for Medicare and Medicaid Services, September 22, 2003.

Similarly, in 1999, social workers accounted for 1% of Medicare home health visits, compared with 48% for nurses and just under 10% for therapists (Komisar, 2002).

Another barrier to the wider use of social work services in home care is the lack of evidence-based research on the effectiveness of social work services. This gap likely reflects the preponderance of medically oriented outcomes, the secondary status of social work in health care, and the lack of meaningful measurement of social work outcomes in home care (Lee & Gutheil, 2003). Moreover, results from the few studies on the impact of social work efficacy in home care are inconclusive (Braun & Rose, 1994; Cloonan, Phillips, Irvine, & Fisher, 1991; Lee & Gutheil, 2003). The literature on social work in home care is mostly descriptive and exploratory and typically addresses two themes: (1) the roles of social work (Davitt & Kaye, 1996; Kerson & Michelsen, 1995; Reese & Brown, 1997); and (2) the obstacles to effective social work practice, including poor coordination with hospital discharge planners (Proctor, Morrow-Howell, & Kaplan, 1996), geographic factors (Naleppa & Hash, 2001), and ethical dilemmas concerning advance directives, assessment of mental competence, and access to services (Egan & Kadushin, 1998; Healy, 1998, 2003; Kadushin & Egan, 2001).

Theoretical Model of Practice

Despite the lack of empirical evidence, the knowledge base, skills, and values of the social work profession would seem to position social workers to be an effective member of the home care team. There are several

theoretical models from psychology, sociology, and gerontology that inform and organize the knowledge base of social work practice with home care clients, such as continuity theory, exchange theory, social constructionism, and Erikson's theory of ego development (i.e., the stages of psychosocial development). Moreover, social work's biopsychosocial approach provides a broader, multidimensional perspective on the client's situation, and is intended to replace the "sickness" model that too frequently influences both medically based and psychodynamically based practitioners (Berkman & Volland, 1997). While in the past, psychological and interpersonal elements of social functioning have been emphasized in social work practice, there is increasing support for integrating biomedical, social, cultural, and environmental knowledge into social work practice (Berkman & Volland, 1997). Taking into account the biomedical, psychological, and social dimensions of the personal environment is useful to social workers in screening and assessing the needs of home care clients and their families, and in identifying effective interventions and needed resources.

Social Work Functions and Case Management

The problems commonly faced by home care clients and their families (detailed in Table 35.2) are diverse and fall into several categories: adjustment to illness, end of life, dementia and behavior management, caregiver issues, suspected abuse or neglect, family conflict, housing arrangements/placement, financial problems, discharge planning, inadequate living arrangements/safety and level of care issues, inadequate social support, mental health, legal issues, non-adherence to treatment, and access problems (CMS, 2003a; Cowles, 2003; Goode, 2000).

In addressing these problems, social workers in home care have assumed case management roles and have designed interventions appropriate for clients in both HHC and homemaker service agencies.

Social workers have been increasingly involved in case management activities—particularly in community-based, long-term care settings for older adults—and the National Association of Social Workers (NASW) has established both practice standards and professional certification as an "Advanced Social Work Case Manager" (National Association of Social

Workers [NASW], 2002; Yagoda, 2004). Although the role of case manager in HHC is not reimbursable and probably engenders conflicts with nursing regarding care coordination responsibilities, some case management activities (such as counseling and resource brokering) are reimbursable services under Medicare.

Although not well documented, Medicaid waiver programs may offer more opportunities for social workers to function as case managers than HHC programs. One such opportunity is provided by the Program of All-Inclusive Care for the Elderly (PACE), a capitated benefit authorized by the BBA of 1997, featuring a comprehensive medical and social service delivery system and integrated Medicare and Medicaid funding for the purposes of helping older adults at risk for institutionalization to continue living at home. In principle, capitated payment allows providers to deliver all services participants need, including social services, rather than limiting them to those reimbursable under the Medicare and Medicaid fee-for-service systems. San Francisco's On-Lok project is the first and best known of the PACE models. Currently there are 14 states with 26 approved demonstration sites, and eight states have included PACE as an option in their state plans (CMS, 2000).

There is no single, widely accepted definition of case management. Yagoda (2004, p. 1) characterizes case management (sometimes referred to as care management or care coordination) as "a highly individualized approach that considers the unique aspects of the person and at the same time provides a holistic orientation that views all aspects of the client system, including the client family, friends, their situation, and their environment." White (2001, p. 162) conceptualizes it as a set of activities "directed at locating and coordinating care from a variety of resources in response to identified need." The National Association of Social Workers (1992, Definition section, para. 2) distinguishes social work case management from other forms of case management, in that it addresses "both the individual client's biopsychosocial status [micro] as well as the state of the social system in which case management operates [macro]." In reviewing various models, we have identified several core functions for social work case management in home care (see Table 35.3): engagement, biopsychosocial assessment/reassessment, service planning, implementation of service plan, coordination and monitoring of service delivery, advocacy, and termination (Cowles, 2003; NASW, 1992; Raiff & Shore, 1993; Yagoda, 2004).

TABLE 35.2. Client Problems in Home Care Addressed by Social Workers

<i>Problem Category</i>	<i>Description</i>
Adjustment to illness	Reaction to new diagnosis, treatment, and/or changes in physical functioning
End of life issues	Grief, loss, impending death, concerns about death and dying
Dementia and behavior management	Cognitive impairment and/or behavior that negatively impacts client's treatment, quality of life, and safety
Caregiver issues	Caregiver burden, caregiver stress, and crises experienced by caregivers such as illness, hospitalization, relocation, and death
Suspected abuse/neglect	Suspected physical or sexual abuse, psychological abuse, financial exploitation, neglect by abuser, or self-neglect
Family conflict	Behavior of family members that obstructs, contravenes, or prevents client's medical treatment or rate of recovery
Housing arrangements/ placement	Need for alternate placement for long-term care, such as assisted living or nursing home
Financial problems	Financial issues that create stress, anxiety, and interfere with client's ability to adhere to treatment plan, e.g., inadequate financial resources to pay for medications or medical equipment
Discharge planning	Need for assistance to make transition when home care services end and to ensure client's needs are met through linkages to community resources
Inadequate living arrangements/ safety and level of care issues	Physical, emotional, social, or home environment issues that negatively affect client's safety; need for increased care/supervision
Inadequate social support	Lack of informal support, social isolation
Mental health	Emotional and psychological aspects of illness that negatively impact the plan of care, such as depression, anxiety, substance abuse, suicidal ideation; need to determine client's decision-making capacity
Legal issues	Need for education and resource linkage to legal services on issues such as advance health care planning, financial power of attorney, representative payer, guardianship, conservatorship, adult protective services
Nonadherence to treatment	Client does not follow health care treatment plan
Access problems	Barriers in access to needed medical care (including transportation) often caused by home care policy or program constraints

Note: Adapted from *Social work practice in home health care*, by R. A. Goode, 2000, New York: Haworth Press.

CHALLENGES AND OPPORTUNITIES FOR SOCIAL WORK PRACTICE

The future of social work practice in home care remains fluid and uncertain. It is constrained by increasingly restrictive reimbursement policies—particularly since 1997—and prospective payment system for HHC, as well as by a growing interest in adopting a consumer-directed approach to home care services for older people, which may limit the need for case managers (Benjamin, 2001; Simon-Rusinowitz & Hofland, 1993). The utilization of case management services is further hindered by the lack of screening instruments that help identify those in home- and community-based services programs who need social work case management (Diwan, Ivy, Merino, & Brower, 2001).

Models

Although these challenges suggest that social workers may be “losing ground” (Dhooper, 1997), models of home care are in place or being proposed that could expand the role of social workers. For example, telehealth programs and psychiatric home care have been discussed as areas where social workers can establish an important clinical role (Berkman, Heinik, Rosenthal, & Burke, 1999; Black & Mindell, 1996; Byrne, 1999). The Veterans Health Administration (VHA), the nation's single largest employer of social workers, has traditionally approached home care as an interdisciplinary program in which social work plays an integral role. Unlike Medicare-certified HHC, the provision of social work services at the VHA does not

TABLE 35.3. Social Work Case Management Functions in Home Care

<i>Core Function</i>	<i>Description</i>
Engagement	Through outreach and screening, identify and engage individual who would qualify for and benefit from case management services.
Biopsychosocial assessment/ reassessment	<p>Assess interplay of physical, environmental, behavioral, psychological, economic, and social factors addressing, but not limited to:</p> <ul style="list-style-type: none"> • Physical and mental health status • Functioning status (ADL/IADL) • Risk (including lethality, safety) • Client's needs and availability of resources in client's social support system (e.g., family, friends, organizational memberships) • Client's customary coping style • Economic status and needs • Equipment and home environment needs • Relevant cultural and religious factors • Input of relevant specialists, including home care team members and client's self-assessment <p>Client's needs and progress should be periodically reassessed as prescribed by the program and/or case manager, or when there is a change in the client's situation.</p>
Service planning	<p>Development of service plan that includes:</p> <ul style="list-style-type: none"> • Client preferences and feedback • Short- and long-term goals consistent with client's values, strengths, and preferences • Achievable, measurable goals with time lines for objectives and plan review • Criteria for success • Emergency plan in advance • With client's input, timely updates based on changes in conditions • Input from home care team • Identification of discipline or individual responsible for specific functions
Implementation of service plan	<p>Provide psychosocial services, including:</p> <ul style="list-style-type: none"> • Counseling and support to empower clients to participate in services • Link clients to resources to strengthen/build client autonomy and self-sufficiency • Service brokering • Crisis management if needed
Coordination/monitoring of service delivery	<p>Coordinate and monitor service delivery to ensure continuity and complementarity of the interventions by:</p> <ul style="list-style-type: none"> • Monitoring service provision for appropriateness, intensity, quantity, quality, and efficacy • Systematically documenting unmet needs and gaps in services/resources • Developing mechanisms to monitor outcomes (e.g., client satisfaction)
Advocacy	<p>Advocate for clients and their families to receive entitlements or obtain needed services, including those provided by social worker's own agency. Tasks include:</p> <ul style="list-style-type: none"> • Helping client to collect evidence of need and qualify for benefits • Explaining client's perspective to others • "Marketing" client to program(s) • Ensuring client's services are not prematurely terminated, and are terminated when appropriate • Encouraging client through role play and support to self-advocate

(continued)

TABLE 35.3. Social Work Case Management Functions in Home Care (continued)

Core Function	Description
Termination	<p>Termination can be planned or unplanned, and involve any of the following activities:</p> <ul style="list-style-type: none"> • Discharge planning • Case transfer • Helping client assess need for continued services and make appropriate arrangements • Counseling and support to allow ventilation of client's feelings about termination • Mutual review and assessment of client's progress and goal achievement • Providing follow-up services to ensure quality and continuity of care

require a physician's order. Instead, social work is considered a primary service by the VHA's Hospital-Based Primary Care Program (the VHA's hospital-based home health program), and the team social worker is required to visit the home in order "to assess the patient's and the home caregiver's psychosocial strengths and weaknesses as well as the adequacy of the formal and informal social support system" (Veterans Health Administration [VHA], 1992, chap. 2.11).

Possible Solutions

Geriatric social work leaders in the areas of health care policy, practice, research, and education have begun to address some of the challenges confronting social work in home care. For example, two studies have been funded by the John A. Hartford Foundation—one on the relationship between social work education and practice in health care (Volland, Berkman, Stein, & Vaghy, 2000) and the other on the impact of the prospective payment system on social work in home health care (Lee & Gutheil, 2003; Lee & Rock, 2001). These studies have produced several recommendations, including (1) enhancing social work curriculum content through a greater focus on health care practice (including case management), outcomes research, and data management; (2) establishing independent case finding for social work services to replace the current system of dependence on physicians and nurses; (3) developing a clearer definition of social work roles in HHC that is understood by other health care professionals; (4) fostering evidence-based research on the effectiveness of social work services; and (5) developing screening instruments for social work services for use in HHC.

In light of current constraints, there is enormous potential for expanding the role of social work in home care and for demonstrating the impact of social interventions on health. Without the evidence on impact, however, it has been difficult to make the case for expanded resources to support social work services. To address this dilemma, advocates need to identify a small number of demonstration programs to test the impact of selected social work interventions with home care clients and to build support for funding both the demonstrations and their evaluation. While a solid evidence base will probably not be sufficient to garner the political support required to enlarge the role of social work in home care, it is certainly necessary if the profession is to expand the service options available to vulnerable populations at home.

Departments of Public Welfare or Social Services

36

Gerontological social work practice aims to address environmental, psychosocial, health and mental, organizational, and societal barriers to physical and emotional well-being of older adults. Gerontological social workers promote responsiveness and effectiveness of social institutions to the needs and social problems of an elderly clientele (Mellor & Lindeman, 1998). Gerontological social workers employed in the public sector serve older adult clients under laws and regulations promulgated at federal, state, and local levels.

Public welfare and social service agencies provide safety net benefits to the truly needy based on the principle of “less eligibility,” a poor law concept made explicit in early nineteenth-century social welfare legislation in both England and America (Axinn & Levin, 1997). Social workers in these public service systems deliver, plan, and administer social welfare services of last resort in the domains of income support, medical care, housing, personal social services, and employment. These services are available to older adult clients living in the community who qualify under law because they are destitute, have no one willing or able to provide for them, or are at risk of harm and lack the capacity to make informed decisions on their own behalf (U.S. House of Representatives, 1999).

SERVICES AVAILABLE

Service programs for older adults in government departments of public welfare and social services include adult protective services (Otto, 2000; Wolf, 1995); emergency cash grant assistance; food stamps and home energy assistance program; Medicaid eligibility determination; home attendant or personal care case management and medical review services; adult foster care (Sherman, 1995; U.S. House of Representatives, 1999); and AIDS case management services (Emlet, 1996).

Indirectly, county departments of public welfare serve older adults raising grandchildren with Temporary Assistance to Needy Families (TANF) and through public child welfare kinship foster care programs (Burnette, 1999). Some counties administer employment programs for older adults. In New York City, the county department of public welfare provides employment services and transitional benefits for older adult receiving general assistance who require up to a year of work credits to qualify for Old Age Survivors and Disability Insurance (OASDI) benefits when they turn 65. Professional social workers

staff this innovative program, called Senior Works (K. Lee, personal communication, May 21, 2004).

LEGAL AUTHORITY (ROLES OF FEDERAL AND STATE GOVERNMENTS), REGULATIONS, OVERSIGHT

State and county public welfare and social service departments are unique settings for professional social work practice. Public sector social work practice is defined by laws enacted at the federal, state, and local levels. The county departments of social services operate under state regulatory oversight. For those state- and county-based public welfare and social service programs funded with federal tax dollars, the federal government is also responsible for oversight activities.

While most states had programs to assist the elderly before the passage of the Social Security Act of 1935 (P.L. 74-271, H.R. 7260, August 14, 1935), public sector social work practice came into its own with the passage and implementation of the Social Security Act of 1935 and the emergency assistance provisions of the New Deal (DiNitto & Dye, 1983). Social workers like Frances Perkins and Harry Hopkins were key players in the development of this federal legislation and its implementation (Axinn & Levin, 1997).

Although public assistance is often associated with aid to families and children, in fact, assistance to the indigent elderly and blind, including social casework and cash assistance, were core components of country welfare programs from their inception. Old Age Assistance (Title 1 of the 1935 Social Security Act) stipulated that state cash grant programs also include services to applicants and recipients to protect them from exploitation or harm, help them attain self-care, and ensure maximum utilization of other agencies providing similar services (U.S. House of Representatives, 1999).

Adult services provided by state and county public welfare agencies are defined by the Social Services Block Grant, enacted in 1981, in Section 2001, as

services directed at the goals of 1) achieving or maintaining economic self-support to prevent, reduce, or eliminate dependency; 2) achieving or maintaining self-sufficiency, including reduction or prevention of dependency; 3) preventing or remedying neglect, abuse, or exploitation of . . . adults unable to protect their own interests . . . ; 4) preventing or reducing inappropriate institu-

tional care by providing for community-based care, home-based care, or other forms of less intensive care; and 5) securing referral or admission for institutional care when other forms of care are not appropriate, or providing services to individuals in institutions. (U.S. House of Representatives, 1999, pp. 1531-1532)

Section 2002, 42 U.S.C. 1397a (2) (1) (A), further defines services as

protective services for adults, services for . . . adults in foster care; services related to the management and maintenance of the home, daycare services for adults; transportation services; information, referral and counseling services . . . health support services and appropriate combinations of services designed to meet the special needs of . . . the aged. (U.S. House of Representatives, 1999, p. 1532)

Low-income home energy assistance is also identified as a service that can be funded through the Social Services Block Grant. While the legislation does not specify that these services must be delivered or managed by professional social workers, in fact, many state and county jurisdictions have determined that professional social workers are well suited for these functions.

PREVALENCE, STRUCTURE (INCLUDING STAFFING), PROCESS

According to a 1991 survey by the National Association of Social Workers (NASW), less than 1% of its membership responded that they worked in the public sector (Gibelman, 1995). There are several reasons for this. One is that across the country, there is a trend toward downsizing state and local government, so that many services formerly provided to the elderly through the public sector are now contracted out to the voluntary or private sector. Another, however, is that many public sector social workers do not work within designated social work titles, and may not appreciate the value of affiliating with other professional social workers through membership within a professional organization. County and state governments often do not keep track of employees who have professional social work degrees but are not working in social work titles. For example, a professional social

worker may work under a civil service title of planner, administrator, commissioner, analyst, or caseworker. It may not be apparent from a professional social worker's civil service title that he or she earned a Master of Social Work degree.

Many county and state departments of social service hire both bachelor's level social service workers and bachelor's and master's level social workers to provide casework and other direct services to public sector clients. The direct service workers are supervised by both preprofessionals and professional social workers. However, social workers also serve in management, planning, and research capacities in the public sector, with job titles ranging from agency commissioner to director of research or budget to senior planner. These positions may not fall under civil service law, and social workers may be appointed to them by mayors, governors, and appointed commissioners.

Not all public sector social services for older adults are provided by professional social workers, however. A survey conducted in California of personnel serving older adults in county adult and aging departments found that only 42% of adult protective services workers, 36% case managers, and less than 10% of other staff had master's degrees in social work (Scharlack, Simon, & Dal Santo, 2002). While the services and competencies needed to service older adults in the public sector, as identified in state laws and regulations, suggest the value of professional social work, there has been greater emphasis on professionalizing public child welfare than adult services.

SPECIAL CONCERNS OF THE POPULATION SERVED

The populations served by departments of public welfare and social services are those defined by law and regulation as indigent and/or requiring the services of the state in the form of *parens patriae*, or "father of the land" (Karp, 1999, p. 8). The state and county welfare departments have their roots in the public charity system begun with English poor law that was brought to colonial America by English settlers. The indigent elderly, and those elderly who lack the capacity to manage their affairs or protect themselves from harm, comprise the geriatric client population of public social welfare programs. These elderly clients are among the nation's most vulnerable residents, and the problems they bring to the service arena can challenge the most experienced workers.

SOCIAL WORK ROLES: CURRENT

The roles of social workers in public sector programs for the elderly are broadly defined. These roles include delivering direct services such as case management and counseling; designing, implementing, evaluating, and monitoring programs; administering programs and projects; conducting outreach; and advocacy (Yankley, 1987). Because the public sector is an interdisciplinary service setting, professional social workers may assume a diverse array of roles, with job titles that may not identify them as social workers (Yankley, 1987).

When professional social workers practice in government settings, they are carrying out legislative and regulatory mandates to serve people with identified characteristics through defined programs with proscribed services. This may appear to limit the autonomy of the professional social workers to engage in independent practice and exercise professional judgment. However, the need for public sector social service workers to identify emergent needs among target populations, design and implement creative ways to meet these needs within the defined structure of legislative mandates, and advocate for systems and legislative change are all part of a public sector social workers' responsibility within government social service departments. This is also consistent with professional social work practice.

Professional social work differs from some other professions, in that the scope of practice is very broad. Lawyers engaging in administrative practice within agencies are not considered to be lawyering, or practicing law. Professional social workers practice social work using many methods, with multiple units of concern, to address diverse and often emergent social problems, in a number of fields of practice (Popple & Leighninger, 2002).

Within public welfare and social service departments, methods practiced by professional social workers include administration, supervision, planning and program development, group work, individual work, and social case work. Units of concern include states and communities, groups, families, and individuals. Social problems addressed by professional social workers serving older adults in state and county public welfare and social service systems include poverty (income assistance and employment services), homelessness (special housing), substance abuse (counseling and case management, domestic violence (residential and nonresidential services), ill health (home care and Medicaid coverage), abuse and

neglect, including self-neglect (protective services), dependent grandchildren (elderly grandparents raising grandchildren in child-only Temporary Assistance for Needy Families cases), and AIDS.

SOCIAL WORK ROLES: HISTORICAL

Public welfare departments evolved out of local social service programs enacted by localities under colonial poor law, and eventually local and state legislative authority. In 1935, with the passage of the Social Security Act of 1935, the federal government assumed a role in supporting the development of social services on local, state, and federal levels.

Elizabethan poor law defined the indigent and impaired elderly as a category of worthy poor entitled to public assistance from local parishes. When America was colonized by English settlers, they brought the concept of local responsibility for the indigent elderly, widows, and children and implemented it in the colonies and eventually the United States of America. This included programs of both indoor and outdoor relief. The indigent homeless elderly without family to provide care or protection often lived in almshouses, a form of indoor relief (Trattner, 1999).

With the industrialization of cities in the nineteenth century, the urban elderly were vulnerable to poverty and homelessness. Pensions and benefits for the indigent elderly were concerns promoted by the settlement house workers in the Progressive era. Some states and counties enacted old age pensions in the early twentieth century. However, it was not until the passage of Title 1 of the 1935 Social Security Act (Old Age Assistance) that federal matching funding was made available to states choosing to provide cash grants and social services to the indigent elderly as part of their county welfare programs.

The importance of social work and social services in public welfare was recognized by the passage of the Title 20 amendment of the Social Security Act in 1975 (Social Security Amendments of 1974, Pub. L. No. 93–647, H.R. 17045, January 4, 2005, title xx, Grants to States for Services, 42 USC 1397), legislated as the Social Services Block Grant (SSBG) in 1981, which provided federal funding for state- and county-based social service programs. In the early days of the public welfare movement, public sector social workers did not identify themselves as specializing in serving specific client populations. However, this began to change when the county welfare departments began to expand and develop specialized social service pro-

grams operated by government. These included services to the community-based elderly.

DEPARTMENT OF SOCIAL WELFARE AND SOCIAL SERVICES PROGRAMS IN WHICH PROFESSIONAL SOCIAL WORKERS SERVE THE ELDERLY

County welfare caseloads did not become specialized in serving the elderly, disabled, and blind until 1962, with the enactment of the 1962 Public Welfare Amendments to the Social Security Act (Wolf, 1995). Included in the Act were provisions for states to receive 75% matching funds for training and a defined list of social services for the needy, blind and disabled. Federal regulations defined persons in need of protective services as those who are unable to act on their own behalf because of limitations in their ability to manage their own affairs, or are living in unsafe conditions, or are exploited or neglected (Wolf, 1995).

The counties' implementation of these regulations included the creation of a special division within the county welfare departments, the Disabled, Aged and Blind (DAB) units, with social workers and case workers assigned to work specifically with the elderly and disabled indigent populations. This included not only ensuring receipt of cash grants but also assisting with the housing, health care, and safety needs of the clientele. According to Burr (1982), Title 1 of the Social Security Act of 1935 mandated county welfare departments to provide protective case work services to indigent elderly in receipt of cash grant Old Age Assistance (OAA).

In 1974, the DAB caseloads were federalized with the implementation of Title 16 of the Social Security Act, Supplemental Security Income (Social Security Amendments of 1972, Pub. L. 92–6031, H.R. 1, October 30, 1972, Title xvi—Supplemental Security Income for the Aged, Blind and Disabled [DAB], or SSI). The Social Security Administration (SSA) assumed centralized responsibility for the eligibility determination and cash assistance for the DAB cases. However, the service needs of this population became the responsibility of country and state public welfare departments (Meller & Mudrick, 1987). Public welfare departments still serve older adults, however, to provide emergency cash assistance, prevent homelessness, or intervene in a crisis situation to enable an older adult to remain in the community, and indirectly through the TANF Program, serving the increasing number of grandparents raising grandchildren on TANF.

Adult Protective Services

The most visible of the adult service programs operated by state and county public welfare departments is Adult Protective Services (APS). While there is controversy about the beginning of APS, an early study was conducted by the National Council on the Aging in 1960, and the White House Conference on Aging in 1961 recommended that there be a coordinated model developed by social agencies, the medical profession, bar associations, and legal aid to improve protective services for the elderly (Otto, 2000). The passage of Title 20 of the Social Security Act in 1974 provided funding for a number of programs that served the elderly, including APS (Mixon, 1995).

Without overarching federal authority, states developed diverse approaches to service delivery for vulnerable older adults through APS service program models. Some APS programs provide case management and other services to vulnerable adults age 18 and above, and others serve only those 60 years of age and older (S. Somers, personal communication, June 28, 2004). Most programs are administered by county departments of social service under state oversight, and provide case management and interdisciplinary crisis intervention services to older adults in need of protection.

In states like New York, state social service and mental hygiene laws and regulations enable APS workers to gain access to households, seek court approval for hospitalization for observation, and apply for guardianships on an involuntary basis if necessary to ensure necessary protection and treatment of incapacitated older adults (Sachs, 1993). Adult Protection Services programs serve vulnerable older adults in crisis situations that require workers to solve complex problems and demonstrate a sophisticated knowledge of risk factors and service interventions (Choi & Mayer, 2000).

Special Housing Programs

In urban areas, single room occupancy (SRO) hotels house many indigent elderly and disabled adults, including those with AIDS. County departments of social services provided case work services to occupants in SRO hotels, in order to stabilize their housing situations. Social workers also administer and provide case work services and program oversight to indigent elderly who are mentally ill or have developmental disabilities served by adult foster care programs.

Adult foster care (AFC) is a housing program operated by the county departments of social services since the 1960s, although its early development may be traced back to the English poor laws in the colonies when unrelated families provided lodging, food, and care to the indigent elderly and were reimbursed with public funds. Its description varies among jurisdictions; however, foster boarding homes are usually residences that house up to six unrelated individuals in private houses. In 1975, AFC was listed as a Title 20 service. Currently these programs are likely to be funded through the SSI institutional rate (Sherman, 1995), and AFC clients must qualify for SSI, a means-tested cash benefits program, as a condition of eligibility. Placement and follow-up are responsibilities of local department of social services, and are carried out by multidisciplinary teams that include social workers, who provide case planning and case management services.

AIDS Services

When AIDS began to affect older adults, either because people were beginning to live longer with the virus or because older people engaged in behaviors that made them at risk of HIV, county welfare departments began to serve them through existing case management programs (Emlett, 1996). Planning for the needs of the indigent elderly with AIDS and serving them in county DSS programs designed for younger clients with AIDS who may have dependent children, or are IV drug users, require professional social workers with gerontological competencies to serve as caseworkers, planners, and administrators to draw on professional gerontology competencies. In large counties, or in New York City, AIDS case management programs may be provided in a separate division of the department of social services. In smaller counties, services to clients with AIDS are provided through county APS programs (S. B. Somers, assistant commissioner, Adult Protective Services, New York State Office of Child and Family Services, personal communication, June 28, 2004).

Means-Tested Entitlements

The indigent elderly utilize food stamps, emergency cash grant assistance, Medicaid, and Medicaid-funded home care. Public sector social workers in APS, Medicaid-funded home care, AIDS, and domes-

tic violence programs may provide access to these public welfare entitlements through case management programs (Sonnag, 1995). Professional social workers operate county food stamp programs, oversee Medicaid eligibility determination processes, and make medical determinations of the need for Medicaid-funded home care services.

Grandparents Raising Grandchildren in TANF and Kinship Foster Care Households

Grandparents raising grandchildren in child-only TANF households have experienced difficulties across the country in accessing needed benefits for their grandchildren through departments of public welfare. Professional social workers have been helpful in assisting them negotiate these systems on behalf of their grandchildren from within the public welfare bureaucracies. Innovative programs like the portal projects implemented in county welfare offices in Tennessee, or in El Paso, Colorado, have provided programmatic supports and special access for custodial grandparents who depend on TANF benefits to raise their grandchildren. The public child welfare programs are experiencing greater numbers of grandparents raising grandchildren as foster parents. The challenges of working with older adults in the child-centered world of public child welfare have prompted interest in gerontological social work education and training for professional social workers in public child welfare (Brownell, Berman, Nelson, & Colon Fofana, 2003).

Domestic Violence Programs

Adult Protective Services provides case management services to the elderly living in the community who are in need of protection, including many who are victims of self-neglect. However, those elderly who are victims of abuse or exploitation and are not candidates for APS, adult homes, or nursing homes can be served by domestic violence shelters operated by the county department of social services, initially through Title 20 funding. Currently many shelters are funded through TANF, with state and local supplementation for elderly victims of abuse who do not qualify for TANF. Complex issues involving informed consent, and need to ensure congruence of service

needs and program fit for older victims of abuse, can require professional social work skills and gerontological competencies (Bergeron, 2001). Special service needs of older domestic violence victims suggest the importance of gerontological social workers in the county domestic violence service systems (Osgood & Manetta, 2002).

FUNDING MECHANISMS

Professional social worker positions in departments of public welfare and social services are generally funded through the same legislative appropriations that fund programs enacted by social welfare legislation in which they work. Most common sources of funding for public welfare social work salaries include Title 19 Medicaid administrative funds, state AIDS funding, and Title 20 Social Services Block Grant funding. For example, Medicaid administrative funds (Title 19) may fund medical social workers and disability review team members in Medicaid-funded home care and Medicaid eligibility; Social Services Block Grant funds are often used to fund social workers' salaries in adult protective services and foster care programs; and food stamp administrative funding pays salaries for social workers in food stamp programs.

Some funding streams, such as Medicaid administrative funding, provide enhanced reimbursement for professional social work services in job categories such as medical or disability review for home care levels of care or Medicaid eligibility determinations. These are recognized by the federal government as requiring social work competencies such as assessment and diagnosis of disabilities.

QUALITY OF LIFE AND QUALITY OF CARE

Professional social workers in departments of public welfare and social services are concerned about meeting basic living and safety needs of elderly clientele. Quality-of-life and quality-of-care issues are significant for professional social workers providing case management and service oversight in programs like Medicaid-funded home care and adult boarding homes. Social workers in adult protective services, AIDS, and domestic violence where victims are elderly are often primarily concerned with addressing crisis situations and ensuring that elderly

clients are safe and have access to basic entitlements and health care.

Professional social workers in these public programs interface with law enforcement and the courts, to ensure safety for their elderly clients, and health and mental health systems, to ensure that emergency needs are met. While clients in Medicaid-funded home care receive care for chronic conditions, and may be served by the department of public welfare for extended periods of time, often the goal of adult protective or domestic violence social workers is to address the client's crisis, stabilize the client's living situation, and refer the client for ongoing services in other service systems before closing the case. Quality-of-life issues are very much in the forefront when an APS social worker provides crisis services to a self-neglecting elder, and quality-of-care issues are of paramount concern for a social worker overseeing an adult foster care household.

CULTURALLY RELEVANT SERVICES

Public sector social workers practice in a highly politicized environment. The public sector faces political pressure from the communities served to provide culturally relevant services to clients and constituents. Most county departments of social services are required to offer translation services to applicants who do not speak English and have no one to translate on their behalf. Professional social work education emphasizes that ethical practice requires the provision of culturally relevant services. This is reinforced through training on culturally competent practice provided by most departments of social service (New York State Department of Social Services, 1997).

Affirmative action requirements in government services have ensured a diverse work force; this includes front line and supervisory social workers in programs that serve older adults. Some counties experience difficulties in ensuring culturally relevant services because workers from other countries are hired through the civil service process. In programs like adult protective services, where elderly clients may lack the capacity to protect themselves from harm, there is a legal obligation for government to provide the needed protection if there are no family members willing and able to do so. However, a growing number of immigrants have joined public agency staff. Some immigrants come from countries and cultures that do not see government as having a role in

life quality enhancement and protective service provision for elders. Those workers coming from such cultures care deeply about service to the community, but may have internalized value systems that conflict with the values of the American social welfare system, reflected in laws and regulations governing public sector programs serving older adults and their families. These differences may create barriers for new immigrant staff in connecting with and effectively serving vulnerable older clients and their families. Professional education and training is critical to address these workforce issues that affect client services.

AGEISM

Any assumption that impairments of older adults are an inevitable part of the aging process can be defined as ageist. It is particularly important that these assumptions are not applied to vulnerable older adults served by protective service or home care programs. This is understood by gerontological social workers responsible for ensuring that clients receive appropriate health and mental health treatment for what may be a treatable and reversible condition. Ageist assumptions that older adults are not capable of making informed judgments about their lives can lead to inappropriate and intrusive interventions that are not made in the best interest of the client.

PRIVILEGE AND OPPRESSION

Public sector social workers often wield enormous power over their clients and their families, particularly if they are providing mandated services through adult protective services or are in a position to approve or deny access to benefits like cash grants and health care. Older adults may be socialized to respect and not question government authority, or conversely to refuse needed services out of a concern about accepting charity. Among the most serious decisions a social worker can make about an elderly client is that of removing them to a nursing home or requesting a legal guardianship.

RURAL/URBAN DIFFERENCES

While elderly clients in urban areas may face crime, isolation, rising housing expenses, and a daunting

pace of life outside their homes, they also are more likely than their rural counterparts to have access to community-based services, public transportation, and accessible health care facilities. The rural social worker working for a department of public welfare or social services must serve elderly clients who live long distances from social service offices, may experience a higher than average level of poverty, may be more dependent than their urban counterparts on family members or significant others who may be abusive or neglectful, and may have a narrower range of available support services (Butler, 2004).

ETHICAL DILEMMAS

Ethical dilemmas are a challenge for geriatric social workers in public welfare and social services. Laws and regulations can mandate overriding the autonomy and judgment of older adults deemed to be at risk of harm. This places professional social workers in conflict with the provision of the NASW code of ethics to respect the autonomy and self-determination of clients. Public sector social workers must also follow laws, regulations, and procedures that limit access to needed services, such as Medicaid-funded home care, for an older client who needs the service but refuses to spend down assets to the legal limit. Public sector social workers may be limited in their ability to directly advocate for serving the needs of elderly clients if legislative decisions or bureaucratic procedures preclude this.

While public social workers can sometimes influence policy decisions or find creative ways of providing service to their older clients, they may also have less flexibility than professional social workers in some not-for-profit organizations because of lack of access to purely discretionary funding. Confidentiality, an important value in client–social work relationships, may be compromised with public sector clients in rural areas, where a visit from a social worker from a public agency can signal to neighbors that the client is experiencing problems with poverty, family members, or health.

Competing values are inherent in social work practice in public welfare settings. Diminished capacity of clients may make informed consent problematic and even impractical. Professional social workers in departments of public welfare and social services face an ongoing dilemma in ensuring a client's safety and well-being while respecting autonomy and freedom of choice (Mixon, 1995).

CONCLUSION

Gerontological social work is not often associated with departments of public welfare and social services. Even in the public sector, gerontological social work is often associated with the state and Area Agencies on Aging funded through the Older Americans Act of 1965 (Older Americans Act, Pub. L. No. 89–73, 89th Congress, H.R. 3708, July 14, 1965) and its subsequent amendments. However, departments of public welfare and social services have served the most vulnerable elderly since the early twentieth century, and professional social workers continue to provide vital services in these practice settings today.

Geriatric Care Management Settings

37

Defining Geriatric Care Management (GCM), let alone social work practice in a geriatric care management setting, requires significantly more space than any single chapter could provide. Just as our profession has struggled throughout its history to define social work and/or social work practice (Bartlett, 2000, 1970; Gordon, 1962; Holosko, 2003), there is no one single definition that can be applied to the practice of GCM. In fact, until recently (McInnis-Dittrich, 2004), there was little, if any, discussion about GCM in any social work practice texts. And while the National Association of Social Workers (NASW) does offer a definition for case management, as well as two levels of certification for case management, they do not offer a specific definition for GCM.

The NASW definition of case management does, however, provide a good foundation upon which to build a working definition of GCM. “Case management is a mechanism for ensuring a comprehensive program that will meet an individual’s need for care by coordinating and linking components of a service delivery system” and, as such, serves as a link between the client and the service delivery system (NASW, 1992). While case management can and does serve as a process that coordinates and links clients with services, it is also “a principle that guides the provision of a full range of services” (Frankel & Gellman, 2004, p. 5). And while other professions (for example nursing, psychology) also have their own definitions for case management, the assessing, coordinating, and linking functions (Robinson, 2000) are common to each.

Until recently, there was little mention of care management and specifically GCM in American social work literature, so the lack of a clear definition is understandable. Interestingly, the British social services adopted the use of the term “care management” as a strengths-based, consumer-driven model of care that includes the same core functions of case management (assessment, care planning, and service coordination; Burns, 1997). And while many support the use of case and care management interchangeably (see, for example, Bodie-Gross & Holt, 1998), some distinctions between the two are noteworthy.

For example, while case and care management are similar, in terms of their shared focus on client assessment, the care management assessment also focuses on how the current situation of the identified client impacts the well-being of all the individuals who make up the identified client’s support system. The current situation is viewed as an opportunity to assess the impact of the presenting situation on the

short- and long-term physical, emotional, financial, and social functioning of the older adult, as well as his or her informal caregiving system (i.e., spouse, life partner, adult child, etc.). “The overall goal is to enable the individual to maintain the greatest amount of independence and dignity, while assisting the client and family with problem-solving and access” (Aronson & Kennedy, 1998, p. 11).

The consumer-driven philosophy of care management also results in a significantly more comprehensive set of tasks and activities for both the client system and the care manager (McInnis-Dittrich, 2004; Parker, 1998). Care management services frequently include supportive crisis intervention, patient and family advocacy, family mediation, and conflict resolution (McInnis-Dittrich, 2004). In addition, unlike most case management models that provide services from 9 to 5 on weekdays, care management services are usually provided in a 24-hours-a-day, 7-days-a-week model. Consequently, because of the expanded roles of the geriatric care manager, another difference between case and care management is that the caseloads of care managers are significantly smaller.

Thus, given some of the differences between case and care management, the authors suggest that care management is as much a philosophical approach as a skill set that is applied in a consumer-driven model. There is a clear emphasis on the risks and strengths of the larger client system, with three guiding principles: (1) emphasizing the relationship between the client system and (care) manager (Brun & Rapp, 2001); (2) the active and efficient involvement of appropriate informal and formal helping networks; and (3) maximizing client self-determination and involvement (National Association of Professional Geriatric Care Managers, 2003).

LEGAL REGULATORY AUTHORITY

Although the practice of care management is not regulated or licensed by any federal or state authority, there have been some recent developments that indicate this will change in the near future. For example, the National Association of Professional Geriatric Care Managers (NAPGCM), incorporated in 1989, has provided consistent leadership that resulted in standards for practice that were adopted in 1992 (see the NAPGCM Web site listed at the end of this chapter), as well as supporting the initial credentialing of care managers. In 1994, NAPGCM joined with the Case Management Institute of Connecticut Commu-

nity Care, Inc., to form the National Academy of Certified Case Managers. This independent organization, which included representatives from a number of aging and disability organizations, then developed and administered the first geriatric care management credential (Parker & McNattin, 2002). The care manager certified (CMC) credential was first offered in 1995, and to date there are approximately (550) care managers who hold this credential. This entry-level credential remains the first and only attempt to develop a care manager credential based on a standardized and validated exam.

Interestingly, at approximately the same time that these efforts were taking place, the much larger Individual Case Management Association (ICMA) was engaged in a similar effort. Following the recommendation of the Certification of Insurance Rehabilitation Specialists, an independent organization called the Commission for Case Manager Certification, consisting of 29 allied organizations, formed to develop and administer the certified case manager (CCM) credential (Parker & McNattin, 2002). Just as there are operational differences in the definitions of care and case management, there is also a significant difference in the two credentials. While individuals with a high school diploma and 12 years of supervised work in the field of care management were eligible to be certified as a care manager, the more medically driven certified case manager credential required all applicants to hold a master’s degree in their profession (i.e., social work, nursing). Table 37.1 provides a listing of the more common credentials held by members of NAPGCM.

Another factor that will contribute to the development of licensing and regulation is the recent increase in the number of programs and certificates in GCM. As academic institutions become more involved with developing curricula for care management, there will also be a growing focus on conducting methodologically sound research to evaluate the effectiveness of GCM. An expanded knowledge base and an increasing number of practitioners, combined with more consumers utilizing GCM services, will highlight the need for licensing and/or regulation.

OVERSIGHT

Although there is no current state or federal policy that provides oversight or regulation for GCM, there is some limited informal oversight for care management provided by NAPGCM, in addition to the indirect oversight that is provided by the regulation and

licensing of social workers or nurses who practice GCM. The oversight provided by NAPGCM is through a formal policy and procedure for addressing client or collegial grievances. Unfortunately, this oversight only applies to members, and is limited to sanctioning or loss of membership, with no legal authority.

The indirect, and stronger, level of oversight does occur through the care manager's primary professional licensing authority. For example, a care manager licensed as a clinical social worker will be subject to the state's oversight of a professional social worker. However, other than the professional (social work, nursing, etc.) oversight from these professions, care managers who are not educated or licensed in an allied profession are not subject to any oversight. In addition to licensing oversight of the various professions, there is also a form of sanctioning or oversight that occurs through membership in a number of professional associations (i.e., NASW, American Nurses Association, American Psychological Association). Again, however, this oversight would be limited to only members of the associations, with little legal authority.

PREVALENCE

There is no single source that provides specific information on the number of GCM agencies or individuals providing care management. The NAPGCM currently lists 1,650 members. However, there are a number of other health-related associations that also have members who practice a model of GCM. In that many continue to use the terms of case and care man-

agement interchangeably, and given the number of professional care/case management associations, and the lack of a single regulatory oversight authority, it is impossible to estimate the actual number of GCMs.

STRUCTURE

In that GCM is a developing area of practice, GCM agencies can range from loosely structured individual solo practitioners who work out of home offices to large private, for-profit companies employing a number of care managers. There are also a number of public and private, not-for-profit agencies, hospitals, and allied health care agencies that are now providing GCM services. And while there has been significant growth in both of these areas, the majority of GCM agencies remain the smaller solo-practitioner type or partnership.

Data from NAPGCM suggest that approximately 62% of members are full-time care managers working as either a solo practitioner or with one other care manager and approximately 27% are affiliated with agencies employing three to five full-time care managers (Knutson & Langer, 1998). The membership consists of approximately 83% who indicate they are structured as a private, for-profit agency.

More recently, a number of for-profit and not-for-profit agencies and institutional settings (hospitals, retirement communities, faith-based, and long-term care insurance providers) have also been offering GCM services. There is currently no way to calculate the number of agencies that fall into this category. Certainly, how GCM fits in the organizational structure of each existing setting, as well as the specific model of care management being practiced, varies greatly. What does appear to be clear is that the model of GCM practiced in these types of setting more closely resembles traditional case management.

As corporate culture becomes more dominant in the care management landscape, the focus has moved from providing only GCM services to a model of care management that is structured to provide a more comprehensive array of eldercare services. Consequently, the structure of these larger entities has become significantly more complex than that of the smaller traditional agencies.

PROCESS

A survey of the membership of NAPGCM identified 10 core services that are provided in the traditional

care management agency. In order of their indicated importance, they are: assessment, care management, information and referral, advocacy, placement, caregiver support, education, crisis intervention, counseling, and entitlements (Knutson & Langer, 1998). However, how each of these are operationalized, as well as how the service is delivered, varies from agency to agency. Although a number of core functions (i.e., inquiry, intake, assessment, and care plan development) are considered basic to case management (see table 37.2), there is no one uniform process for how geriatric care managers provide these services. Most care managers will provide basic core functions such as managing inquiries, assessing clients, developing care plans, and providing referrals, although not all care managers will provide advocacy, ongoing monitoring, clinical or crisis intervention, or reassessment functions.

Inquiry. The basic core function of initial inquiry can vary greatly. For example, with the private fee-for-service model, it is not unusual for the care manager to spend a great deal of time listening to the caller’s problems (with an elderly relative), explaining what care management is, how it is customized according to the needs of the client, and why it may be an appropriate alternative. It is also during the inquiry phase that the care manager provides information about the fees associated with the services. In the public, not-for-profit model, one might spend less time explaining why care management is the right service and more time explaining the menu of services available.

Assessment. “Underlying good care management is good assessment” (Aronson & Kennedy, 1998, p. 11).

Some care managers begin the assessment by visiting with the identified client, while others will begin the assessment process with the person who initiated the contact (usually, but not always, a family member). This empowers the care manager to initiate the process of developing a more complete assessment of the entire client system. It also provides the care manager with important information about family dynamics. We would like to emphasize the importance of the family/caregiver consultation as a part of the GCM assessment. This is one of the features that distinguishes care from case management. In order to empower the client system with the most appropriate resources, a good understanding of the risks and strengths of the family/caregiver system is vital. A comprehensive genogram of the entire family system helps to identify important points of support as well as identify potential areas of concern. This is then used to develop a more proactive care plan.

A strengths-based assessment of the client must include a functional assessment (Green, 2002) of the client system. Functional assessment is the key to understanding the impact of medical illness on the older adult (Gallo, 2000) and those involved with the older adult. Care managers can use scales measuring the status of activities of daily living (ADLs) such as bathing, grooming, dressing, walking, and so on, and scales measuring Instrumental activities of daily living (IADLs) such as shopping, driving, money management, and so on. (A more complete discussion of geriatric assessment can be found in part D of this handbook.)

The assessment should also include a mental status assessment that includes both cognitive function-

ing and psychiatric evaluation. Again, there are a number of scales that can be used to determine cognitive impairment, but it is the experience of the authors that the Mini Mental Status Examination (MMSE) is one of the most widely used. Social work care managers will also assess for level of depression and anxiety, as well as caregiver-related stress and burden. A complete assessment also includes an evaluation of environmental (home or current residence), financial (for current and future planning), legal, and social needs. Because there is no universal GCM tool that addresses all areas of the assessment process (Aronson & Kennedy, 1998), the depth and quality of the assessment significantly varies among care managers.

Care plan. Although there has been some effort to develop GCM protocols for specific types of presenting situations (diabetes, dementia, etc.), there are as many differences in the development of the care plan as there are in the assessment process. The challenge is often balancing the wishes of the client with issues of safety, affordability, and practicality. The care manager must also develop a plan that has a high probability of working (Jackson, 2000). It is incumbent upon the care manager to be knowledgeable about resources and to be clinically astute, creative, persistent, flexible, and nonjudgmental when developing a plan of care.

The use of written care plans with clearly articulated problems, goals, and interventions is important to successful outcomes. Verbal care plans that are not clarified in writing can frequently lead to confusion and misunderstanding that eventually sabotage the care management process. Given the consumer-driven approach of care management, both the problems identified, as well as the intervention proposed, may not always appear to be traditional social work practice. For example, an intervention to decrease the client's level of depression and increase his socialization may require a more social atmosphere, such as going to lunch, hitting golf balls, or shopping. A non-threatening, more social venue can be used to overcome resistance and lead to productive relationship building. Each of these opportunities is used to develop a working alliance with the client in order to accomplish some of the more difficult tasks that will follow.

Brokering versus providing services. As discussed earlier, there are various models of GCM. While some care management agencies only provide a comprehensive list of potential referrals, others make the contact and arrange for the services. There are other

models of care management, especially in the larger corporate models, that provide the client with all the services. While there is no agreement on which model is better, each has advantages and disadvantages. Care managers who "outsource" every service can shop and select from multiple providers. The in-house, one-stop shopping type of model provides for a seamless and integrated network of services (home care, equipment, medical, etc.).

Care management. Perhaps no single process or function will vary as much as the care management process. Care management, used in this context, refers to the ongoing process whereby the care manager engages the older adult in a process of building a relationship to work on specific areas of concern. Just as in the example given earlier, a private, fee-for-service model can provide the care manager with the time to use a variety of techniques to build this pivotal relationship with the client, without the pressure of time limitation.

Throughout the care management process, the geriatric care manager will simultaneously reassess the situation and make appropriate adjustments in the care plan. When the situation does allow for this ongoing care management, the role of the care manager is to anticipate future needs and provide the family with proactive approaches to maintain the client's health, well-being, and quality of life.

HISTORY OF CARE MANAGEMENT

Although the roots of case management can be traced as far back as the early writings of Mary Richmond (1917), the settlement houses of New York and Chicago (Frankel & Gelman, 2004), and the early work of the board of charities established in 1883 by the state of Massachusetts to coordinate programs and services for the poor and infirm (Weil & Karls, 1985), the history of GCM is not as long or as illustrious. A relatively recent practice model, GCM was initially adopted by a private entrepreneurial group of social workers in the early 1980s.

The history of GCM can in part be connected to the growing number of aging persons with complex physical, emotional, financial, and psychosocial needs who are living longer, institutional changes in the role of social work in acute health care settings, and family support systems (i.e., spouse, adult children, grandchildren) that have lacked the knowledge, time, and resources to advocate and navigate through the increasingly complex network of aging services. As

GCM has been a consumer-driven response to the needs of older adults and their family members, this consumer-driven philosophy remains a cornerstone of GCM.

The complicated and complex network of services and programs provided by the policies of the Older Americans Act (1965, 1992, 2000), while well intended, lacked both accessibility and adaptability to meet the diverse needs of the aging population. Thus it was in this context that a small group of social workers from a variety of private practice settings came together to form what eventually became the National Association of Private Geriatric Care Managers (Cress, 2001). From its early inception, this association struggled to separate and distinguish its practice from case management and to establish practice guidelines, codes of conduct, and ethical standards, many of which were rooted in the standards of practice in social work and nursing. In an attempt to reach out and include practitioners who were mostly associated with community-based case management practice, the organization changed its name to the National Association of Professional Geriatric Care Managers. While today this organization has grown to more than 1,600 members from both private and public agencies, the vast majority of its members are private practitioners.

The authors have frequently been asked how and why they started in the field of GCM. Geriatric care management is one of the few opportunities where a social worker can use all of his or her social work education and training without the limited resources faced by our colleagues in many of the other social work settings. To quote some of the original founders of NAPGCM, “I got frustrated with paper instead of people,” or “I wanted to be able to customize services for older people and their families and provide quality services” (White, 2004, p. 4).

POPULATIONS SERVED

GCM agencies, especially the private fee-for-service agencies, serve a relatively small niche segment of the population. Given that the fee structure of the private agency can range from \$75 to \$150 per hour, the population served is for the most part upper-middle-class or wealthy professional adult children of older adults. The adult children are typically seeking services on behalf of a parent(s) who frequently has some degree of physical and/or cognitive impairment. Perhaps it is an age cohort perspective of a social work type of ser-

vice, but the older adults seldom seek GCM services on their own. However, it has been projected that as the baby boomers age, a growing number of informed and sophisticated consumers will seek out GCM services. Certainly, given this cohort’s youth-oriented consumerism (Gilleard & Higgs, 2001), there will be a growing need for professionally delivered and consumer-directed care to help navigate the increasingly fragmented and complicated health care system.

While the adult children currently contracting for GCM services are primarily well-educated professionals, their parents are more heterogeneous. It is not uncommon for a care manager to work with older adults who range from those with limited education who worked in a wide range of unskilled, government, and semiskilled professions to those who are well-educated, accomplished professionals. Historically, it is common for the person making the initial call to be an adult daughter or daughter-in-law on behalf of an older relative. More recently, a growing number of men are initiating contact for GCM services, as well as receiving GCM services (Kosberg & Morano, 2000).

SOCIAL WORK ROLES

Historically, many of the roles for social workers in the GCM setting are similar to those in traditional case management settings. The roles for social workers in the private, for-profit settings, however, also include the constant need to educate providers and consumers about GCM and how it fits into the continuum of care. When asked what the biggest challenge in starting a GCM business was, a former president of NAPGCM stated: “Marketing, marketing, marketing.” No one knew what care management was, and few were interested in care of elders unless they had a personal experience” (White, 2004, p. 4).

Depending on state licensing regulations, the BSW practitioner can practice independently as a geriatric care manager; however, state licensing regulations can restrict the use of the title “social worker.” The BSW can also work with, or be employed by, a GCM agency to perform a variety of other functions, such as care manager assistant, care coordinator, or administrative assistant. Care manager assistants and care coordinators can be responsible for working with the care manager to implement the prescribed care plan. Depending on the size and scope of the agency, this can involve accompanying clients to medical appointments, negotiating with service providers, coor-

dinating care, and reconciling insurance-related issues. Agencies that charge lower fees for the services of a care manager assistant indicate that this is more cost effective to the consumer and therefore assists in selling the product.

Social workers with an advanced degree, such as MSW or LCSW (LCSW, LCSW-C, etc.), also function in a variety of roles. As solo practitioners, they will usually have to perform all functions, including clinical and administrative. The ultimate responsibility for the well-being of clients and the business is that of the geriatric care manager alone (Modigliani, 2004). It is not an exaggeration to say that in the consumer-driven, fee-for-service model, the geriatric care manager will fill whatever role is needed to accomplish the stated goals while always practicing within accepted ethical standards. Descriptions of some of the common roles for social workers in the field of GCM follow.

Interdisciplinary team member. Given the fragmentation of health care services (Hoenig, Nusbaum, & Brummel-Smith, 1997), the role of team member is frequently one of the most important roles for the social work care manager. With a grounded understanding of systems theory, this practitioner is uniquely qualified to represent the needs of both the identified patient and his or her caregivers on interdisciplinary care teams in a number of different health care settings (i.e., hospital, acute or long-term care settings, etc.). Interdisciplinary practice is a way of thinking as well as an approach to working with others (Netting, 1998).

This role becomes even more important in that they are frequently the only professionals that can connect the multiple interdisciplinary teams as the client progresses throughout the continuum of care. For example, the cognitively impaired person with a hip fracture will experience different interdisciplinary teams in the hospital, acute care, rehabilitative care, and home care settings. As was recently highlighted in a report from The National Consensus Conference on Improving the Continuum of Care for Patients With Hip Fracture (2002), “the pathogenesis of hip fracture is multi-factorial, and there is an increasing disconnect along the hip-fracture continuum of care which results in patients receiving fragmented post-acute care. As a result, patients often receive fragmented care” (p. 671).

Advocate. A significant part of effective care management involves advocating with multiple health care systems (hospitals, insurance, public agencies on aging, etc.) and providers (physicians, therapists,

medical equipment providers, etc.). Certainly this role is not unique to GCM, but the social work geriatric care manager uses a systemic orientation and an ecological approach that provide an excellent foundation for understanding the importance of advocacy that frequently goes beyond just advocating for the patient. Since the family is employing the geriatric care manager, it is therefore incumbent upon the care manager to advocate for and represent the needs of the entire client system (identified patient and caregivers).

Family mediator. Another role for the social work care manager is that of family mediator. Given the ecological approach to GCM and the competing demands of caring for an older adult, family mediation is critical. Again, while some GCM agencies might refer the client and family to a family therapist or psychologist, some GCM agencies employ clinical social workers so that they can fulfill this role. The social worker’s education and training in systems, group work, and family therapy provides the skills to facilitate healthier family dynamics that have both short- and long-term implications.

Supervisor. A licensed clinical social worker can provide supervision for other MSW or BSW geriatric care managers. The size and scope of the agency will determine the amount of time spent with direct client contact versus other supervisory functions. In the model of care management we practice, every care manager participated in both individual supervision, as well as weekly care planning team conferences. Geriatric care managers who are sole proprietors are strongly encouraged to contract for clinical supervision or meet regularly with colleagues to discuss cases and issues.

Administrator. Finally, the administrative role is another crucial role for social workers in a GCM setting. As was discussed earlier, many of the original GCM practices were solo MSW practitioners who came from either the health care arena or private psychotherapy practices. Consequently, the administrative roles included everything that needed to be done to remain in operation. Developing budgets and business and marketing plans, hiring and supervision of staff, developing the care management protocol (clinical forms, fee structure, etc.), handling all inquiries, as well as developing relationships with other providers and referral sources, are just some of the administrative roles that can be filled by the MSW.

While each of these roles could occur in either the private, fee-for-service model or the public agency that is doing GCM, another role specific to the public

sector is that of fund-raiser and/or grant writer. Because the majority of public settings are more closely associated with a case management model, where services are significantly more restricted by the source of reimbursement, it is important that the funding of the agency keeps up with the demand. Consequently, the MSW can frequently be the individual who is responsible for updating potential funding sources, as well as actually preparing the necessary applications.

As the profession of GCM continues to grow, and as the regulation of GCM develops, many of the roles discussed in this chapter will remain in place. The more the public sector moves from the current case management model to a more consumer-driven GCM model, the more the roles for social workers will continue to expand. However, it is unlikely that GCM in the public sector will ever be able to provide the 24/7 model of GCM that currently exists in the private, fee-for-service models.

REIMBURSEMENT

Family members who are contracting for services most often pay for GCM services. Although there has been an increase in long-term care insurance providers who do offer a care management benefit (see table 37.3), this provides minimal reimbursement. While a fee-for-service model of reimbursement does provide for the ability to be completely consumer driven, it also presents a number of difficult ethical dilemmas for the practitioner, the most reoccurring one being “Who is the client?”

QUALITY OF LIFE AND QUALITY OF CARE

Perhaps one of the hallmarks of professionally sound GCM is the focus on developing care plans that maximize the quality of life and the quality of care. In that quality of life is directly impacted by the quality of care, the ecological approach of GCM is particularly focused on how the care manager is able to develop a seamless aging network in a fragmented system of care. Given the increasing rate of health care specialization, which unfortunately further complicates an already complex, fragmented system of care, the coordinating focus of GCM cannot be overstated.

Quality of life is also directly and indirectly impacted by GCM. As the care manager assesses both the short- and long-term needs of the client system, there is an opportunity for a proactive approach to

improving the quality of life of the identified client and his or her larger caregiving system. In that there can often times be competing demands on the part of the identified client and his or her caregiving system, this focus on quality of life does not come without a number of ethical conflicts. For example, when the client asks to remain at home, the strain (financial, physical, or emotional) on his or her family needs to be considered. Consequently, balancing quality-of-life issues is not always a simple or clear decision and can frequently result in ethical dilemmas for both the care manager and the family members involved.

CULTURALLY RELEVANT SERVICES

Perhaps one of the least discussed or understood areas of GCM services is that of providing culturally relevant services. In that care management is for the most part a private, fee-for-service model of social work practice, there could be an assumption of homogeneity for those with adequate financial resources. And while there is limited socioeconomic heterogeneity among the users of care management services, the cultural values of both identified clients and the familial caregivers could influence both the reporting of and response to impairment and disability (McGahan, 2000). While those from a white American background might be comfortable with the concept of hiring caregivers and a professional consultant, such as a care manager, those from an African American or Hispanic background are more inclined to manage the responsibility of caregiving within the family system.

However, given the projected growth of the minority populations, the projected growth in the number of more affluent from diverse cultural backgrounds, and the growing number of older adults who have emigrated to be closer to their adult children, culturally sensitive services will be required. In addition to this more obvious description of culture, another important aspect of culture refers to the culture of the different age cohorts (Gilleard & Higs, 2001). The perceptions held by today’s “oldest old” about using any type of clinical social work service will be significantly different from the perceptions of the aging baby boomers.

In addition to cultural factors related to age cohort, race, and ethnicity, there has also been some discussion about issues related to GCM practice with men (Kosberg & Morano, 2000), as well as with gay, lesbian, bisexual, and transgender older adults

TABLE 37.3. Example of Long-Term Care Insurance Coverage of Care Management Services

<i>Insurance Company</i>	<i>Type of Coverage</i>	<i>Authorized Providers</i>	<i>Coverage</i>
John A Hancock	Optional benefit service to assist with determining care and treatment plan	Not specified	Up to 10 times the daily benefit, or 1/3 of monthly benefit per year; can be paid before elimination period; does not reduce maximum benefit
GE Capital	Optional benefit; privileged care coordinator assesses need, develops care plan, helps choose and monitor care; benefits are enhanced if care coordinator is used	Privileged care coordinator (not specified)	Does not reduce maximum benefits; elimination period reduced
Massachusetts Mutual	Optional benefit; personal care advisor is available through company to assist with eligibility for benefits, appropriate level of care availability of facilities Care coordination by R.N. to assess and coordinate appropriate care, assist with claims documentation	Personal care advisor Care coordinator, R.N. specified	Does not reduce maximum benefit
Met Life	Needs assessment; one free needs assessment by a care management organization selected by insurance company of independent care management organization	Selected by company or by insured	Up to lifetime maximum of \$250; can reduce daily care benefit
Prudential	Optional; toll-free referral and process services; can be used during elimination period; home visits; coordinate care; advise about options	Private care consultant licensed not associated with Prudential	Does not reduce daily benefit; 20 times nursing home daily benefit can be used during elimination period

Note: All information was obtained from the promotional materials of the listed providers.

(Cahill, 2002; Healy, 2002; Sullivan, 2002). Suffice it to say that, given the expected demographic changes, as well as the diverse lifestyles of those elders of the future, there is a need for further research with culturally diverse older adults and their familial caregivers.

SUGGESTED CARE MANAGEMENT WEB SITES

<http://caremanagement.dce.ufl.edu>

The University of Florida Division of Continuing Education and Center for Gerontological Studies offer a certificate in GCM. The certificate is designed to enhance the ability of health and social service profes-

sionals to manage the care of the elderly in a variety of settings, including the home. The certificate is also designed to develop the ability of recent graduates in health-related fields to manage the comprehensive care of our aging population. The program is currently offered to geriatric care professionals, care and case managers, registered nurses, social workers, and members of other health-related professions who are involved in care of the elderly.

www.acmaweb.org

The American Case Management Association, Inc. (ACMA) is a nonprofit organization that was established as the professional association that offers solutions to support the evolving collaborative practice of

hospital/health system case management. The ACMA endeavors to provide a forum for interdisciplinary collaboration. Full and associate memberships are available for individuals who are responsible for and functionally providing case management services. Student memberships are also available for individuals in the process of learning case management services.

www.cmsa.org

The Case Management Society of America is an international, nonprofit organization founded in 1990; it is dedicated to the support and development of the profession of case management through educational forums, networking opportunities, and legislative involvement. The mission of this organization is to promote the growth and value of case management and to support the evolving needs of the case management professional.

www.caremanager.org

The National Association of Professional Geriatric Care Managers (NAPGCM) is a nonprofit, professional organization of practitioners whose goal is the advancement of dignified care for the elderly and their families. With more than 1,600 members, NAPGCM is committed to maximizing the independence and autonomy of elders, while striving to ensure that the highest quality and most cost-effective health and human services are used when and where appropriate.

www.naccm.net

The National Academy of Certified Care Managers (NACCM) is "Committed to quality and competent care management practice. This association works to meet this commitment by assuring individual competence to perform the full range of care management tasks through a validated, standardized examination that tests the skills, knowledge, and practice ethics needed to serve consumers.

www.ctcommunitycare.org

Connecticut Community Care, Inc. (CCCI), is a nonprofit agency that The mission of CCCI is to provide care management services to older individuals, and other persons with similar chronic care needs and their caregivers, and to assist them in remaining as independent as possible in the most cost-effective manner. This agency will continue to be the premier provider of long-term care management to low-income elderly in Connecticut. In addition to the direct service component, CCCI has been a leader in the field

of geriatric care management through the organization's educational division, Care Management Institute (CMI), which is a founding member of the National Academy of Certified Care Managers (NACCM), an accreditation organization that offers the designation of certified care manager to care managers throughout the country. The institute's faculty has extensive experience in areas associated with care management and geriatric program design, from service provision to benefit administration and data analysis to research. These skilled practitioners and experienced administrators understand the needs of the older population and the role of effective management in the conservation of limited resources.

Hospices

38

This chapter discusses social work practice in hospice settings with older people and their families. The chapter's introduction sets the context by providing both historical and current perspectives on hospice care, including a differentiation between end-of-life, palliative, and hospice care, and it integrates current utilization and length-of-stay information from the National Hospice and Palliative Care Organization (NHPCO). The chapter's three main sections discuss (1) regulations and policies that guide hospice social work, (2) hospice care environments, and (3) hospice social work with older adults and their families. Although people of all ages enroll in hospice, this chapter focuses on older patients and their families. The chapter was guided by focus group discussions and in-depth interviews with 21 hospice social workers, whose expertise made these regulatory, care environment, and practice issues come to life.

Historically, "hospice" comes from the same linguistic root as "hospitality" and can be traced back to medieval times, when it referred to a place of shelter and rest for weary or ill travelers on a long journey (Saunders, 2000). Currently, hospice has many meanings; it is a philosophy, a type of care, a benefit, and a health care program that is offered in different settings. The *hospice philosophy* affirms life, neither hastening nor postponing death. *Hospice care* focuses on the patient and family as a unit, recognizing death as the final stage of life, and enabling terminally ill people to continue an alert, pain-free life so that their last days may be spent with dignity and quality, surrounded by their loved ones. The *Medicare Hospice Benefit* (MHB) establishes coverage of comprehensive care for people with a prognosis of six months or less and who decide to stop treatments that are aimed at curing the illness. *Hospice programs* provide care in patients' homes, hospitals, nursing homes, assisted living facilities, free-standing inpatient units, and hospice houses within some communities (National Hospice and Palliative Care Organization [NHCPO], 2004).

The first hospice, St. Christopher's in London, was founded in 1967 by Cicely Saunders, who had been trained as a social worker, nurse, and physician. Hospice care began in the United States during the 1970s and was signed into law as a health care benefit in 1982. Since that time, the hospice movement has grown and changed, being influenced by demographics, advancing medical technology, and healthcare financing. Presently, more than 70% of those who die each year are over age 65 and have experienced an extended dying process from gradually progressive con-

ditions such as heart disease, kidney failure, and cancer (Field & Cassel, 1997). Health care cost containment efforts have shortened hospital stays and encouraged the utilization of less acute environments for care. In combination, these changes have influenced care for people who are terminally ill (Bern-Klug, Gessert, & Forbes, 2002; Luptak, 2004).

Recent trends have stimulated the development of new approaches that are aimed at improving care for people who are dying. The terms “end-of-life care,” “palliative care,” and “hospice care” are sometimes used interchangeably; for the purpose of conceptual clarity, definitions are critical. *End-of-life care* refers broadly to the physical, psychological, spiritual, and practical dimensions of care that is provided for people who are dying in all settings, including ICUs or emergency departments (IOM, 1997). *Palliative care* seeks to prevent, relieve, reduce, or soothe the symptoms of disease or a disorder without effecting a cure. Although this term is most often used within the end-of-life context, palliative care is not restricted to those who are dying, and is also important to people with chronic pain. Palliative care is delivered by interdisciplinary teams and consultation services in hospitals, nursing homes, and outpatient settings and sometimes in conjunction with hospice services. As a model for the delivery of end-of-life care, *hospice programs* provide palliative care for people whose illness is expected to end in death within six months.

Social work practice in palliative and end-of-life care settings has become a specialty field of practice (National Association of Social Workers [NASW], 2003). Hospice social work is a subspecialty of this field, sharing common features with practice in other end-of-life care settings, but also encompassing features that are unique and distinct. Further, distinctions can be drawn between the issues that characterize social work practice in different hospice settings, (e.g., home, nursing home, or residential unit).

AN OVERVIEW OF HOSPICE CARE

Current estimates by the National Hospice and Palliative Care Organization indicate that 3,200 operational hospice programs provided care to more than 885,000 terminally ill people and their families in 2002 (NHPCO, 2004). Hospices operate in all regions of the country; about one quarter (24%) are located in urban areas, a larger number can be found in rural areas (38%), and some cover both urban and rural

areas (38%). Some hospice organizations have only one office, while others have multiple delivery locations; half are free-standing entities (50%), about one-third are affiliated with hospitals (31.5%), some are connected with home health agencies (18%), and a smaller number were affiliated with nursing facilities (<1%). Hospices also have varying financial structures; a majority are nonprofit (69%), a smaller number were for-profit organizations (27%), and a small number are run by the government (3%) (NHPCO, 2004).

Hospice patients die in a variety of settings: at home (57.9%), in a nursing facility (21.5%), in a hospice unit (4.8%), in a hospital (9%), in free-standing inpatient hospice units (4.1%), and in residential care settings (2.7%) (NHPCO, 2004). More patients died from cancer (50.5%) than other terminal conditions. The top five noncancerous causes of death in hospice include end-stage heart disease (10.7%), dementia (8.3%), lung disease (6.7%), end-stage kidney disease (3%), and end-stage liver disease (1.6%). Although growing numbers of hospice patients demonstrate the increasing societal awareness of hospice, the average length of stay (LOS) continues to be about 51 days (less than 2 months); the median LOS is 21 days. Considered together with the fact that 34% of all hospice patients die within 7 days of admission, these statistics indicate a large number of short stays (NHPCO, 2004).

REGULATIONS AND POLICIES THAT GUIDE HOSPICE CARE

Federal, state, and organizational policies shape the experience of people who are dying and their family members, as well as social work practice in hospice settings. This section briefly addresses the major regulations that influence hospice care: MHB, Medicaid, the Patient Self-Determination Act, and organizational policies about resuscitation and rehospitalization.

Medicare. The MHB pays for a majority (80%) of hospice care in the United States (NHPCO, 2004). To utilize Medicare hospice benefits, an individual must: (1) have been certified by two physicians as having a life expectancy of six months or less if the disease runs its normal course, (2) have chosen to forgo curative treatment, and (3) be enrolled in a Medicare-approved program (Social Security Act, 42 C.F.R. 418, 2000). Medicare part A covers noncurative medical and support services for terminal care, which include physician services, nursing care, medical appliances and supplies,

drugs for symptom management and pain relief, short-term inpatient and respite care, homemaker and home health aide services, counseling, social work services, spiritual care, volunteer assistance, and bereavement counseling (NHPCO, 2004).

Medicare hospice rates vary according to the type of care that is provided. *Routine home care* covers care in a home setting (e.g., own home, family members' home, assisted living facility or nursing home). *Continuous home care* covers skilled services for a period of at least 8 hours within a 24-hour period for brief periods of crisis and only as necessary to maintain the terminally ill individual at home. *General inpatient care* involves interventions for pain control or symptom that cannot feasibly be managed at home and is delivered in hospitals, nursing homes, or inpatient hospice facilities. *Inpatient respite care* is covered for no more than 5 days at a time, when caregivers become ill or need a break. The variable fee structure of the MHB has made it possible for hospice organizations to develop new ways of providing care, consequently also meeting individual patient and family needs and preferences (Code of Federal Regulations, 2000).

The MHB "6-month rule" initially required beneficiaries to be within 6 months of their death to be eligible for hospice. However, because many people experience a long, slow decline from a terminal illness, the 6-month rule became a barrier to hospice utilization (Code of Federal Regulations, 418.22, 2000; Lynn, 2002). The Balanced Budget Act of 1997 amended the MHB and established differential benefit periods: an initial 90-day period; a subsequent 90-day period; an unlimited number of subsequent 60-day benefit periods for as long as the patient remains terminally ill (Hospice Association of America [HAA], 2002).

Increasingly, all health care services in the United States, including Medicare benefits, are financed through managed care organizations (MCOs). When a person who has both Medicare and a managed care plan elects hospice, the services must be provided through a Medicare-approved hospice, and the individual must meet the eligibility requirement. The patient does not need a referral and is not required to disenroll from the MCO. Medicare pays for attending physician charges and for services that are not related to the patient's terminal illness (Centers for Medicare and Medicaid [CMS], 2003; Yagoda, 2002).

Medicaid. Medicaid hospice benefits vary dramatically between states because broad federal guidelines provide wide latitude in eligibility, benefits, and payment mechanisms (Kaiser Family Foundation, 2004; Tilly & Wiener, 2001). Hospices that are Medicare certified must offer all services required to relieve the

symptoms of a terminal illness, even if the patient is not covered by Medicare and does not have the ability to pay (NHPCO, 2004). However, to participate in Medicaid, hospices must meet Medicare's conditions of participation, which require that an interdisciplinary team supervise or deliver a defined set of services that are based on a written plan of care (Code of Federal Regulations, 418.22, 2000). Although Medicaid accounts for only about 7% of total hospice revenue, it is a significant source of funding for the 35% of older people who use nursing home care during the last year of life (Spillman & Lubitz, 2000).

The Patient Self-Determination Act requires that all health care agencies ask about advance directives, recognize patients' written wishes, and provide educational materials about end-of-life decision-making (Caring Connections, 2001). As a result, in many settings, social workers introduce, discuss, and help people complete one or both types of advance directives: (1) living will and (2) medical power of attorney (POA). A medical POA is sometimes called a health care proxy, durable power of attorney, or health care agent. Particularly when end-of-life decisions have not been made before admission, social workers assist patients and families in identifying options and articulating their preferences during the early stages of hospice care. Finally, discussions of *Do Not Resuscitate* (DNR) or *Do Not Re-hospitalize* (DNH) orders are part of the hospice admission process and social work assessment. HOSPICE CARE ENVIRONMENTS

Certified hospice programs provide the same core services in all settings. The development of different care environments has made it possible and sometimes desirable for hospice patients to move between different environments as the illness progresses. Each care environment is briefly described in this section.

In-home care is provided in a patient's or caregiver's house, apartment, or trailer, as well as in assisted living facilities, senior apartment complexes, or retirement facilities. Comprehensive home care includes durable medical equipment, prescription delivery, and visits from each team member. An on-call system is available for crises that occur at any time. Most hospice care is provided in home settings (NHPCO, 2004).

Hospital-based hospice care is usually short-term care and is provided in different arrangements. Beds may be located within a designated hospice unit, scattered throughout the institution, or located within a limited area of the hospital, such as an oncology floor. Care is reimbursed at the general inpatient rate.

Free-standing hospice inpatient units are facilities that provide only inpatient hospice care. Established by a parent hospice organization that also provides care in other environments, these facilities offer short-term inpatient stays for one of three reasons: (1) acute symptom management is needed (e.g., pain, seizures, or nausea are intractable), (2) there is a caregiving system breakdown and respite is needed, or (3) the final hours and days of a person's life are unmanageable at home.

Residential hospice units are home-like and non-medical settings where terminally ill people can relocate to receive care for weeks to months before death when there is no able caregiver at home. Presently, the number of residential hospice facilities is small but increasing. Hospice programs with residential units (a "hospice house") have been developed in response to the growing need for inpatient care and utilize a variety of funding sources, often combining MHB routine home care payments, Medicaid benefits, managed care and other commercial insurance arrangements, sliding fee scales, and charitable giving (NHPCO, 2004).

Nursing home-based hospice care is delivered in one of two situations: either (1) a resident of a nursing home is determined to be terminally ill and a hospice is called to assist with end of life care, or (2) a hospice patient is admitted to a nursing home because care needs have exceeded what can be provided in a less

acute setting such as a home or an assisted living facility.

Bereavement counseling. Bereavement counseling is provided under the MHB for the family members of people who died in hospice care, for 13 months after the death. Although the MHB does not stipulate the educational background of bereavement counselors, many hospice organizations employ social workers in these positions. Bereavement counseling is offered by telephone, in an agency setting, or in the relative's home.

HOSPICE SOCIAL WORK WITH OLDER ADULTS AND THEIR FAMILIES

Social work practice in end-of-life and palliative care settings has "come of age" (Beresford, 2003). Recently, new energy and attention have been focused on developing guidelines for social work practice in end-of-life care. Collaborative efforts have involved the Project on Death in America's Social Work Leadership Development Program, the Social Work Section of the National Council of Hospice and Palliative Professionals (NCHPP), and the National Association of Social Workers (NASW). Some of the sources of additional information that can be used to guide social work practice in hospice settings are presented below.

As a subspecialty of social work in end-of-life care, hospice social work is guided by policies that regulate the MHB, influenced by the environments in which care is rendered and reflective of the specific needs of individual terminally ill people and their families. The work of a hospice social worker includes meeting Medicare guidelines and completing required paperwork, working closely and meeting regularly with interdisciplinary team members, making home and facility visits, and fulfilling on-call responsibilities. Hospice social workers weave together their knowledge of regulations, organizations, and programs, as well as the interpersonal and family dynamics that occur at the end of life. Hospice social work is about helping people deal with the changes and losses that accompany the end stage of a terminal illness within a program that aims to ease suffering and prepare the individual for death and help the family in bereavement. Two types of hospice social work are described in this section: (1) components of social work practice that are common to all hospice settings, and (2) components of social work practice that are specific to each hospice environment. Conceptualization of the overall features of hospice social work with older people and the differences found across settings was guided by focus group discussions with social work practitioners from two hospice organizations.

OVERALL FEATURES OF HOSPICE SOCIAL WORK

Organized by concepts from the ecological framework, the overall features of hospice social work can be viewed as an integration of macro, mezzo, and micro practice (see Table 38.1).

The *macro* practice elements of hospice social work include knowledge of regulations about: financing and eligibility, transitions between different environments of care, and the end-of-life decision-making. Hospice social workers are interpreters; they explain policies to patients and families, while simul-

taneously analyzing and describing the patient's social context to the interdisciplinary team. For example, to be eligible for hospice, doctors must certify that a patient is in the final 6 months of life, and the patient must acknowledge that the condition is terminal and agree to forego curative treatment (Becker, 2004; Stein, 2004). When people resist or struggle with these guidelines, social workers interpret the policies for them and work through the issues to attain a mutually beneficial outcome. Complex ethical issues can emerge during the course of hospice care that involve the patient's medical condition, involvement (or lack) of family, or the avoidance of discussing terminality; thus, social workers are often required to incorporate medical and social work ethics in problem resolution (Csikai, 2004).

Macro elements of hospice social work also involve contributions to volunteer training, public education, and community outreach. While working with community agencies, social workers educate others about hospice guidelines and services, they determine eligibility, and they help dispel myths about hospice. Finally, social workers assist their employing hospice organization in balancing fiscal realities with patients' needs. Through the process of problem resolution, social workers help maintain the continuity of patient care (measured as nights in continuous care), manage the average cost per patient, and enhance patient/family satisfaction (Reese, Raymer & Richardson, 2000; Yagoda, 2002).

The *mezzo* practice components of hospice social work involve interdisciplinary teamwork and the integration of knowledge about organizational, team and group dynamics, team roles and boundaries, and varied environments of care. Social workers conduct family conferences (e.g., about disposition, transfer, or death), advocate for the patient/family with team members, and negotiate referrals and services with community agencies.

Teamwork can involve both role "overlap" and "blur" with other disciplines and calls for professionals to be simultaneously flexible and assertive (Christ & Sormanti, 1999; Reese & Sontag, 2001; Wesley, Tunney, & Duncan, 2004). Hospice social workers work closely with each member of the team, often making joint visits to a home or facility and combining expertise to help a patient/family. True interdisciplinary teamwork emerges when professionals are both "understanding of" and "understood by" each other. It is as important for the other professionals to grasp the integrated macro, mezzo, and micro components of the social work role as it is for social workers to un-

TABLE 38.1. Hospice Social Work With Older People

Macro Practice*Knowledge of:*

- Hospice financing regulations: Medicare, Medicaid, MCO
- Advance directives: health care proxies, living wills
- Do Not Resuscitate or Rehospitalize orders; Family Medical Leave Act

Skills to:

- Assess eligibility determination (e.g., Medicaid LTC)
- Interpret regulations for people who are making end-of-life decisions
- Clearly articulate social work values, ethics
- Communicate patient's financial concerns effectively to hospice organization
- Negotiate resources with the community agencies; educate about hospice

Mezzo Practice*Knowledge of:*

- Organizational, team, and group dynamics
- Interdisciplinary team roles and boundaries
- Different environments in which hospice care is provided

Skills to:

- Be flexible and assertive with overlapping roles
- Interpret psychosocial dynamics and social context to team members
- Conduct family conferences (e.g., disposition, transfer, death)
- Advocate for patient/family with team members, community agencies
- Arrange transitions between hospice units (e.g., hospital to nursing home)

Micro Practice*Knowledge of:*

- Biological and psychological processes of dying
- Religious and faith-based practices at the end of life
- Pain and symptom exacerbations and management (e.g., when to call for help)
- Grief; physical, emotional, social responses to loss
- Grief vs. depression in patient and caregiver

Skills to:

- Conduct a rapid, biopsychosocial assessment; build rapport quickly
- Be present during difficult, painful, emotional times; deal with tears and anger
- Use direct and sensitive language to discuss and educate about death and dying
- Assess symptoms of exacerbated substance use and mental illness with loss
- Provide patient/family intervention (e.g., conflict resolution, crisis intervention)
- Anticipate/plan with families about needs following death

Note: This list is representative but not exhaustive; it was compiled with the assistance of hospice social workers from Hospice Buffalo and Niagara Hospice.

understand the parameters and potential conflicts that their colleagues face. For example, social workers who understand the stressors faced by nurses who work to manage uncontrolled pain when the family does not want the person to have morphine, or the dilemmas that chaplains face when asked to perform a funeral service for a patient they met once, can foster stronger

relationships. A well-functioning hospice team is a model of interdisciplinary collaboration.

Social workers also utilize their skills to provide conflict resolution and emotional support for their team members (Christ & Sormanti, 1999; Reese et al., 2003). Examples of the conflicts that social workers have helped their teams resolve include: professional-

personal boundary issues, differences in approach to self-determination, interdisciplinary “turf” issues, differences in perspectives on confidentiality, possible interventions, and possible approaches to diversity issues (Reese et al., 2000).

The micro, or direct practice, elements of hospice social work include but are not limited to: the psychosocial issues that accompany the physical and functional losses of terminal illness; the social, spiritual, religious, and cultural responses to dying; end-of-life preferences and decision-making; facilitation of transitions between environments of care (e.g., hospital to home hospice care); and grief work. Also particularly germane to a chapter on hospice social work with older people is that social work practitioners must differentiate between three processes of decline—(1) physical and cognitive decline accompanying a terminal illness, (2) comorbid conditions, and (3) normal aging—and help families understand the differences.

Clinical work with people who are dying requires the ability to conduct a rapid biopsychosocial assessment and to build rapport quickly, because sometimes only one visit occurs before death (Stein, 2004). The individual experience of terminal illness and the process of caring for someone who is dying are perhaps two of the most intimate, personal, and emotional times in life. Hospice social workers bring the “gift of presence”; sometimes just listening can help a family through the ravages of a death experience. Hospice social workers use direct and sensitive language to discuss death and become comfortable dealing with tears, anger, and emotional intensity. Social workers are the team members who are called on to assess and intervene when a patient or caregiver is demonstrating symptoms of exacerbated substance use and mental illness as a way of coping. Social workers provide family interventions, which include conflict resolution and crisis intervention. Because most people provide care for a dying relative infrequently, family members often benefit from situation-specific support and information. Finally, social workers anticipate and help families plan for their needs after death (e.g., social support, financial concerns, grief counseling)

HOSPICE SOCIAL WORK IN VARIED ENVIRONMENTS

Not all terminal illnesses are the same; thus many paths lead to hospice. Some patients and their loved

ones may have been dealing with the terminal diagnosis for months or years and have expected that hospice admission would eventually occur. Other patients may receive a definitive diagnosis late in the course of a disease and feel that discussion of hospice occurred abruptly and without warning. Admission to hospice is also influenced by the series of decisions that patients and their families make during earlier stages of the illness, the care environments that are available, the ill person’s needs, and how the family can meet them. Subsequently, after admission, patients may move between different hospice environments of care. Each care environment creates a different end-of-life context and patient/family experience. Practice in each environment is briefly described here.

In-home hospice. Home or facility visits present unique opportunities to know and understand the individual within the environmental, social, and family contexts. Home environments vary widely from stark to lavish, clean to unkempt, and rural to urban. Pets may or may not be present, and if they are, there may be one or many who range from friendly to frightening. Home visits make it possible to incorporate visual assessment of items such as family photos or memorabilia, and these help the social work assessment come to life. Home visits also offer the opportunity to assess the environment for needs that the person may have as the disease progresses (e.g., the presence of stairs, proximity of the bathroom). Consequently, hospice social work assessment in the home environment requires the use of active observation and inquiry.

Hospice home care can involve being present when the terminally ill person is having intense pain or symptom exacerbations. A general understanding of symptom management is important, as well as knowledge about when to call for assistance. Establishing a caregiving system is a priority for home care social workers; learning who will stay with the person and if caregiving is the responsibility of one person or shared by many, together with an assessment of the caregivers’ knowledge of dying and physical abilities, is essential. People who live alone may require assistance with placement or a discussion about how to manage physical needs as the disease progresses. Social work practice in the home setting always requires flexible thinking and adaptability to develop a plan that is well grounded within the social context.

Home care that occurs in assisted living, senior, or retirement facilities is accompanied by some additional challenges. Understanding the facility’s policy

TABLE 38.2. Hospice Social Work in Varied Environments

<i>Environment</i>	<i>Environmental Issues</i>	<i>Practice Issues</i>	<i>Salient Knowledge/Skills</i>
In-home care: individual residence	Homes range from: trailers & apartments to large houses; rural to urban locations; clean/tidy to dirty/odorous; Pets: friendly or frightening Photos, memorabilia help assessment come to life	Assess social context & environmental needs Understand caregiving system, assess abilities & knowledge Assist people who live alone	Adaptability & flexible thinking Community networking Use home environment for a “living” psychosocial assessment Quickly assess family dynamics; build rapport
In-home care: assisted living, retirement, senior housing	Facilities range from: communal living/dining (all apartments open on core area) to individual apartments with kitchens; & no structured contact with others Staff can be very comfortable or uncomfortable with dying	Rapport with facility Educate staff about EOL Collaborate with the staff Understand facility policies	Increased acuity may require transfer Evaluate safety: an alarm system? Family conferencing/planning (re: transfer, loss)
Free-standing inpatient units	Nonhospital setting Children, pets allowed Family can stay; open visiting hours Comfortable surroundings 24-hour nursing care	First contact may be in the final hours/days of life High intensity, urgency of work; frequent death Ongoing observation of pain, symptoms of dying, and death	Crisis intervention; support families about death; plan and prepare for bereavement Boundary concerns (emotions, burnout, transference)
Nursing home (NH)-based hospice care	Resident becomes terminally ill and hospice called in (long-term placement) <i>or</i> Hospice patient is admitted to the nursing home (new placement)	Assess nursing home culture (is hospice welcome or a threat?) Help patient accommodate to NH living	Advocate for the resident Support and educate family Clarify lines of communication (when to contact NH, hospice) Facilitate eligibility for Medicaid
Residential hospice facilities	Home-like, non-acute care Lives alone, no caregiver Family/friends are unable to manage EOL care	Longer term stay may allow for reminiscence, planning, family meetings Transitional plans needed; will the person stay here until death	Patient hasn’t entered functional decline Loss of home, social support, routine, independence Anticipate approaching death
Hospital-based hospice	Acute care facility Designated hospice beds, floor <i>or</i> Beds scattered throughout hospital	Team within a team (hospice plus hospital staff) Balancing the fiscal realities faced by hospice and hospital care (discharge planning may be a priority)	Discharge planning Describe and explore options with people at very difficult times
Bereavement counseling	Telephone contact In-home counseling In-agency counseling	Hospice social worker following the person in bereavement <i>or</i> separate bereavement counselors	Being comfortable with tears, anger, intense emotions; readiness for bereavement counseling is individual/unique

Note: This list is representative but not exhaustive; it was compiled with the assistance of hospice social workers from Hospice Buffalo and Niagara Hospice.

on having residents who are becoming dependent remain in the facility is important. Some facilities will allow dying residents to remain as long as additional caregivers are available; others require that residents who need increasing care must transfer out. In addition, social workers may enlist the help of friends or neighbors in the facility, or they may reach out to help them with the loss.

Free-standing inpatient units. Social work practice with people who are temporarily admitted for symptom management or respite requires an assessment of the patient/family plan for disposition and of whether the person will return to the home setting or need placement in a nursing home. The inpatient unit social worker may conduct a family conference and initiate discharge planning immediately after admission. If the hospice patient is admitted because the terminal decline becomes unmanageable in the home setting, the social work role involves assessment of the family's understanding of the approaching death, death education, anticipation of needs, and support through the dying process.

Residential hospice facilities. Social work practice with people who have moved into a "hospice house" involves assessing the person's previous lifestyle, illness trajectory, and end-of-life preferences. Residents of a hospice house may be able to manage some of their own personal care and thus "live with dying" over a period of months. This affords the opportunity to develop a longer term relationship with residents.

Hospital-based hospice units. Because hospital-based hospice care is generally very temporary, social work practice in hospital-based hospice units is disposition-focused. Social workers discuss options for transfer with family members, and planning may focus on what Medicare and other insurance policies cover (Stein, 2004). In some situations, even while patients are actively dying, there is ongoing pressure to place the patient elsewhere. Balancing the discharge planning pressures with patient and family needs in this setting presents unique and distinct pressures.

Nursing home-based hospice care involves additional medical, nursing, social work, and pastoral care services that are provided on top of the routine nursing home regimen. The focus of social work practice with nursing home residents who are hospice patients depends on whether the nursing home resident became terminally ill and hospice was called in or the hospice patient was relocated to the nursing home. If the patient was a long-term nursing home resident, the social work assessment attends to the existing re-

lationships that the resident has with others (staff and patients) as well as the quality of the ongoing relationship between family members and the nursing home. If a hospice patient relocates to a nursing home, social work can assist the person/family in adapting to nursing home life and facing an approaching death.

"Team within a team" phenomenon. Hospice care that is provided in any facility setting (assisted living, nursing home, or hospital-based care) generates a "team within a team" phenomenon. The hospice team enters an environment in which there are previously existing relationships between the patient, family, and staff and existing structures for service delivery and communication. The hospice team brings a specific, focused approach to end-of-life care, which can be welcomed or seen as a threat. The potentially complex three-way relationship requires the hospice team to create a partnership with the facility. Hospice social workers who work in this type of host setting may become involved in problem resolution with the facility's administration or in death and hospice education, which aims to help both the staff and residents deal with the person's decline and approaching death.

Bereavement counseling. It is important to emphasize that grief and loss issues are pervasive in hospice social work; thus social work practitioners in all settings encounter and work with patient and family grief responses. Bereavement counseling is a specifically focused intervention that is provided to help family members integrate the losses they have experienced after the person has died. Two different models of bereavement counseling exist: (1) the social worker who has followed the patient/family before death remains available to them afterward, and (2) following the death, a new person invites their participation in individual or group counseling.

CONTINUING CHANGE— FUTURE CHALLENGES

Three converging trends are precipitating both ongoing change and future challenges for hospice and for social workers in all areas of aging and end-of-life care, as follows.

Demographic imperatives. Presently, more than 80% of the people who utilize hospice services are over age 65, and indicators suggest that this trend will continue. The growth in numbers of hospice organizations and people who use this program indicate in-

creasing recognition of the importance of care that is patient and family focused and is delivered within a variety of environments.

Healthcare financing. Reimbursement cuts, mergers, more stringent benefit management, and focused medical review have forced many hospices to closely examine their business practices (Reese et al., 2000). In addition, costly new drugs and treatments such as palliative radiation have increased the average cost to hospices faster than the reimbursement rates. The fixed Medicare per diem rate that is paid to hospice providers often is insufficient to cover daily services, particularly when patients have short hospice stays and extraordinary expenses. Medicaid benefit limitations are too low to allow hospices in some states to provide the most advanced types of pain relief (Tilly & Wiener, 2001).

Hospice utilization. Clear patterns of utilization have emerged, indicating that hospice is used by some groups more than others and in ways that diverge from program expectations. Remarkably, the majority (82%) of hospice patients are white. A significant number of people have short stays; 35% die within 7 days of admission; and the median LOS hovers at around 21 days (NHPCO, 2004). These statistics suggest that the hospice program as it is presently structured does not appeal to people in some racial and ethnic groups (Reese, Ahern, Nair, O’Faire, & Warren, 1999). In addition, despite increased knowledge about the program, many people do not wish to enter the program until the very final stage of life. Deeper understanding about individual racial and cultural differences, as well as ideologies and preferences about care at the end of life, is needed; the outcomes will influence future program evolution.

Hospice has developed many meanings since its inception, and these trends demonstrate that the progression will continue. As a core component of the hospice program, gerontological social workers have significant opportunities to advocate for patient/family needs and to be a voice for the issues and concerns of terminally ill older adults and their families in the midst of ongoing policy and program change.

Grateful acknowledgment is made of the knowledge, wisdom and experiences shared by 21 social workers from Hospice Buffalo and Niagara Hospice who participated in focus group discussions about hospice social work to guide the development of this chapter.

Community Mental Health Centers

39

Although the majority of the elderly population has sound mental health, studies indicate that almost 20% of this age group experience mental health disorders (U.S. Department of Health and Human Services, 1999). The correlation between elder mental disorders and physical illness, poor social support, and disability presents unique challenges for the mental health care system. The vast majority of older persons suffering from mental health disorders (69.2%) reside in the community (Rowland, Burns, Schafft, Randolph, & McAninch, 1997). Therefore, it is imperative that effective community-based options for mental health treatment be available for older adults. Over the past several decades one community-based option has been Community Mental Health Centers (CMHCs). These centers, which gained prominence in the 1960s and 1970s through the support of direct federal funding, received federal funds to provide comprehensive, community-based mental health services to all citizens residing within established catchment areas. Federal mandates directed CMHCs to provide culturally sensitive mental health and substance abuse services, and to address the needs of high-priority clients, including the severely mentally ill, older adults, and children. Over time, however, CMHCs have been barraged by changing political, social, and economic realities. These realities have brought about an evolution in the CMHC system. Today, community-based mental health care agencies are sustained by a variety of funding mechanisms, provide a diversified array of services, and target various client populations.

EARLY HISTORY (1963–1980)

After World War II, a growing consensus among psychiatrists and others in the mental health community held that psychosocial and psychoanalytic therapy within community settings offered greater treatment efficacy than did mental health treatment within institutionalized settings (Grob, 1991). The discovery of psychotropic medications to treat schizophrenia and other mental health disorders decreased the need to house the severely mentally ill in state institutions and heightened professionals' and mental health advocates' interest in community-based treatment. *Action for Mental Health*, a summary report of the Joint Commission on Mental Illness and Health (Appel & Bartemeier, 1961), reflected this sentiment and highlighted the need for community-based mental health services. The newly elected president, John F.

Kennedy, read this report and came to believe in the need for a federal mental health policy that would foster the movement from institution-based to community-based mental health services. In 1963, President Kennedy called for a “bold new approach” in the treatment of the mentally ill and recommended that Congress authorize grants to the states for the development of comprehensive community mental health centers (Cutler, 1992). President Kennedy’s address marked the beginning of the community mental health center movement in the United States (National Council for Community Behavioral Healthcare, 2003). Later in 1963, the Mental Retardation Facilities and Community Mental Health Centers Construction Act (1963) was signed into law. Because of lobbying from the American Medical Association and congressional opposition, staffing for these centers was omitted from the Act, and only allocation for construction of buildings was included. However, in 1965, under President Johnson, funding amendments for staff were passed. From 1965 through 1970, designated mental health catchment areas all across the country began to apply for federal funding to build and develop CMHCs.

The original centers were mandated to provide five services: inpatient, outpatient, day treatment, crisis services, and education and consultation. In addition, each center was to serve 75,000 to 200,000 persons in a defined catchment area, and continuity of care was to be provided to all clients served (Naerman, Haskins, Robinson, Zook, & Wilson, 1978). The CMHCs Construction Act stipulated that local communities appoint boards that were composed of mental health professionals, consumers, and family members and were reflective of the community racial, ethnic, and demographic profile, to help guide the development of needed services. In 1975, Congress passed a series of amendments to the CMHCs Construction Act. A new CMHC definition mandated the comprehensiveness and accessibility of mental health services for all clients regardless of ability to pay. The amendments also served to further increase the spectrum of services offered by federally funded CMHCs. Services to older adults and children were required, as were drug abuse services and follow-up services such as halfway houses. As a result of the original Act and the subsequent amendments, 445 CMHCs were funded between 1968 and 1975 (Smith, 1984). By 1981, when direct federal funding was eliminated, 754 catchment areas nationwide had applied for and received funds for the development of CMHCs (Cutler, 1992).

As the result of the new federal mental health policy and the passage of Medicaid and Medicare, the population of state mental hospitals began to decline rapidly. “Deinstitutionalization,” the movement of persons with severe mental health disorders from state hospitals to the community, occurred rapidly throughout the 1960s and 1970s. The intent behind the deinstitutionalization movement was for persons with mental health disorders to receive needed treatment and services in community-based settings. The CMHCs were designed to play a vital role in meeting the needs of and maintaining the severely mentally ill in the community.

Although the new centers were set up as an alternative to state hospitals, in reality, they did not serve the same clientele. Persons with severe mental illness continued to receive services in state hospitals or from state hospital aftercare programs. The CMHCs focused more on a new group of clients and provided insight-oriented therapy to those with less severe illnesses who, in the past, did not have access to services. Thus, while those with severe mental illness were leaving institutionalized care, adequate support mechanisms to provide needed care within the community were not readily available (Grob, 1991). In 1977, President Carter appointed his wife, Rosalyn, to head the President’s Commission on Mental Health, which held public hearings to examine the status of persons with mental health disorders. The commission found a lack of services to meet the needs of deinstitutionalized persons with severe mental illness. As a result, the National Mental Health Systems Act (1980) authorized an additional \$800 million and gave priority to vulnerable groups, including the severely mentally ill, children, and older adults.

However, in 1981 President Reagan signed the Omnibus Budget Reconciliation Act (1981), which cut 25% of all CMHC funding and eliminated direct federal funding of CMHCs. The additional monies authorized through the National Mental Health Systems Act (1980) were written off. Federal funds were converted into block grants to be distributed by the states, according to the states’ estimations of the mental health needs of their own citizens. The CMHCs were stripped of their federally qualified status, and the previous mental health service requirements established by the CMHCs Construction Act and its subsequent amendments were eliminated. Thus, the new legislation dramatically reduced the federal government’s involvement in shaping mental health programs and services and shifted this responsibility to states and local communities (Pardes, 1990). Follow-

ing OBRA 1981, the financial status of CMHCs became precarious. In an effort to cope with this reality, CMHCs changed their staffing patterns to include less highly paid personnel, focused their services more on the severely mentally ill, and began to experiment with alternate sources of funding (Cutler, 1992).

CURRENT SITUATION (SINCE 1981)

Currently, the structure of the mental health care system is intergovernmental, involving federal, state, and local entities (Coddington, 2001). The federal government, through the Community Mental Health Services Block Program, awards grants to states to provide community-based mental health services to their citizens and thereby reduce psychiatric hospitalizations. The Community Mental Health Services Block Program works closely with each state to develop a state mental health plan, and states may use block grant monies to fund CMHCs. The assumption underlying the block grant program is that mental health needs vary from state to state, as do effective mental health treatment approaches. The block grant supports the grassroots involvement of key stakeholders in mental health services at the local, state, and federal levels. For this reason, each state is required to have a mental health planning council to review and provide input for the state's mental health plan (Substance Abuse Mental Health Services Administration [SAMHSA], 2004). Each state, therefore, establishes its own approach to the structure and funding of community-based mental health treatment. Because of diversity within states' geographic regions, some states have given those at the local level the ability to customize mental health service offerings and organizational structures. Thus, although at one point in time, federally funded CMHCs shared a common mandate and offered a required set of services, CMHC programs have increasingly diversified, since "the organization, structure and funding of CMHCs varies from state to state as does the per capita funding of mental health programs from state sources" (Callicutt, 1997, p. 12).

Decreased federal and state funding over the past several decades coupled with soaring health care costs have challenged the stability of centers offering mental health services to the public. In order to respond to changing governmental priorities and evolving market forces, mental health centers have had to put together an increasingly complex array of funding streams, including Medicare, Medicaid, fee-for-service, employee assistance contracts, local funding,

managed care contracts, and block grant money (Broskowski & Eaddy, 1994). Because each of these funding mechanisms may cover varying services and offer differential reimbursement levels, the type and amount of mental health services offered may vary greatly from center to center. One study that analyzed payer sources for and type of services offered by CMHCs found that those centers that rely more heavily on public funds target their services more strongly to clients with severe mental illness, while centers supported primarily by private funds focus on those with less serious mental disorders (Hadley, Culhane, Mazade, & Manderscheid, 1994). Because of increasing financial challenges, many CMHCs are no longer able to offer comprehensive services. Their boards of directors must decide which population(s) will best benefit from the center's services and then develop a business plan and marketing strategy to ensure adequate funding for services offered (Dyer & Williams, 1994).

In response to the forces just outlined, states and CMHCs have begun to experiment with managed behavioral health care. States have focused on publicly funded managed care systems for state employees, Medicaid beneficiaries, and the indigent. In 1988, Massachusetts was the first state to employ managed care for its behavioral health care needs. Many states now have Medicaid managed care, in which mental health services for those receiving public assistance are capitated. Utah's managed Medicaid plan, for example, involves contracts between the state and CMHCs that serve regional catchment areas. Reports on the impact of managed care on services provided by CMHCs vary. In Massachusetts, CMHC providers surveyed after the establishment of Medicaid managed care indicated that the service continuum of mental health services provided expanded as the result of managed care (Cohen & Bloom, 2000). A study done in New York state, however, revealed that managed care resulted in significant changes in the types of mental health service provided, with decreases in open-ended psychotherapy and psychological testing and increases in medication management, brief therapy, and crisis intervention (Cypres, Landsberg, & Spellman, 1997).

In summary, over the last 40 years CMHCs have undergone multiple evolutions. The CMHC Construction Act of 1963 and its amendments brought about a common definition and mandated service offerings for federally funded CMHCs and highlighted the role of CMHCs as providers of a wide array of mental health services for community-based popula-

tions. The devolution of mental health policy to the state and local levels, however, coupled with decreased government funding of mental health services and the rise of managed behavioral health care, has led to greater diversification in the structure and organization of community mental health service agencies and in the services they provide.

STAFFING

Community mental health centers are staffed by a variety of mental health professionals, including social workers, nurses, psychologists, and psychiatrists. It has been estimated that 50% of all mental health treatments in the United States are provided by social workers (Rosen & Persky, 1997). In 1977, Blank defined the role of social workers in community mental health centers as that of advocates and community liaisons. According to Blank (1977), social workers bring the individual mental health client, groups of clients, and communities together. Social workers are responsible for assessing the social strengths and weaknesses of clients and coordinating services with community resources to meet the client's needs and maintain the client in the community at his or her highest practicable level of functioning (Blank, 1977). In a survey of 200 licensed mental health organizations in New York, Cypres et al. (1997) found that 45% of the employees were social workers. Cypres et al. noted that the number of social workers in mental health organizations had increased over the past four years, but due to the managed care movement, the number of social workers in mental health is expected to decrease in the future. Among the many services provided by social workers are psychosocial assessments, information and referral services, therapeutic interventions, skills training, and crisis intervention. Specialized gerontological education and experience serve to better equip social workers to address the unique mental health needs of older adults.

CMHCS AND OLDER ADULTS

The goal of community mental health centers is to encourage maximum independence as clients receive mental health care in the community to prevent the need for institutionalization (Kent, 1990). Clients participate in the therapeutic relationship by assisting with the creation of goals and objectives, and by executing action plans that are designed to enhance their

level of functioning and continue their independent lifestyles. In 1988, Light, Lebowitz, and Bailey surveyed 290 CMHCs nationally to assess the number of older adults receiving services and the types of services rendered to this special population. Light et al. found that 281 of the 290 community mental health centers surveyed provided services to older adults. On average, almost 11% of the clients served were aged 60 and over. Approximately 52% of the centers identified themselves as offering *specialized* services for older adults. Centers with specialized older adult programs employed staff with increased gerontological knowledge, training, and skills, and as a result, these centers served a greater proportion of clients aged 60 and over (almost 16%, compared to 11%). In order to reach older adults, most CMHCs surveyed partnered with other agencies in the aging network to leverage resources, coordinate planning and training, and increase mental health service usage by older adults (Kent, 1990; Light et al., 1988; Lebowitz, 1988). Facilities that partnered with other senior service agencies reported serving a greater proportion of clients aged 60 and over than those that did not seek out partnerships in the aging network (Light et al., 1988).

Mental health disorders among older adults are undertreated, and older adults are underrepresented in CMHCs. Several reasons for the undertreatment of older adults in community-based mental health care settings have been proposed. Lebowitz (1988) suggested that most mental health professionals have limited training and experience in differentiating normal age-associated changes from changes requiring clinical or medical attention. The lack of adequate gerontological training has created a workforce of practitioners who are not prepared to work with this special population. In addition, practitioners may be unable to assess mental health problems and intervene to assist older adults in resolving their mental health issues. Second, many older adults, their families, and other potential referral sources for mental health services do not recognize the signs and symptoms of mental health problems (Lebowitz, 1988). Many community mental health centers lack an aggressive outreach program to raise awareness of mental health issues among older adults within the community and generate increased referrals (Lebowitz, 1988). Third, ageism among staff of CMHCs and other referring professionals can lead to the mistaken belief that mental health problems among older adults are neither preventable nor treatable. Therefore, no action is taken to assist older adults exhibiting mental health changes. In addition,

many older adults and their families have ageist beliefs that negatively influence their perceptions of the usefulness of mental health care for older adults and their decisions to access community mental health services (Lebowitz, 1988; Rosen & Persky, 1997). Finally, a social stigma inhibits older adults' use of mental health services due to embarrassment or fear (Kent, 1990; Light et al., 1988). These issues pose barriers that mental health centers must address in order to increase the accessibility of mental health services to older persons within their communities.

REFERRALS

Older adults make the decision to use CMHCs or are referred for mental health services for a variety of reasons. Unfortunately, many wait until their mental health condition is exacerbated before seeking services. Kent (1990) revealed that most individuals do not use mental health services until their situation reaches a crisis level. Situations that result in referral for older adults to community mental health services include depression, memory problems, personality changes, inappropriate behavior, family conflicts, communication problems, chronic illnesses, loss of a spouse or friends, decreased income, and contraindicated drug interactions (Swan, Fox, & Estes, 1986; Kent, 1990; Mosher-Ashley, 1993). In a study of 298 clients over the age of 59 receiving mental health services at CMHCs in Massachusetts, Mosher-Ashley (1993) found that most community-dwelling clients were referred for depression or family conflicts. Residents of long-term care facilities were most commonly referred for the management of behavior problems or emotional problems.

In a random probability sample of 532 adults aged 70 and over in Arkansas, Chumbler, Cody, and Beck (2001) found three factors that increased utilization of community mental health services among older persons. To begin with, Chumbler and his associates found that individuals with impairments in activities of daily living or impairments in instrumental activities of daily living were more likely to use mental health services than those with no impairments. Second, researchers found that as age increased, mental health service use also increased. Finally, those receiving informal care were more likely to use CMHCs than those who were not receiving informal care.

Referrals to CMHCs come from a variety of sources. Families, social workers, hospitals, information and referral centers, physicians, court systems,

churches, long-term care facilities, and other agencies are among the many referral sources (Kent, 1990; Mosher-Ashley, 1993). According to Mosher-Ashley (1993), most referrals are made by social workers at other agencies, while the fewest referrals come from self-initiated contact. For this reason, education outreach efforts by CMHCs that serve to increase referral sources' understanding of recognizable warning signs of unmet mental health needs among older adults are critical.

SERVICES PROVIDED

Community mental health centers provide a variety of direct and indirect services for older adults. Direct services include assessments, case management, comprehensive medical exams, support groups, information on community resources and referral to other agencies, medication monitoring, and a variety of therapeutic interventions, including psychotherapy, cognitive restructuring, behavior modification, grief therapy, and skill development in the areas of stress management, assertiveness, and self-esteem (Kent, 1990; Light et al., 1988; Swan, Fox, & Estes, 1986). Indirect services include case consultations with long-term care facilities and community education and training (Kent, 1990; Light et al., 1988; Swan et al., 1986). Other services that are available at some CMHCs include transportation to and from appointments, recreational activities, respite, adult daycare, and partial day treatment programs (Light et al., 1988; Swan et al., 1986). Notably, CMHCs do not limit the provision of services to the confines of their center. Services are also provided in long-term care facilities, senior centers, in congregate nutrition sites, and in the clients' homes (Kent, 1990; Light et al., 1988).

Dementia-related conditions and accompanying behavior problems can be particularly challenging for caregivers and mental health professionals. Family caregivers and staff of long-term care facilities turn to mental health professionals in CMHCs for assistance in learning to better manage the symptoms of dementia. Individuals in the early stages of dementia also benefit from therapeutic interventions that help to maintain their present level of functioning and help them adjust to the changes they encounter as the disease progresses. Mosher-Ashley and Witkowski (1999) surveyed 36 community mental health centers in Massachusetts that provide services to older adults. Of these 36 agencies, 75% provided services to people with dementia. These CMHCs provided services to

families, long-term care facilities, and individuals with dementia. Services commonly provided to families included counseling, family therapy, and support groups. Families also commonly received case consultations to assist them in managing behavior problems in people with dementia. In long-term care facilities, staff of CMHCs provided case consultations, staff training, counseling to residents with dementia, and assessments. People with dementia received individual counseling, assessments, and group treatments, as appropriate. In some cases, additional services, including psychological/psychiatric evaluations, medication monitoring, case management, adult daycare, outreach efforts, and education for other agencies were also provided. Reported benefits for caregivers and people with dementia included decreased anxiety, decreased depression, increased understanding of the disease process and behavior problems, increased adjustment, and decreased stress. However, treatment efforts were not always productive because of the cognitive impairments of clients with dementia.

Termination of services. Dropout rates are high among clients at CMHCs. According to a study of dropout from community mental health services (Lerner, Zilber, Barasch, & Wittman, 1993), 50% of clients drop out during the first 3 months. Common reasons for dropout include transportation difficulties, low socioeconomic status, and decreased motivation (Fraps, McReynolds, Beck, & Heisler, 1982; Trepka, 1986; Vaslamatzis & Verveniotis, 1986). The therapeutic relationship between the older adult client and the therapist can be dissolved under a variety of circumstances. Mosher-Ashley (1994) conducted research on 298 adults over the age of 59 receiving mental health services from CMHCs in two Massachusetts counties between 1980 and 1986 to determine the reasons for termination of services and factors associated with client persistence in therapy. Of these 298 clients, 180 were no longer receiving mental health services from the CMHC at the end of 1986. The client terminated in 59% of the cases, the therapist terminated in 32%, and 9% were terminated on the basis of mutual agreement of the therapist and the client. In addition, 37.5% dropped out by the fourth visit. One-third of the self-terminated clients cited no need for therapy as their reason for termination. Fifteen percent terminated because they no longer wanted to participate, 10% felt as though therapy wouldn't help, 6% were concerned the therapeutic process would be too painful, 4% moved, and 19%

just didn't return for the remainder of their appointments.

Mosher-Ashley (1994) found a statistically significant difference between the dropout rates of clients residing in the community and those residing in long-term care facilities. Therapists terminated approximately half of the cases of individuals in long-term care facilities, compared to one-fifth of those residing in the community. The most common reason for therapist-terminated cases was the presence of an organic brain syndrome that interfered with the therapeutic relationship. On average, community-residing clients dropped out more often than those in long-term care facilities (70% compared to 26%). According to the therapists' assessment of client dropout rates, only 10% of clients residing in the community and 8.4% of clients residing in long-term care facilities terminated with improvement. In assessing the factors associated with persistence, Mosher-Ashley (1994) concluded that self-referral was not related to persistence.

FUTURE DIRECTIONS

As the aging population continues to grow, CMHCs will be faced with the challenge of providing mental health services to an increasing number of older clients. In order to meet the needs of older adults more effectively, it is necessary that CMHCs equip themselves with knowledgeable and skilled staff. Currently, most staff in CMHCs have no specialized geriatric training (Weitzman et al., 1998). Lebowitz (1988) found that increased staff training in gerontological issues resulted in a broader range of services being offered to older adults and a 50% increase in utilization of mental health services by older adults. Comprehensive training initiatives are necessary to better enable existing staff to meet the needs of older adults. To begin with, staff must be able to recognize the difference between the normal aging process and mental health problems (Kent, 1990). Without a basic understanding of normal age-associated changes, therapists cannot effectively assess and intervene in mental health problems that older adults may experience. It is also important for therapists to be able to recognize the relationship between mental health problems and physical illnesses (Rosen & Persky, 1997). Other specific areas where CMHC staff require increased gerontological training include depression, dementia, clinical assessment, pharmacological issues, case management, and barriers to accessing services

(Rosen & Persky, 1997; Weitzman et al., 1998). Experts also contend that due to the growing managed care movement, CMHC staff must enhance their knowledge of brief therapy, and of emergency and crisis interventions for older adults (Cypres et al., 1997). In conclusion, addressing the mental health needs of community-based older adults will require increased attention to policy, gerontological training of mental health service providers, service accessibility, and collaboration between community mental health centers and providers within the aging network (Rosen & Persky, 1997; Lebowitz, 1988).

PHILIP A. ROZARIO

Senior Centers

40

Senior centers, or multipurpose senior centers, serve many important social and recreational functions in the continuum of community-based services for older adults. According to the National Council on the Aging (NCOA), senior centers embody the beliefs of human growth and humanism, in that their underlying philosophy espouses the continued growth and development of older individuals with ambitions, capabilities, and creative capacities (in Lowy, 1985). These principles are in line with the promotion of successful and productive aging that has gained salience in contemporary gerontology (Moody, 2001). Further, as community-based services for older people, senior centers are well suited to promote the values of the Older Americans Act, which seeks to maximize independence, support individual preferences, and empower consumers to assume meaningful roles in program governance (Justice, 1997).

OVERVIEW

Definition. Notwithstanding the lack of agreement on the definitions of senior centers with regard to their programmatic content and delivery (Krout, 1989), the National Institute of Senior Centers (1990) defines a *senior center* as “a community focal point . . . where older adults come together for services and activities that reflect their experience and skills, respond to their diverse needs and interests, enhance their dignity, support their independence, and encourage their involvement in and with the center and the community” (cited in Wagner, 1995a, p. 4). This definition emphasizes the role the senior center plays in the serving the total needs of the older person within his or her community.

The 1973 amendments to the 1965 Older Americans Act officially introduced the term *multipurpose senior center*, “as a community facility for the organization and provision of a broad spectrum of services for older persons (Gelfand, 1999, p. 139). However, the term *multipurpose senior center* remains vague, as it could refer to the goals or content of programming, or the types of individuals served by these centers (Krout, 1989). In an online publication on exemplary senior center programs, the NCOA (n.d.) described senior centers as vital community-based social and nutritional supports that help older adults remain independent in their respective communities. Lowy (1985) defines senior centers as “community (facilities) in which older people come together to fulfill many of their social, physical, and intellectual needs” (p. 274).

Smiley (1995) contends that senior centers traditionally offer a wide range of protective care services and a place to socialize and find a sense of community and are located in a place convenient for the people they serve.

The difficulty in defining senior centers lies partially in the differences in their models of delivery. Some use a social agency model, and others employ a voluntary organization model. According to Sabin (1993), senior centers employing the social agency model are more likely to have programs and services that are geared to the survival needs of their members, while senior centers employing the voluntary organization model are more likely to create opportunities for the recreation and self-expression of their members. To better define senior centers, Krout (1993) offers several criteria that should include the minimum numbers of days and hours of operation and the minimum number of paid staff, as well as the minimum number and types of activities that a center has to have in order to qualify as a senior center.

Legal authority. Senior centers existed long before the legislation that authorized them. However, the Older Americans Act (OAA) of 1965—and the subsequent amendments—is considered to be one of the main impetuses for their expansion (Krout, 1989; Lowy, 1985). Unfortunately, the absence of separate funding authorization under the OAA for senior centers and the discretionary nature of funding for senior centers have forced senior centers to compete with other community-based social services for relatively meager federal funding under Title 3 of the OAA (Council of Senior Centers and Services of New York City [CSCS], 2002; Gelfand, 1999; Justice, 1997; Krout, 1989; Lowy, 1985).

Currently, there is no separate provision for the acquisition, alteration, or renovation of existing facilities to serve as senior centers under the OAA (Gelfand, 1999; Krout, 1989). Along with other public social programs, senior centers face cost-cutting and cost-containment trends that have become a part of the social welfare landscape since the 1980s. Indeed, the percentage of support for senior centers from the OAA has “consistently dwindled,” despite the acknowledgment of their important role in the continuum of community-based services for older adults (Wagner, 1995b). Low levels of funding have forced senior centers to “accomplish extraordinary work on extremely frugal budgets” (Smiley, 1995, p. 29). Further, Justice (1997) argues that there has been a serious mismatch between the lofty goals of the OAA and the meager resources that are set aside by the federal

government. In their national survey of health and supportive services in the aging network, the NCOA (2001) reported that high-quality programming does not necessarily require large funding.

Senior centers rarely receive funding from a single funding source (Krout, 1989). Gelfand (1999) identifies various federal government funding sources. Although public funding is an important source of funding, few senior centers rely exclusively on private funding. Many centers combine public and private dollars. Senior centers that receive OAA funding are encouraged to develop a “contribution schedule” that provides senior center participants with the opportunity to contribute to defray the cost of services (Title 3 of OAA, 2004). In addition, “in-kind contributions,” in the form of free space and staffing support, while difficult to quantify, are another important funding source (Gelfand, 1999).

Interestingly, senior centers are not licensed by any state or federal agency. Through the self-assessment instrument, the NCOA provides guidelines to senior centers for the improvement and maintenance of quality services. These guidelines help centers assess the extent to which they adhere to the standards of good practice, plan for growth, and identify areas for training and need for technical assistance (Lowy, 1985). The lack of licensing, thus, has contributed to a lack of consistency in the type, amount, and quality of services that are offered at senior centers nationwide. However, Title 3 of the OAA (2004) states that the facility that houses the senior center should comply with existing “health, fire, safety, building, zoning, and sanitation laws, ordinances, or codes.” Because of the lack of registration and licensing standards, there is no exact census of senior centers in the United States (Lowy, 1985).

Structure. A number of researchers have argued that the choice of a facility plays a role in making the senior center attractive and accessible to older people (Gelfand, 1999; Krout, 1989). Depending on their history and funding source, senior centers can either be free-standing facilities or part of community-based social agency. It is not uncommon to find senior centers housed in a variety of facilities that can include old schools, community centers, churches, housing projects, and purpose-built centers (Krout, 1989).

The accessibility of senior centers remains an important issue for service providers. Transportation continues to be a major concern for many older adults, especially for those who are not able to drive on their own. In a small study in Maine, the National Eldercare Institute on Multipurpose Senior Centers

and Community Focal Points (1995) found that inadequate transportation was one of the major problems faced by older adults in Knox County. The issue of inadequate transportation is especially salient for older adults in living in suburban and rural areas, where public transportation is inadequate or nonexistent. In addition, rural centers are more likely to have less space, fewer paid staff (Wagner, 1995a), and fewer activities and services (Krout, 1994) than their nonrural counterparts. Over half of all senior centers are located in cities (Lowy, 1985).

In his national study of senior centers, Krout (1989) found that more than a quarter of senior centers did not have full-time paid staff, while half of the centers had less than three full-time paid staff. Agencies that run centers at multiple sites might have staff working at different sites on different days. As such, most senior centers rely overwhelmingly on part-time volunteers to meet their staffing needs (Krout, 1989). For this reason, Smiley (1995) argues that centers have not been able to attract better-qualified professionals to fill key positions and may not be well positioned to compete with other service providers for human resources in the evolving aging network.

Services available. Senior centers are seen as an essential source of “vital community-based social and nutrition supports that help older Americans to remain independent in their communities” (NCOA, n.d.). The guidelines provided by the NCOA specify that “a senior center shall provide a broad range of group and individual activities and services designed to respond to the interrelated needs and interests of older people in its service area” (cited in Lowy, 1985, p. 291). However, the type and number of services that are available are constrained by the funding and staffing levels of the senior centers (Krout, 1989). In some centers, educational programs are peer-led, which has the added benefit of tapping on the expertise of the older person.

Most senior centers provide a combination of services, education, and recreation programs; information and referral that include printed materials on community services and government programs for older adults, volunteer opportunities, nutrition programs, and health promotion programs (Gelfand, 1999; Lowy, 1985; Krout, 1989). Senior center programming can be broadly divided into two categories: recreation-education programs and services (Gelfand, 1999; Krout, 1989). Lowy (1985), on the other hand, specifies four types of services: direct services, which include recreation-education programs as well as social and nutritional services; services that

are offered by other institutions or organizations in the community; community action, which includes transportation and advocacy services; and training and consultation services. Well-planned programs can promote “healthy aging,” which “encompasses . . . intellectual, emotional, social, vocational, and spiritual health,” thus enabling older adults to successfully age in place (NCOA, n.d.).

Further, the type and amount of services offered influences the attractiveness of a particular senior center to a certain kind of client or consumer group. Cutler and Danigelis (1993) found that senior center participants were more likely to be older, women, better educated, lower income, and in better subjective health. In a case study of one senior center in Allegheny County in Pennsylvania, 81% of men attributed their attendance to the social-recreational activities, such as shooting pool, playing cards, and socializing with their friends at the center; while more than 50% of them listed the noontime meals as the reason for their attendance (National Eldercare Institute on Multipurpose Senior Centers and Community Focal Points, 1995).

According to Sabin (1993), the type of programming offered at a senior center reflects one of two models: the social agency model and the voluntary organization model. In testing the relevance of the delivery models, Sabin (1993) found support for both the social agency model, in that senior center participants were older, less educated, and nonwhite, as well as the voluntary organization model, in that participants tended to be socially active rather than isolated.

In their aim to be the focal point in the community for older adults, senior centers need to plan programs that are culturally sensitive for an increasingly diverse older population (Urbach, 1995). Cultural sensitivity includes offering culturally appropriate meals and programming. With an increasing number of foreign-born older adults, it is also important that centers employ staff who are effectively bilingual, so as to reduce the miscommunication that might occur. Further, Wagner (1995a) proposed that service providers stay committed to the inclusion of community representatives in their program planning.

Sagy, Antonovsky, and Adler (1990) posit that the tension between disengagement and continued involvement (as operationalized by activities) is a core crisis of later adulthood and a given cultural context of Western societies. They argue that Western culture places a premium on active involvement in life. Indeed, much of the programming at senior centers may reflect this cultural bias, leading some critics to

wonder if we are promoting a busy-ethic in later life, especially since we have not developed any significant roles for older adults who are retired from their work roles (Ekerdt, 1986). Thus, service providers should seek the input of older adults on planning meaningful activities, so that center participants are not merely killing time at senior centers.

POPULATION SERVED

According to Wagner (1995a), senior center participants reflect the diversity of the communities that these centers serve. In his examination of the changes in senior center participants, Krout (1994) found support for aging in place among participants, but found no support for the argument that centers were serving a significantly better off population. In his study of eight senior centers, Krout (1989) found that more than two-thirds of the participants were women, and the median age of participants was 72 years. However, people of color remain underrepresented in senior participation (Krout, 1989; Wagner, 1995a), resulting in the policy emphasis on serving older people of color. Under the OAA Title 3 regulations, area agencies have to specify how they intend to increase “low-income minority” participation as a condition for the receipt of OAA funds (2004).

SOCIAL WORK ROLES (HISTORICAL AND CURRENT)

Social workers have been instrumental in the development and growth of senior centers (Lowy, 1985). Because of funding limitations, most centers do not have specific social work positions, though social workers do function as center administrators. Of the seven exemplary senior centers highlighted by the NCOA (n.d.), none of them specifically mentioned a social worker on staff. Social workers who espouse values of self-determination and social justice can infuse these values into the program planning and delivery processes. In terms of programming, social workers can help older adults deal with issues on life transitions, run group and individual counseling sessions for people with mental health problems, plan socialization opportunities, organize advocacy and action groups, and provide case management services.

CRITICAL ISSUES AFFECTING SENIOR CENTERS

It is important to note that senior centers serve an important function in an age-segregated society, where leisure is considered the reserve of older adults and society has yet to develop meaningful roles for later adulthood. In such a context, society might continue to view older adults as drains on societal resources. In response to the public debates on generational equity in the 1980s, the aging movement responded by promoting productive aging, which recognizes the current contributions of older adults to the well-being of the community and nation (Moody, 2001). Thus, it becomes increasingly important that senior centers move beyond serving the leisured needs of older adults and expand their programming to promote other needs—such as increasing opportunities for volunteering, employment, and caregiving, according to the wishes of older adults. For example, intergenerational programming that meets the needs of grandparents who care for their grandchildren may be a concrete way for senior centers to respond to the changing realities of later adulthood.

Most older adults prefer to remain in their homes for as long as possible, and senior centers serving as community focal points are well placed to address the needs of older adults who are aging in place. The opportunity to age in place is not only beneficial to the older individual but also to his or her community. The Council of Senior Centers and Services (CSCS) of New York City (2002) stated that senior centers are an integral component of the community, enabling the older person to successfully age in place. With the expected increases in the numbers of older adults with frailty, there is a need for senior centers to respond to this burgeoning group of older adults (Krout, 1995; Wagner, 1995b). However, Cox and Monk (1990) found that center directors are less inclined to work with older adults with mental impairments than those with physical and sensory impairments. Although senior centers are not recognized as key components of the long-term care system for older adults who are at risk for institutionalization (Krout, 1996), some current participants have serious chronic illness and disabling physical conditions, and live alone. According to Krout (1996), programming for frail older adults could include health promotion, health assessment and referral, and special services for people with sensory impairments, as well as group work for older adults with mental health problems. Another future challenge facing senior centers is the aging baby

boomer generation. This group of older adults is expected to have higher levels of education. Wagner (1995b) argues that senior centers should face the challenge of making themselves relevant for the baby boom generation, whose members are likely to have higher expectations with regard to types and quality of programming. However, to better respond to the diverse needs of an aging population, senior centers need to adopt new methods and make creative use of their limited space (Urbach, 1995).

Interestingly, we have to question the adequacy of institutional arrangements of senior centers in their provision of opportunities for socialization for older adults (Hagestad & Dannefer, 2001). Senior centers play an important role in providing a structure for socialization needs of older adults, as people meet and make friends while participating in social-recreational activities (Adams, 1993). Further, social relations have long been recognized as protective to the well-being of older people (Avlund et al., 2004). However, it is unclear that senior centers are successful in providing opportunities for positive social relations that enhance the well-being of their participants. In a study on formal and informal network factors on morale, Litwin (1999) found that higher levels of activity at the senior centers were positively related with higher levels of morale among older participants. Conversely, respondents who reported higher levels of fellow senior center participants in their network were more likely to report lower morale (Litwin, 1999). In another study by Mui (1998), about a third of the respondents who were participants of senior centers and congregate meal programs reported that they had not had contact with friends in the past week. Although the frequency of their attendance at these centers is unknown, it is still interesting to note that a larger number of respondents may not have considered fellow participants at senior centers and congregate meal sites as part of their friendship network.

CONCLUSION

Senior centers have served the social-recreational needs of many older adults, despite their low funding and staffing levels. Social work has made and can continue to make important contributions to the senior center movement. Many agree that as community focal points, senior centers are well placed to serve the growing numbers of older adults who age in place with the necessary input of human and financial re-

sources. Further, senior centers will have the added challenge of making themselves relevant to the aging baby boomers.

Historically health social work practice developed in response to the social, environmental, and social-context needs of individuals with health problems. Working with individuals on the issues resulting from and impinging on their medical conditions is a constant theme through the 100-plus years of the history of health social work practice. This has become more essential in our increasingly complex society. To this end, social workers have extensive experience in assisting individuals and families in navigating complicated organizational structures and safety net systems, serving as advocates and sources of essential comfort and support. As medicine has evolved, social work has also become an intermediary between competing interests. The growth of managed care presents yet another opportunity for social workers to apply their skills in negotiating disparate needs, following their core values in achieving their desired goals. Managed care has significantly impacted the social work profession through its demand for limited services, cost containment, and evidence-based practices. With the growth of managed care use, particularly among older adults, social workers must be prepared to adapt their practices to meet these new demands while continuing to advocate for quality improvement and social justice.

Health Maintenance Organizations and Managed Care Companies

41

DEFINITION OF MANAGED CARE

Since its inception in 1929, managed care, defined as a system that integrates financing and delivery of medical care through contracts with physicians and hospitals that provide comprehensive health services to enrolled members in exchange for a monthly premium, has continued to grow across the United States. The primary aim of managed care organizations is to control costs, quality, and access to health care services for enrolled members. This is achieved by serving as a third party that bridges payers, providers, and patients together to provide cost-effective medical care by organizing the coordination and provision of care among doctors, hospitals, and other providers.

Funding mechanisms. The term *managed care* is an umbrella under which several financing and organizing models exist, such as health maintenance organizations (HMOs), preferred provider organizations (PPOs), and point-of-service financing and delivery of services. Managed care organizations operate

under a capitated fiscal structure. This means that the providers, whether they be hospitals, physicians, or medical groups, agree to accept a preset payment in exchange for provision of health care services for a group of people. The medical care provider receives a payment for each member in exchange for a comprehensive set of medical services. The rate of service use by the member does not affect the payment given to the provider. In some cases there may be a monthly premium per enrolled member, in others a case rate with a maximum payment amount for an episode of care. In all cases, the reimbursement has a cap and is designed to reward prudence on the part of the provider.

Health maintenance organization. These organizations offer prepaid, comprehensive health coverage for both hospital and physician services. The HMO is paid monthly premiums or capitated rates by the payers, which include employers, insurance companies, government agencies, and other groups representing covered lives.

Preferred provider organization. This is a partnership of providers, such as a hospital and physician group, that agree to render particular services to a group of people for discounted rates under contract with a private insurer. A PPO can also be a legal entity, or it may be a function of an already formed health plan, HMO, or PPO. The entity may have a health benefit plan that is also referred to as a PPO. Preferred provider organizations are a common

method of managing care while still paying for services through an indemnity plan. Most PPO plans are point-of-service plans, in that they will pay a higher percentage for care provided by providers in the network. However, the insured population may incur out-of-pocket expenses for covered services received outside the PPO if the charge exceeds the PPO payment rate.

PREVALENCE OF MANAGED CARE

Since its inception, the rate of enrollment of managed care members has continued to rise, with the largest enrollment following the initiation of the Medicaid and Medicare managed care plans. Overall, more than 71 million people nationwide are enrolled in managed care, and an additional 113 million have PPO plans. Currently, 57% of Medicaid, 14% of Medicare recipients, and 91% of those commercially insured are enrolled in a managed care plan plans (see Figure 41.1). Projected to continue to rapidly increase, enrollment in managed care plans has actually plateaued and somewhat declined in recent years as skyrocketing health care costs have resulted in reduction of benefits offered by managed care organizations. According to the Kaiser Family Foundation (2004), these declines are due to plan withdrawals from some areas because of shrinking Medicare rates, reduced benefits, and higher premiums.

FIGURE 41.1. National HMO Enrollment. Note: From Managed care fact sheet managed care national statistics, Available: <http://insurance.about.com/gi/dynamic/offsite.htm?site=http%3a%2f%2fwww.mcareol.com%2ffactsht%2ffactnati.htm>.

THE MANAGED CARE DEBATE

Managed care has been the target of both censure and praise among health care practitioners, advocates, and policy pundits.

Critics of managed care . . . contend that managed care potentially compromises quality by withholding needed services and that the intensity of these services can be guaranteed only by a fee-for-service system of payment that protects patients from underutilization. (Lachs & Ruchlin, 1997, p. 24)

Yet under fee-for-service medicine, other special hazards exist: care is not coordinated, resulting in overutilization of services, as well as some needs falling through the cracks, and dramatic levels of medication errors (the fifth leading cause of death).

Some geriatricians and researchers have asserted that the purpose of medicine with older populations is to keep people well/functional through coordination, follow-up, and preventive/lifestyle care. A reimbursement system that would pay for promoting and preserving health and function is desirable instead of waiting for advanced decline, injury, or illness to rush expensive rescue to the patient. The search is for the right care in the right place at the right time. The essential focus is on health and prevention, versus allocating most payments for late stage, expensive preventable conditions. Ideally, managed care is designed to permit pursuit of this clinical philosophy, although it often falls short.

Fee-for-service medicine, however, also suffered from misalignment of incentives, as it lacks proper balances to contain costs. This dilemma is derived from two central causes: (1) reimbursement with minimal incentive to focus on early detection and prevention of injury and functional decline that typically precedes a medical crisis, but rather generous reimbursement for managing the medical crisis once it occurs, and (2) multiple payers, providers, and systems, with no single entity with global clinical or fiscal responsibility. This system doesn't maximize functional status and quality for older adults, the central goal of modern geriatric medicine.

The case can swing the other way in quality and value-based managed care arrangements, as demonstrated by some of the major nonprofit integrated HMOs like Kaiser Permanente and Group Health Puget Sound. In these instances, where the system has aligned financial incentives through co-ownership by

the payer, the medical group, and the insurance program, the high potential of managed care can be reached. In these systems, there are serious efforts to identify the best investments in health through prevention and early intervention. Some managed care systems have created a reputation for withholding essential and timely care, but the great nonprofit integrated managed care systems have actively pursued the promise of this health care financing system.

REGULATORY AGENCIES

Throughout the past two decades, all health care providers, including managed care organizations (MCOs), have had increasing regulations imposed, largely due to public displeasure with rising costs, coupled with increasing allegations of misconduct. Although more than 100 bills have been introduced in Congress in an effort to regulate MCOs, the primary health care oversight mechanism continues to remain enforcement of accreditation standards by federal and state agencies. Key governing bodies include the Joint Commission on Accreditation of Healthcare Organizations (JCAHO), the National Committee on Quality of Care (NCQA), and judicial rulings. Although accreditation is voluntary, more and more health care purchasers (such as employers) are requiring accreditation. Although accreditation does not provide legal jurisdiction over providers, including the MCO, it does provide a mechanism for ensuring standard levels of quality through the development of practice guidelines, performance standards, and expected clinical outcomes. Further, data publicly reported by regulatory agencies such as NCQA and Health Plan Data and Information Sets (HEDIS) provides an additional source of oversight and quality marker for health plan purchasers and consumers.

Although these regulatory agencies are necessary in order to assure that health care providers are delivering high-quality care, serious consequences have resulted from the policies they created. Increasing regulatory review by public entities has pushed providers to provide an exacting search for the right amount of the right care—to not exceed care needed but to assure timely access to essential care. This is a difficult task, considering the great amount of diversity in health care needs that exists among the population. Controversies have raged about what insurers should pay for, which care is experimental and excluded, what care is essential, and when access to special care and medications is appropriate.

SOCIAL WORK ROLES IN HEALTH CARE

Although the history of health and mental health social work practice is rooted in public and teaching hospitals, centering around acute episodes that require hospitalization, current fiscal pressures on our health care system have encouraged the shift of social work from the hospital to the community setting. Social work practice in the hospital setting has largely been advanced through advocacy or prescribed by regulatory agencies. In the 1970s, Medicare conditions of participation for hospitals were developed, requiring health care organizations to participate in the Medicare and Medicaid programs. These standards are used to improve quality and protect the health and safety of beneficiaries. A new requirement imposed by these standards was to have trained social workers (MSWs) available to patients in all hospitals, preferably through organized departments, which transformed social work practice in these settings. Similar requirements for skilled nursing homes and home health services led to the emergence of social work practice within these care settings, although the social work role in these settings never developed as dramatically as in hospitals. With the establishment of the Medicare Hospice benefit in the late 1980s, the role of the social worker was further expanded through the mandate of social services in this organized and “capitated” program that brought comprehensive end stage care to terminally ill patients.

Also, in 1970 the JCAHO adopted standards that included the availability of social services to patients admitted to the hospital and their families. As a result, hospitals across the nation began to support organized social work departments that provided a range of services centered around the hospital setting, including emotional support, referral and resource mobilization, health education and transition/discharge planning services. These services gradually grew into fields of specialization around specific medical scenarios such as rehabilitation, cancer, neonatal units, and discharge planning for other common conditions. This was especially new in the western states, where the history and traditions of health care and hospitals were not as well established as in the East and Midwest.

When diagnostically related groups (DRGs), an early version of managed care, were introduced in 1984, lengths of stay in hospitals shortened dramatically, and patients were moved to community care much earlier. Before this, patients remained in hospitals for longer periods of time, permitting the social

work intervention to include crisis intervention, counseling, and health education. In many instances, social work staffs grew substantially in these settings. Following the introduction of DRGs, the hospital social work role shifted dramatically, as hospital lengths of stay were limited, reducing time for counseling and increasing pressures to focus on safe and rapid discharge plans. In addition, the role of nursing was evolving, leading to competition from nurses for the traditional social work roles of discharge planning.

The 1980s and 1990s were also a time of rapid growth for managed care. Managed care had been primarily confined to the West Coast due to legislative actions that restricted insurance companies from contracting with select providers. Following the introduction of prospective payment into Medicare, states began to repeal this legislation, and the growth of managed care rapidly escalated. This growth in managed care brought dramatic redesign to the health care system, emphasizing cost-containment strategies, including utilization review, outcomes-based practices, and preventive medicine aimed at transferring the site of care from acute care facilities to outpatient settings.

This shift in focus significantly influenced the roles of all, including the social worker. Social workers no longer had the luxury of providing care without evidence of the effectiveness of that care. Effectiveness could not be limited to simply measuring client satisfaction, or even improvement in patient level health outcomes. Social workers are now charged with showing effectiveness in terms of

concrete and identifiable therapeutic gain . . . achieved, in the quickest amount of time, and with the least amount of financial and professional support. This means that not only must the treatment that social workers provide be therapeutically necessary and effective, it must also be professionally competitive with other disciplines that claim similar treatment strategies and techniques. (Dziegielewski, 1998, p. 261)

Thus social workers must now consider the cost-benefit of their practice and how it is uniquely different from other professional disciplines. Within the inpatient setting, management of departments was consolidated and layers of leadership reduced, to lower costs as managed care continuously forced contract rates for hospital stays downward. Studies have documented that many social work department directors either lost their administrative roles or had to assume

a broader scope of services in addition to social work. More recently, the value of social work and of interdisciplinary practice, as well as the nursing shortage, has led to restoration of social work in many settings. The shift to capped payments initially led to cuts in social work, but over time, research has begun to suggest that overall cost per case is lower with interdisciplinary care, with social work playing a key role.

The growing need for case management to care for increasing rates of chronic conditions also contributed to the social work role shift. Chronic illness has become the dominant focus of health services in recent years, and the key role of self-care in outcomes has become clear through research. The role of social work in addressing patient empowerment and identifying and treating high risks, such as depression, has helped to advance the role of social work in managed care in recent years, laying ground for developing the social work contribution and expanding the social work presence based on this new evidence.

Noting the impact of policy changes that resulted in reduced length of hospital stay and the growing role of primary care in the community, social work leaders pioneered and began to evolve new programs. The changing complexity brought by increasing numbers of individuals with multiple chronic conditions called for a continuum of care included social work components within various care settings. For example, observing that Medicare patients averaged almost one visit per month to their physician, social workers at Huntington Hospital, with funding from the John A. Hartford Foundation, developed social work models of service for the physician office. Great interest in this model led to multiple replications across the nation.

The rise of managed care has also impacted the role of the social worker in mental health. Throughout the past several decades, psychiatrists, psychologists, and social workers have been trained to address the needs of the mentally ill; however, social workers remained in a lower professional category, with lower pay, lesser respect, and more limited roles. As managed care companies have taken over the management of mental health services through their payer influence, social workers have emerged as the provider of choice, delivering 65% of all psychotherapy and mental health services, partly due to generally lower fees and similar skill sets. Psychiatrists have been moved to specialization in medications management. Recent research has demonstrated that placing social workers in primary care offices to address mental health issues helps capture patients for mental health services at an earlier and more appropriate stage and permits many to use and benefit from ser-

vices they would avoid if labeled mental health and requiring going to a new setting.

On the downside, however, are the parallel limitations on types of mental health care and numbers of visits. Long-term ongoing therapies have been replaced with limited, short-term, behaviorally oriented interventions. Moreover, practitioners report that managed care constraints have increased the need for use of medication as an adjunct therapy.

QUALITY OF LIFE, QUALITY OF CARE, AND ETHICAL DILEMMAS

For the last two decades, the ethics of managed care has been under fire. Simply defining managed care as a cost-controlling agent lends fuel to the growing barrage of criticism and questions about the ethics involved in caring for individuals under a cost-containment system. Critics of the managed care system are quick to point to traditional social work values (service, social justice, dignity and worth of the person, importance of human relationships, integrity, and competence) and the inconsistency of these values with care provided in the controversial end of the managed care continuum. These values are compromised when social work care focuses on economics and cost containment in exchange for quality professional care. Within the medical managed care environment, social workers work with increasingly diverse issues in health care, such as declining hospital admissions, reduced lengths of stay, increased restrictions, and increased cost containment methods. The disparate goals of the organization and the social worker create role conflict, placing the social worker in the uncomfortable position of choosing between job security and quality of care for the client.

Several professional ethical challenges of managed care have been identified. In some instances, reduced access to medical services has been shown to be associated with poorer outcomes. If social workers are being asked to inappropriately decrease length of services or circumvent service use, it places them in an ethical dilemma of having to choose between adequate quality of care and conforming to their employers' demands. Perhaps most important, these limitations reflect a higher level of payer control over clinical practice, threatening the integrity of the physician and the social worker.

Further, within immature managed care environments, the social work role often is viewed as an expendable and nonessential service, easily seen as

obsolete within this streamlined, cost-efficient environment. Social work roles are frequently viewed as adjunct to medical services and not “required,” or professional social workers may be replaced with untrained paraprofessionals who are not trained to perform social work roles. This can swing both ways, however, as we see the replacement of doctorate-level professionals within the mental health arena, where master’s level and licensed social workers are replacing doctoral-educated mental health professionals such as psychiatrists and psychologists. The following list (from Scanlon, 1997, as cited in Camunas, 1998, p. 8) delineates the issues and challenges of managed care.

1. Tension between cost containment and quality of care
2. Threats to the patient/professional relationship
3. Policies that constrain professional judgment
4. Safeguarding patients from harm
5. Allocation of decision-making authority
6. Financial incentives
7. Abandonment of patient

Managed care advocates remind us that cost containment is not inherently evil. In fact, some discipline in health care allocation was needed, and managed care was brought in as a reform effort. That is why some suggest that managed care actually eliminates moral problems often encountered in fee-for-service systems, where financial incentives exist to provide unnecessary care. Managed care offers a balance to these allocation dilemmas. Further, it provides an environment and fiscal structure that can allow for much greater flexibility and innovation in medical models of care and special services.

In a monograph on organizational interventions to improve health outcomes of older individuals, Reuben (2002) classifies these organizational interventions into two groups: (1) component models, models that can be integrated into the existing model of care but do not fundamentally change the health care system, and (2) systems changes, which includes models that require significant changes in the delivery of health care. While the results of these interventions are mixed, several studies have found that these innovations can improve care. Effective component models include new services such as disease management programs that have been found to be effective in improving patient health while decreasing costs of care.

Kaiser Permanente Southern California offers an illustration of a systems change in their modification

of the hospice benefit to develop a new program aimed at providing palliative care and pain relief for patients in the last year of life. The In-Home Palliative Care Program reduced ICU deaths, expanded home care, and thus improved patient satisfaction with care and increased the likelihood of patients’ dying in their preferred environment, as well as reducing acute care service use and associated costs. This model demonstrates the flexibility of the managed care environment to develop and test new models of care aimed at improving both patient and system-level outcomes.

SPECIAL CONCERNS OF POPULATION SERVED

In the 1980s, Medicare introduced a prospective payment system for Medicare beneficiaries that allowed HMOs to enroll Medicare beneficiaries. This change in the Medicare benefit contributed to an increased growth in managed care, largely through the enrollment of older adults. Thus older adults, in particular, have been affected by the rise in managed care and impacted by the evolving role of the social worker. Concerns of older adults vary considerably, as does the population itself. Healthy older adults require much the same care as younger populations, plus special models to address their added care needs, as issues particular to aging encroach. Multiple chronic conditions, such as arthritis, diabetes, respiratory and cardiac problems, and Alzheimer’s, emerge. Treatment of these diseases not only requires the use of preventative medicine and techniques aimed at slowing the progression of the conditions but also extended self-care, which requires investment in education and lifestyle change support.

Older adults and their families fear there will be a lack of access to the receipt of the right services when needed in a managed care setting. In a study comparing older adults’ access to care, differential access to specialists was noted under managed care. Of greatest concern was that older HMO members had inadequate identification and treatment of pain, although this is a widespread medical problem outside of managed care as well. Older adults anticipate developing multiple chronic conditions and experiencing threats to their functional abilities and want help optimizing their health as they age. At the same time, they want protection from high premiums and out-of-pocket costs, low copays, and other essential financial protections.
